Preface

In 1987, the U.S. Department of Energy (DOE) directed the Pacific Northwest Laboratory, which is operated by Battelle Memorial Institute, to conduct the Hanford Environmental Dose Reconstruction (HEDR) Project. The DOE directive to begin project work followed a 1986 recommendation by the Hanford Health Effects Review Panel (HHERP). The HHERP was formed to consider the potential health implications of past releases of radioactive materials from the Hanford Site near Richland, Washington.

Members of a Technical Steering Panel (TSP) were selected to direct the HEDR Project work. The TSP consists of experts in the various technical fields relevant to HEDR Project work and representatives from the states of Washington, Oregon, and Idaho; Native American Tribes; and the public. The technical members on the panel were selected by the vice presidents for research at major universities in Washington and Oregon. The state representatives were selected by the respective state governments. The Native American tribes and public representatives were selected by the other panel members.

A December 1990 Memorandum of Understanding between the Secretaries of the DOE and the U.S. Department of Health and Human Services (DHHS) transferred responsibility for managing the DOE's dose reconstruction and exposure assessment studies to the DHHS. This transfer resulted in the current contract between Battelle, Pacific Northwest Laboratories (BNW) and the Centers for Disease Control and Prevention (CDC), an agency of the DHHS.

The purpose of the HEDR Project is to estimate the radiation dose that individuals could have received as a result of radionuclide emissions since 1944 from DOE's Hanford Site. A major objective of the HEDR Project is to estimate doses to the thyroid of individuals who were exposed to iodine-131. A principal pathway for many of these individuals was milk from cows that ate vegetation contaminated by iodine-131 released into the air from Hanford facilities.

The HEDR Project work is conducted under several technical and administrative tasks, among which is the Environmental Monitoring Data Task. Members of the Environmental Monitoring Data Task have developed databases of historical environmental measurements. These databases include iodine–131 concentrations for vegetation samples collected on and around the Hanford Site since 1944, the initial year in which the chemical separation plants were operated and whose effluents led to the release of radioactive iodine. These data will be used to assist in the HEDR model validation studies.

To date, the vegetation data for 1945-1947 have been published (Denham et al. 1993a). Because the factors used from 1945-1951 to convert raw count data to iodine-131 activity levels (correction factors) and to adjust reported iodine-131 activity levels (conversion factors) did not account for all parameters affecting counting efficiency, other conversion and correction factors need to be applied. The conversion and correction factors for the 1945-1947 vegetation data have been developed and

published (Mart et al. 1993). The data presented here are the iodine-131 vegetation data for 1948-1951. The conversion and correction factors for these data are in Denham et al. (1993b). With the public availability of the 1948-1951 data and the conversion and correction factors that apply to the data (Denham 1993b), HEDR Project Milestone 0502B has been fulfilled.

Summary

This report is a result of the Hanford Environmental Dose Reconstruction (HEDR) Project whose goal is to estimate the radiation dose that individuals could have received from emissions since 1944 at the U.S. Department of Energy's Hanford Site near Richland, Washington. To support this goal, members of the HEDR Project's Environmental Monitoring Data Task have developed databases of historical environmental measurements, including iodine-131 concentrations in vegetation collected near the Hanford Site from 1945 through 1951. These were the years of peak iodine-131 emissions, and iodine-131 was one of the key radionuclides that would affect radiation dose to the public. This report includes a listing of iodine-131 data for vegetation samples collected near Hanford from 1948-1951. Similar data for the period 1945-1947 were reported previously (Denham et al. 1993a). These data will be used to assist in the HEDR model validation studies.

Appendix - Iodine-131 in Vegetation, 1948-1951 . . . . . A.1

1948-1951 Vegetation Databases

With dBASE III PLUS, data in the 1948, 1949, 1950, and 1951 vegetation databases were compiled from published and unpublished (draft) reports and from unpublished historic counting room data cards. The original counting room data cards were located in the Records Holding Area of the Federal Records Center in Richland, Washington. Data cards had either been sorted by location into individual file folders or compiled in notebooks and identified by sampling trip name. Some of the notebooks contained the original field collection data sheets and maps of the area sampled. The field collection data sheets were useful for translating the sample numbers on the counting room data cards to location names and for identifying the type of vegetation sampled.

