Spectroscopic Imaging, Diffraction, and Holography with X-Ray Photoemission

Wednesday
August 14, 1991
at
Lawrence Berkeley Laboratory

⇨ The day before the ALS Annual Users' Association Meeting (August 15–16) ⇦

X-ray probes are capable of determining the spatial structure of an atom in a specific chemical state, over length scales from about a micron all the way down to atomic resolution. Examples of these probes include photoemission microscopy, energy-dependent photoemission diffraction, photoelectron holography, and X-ray absorption microspectroscopy. Although the method of image formation, chemical-state sensitivity, and length scales can be very different, these X-ray techniques share a common goal of combining a capability for structure determination with chemical-state specificity. This workshop will address recent advances in holographic, diffraction, and direct imaging techniques using X-ray photoemission on both theoretical and experimental fronts. A particular emphasis will be on novel structure determinations with atomic resolution using photoelectrons.

Organizers

Brian Tonner, U. of Wisconsin/Milwaukee
Chuck Fadley, LBL
Fred Schlachter, LBL
Michael Van Hove, LBL

Spectroscopic Imaging, Diffraction, and Holography with X-Ray Photoemission

August 14, 1991
Lawrence Berkeley Laboratory
Building 66 Auditorium

-- Workshop Agenda --

Tuesday Evening, August 13:

5:00 - 7:00 P.M.	Registration	Shattuck Hotel Lobby

Wednesday, August 14:

7:45 A.M.	LBL Shuttle Bus Service	Shattuck Hotel to LBL, Bldg. 66 Auditorium
8:00	Registration Continues	Coffee in Auditorium Lobby Area

Introduction
Chair: Louis Terminello (LLNL)

8:30	Introduction to the ALS	A. S. Schlachter ALS–LBL
8:45	Spectromicroscopy and Holography in Materials Science	B. Tonner SRC
9:15	Concepts in Soft X-ray Holography	A. Szoke LLNL
9:40	BREAK	Coffee in Auditorium Lobby Area

Photoelectron Holography

10:00	From Photoelectron Diffraction to Surface Crystallography	J. J. Barton IBM T. J. Watson Research Center
10:40	Atomic-Resolution Photoelectron Holographic Crystallography	D. Saldin Univ. of Wisconsin–Milwaukee
11:20	Prospects for Advanced Photoelectron Diffraction	C. S. Fadley Univ. of California–Davis & LBL
12:00 Noon	LUNCH	LBL Shuttle Bus Service to LBL Cafeteria

-- Workshop Agenda, cont. --

Advances in Photoelectron Diffraction Theory and Experiment

Chair: Piero Pianetta (SSRL)

1:30 P.M.	Theoretical Developments in Photoelectron Diffraction	M. Van Hove LBL
1:50	Efficient Multiple-Scattering Methods in Photoelectron Diffraction	J. Rehr Univ. of Washington
2:20	Lattice-Site and Chemical-State Specific Photoelectron Diffraction	S. Chambers Boeing High Technology Center
3:00	Photoelectron Diffraction of Magnetic Ultrathin Films	J. Tobin LLNL
3:30	BREAK	

Photoemission Microscopy

4:00	Direct Imaging Photoemission Microscopy: Past, Present, and Future	E. Bauer Univ. Clausthal
4:45	High-Resolution Scanning Photoemission Microscopy	H. Ade SUNY-Stony Brook
5:30	ADJOURN	LBL Shuttle Bus Service to Shattuck Hotel
6:00–8:00	ALS Users' Association Meeting Reception	Shattuck Hotel

Preface

An Advanced Light Source (ALS) workshop on "Spectroscopic Imaging, Diffraction, and Holography with X-Ray Photoemission" was held at the Lawrence Berkeley Laboratory on August 14, 1991, in advance of the fourth ALS Users' Association Annual Meeting. The workshop was one in an ongoing series with the charter to identify and explore new scientific opportunities for high-brightness, third-generation VUV and soft x-ray synchrotron light sources, in general, and the ALS, in particular. The topic reflects the rapidly advancing progress in experimental techniques based on photoelectron spectroscopy. These techniques extend the traditional chemical-state specificity of photoelectron spectroscopy that is reflected in the well-known alternate name "electron spectroscopy for chemical analysis"—or ESCA. The extensions are in two rather different directions.

