MASTER

### **NUCLEAR DATA AND MEASUREMENTS SERIES**

The Nuclear Data and Measurements Series presents results of studies in the field of microscopic nuclear data. The primary objective is the dissemination of information in the comprehensive form required for nuclear technology applications. This Series is devoted to: a) Measured microscopic nuclear parameters, b) Experimental techniques and facilities employed in data measurements, c) The analysis, correlation and interpretation of nuclear data, and d) The evaluation of nuclear data. Contributions to this Series are reviewed to assure technical competence and, unless otherwise stated, the contents can be formally referenced. This Series does not supplant formal journal publication but it does provide the more extensive information required for technological applications (e.g., tabulated numerical data) in a timely matter.

## PREFACE

This report contains material which was prepared for presentation at a meeting of the ENDF/B Dosimetry File Task Force held at the National Bureau of Standards, Gaithersburg, Maryland, during the period March 25-31, 1977.

ABSTRACT

A simple procedure for analyzing the sensitivity of computed spectrum-average cross sections to detailed properties of excitation functions for threshold nuclear reactions commonly used in reactor dosimetry is described. The approach is based upon consideration of two energy-dependent functions F and G defined by the formulas

$$F(E) = \int_0^E \sigma(\epsilon)\phi(\epsilon)d\epsilon$$

$$\text{and } G(E) = \int_0^E \sigma'(\epsilon)\phi(\epsilon)d\epsilon,$$

where  $\sigma$  is the differential excitation function,  $\sigma'$  is its first derivative with respect to energy, and  $\phi$  is the neutron spectrum used in computing the spectrum-average cross section  $\langle\sigma\rangle$ . This procedure is shown to be useful in identifying specific needs for improved differential data and as a tool to be employed in performing evaluations. Several examples are presented to illustrate the subject matter.

---

\* This work performed under the auspices of the U.S. Energy Research and Development Administration.

## I. INTRODUCTION

The development of accurate, reliable reactor dosimetry techniques ranks high among the priorities of reactor research programs in several countries including the U.S.A. The implications are profound since they encompass major issues such as safety (monitoring the structural integrity of containment vessels and key components of heat transfer systems) and economics (fuel cycle management). There are three essential ingredients required in order to develop reactor dosimetry technology to the level of maturity required for the routine demands associated with application in the electric power industry:

- i. Accurate, reliable and relatively simple procedures are required for the measurement of reaction rates experienced by dosimetry monitors during routine operation of power reactors.
- ii. The microscopic differential cross sections for a basic set of dosimetry monitor reactions need to be known with a precision adequate to satisfy the requirements for this application. Taken together, these reactions must encompass a wide range of spectral sensitivities (from thermal energies to many MeV).
- iii. Efficient and mathematically rigorous numerical procedures are needed in order to unfold reactor spectra and deduce neutron doses from the observed reaction rates for the monitors.

Items (i) and (iii) appear to present no real difficulties; however, limitations in the cross section data base are primarily responsible for impeding progress in the development of reactor dosimetry technology.

Granted that the establishment of an accurate data base of microscopic differential cross sections is crucially important for future development of the technology, it is worthwhile to examine what steps are to be taken in order to achieve this objective. It seems clear, in general terms, that progress will come from a combination of improved differential measurements and careful evaluation of existing data using consistent cross section standards and accurate supplementary non-neutron data (e.g. decay properties). The microscopic neutron cross sections are fundamental quantities and knowledge of these parameters may be required in the future for other technologies (e.g. medical applications). Therefore, it is suggested that development of an accurate data base for these cross sections should not be unduly influenced by expediencies having their origin in the desire to satisfy certain requirements of reactor technology. More specifically, cross section values should not be adjusted in order to obtain convenient consistency in the limited context of current reactor applications, with no regard to the possible implications for other technologies.

