

Contract No. 215, DA-18-108-405-Cml-215
Western Reserve University
Principal Investigator - Richard B. Stoughton, M.D.
Project Officer - Frank J. Vocci, Basic Toxicology Branch

Utilizing a biologic reaction (vasodilation) the nature of the intradermal barrier has been studied by measuring the penetration of nicotinic acid and seven of its derivatives in man. The partition coefficients and the absolute solubilities of these substances were determined from water/ether systems. A correlation was shown to exist between the absolute and relative solubilities of these compounds with their relative ease to penetrate the corium (percutaneous absorption).