In the first, photoelectron spectroscopy becomes spatially resolved photoelectron microscopy or spectroscopic imaging, by which chemically specific spectral features of inhomogeneous surfaces can be mapped with a spatial resolution eventually reaching about 100 Å. In the second, the interference between photoelectron waves that are scattered by atoms as they make their way out of the surface and those that are unscattered gives rise to angular distributions in the photoelectron intensity that can be used to obtain structural information at the atomic level. In photoelectron holography, this information takes the form of atomic-resolution images of the atoms around an emitting atom in a specific chemical state. Feasibility experiments accomplished with conventional x-ray tubes or existing synchrotron light sources well demonstrate the promise of these techniques. But it is clear that their full fruition awaits the availability of the ALS and other facilities like it, where high brightness will make it possible to perform experiments of high spectral, angular, and spatial resolution with reasonable count rates.

Spectroscopic imaging techniques fall into two broad categories: direct imaging and scanning. Ernst Bauer (Technische Universität Clausthal, Germany) reviewed the prospects for spatially resolved chemical analysis with direct imaging methods. In direct imaging, electron optics (electrostatic or magnetic lenses) or a strong solenoidal magnetic field are used to collect photoelectrons and to preserve their spatial relationship on the way to an area detector. In photoelectron microscopy, the ensemble of detected electrons of all kinetic energies generates the image. The addition of an electron-energy analyzer gives direct imaging chemical-state specificity because the image contains only electrons with kinetic energies corresponding to a specific spectral feature, such as a chemically-shifted peak. Harald Ade (SUNY-Stony Brook) provided an overview of scanning spectroscopic imaging. For scanning, it is necessary to focus the x-rays to a small spot, which is rastered across the sample (in practice, the sample is moved through the spot) to generate the image. There are several methods of focusing the x-rays with somewhat complementary strengths and weaknesses. As in direct imaging, it is

possible to do simple photoelectron microscopy by collecting all the photoelectrons or chemically specific imaging with the use of an electron-energy analyzer. At this early date, it seems likely that both the direct imaging and scanning techniques will find considerable application in the analysis of materials, surfaces, and interfaces. The ALS will be equipped with instruments of both types.

Effects due to the interference of photoelectron waves have a venerable history in synchrotron radiation. For example, the high intensity of synchrotron radiation made x-ray absorption fine structure (XAFS) spectroscopy into a practical tool for obtaining interatomic distances in both ordered and disordered materials. In XAFS, the interference between the wave emitted by an atom absorbing an x-ray photon and those scattered back toward the emitter by neighboring atoms modulates the absorption cross section, thereby giving rise to the well-known XAFS oscillations above the absorption edge. The oscillations can be Fourier-inverted to extract the radial distances between the emitter and the scattering atoms. More recently, photoelectron diffraction has been developed into a technique for obtaining detailed geometrical information about the arrangement of the scattering atoms surrounding an emitter. In a diffraction experiment, the interference between scattered and unscattered photoelectron waves creates a diffraction pattern at the detector. The detector maps the pattern by moving around the solid angle surrounding the specimen surface at fixed photon and electron energies. The resulting angular distribution of photoelectron intensity reflects the geometry of the scattering atoms. As in spectroscopic imaging, fixing the photon and electron energies selects an emitter atom in a specific chemical state. Alternatively, it is possible to map the diffraction pattern by scanning the wavelength of the photoelectron wave at a fixed angle—a technique variously called energy-dependent photoelectron diffraction or angle-resolved photoelectron fine structure (ARPEFS). To ensure that the same emitter state is excited throughout the experiment, the photon and electron energies are scanned in concert.

At the workshop, Scott Chambers (Boeing High Technology Center) demonstrated the applicability of photoelectron diffraction to the relationship between surface band bending and surface structure when selenium or tellurium are on a gallium arsenide (001) surface. In particular, selenium, which is important for surface passivation of gallium arsenide, is found several layers below the surface on arsenic sites, forming a gallium selenide arsenide layer, whereas tellurium remains at the surface. Chambers also discussed the formation of a ternary nickel gallium arsenide layer when nickel is on a gallium arsenide surface, a process that involves the interplay between interface chemistry and epitaxial regrowth. James Tobin (Lawrence Livermore National Laboratory) showed how photoelectron diffraction at low electron energies could be used to study ultrathin magnetic films of iron on copper. At low energies, photoelectron diffraction is strongly surface sensitive, thereby allowing surface alloys to be distinguished from overlayers and permitting the investigation of structure with coverage. Magnetic order can be detected by excitation of multiplet-split core states, but these experiments would be considerably enhanced by the use of electron spin detectors and circular polarization.