Of course, it is understandable why it has been tempting for scientists who have borne the responsibility for developing a viable dosimetry technology to resort to expedient solutions to bypass difficulties which were encountered as a result of the poor quality

of the available differential data. Fortunately, the situation has improved considerably in the last several years, owing to availability of new differential data which has emerged from research programs in several countries. It now appears possible to progress toward achievement of the goals of dosimetry technology without resorting to questionable scientific procedures.

Within limits consistent with this admonition, it is reasonable to employ benchmark fields as tools in the process of developing a differential cross section data base which is adequate for dosimetry applications. The benchmark facilities should be characterized by a high degree of reproducibility, well-known spectral properties, and structural simplicity to facilitate the interpretation of experimental results by means of computations. Furthermore, it is desirable to have some benchmark fields with spectra resembling those of power reactors. Reaction rate measurements in benchmark fields can serve to check on the consistency of currently recommended differential data sets. This can be very useful for pointing out apparent problem areas. However, the results of reaction rate measurements in benchmark fields should not be used to renormalize or otherwise adjust differential data, for to do this would be tantamount to an acceptance of the reaction rates, or equivalently, the spectrum-average cross sections, as fundamental quantities. Discrepancies in benchmark field reaction rate measurements (assuming that the fields are correctly characterized) can serve to identify needs for additional monoenergetic measurements designed to yield improved accuracy for the relevant

differential cross sections. It is incorrect to assume that real progress can be made in development of dosimetry technology by simply adjusting the differential cross sections without the guidance offered by new experimental microscopic data.

The objective of this report is the description of a simple formalism which is useful in analysis of the sensitivity of integral reaction rates to the details of differential cross section data. The purpose of performing such analyses is to decide how to best concentrate the expenditure of funds and manpower in the measurement of differential cross sections in order to establish a data base which is sufficiently accurate for dosimetry applications.

The mathematical formalism is presented in Section II. Some examples which illustrate the application of the method are presented in Section III. Emphasis is placed on threshold dosimetry reactions rather than reaction processes which are sensitive to low-energy neutrons, however the approach need not be limited to this category of monitors.

## II. FORMALISM

The reaction rate for a dosimetry monitor in an integral field  $\phi$  is related to the spectrum-average cross section  $\langle\sigma\rangle$  defined by the formula

$$\langle\sigma\rangle = \int_0^\infty \sigma(\epsilon) \phi(\epsilon) d\epsilon , \quad (1)$$

with the constraint of normalization

$$\int_0^\infty \phi(\epsilon) d\epsilon = 1 \quad (2)$$

required for the function  $\phi$ .

Let us define a function

$$F(E) = \int_0^E \phi(\epsilon) \phi(\epsilon) d\epsilon , \quad (3)$$

which is related to the spectrum-average cross section by the expression

$$\langle \sigma \rangle = F(\infty) . \quad (4)$$

The function  $F$  is useful because it provides a means for examining the contribution to the spectrum-average cross section which comes from specific energy intervals. For example, the fractional contribution  $f(E_1, E_2)$  to the spectrum average, corresponding to the energy interval  $(E_1, E_2)$ , is given by the formula

$$f(E_1, E_2) = [F(E_2) - F(E_1)] / \langle \sigma \rangle \quad (5)$$

It has been decided that a practical cutoff for the energy integrations of Eqs. (1) and (2) is 20 MeV and this has been selected as the upper limit for the ENDF/B-IV Dosimetry File [1]. Thus,

$$\langle \sigma \rangle \approx F(20 \text{ MeV}) \quad (6)$$

is assumed for most cross sections and spectra of interest for current dosimetry applications.

Eq.(5) is the starting point for the present sensitivity analysis.

Let

$P_\sigma$  = an assumed percentage change in the normalization of  $\sigma$  in the interval  $(E_1, E_2)$ ,

$P_N$  = the percentage change in the computed  $\sigma$  resulting from this change in  $\sigma$  within the interval  $(E_1, E_2)$ ,

then

$$P_N = P_\sigma f(E_1, E_2), \quad (7)$$

with  $f$  computed using Eqs.(3) and (5).