As indicated by Gydesen (1992), all information needed to date to reconstruct the radiation doses has been identified, sought, retrieved, evaluated, declassified, and made available. The amount of vegetation data available in the documents for 1948-1951 varied. The least amount of data was found for 1948 and the most for 1951. Data for 1949 and 1950 were plentiful. Published average values represent a significant share of the 1948 database, but the bulk of the data for 1949, 1950, and 1951 were for individual samples and were obtained from the counting room data cards. Not all recovered data were entered in the 1948-1951 vegetation databases because of problems identifying specific sampling locations, including some data for the north Pasco/Ringold area. However, the databases include a large percentage (80-90 percent) of the recovered data and are deemed to accurately represent concentration values and net counting rates for samples collected at most locations during these years.

Reported data were usually average and/or maximum values expressed in terms of concentration per unit mass (μCi/kg). The counting room data consisted of information for samples collected at individual locations on specific dates. These counting room data included gross background and net counting rates, counting times, shelf numbers, and, sometimes, correction factors for each sample as well as sample sizes and collection and analysis times.

Two significant releases of iodine-131 occurred during the 1948 through 1951 time period. An experiment in early December 1949 (the "Green Run") and equipment failures in the spring of 1951 (the silver reactor failures) resulted in larger than normal releases of iodine-131 into the atmosphere. Subsequent vegetation sampling showed elevated levels of iodine-131 on samples collected off site. Special vegetation samples were collected at many nearby and distant offsite locations following the Green Run to help define the area and intensity of impact. Additional sampling was also conducted following the discovery of the silver reactor failures in early spring 1951, but a fairly extensive routine sampling operation was already in place. All of the available data collected at offsite locations following these two events have been included in the 1949 and 1951 vegetation databases.

The data reported for samples collected during the first seven months of 1948 were labeled as iodine-131 but were actually a measure of total beta. A chemical extraction procedure to separate iodine-131 from other longer lived beta emitters was under development in 1948, and the first data for iodine-131 "in" vegetation started appearing in the published reports around August 1948. From August through November 1948, while the extraction technique was being perfected, both iodine-131 "in" vegetation data and "on" vegetation data were reported. The "on" and "in" vegetation

terminology was used for a few months in the published reports to differentiate between the old analytical method and the new chemical extraction procedure, respectively. "On" vegetation data were not reported in the published reports after November 1948. From December 1948 through the end of 1951, most reported vegetation data included both iodine-131 concentrations in vegetation and concentrations for longer half-life beta emitters. However, a noteworthy exception to this occurred following the Green Run in early December 1949. Samples collected and analyzed during the period immediately following the Green Run were only analyzed for iodine-131.

All database entries have been verified for accuracy by comparing them to the information in the original document. When possible, verification was done by an individual who did not participate in the initial data entry. A hard copy of each database, signed and dated by the person or persons verifying the data, has been retained in the HEDR Project Office files.

1948-1951 Vegetation Data in this Report

Because of the large size of the databases, only one printed copy of the data presented in this report is provided in the U.S. Department of Energy Richland Operations Office Public Reading Room, located on the campus of Washington State University in Richland, Washington. Diskettes of this report are available from the Technical Steering Panel (c/o K. CharLee, Office of Nuclear Waste Management, Department of Ecology, Technical Support and Publication Information Section, P.O. Box 47651, Olympia, Washington 98504-7651).

The diskettes have been converted from a dBASE format to a text file format to make the diskettes as user friendly as possible. Therefore, the data on the diskettes cannot be manipulated as would be possible with a dBASE file. The databases have been edited and shortened to make them easier to view and print. Each complete database consists of as many as 25 individual data fields (columns). The fields (columns) provided in this report contain the data being used by HEDR Project staff and of greatest interest to both the Technical Steering Panel and the general public. A reader interested in any of the other data available (data for longer half-life beta emitters, cross references, time the sample was collected, etc.) should contact the HEDR Project Office.