Normalization considerations are not the only ones which may be encountered in the development of accurate differential cross sections for applications. There is also the matter of energy scale definition. Differential cross sections are measured using monoenergetic techniques and it is well known that uncertainties exist in the determination of energy scales.

Assume that the function  $S$  represents an assumed excitation function which is related to the  $\sigma$  by the expression

$$S(E) = \sigma [E + \delta(E)] \quad (8)$$

where  $\delta$  represents a small energy-dependent shift of the neutron-energy scale. The magnitude of  $\delta$  generally increases with energy, but only gradually. The ratio  $\delta/E$  is a small quantity so it is reasonable to consider using a Taylor series expansion to approximate Eq.(8):

$$S(E) \approx \sigma(E) + \delta(E) \sigma'(E) + \frac{1}{2} \delta^2(E) \sigma''(E) \quad (9)$$

where  $\sigma'$  and  $\sigma''$  are first and second derivatives of  $\sigma$  respectively.

The relative importance of the individual terms in this expansion can be examined by means of a numerical example which is representative of typical applications for this formalism.

The greatest sensitivity to energy scale definition for threshold reactions is in the threshold region. A reasonable approximation

to threshold behavior of an excitation function is

$$\sigma(E) \sim a \exp(bE), \quad (10)$$

so that

$$\sigma'(E) \sim b \sigma, \quad (11)$$

$$\sigma''(E) \sim b^2 \sigma. \quad (12)$$

For this model, the ratio of the first-order to zeroth order terms is

$$\rho_1 = b \delta(E), \quad (13)$$

and the ratio of the second-order to zeroth order terms is

$$\rho_2 = \frac{1}{2} b^2 \delta^2(E). \quad (14)$$

Typically,  $b \approx 2.3$  which corresponds to an order-of-magnitude increase in  $\sigma$  for an energy increase of  $\sim 1$  MeV in the threshold region. An uncertainty in the energy,  $\delta$ , of  $\sim 0.01$  to  $0.02$  MeV is quite possible for a reaction with a threshold in the vicinity of a few MeV. Consequently,  $\rho_1 \approx 0.02$  to  $0.05$  and  $\rho_2 \approx 0.0003$  to  $0.001$ . So, it is entirely reasonable to neglect the second- and higher-order terms of the Taylor series expansion.

The relationship between the assumed excitation function  $S$  and the true cross section  $\sigma$  is well approximated by the formula

$$S(E) = \sigma(E) + \delta(E)\sigma'(E). \quad (15)$$

In terms of the spectrum average, defined as in Eq.(1), we have

$$\langle S \rangle = \langle \sigma \rangle + \langle \delta \sigma' \rangle. \quad (16)$$

Let us define a function  $G$  as follows:

$$G(E) = \int_0^E \sigma'(\varepsilon) \phi(\varepsilon) d\varepsilon. \quad (17)$$

The effect of an energy scale shift in the interval  $(E_1, E_2)$  will be shown to be related to the function  $g$  defined by

$$g(E_1, E_2) = [G(E_2) - G(E_1)] / \langle \sigma \rangle . \quad (18)$$

It happens that the function  $\delta$  varies so gradually with energy that it can be approximated by a constant  $\bar{\delta}$  in a typical interval  $(E_1, E_2)$ . Let

$P_E$  = the percentage change in the computed  $\langle \sigma \rangle$  resulting from energy scale uncertainty, defined by the function  $\delta$ , in the interval  $(E_1, E_2)$ ,

then

$$P_E = \frac{100}{\langle \sigma \rangle} \int_{E_1}^{E_2} \delta(\epsilon) \sigma^1(\epsilon) \phi(\epsilon) d\epsilon \approx 100 \bar{\delta} g(E_1, E_2) . \quad (19)$$

It follows from the preceding formalism that what is needed for routine sensitivity analyses are tables of the functions  $F$  and  $G$  vs. energy. These tables can be computed using evaluated cross sections (e.g. ENDF/B-IV [1]). Tabular information, prepared for several benchmark fields, can be used in planning future measurements aimed at improving the data base, or in clearly defining the implications of proposed changes in differential cross sections including segment re-normalization and energy scale adjustments.

### III. APPLICATION OF THE METHOD TO SELECTED EXAMPLES

Various benchmark fields have been employed in the testing and validation of differential data sets for dosimetry applications [2].

It is not practical to examine all these possibilities in the present work. The formalism of Section II is quite simple, so the interested reader can readily generate the tabular information needed to apply the method for any specific cases desired.

One neutron field which is universally accepted as a standard is the neutron spectrum resulting from thermal-neutron induced fission of  $^{235}\text{U}$ . The energy range from 0.25 to 8 MeV is an important one for threshold dosimetry reactions, and this spectrum can be represented to within  $\leq 2\%$  by the Maxwellian function

$$\phi(E) = C E^{\frac{1}{2}} \exp(-1.5 E/E_{av}) , \quad (20)$$

with  $E_{av} = 1.97$  MeV, in this energy range [3]. A collection of 22 threshold reactions from the ENDF/B-IV Dosimetry File [1] has been investigated using this standard spectrum. Relevant graphical and tabular information appear in the Appendix. Graphs of  $\sigma \phi$  are useful because they indicate the energy regions for which normalization considerations are important. Likewise, plots of  $\sigma' \phi$  point out energy regions for which energy scale definition is crucial. The examples given below are used to illustrate the method of analysis developed in this work. These examples make use of some, but by no means all, of the material in the Appendix.

Group structure formalism has not been used in the present work. Integrals of the form

$$\zeta = \int_0^E I(\epsilon) d\epsilon \quad (21)$$

are approximated by the finite sum

$$\zeta \approx \sum_{i=1}^n I(\epsilon_i) \Delta \epsilon \quad (22)$$

with  $\Delta\epsilon = 0.001$  MeV,  $\epsilon_i = (0.001)i$  and  $n$  is such that  $E \approx (0.001)n$ .

Interpolation laws specified in the ENDF/B-IV Dosimetry File [1] have been utilized in calculating  $\sigma(\epsilon_i)$ . The derivative  $\sigma'(\epsilon_i)$  is approximated by the expression

$$\sigma'(\epsilon_i) \approx \frac{1}{\Delta\epsilon} [\sigma(\epsilon_{i+1}) - \sigma(\epsilon_i)]. \quad (23)$$

#### The $^{56}\text{Fe}(n;p)^{56}\text{Mn}$ Reaction

This reaction has been designated as a Primary or Category I reaction because of the good agreement which has been observed between the results of integral measurements in benchmark fields and spectrum-average calculations based on ENDF/B-IV differential cross sections. To be considered for inclusion in Category I, consistency of the order of 3-5% is required for benchmark test results.

This reaction has a broad threshold region and it is apparent from the appropriate plot in the Appendix that the spectrum-average cross section is sensitive to the definition of the energy scale over the range 4-11 MeV. An uncertainty  $\bar{\delta} \approx 0.03$  MeV for the energy scale in this region is a very likely possibility for this reaction. Utilizing the appropriate G values from the Appendix and Eq.(19), it is found that the computed  $\langle \sigma \rangle$  for  $^{235}\text{U}$  fission could be in error by  $\approx 2\%$  as a result of this effect alone. This is not a large error, but it seems that it may be a matter of luck that the ENDF/B-IV evaluation for this reaction yields benchmark consistency of Category I caliber.