The data presented in this report only include iodine-131 concentration and counting rate data for vegetation samples collected off the Hanford Site, the area of greatest interest to the HEDR Project. Each entry (database record) is sorted or indexed according to 1) the collection location and 2) the collection date. The other data fields provide information on sample type (type of vegetation), the number of samples collected, concentrations of iodine-131 in vegetation samples, sample counts and associated counting uncertainties, a reference for each record, and notes. Specifically, the data fields provided in this report are:

Collection Site - The specific location or general area where the sample was collected.

Collection Date - The date the sample was collected.

Sample Type - The type of vegetation collected. The general term "vegetation" or "veg" was used when a more specific identification was either unknown or uncertain. The monthly reports generally did not provide information on vegetation type. The field collection data sheets almost always listed either the plant name or a plant specific letter code. This code has been partially deciphered because some of the field collection data sheets listed both the plant names and corresponding code letters. Some of the code, however, still remains unsolved. Several telephone calls were made to former field collection personnel, but no one could clearly remember to what the code letters corresponded. All available code letters have been included in the database. Counting room data cards also contained letter codes to identify the plant type being analyzed, but the sample code letter on the counting room card did not always match the letter code on the corresponding field collection data sheet. When a discrepancy of this kind arose, the field collection data sheets were assumed to contain the correct identification. This may or may not be true because many of the field sampling personnel were probably not trained in specific plant identifications.

A - alfalfa

B - unknown

C - cheat grass (?)

DC - unknown (dead/dried cheat grass?)

DG - unknown (dead/dried grass?)

DT - unknown (dead/dried thistle?)

DW - unknown (dead/dried weed?)

E - evergreen

G - grass

L - unknown

O - wheat

P - unknown (pine?)

R - rabbitbrush

S - sagebrush

T - tumbleweed or Russian thistle

TH - unknown (thistle?)

W - weed

X - unknown

# of Samples - The number of samples collected. This is important for the published average data only. A zero in this column means the number of samples is unknown.

I-131 Avg (μCi/kg) - The individual iodine-131 sample concentrations from counting room data cards and unpublished monthly reports or average iodine-131 values reported in published reports. For the 1948 database, "on" denotes the early measurements of total beta and "in" denotes the later measurements using a chemical extraction procedure.

I-131 Corr. Count - The corrected net sample counting rates of iodine-131 obtained from the counting room data cards. Again, "on" and "in" distinguish between the two measurement methods used in 1948.

I-131 +/- - The uncertainties reported with the corrected net sample counting rates of iodine-131. Uncertainties were generally, but not always, reported. They express 95 percent confidence interval on the true counting rate (1.645 x standard deviation). Again, "on" and "in" distinguish between the two measurement methods used in 1948.

Reference - The document number of the published documents or the Federal Records Center box number where the data for a particular sample were located. "UMR" was used to indicate data obtained from unpublished (draft) monthly reports. The draft reports sometimes contained specific data that were summarized or averaged in the published versions. A "Resources" section in this report provides the reader with the complete reference information for each document.

Notes - Several letters and symbols have been used in this category to further explain the data:

A - Indicates that the iodine-131 μCi/kg value was reported with a less than (<) sign.

$ - Indicates that the sample was counted and that the reported concentration was actually zero (0.000). The dBASE III PLUS software automatically inserts zeroes into all empty spaces, making it nearly impossible to tell an actual zero from a database zero.

RI - Indicates some of the samples were counted more than once. This was usually done if the initial count was suspect and again if the recount value was questionable. In the databases, a recount usually follows the initial count (in other words, both are listed in the database, one right after the other). An RI in the notes column for the 1948 database indicates a recount of an individual "in" vegetation iodine-131 sample. For the 1949-1951 databases, an RI indicates a recount of an iodine-131 sample. Sometimes recounts were averaged with the original data, and a single concentration was given. Sometimes several recounts were averaged and a concentration was given, but a concentration for the original sample data was not given. Concentration data for recounted samples were only included when they could be related to a specific sample.

RB - Indicates a recount of an "on" vegetation sample, specific to 1948. Both concentration and counts values are affected.