#### The $^{238}\text{U}(n;f)$ Reaction

At a recent Specialists Meeting on fast-neutron fission for isotopes of uranium and plutonium [4], a controversy arose concerning

definition of the energy scale for  $^{238}\text{U}$  fission in the vicinity of threshold. The possibility of an uncertainty  $\bar{\delta} \sim 0.02$  MeV was raised. How significant is this from the point of view of dosimetry applications? It is clear from the appropriate graph of  $\sigma^* \phi$  in the Appendix that the energy interval 1-2 MeV is the only one of any importance for this consideration. A calculation based on Eq.(19) and values of G in the Appendix yields an uncertainty of  $\sim 1\%$  in  $\langle \sigma \rangle$  for a  $^{235}\text{U}$  fission spectrum. This error is not large enough to produce any significant problems.

#### The $^{115}\text{In}(n;n')$ $^{115m}\text{In}$ Reaction

An evaluation of this reaction has recently been undertaken for the ENDF/B-V Dosimetry File [5]. This new evaluation is based entirely on differential data (as it should be) and there are some obvious differences between this evaluation and the corresponding ENDF/B-IV evaluation [1]. The calculated spectrum-average cross section for  $^{235}\text{U}$  fission neutrons differ by  $\sim 13\%$  for these two evaluations. The spectrum-average cross section calculated using the recent evaluation appears to be in good agreement with the currently accepted integral value [6].

Which differences in these evaluations are significant from the point of view of the spectrum-average cross section? Energy scale definition is only significant for the energy range 0.5 - 2 MeV. Allowing for an uncertainty  $\bar{\delta} \sim 0.01$  MeV at these energies, it is found that an uncertainty of  $\sim 0.5\%$  is introduced into the computation of the spectrum-average cross section. This is negligible,

so one turns to consideration of normalization effects. From Figs. 2 and 3 of Ref. 5, it is seen that the most obvious differences between the two evaluations for the  $^{115}\text{In}(n;n')$   $^{115m}\text{In}$  reaction are found in the energy regions 0.5 - 0.6 MeV, 0.7 - 1.0 MeV, 2 - 4 MeV and 5 - 7 MeV. Using the analysis described in this report, it is seen that the  $\sim 10\%$  difference in the region 2 - 4 MeV is by far the most significant insofar as the spectrum-average cross section is concerned. The results of two recent differential measurements [7,8] agree very well in this important region. The new evaluation [5] relies heavily on these consistent data sets in this region. This may explain why the spectrum-average cross section computed using the new evaluation agrees with the measured integral value.

#### The $^{46}\text{Ti}(n;p)$ $^{46}\text{Sc}$ Reaction

Although the threshold for this reaction is 1.62 MeV, there are no monoenergetic data upon which to base an evaluation in the threshold region below  $\sim 3.7$  MeV. In a recent evaluation, it was necessary to determine the shape of the differential cross section in this region by means of statistical model calculations [9]. How important is this energy region from the point of view of dosimetry applications? What priority should be given to performing differential measurements at these energies? The table of F values for the  $^{46}\text{Ti}(n,p)$   $^{46}\text{Sc}$  reaction, which is contained in the Appendix, can be used to readily show that  $\sim 11\%$  of the contribution to  $\langle \sigma \rangle$  for a  $^{235}\text{U}$  fission spectrum comes from energies  $< 3.7$  MeV. The differential

cross section estimated from model calculations could be in error by as much as 20% in this region which would lead to an error of  $\sim 2\%$  in computation of the  $^{235}\text{U}$  spectrum-average cross section and significantly larger errors for softer spectra characteristic of a power reactor. Measurements for at least a few energies below 3.7 MeV are needed in order to verify the excitation function derived from model calculations.

#### The $^{47}\text{Ti}(\text{n};\text{p})^{47}\text{Sc}$ Reaction

A feature of both the ENDF/B-IV [1] evaluation and a recent evaluation by Philis et al. [9] is the presence of a cusp in the excitation function between 2.2 and 2.6 MeV. Just how large an effect does this cusp have on the  $^{235}\text{U}$  spectrum-average cross section for this reaction? Elimination of the cusp would be equivalent to lowering the cross section by  $\sim 15\%$  in this range. From Eq.(7) and tabular information the Appendix, it can be shown that the effect of removing the cusp is a reduction of the spectrum-average cross section by  $< 2\%$ . The presence of the cusp appears to be substantiated by the existing experimental data; however, the significance of its presence is modest from the point of view of dosimetry applications.

There are many other examples of the application of this method of analysis which could be included in this report; however, the objective of this report is to describe the method rather than to exhaustively survey the current status of differential dosimetry data.

## APPENDIX

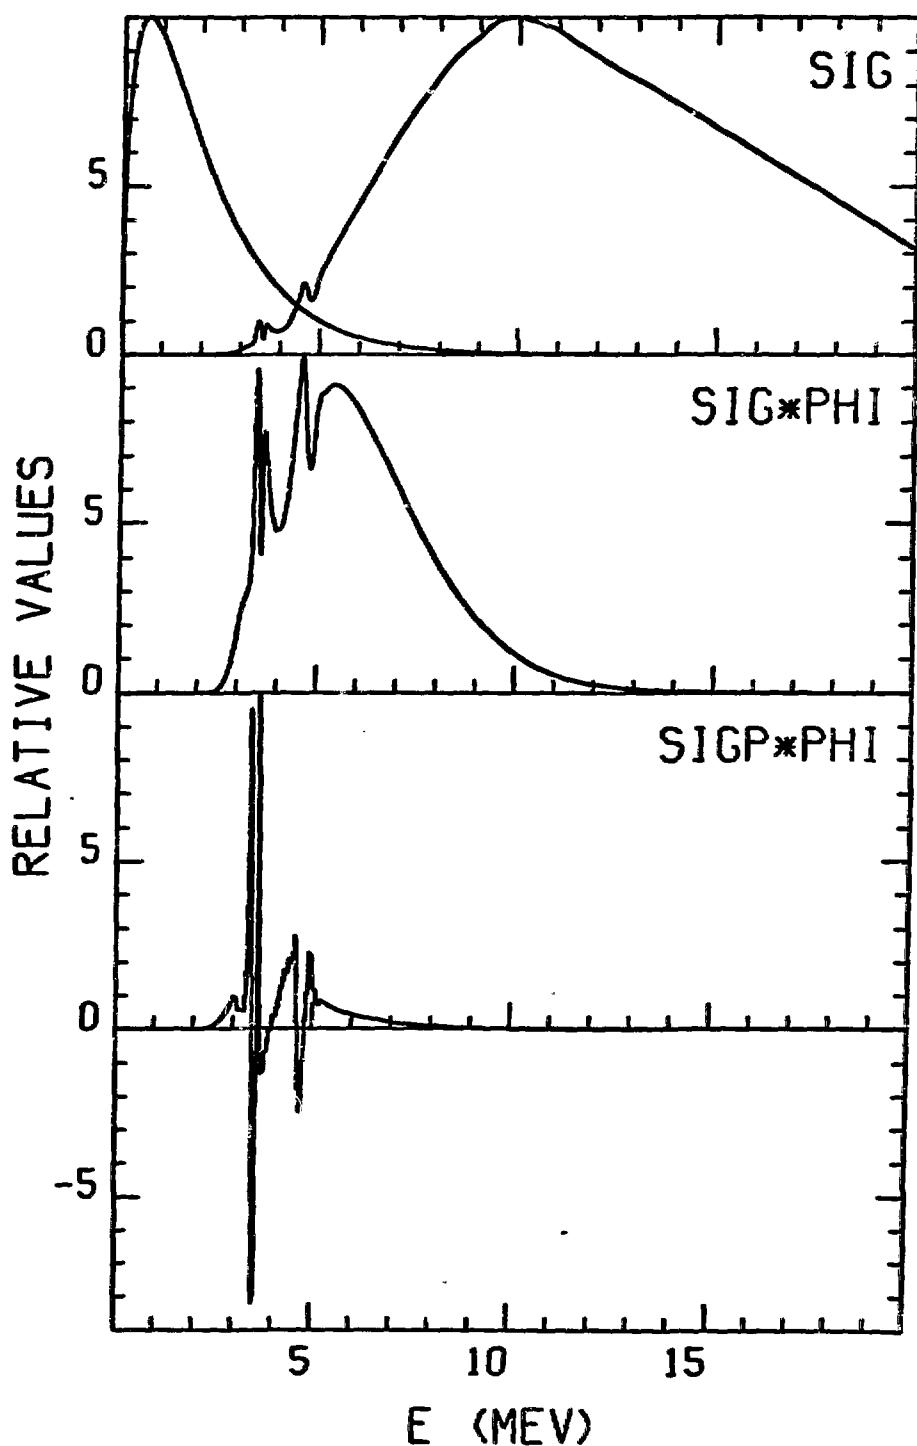

### GRAPHICAL AND TABULAR INFORMATION CORRESPONDING TO THE RESPONSE OF SEVERAL THRESHOLD REACTIONS TO A $^{235}\text{U}$ THERMAL-NEUTRON FISSION SPECTRUM

Calculations were performed for the following threshold reactions using values from the ENDF/B-IV Dosimetry File [1]:

- $^{27}\text{Al}(\text{n};\text{p})^{27}\text{Mg}$
- $^{27}\text{Al}(\text{n};\alpha)^{24}\text{Na}$
- $^{32}\text{S}(\text{n};\text{p})^{32}\text{P}$
- $^{46}\text{Ti}(\text{n};\text{p})^{46}\text{Sc}$
- $^{47}\text{Ti}(\text{n};\text{n},\text{p})^{46}\text{Sc}$
- $^{47}\text{Ti}(\text{n};\text{p})^{47}\text{Sc}$
- $^{48}\text{Ti}(\text{n};\text{n},\text{p})^{47}\text{Sc}$
- $^{48}\text{Ti}(\text{n};\text{p})^{48}\text{Sc}$
- $^{55}\text{Mn}(\text{n};2\text{n})^{54}\text{Mn}$
- $^{54}\text{Fe}(\text{n};\text{p})^{54}\text{Mn}$
- $^{56}\text{Fe}(\text{n};\text{p})^{56}\text{Mn}$
- $^{59}\text{Co}(\text{n};2\text{n})^{58}\text{Co}$
- $^{59}\text{Co}(\text{n};\alpha)^{56}\text{Mn}$
- $^{58}\text{Ni}(\text{n};2\text{n})^{57}\text{Ni}$
- $^{58}\text{Ni}(\text{n};\text{p})^{58}\text{Co}$
- $^{60}\text{Ni}(\text{n};\text{p})^{60}\text{Co}$
- $^{63}\text{Cu}(\text{n};\alpha)^{60}\text{Co}$
- $^{65}\text{Cu}(\text{n};2\text{n})^{64}\text{Cu}$
- $^{115}\text{In}(\text{n};\text{n}')^{115m}\text{In}$
- $^{127}\text{I}(\text{n};2\text{n})^{126}\text{I}$
- $^{232}\text{Th}(\text{n};\text{f})$
- $^{238}\text{U}(\text{n};\text{f})$

A 0.1-MeV interval was selected for the tables, and values of  $\sigma$  (SIG),  $\sigma'$  (SIGP),  $\phi$  (PHI),  $\sigma \phi$  (SIG\*PHI), F,  $\sigma' \phi$  (SIGP\*PHI), and G vs. energy E are provided. Plots of  $\sigma$ ,  $\phi$  (shown with  $\sigma$  but not labelled),  $\sigma\phi$  and  $\sigma'\phi$  are included, along with the tabular information, for each reaction. Discontinuities in the  $\sigma'\phi$  plots result from shortcomings in the evaluated  $\sigma$  curves and in the interpolation laws utilized in the computations.