What makes photoelectron diffraction strongly surface sensitive at low electron energies (<200 eV) is the presence of multiple scattering—the photoelectron wave scatters from more than one atom on the way to the surface. In contrast, at high electron energies (>500 eV), the scattering is dominated by a single atom and the scattered wave tends to be concentrated in the forward direction along the axis connecting the emitter and the scattering atom, so that photoelectrons from deeper in the bulk can escape. To make a quantitative connection between diffraction patterns and atomic structure, a theoretical treatment of the scattering process is required. Michel Van Hove (Lawrence Berkeley Laboratory) provided an update of the numerous factors involved in constructing a model, such as deciding when multiple scattering must be accounted for and the possible inclusion of thermal vibrations. The computer time required to obtain structural information mounts rapidly as the number of scattering events grows, making accurate multiple-scattering calculations impractical. John Rehr (University of Washington) surveyed several methods of making approximate calculations and concluded that a method based on a separable Green's function matrix was both accurate and computationally efficient.

To obtain structural details, such as the path lengths between the emitter and scattering atoms, it is not necessary to record the entire diffraction pattern. It suffices to make selective scans to generate spectra that can be inverted to yield the structural data. In ARPEFS, for example, Fourier inversion of the energy-scanned spectrum gives information similar to that obtained with XAFS. With patience or with modern display-type analyzers, however, it is possible to make angular scans that cover much of the solid angle surrounding the specimen surface. The display-type analyzer simultaneously collects energy-selected photoelectrons in an angle-resolved mode over a large solid angle. Inversion of this two-dimensional diffraction pattern yields three-dimensional maps of the positions of the scattering atoms. In this case, the diffraction pattern plays the role of a hologram produced by the interference of the unscattered (reference) wave and the scattered waves that is then reconstructed by computer to obtain an image of the objects causing the scattering. It is important to remember, however, that this "atomic-resolution" is not to be compared with the 100-Å resolution promised for spectroscopic imaging. Photoelectron holography images are obtained by averaging over the entire illuminated area (perhaps a spot 10 micrometers in diameter) of what one hopes is a homogeneous area. It is, of course, possible in principle to conceive of a spatially resolved holography experiment with 100-Å resolution, but such a feat will require x-ray optical components with improved transmission.

To open the discussion of photoelectron holography, Brian Tonner (University of Wisconsin–Milwaukee) provided a broad overview of the present capabilities of photoelectron holography. In particular, the technique gives easily interpreted chemical-state information, provides three-dimensional images with 0.5-Å resolution (0.05 Å with modeling), can generate images of both surface and sub-surface atoms, has no need for long-range order, and is widely applicable to metals,

semiconductors, and insulators. Abraham Szoke (Lawrence Livermore National Laboratory) then gave a historical overview of the development of this technique, which dates back to 1975, summarized methods of generating holograms, and introduced the problem of reconstructing holograms. Dilano Saldin (University of Wisconsin–Milwaukee) explained in some detail the theoretical and experimental application of holography with x-ray excited Auger electrons in copper. Charles Fadley (University of California at Davis and Lawrence Berkeley Laboratory) reviewed the results of several experiments in an attempt to assess the prospects for photoelectron holography by answering such questions as: Why does holography work as well as it does, how much information can be obtained from high-angular-resolution data, how can the data be treated to reduce artifacts and improve the information content, and what are the pros and cons of electron holography at high and low electron energy? John Barton (IBM–T.J. Watson Research Center) discussed the extension of electron holography to inverse diffraction by recording three-dimensional diffraction patterns. This technique can be visualized as multiple-wavenumber holography in which several data diffraction patterns are recorded, each at a different electron energy (the photon energy moving in concert, as in ARPEFS, so that the same emitter state is excited throughout the experiment). A principal benefit is that the influence of multiple scattering and artifacts is reduced, making reconstruction of the image more straightforward.

Introduction to the Advanced Light Source

A.S. Schlachter

Lawrence Berkeley Laboratory

先進光源

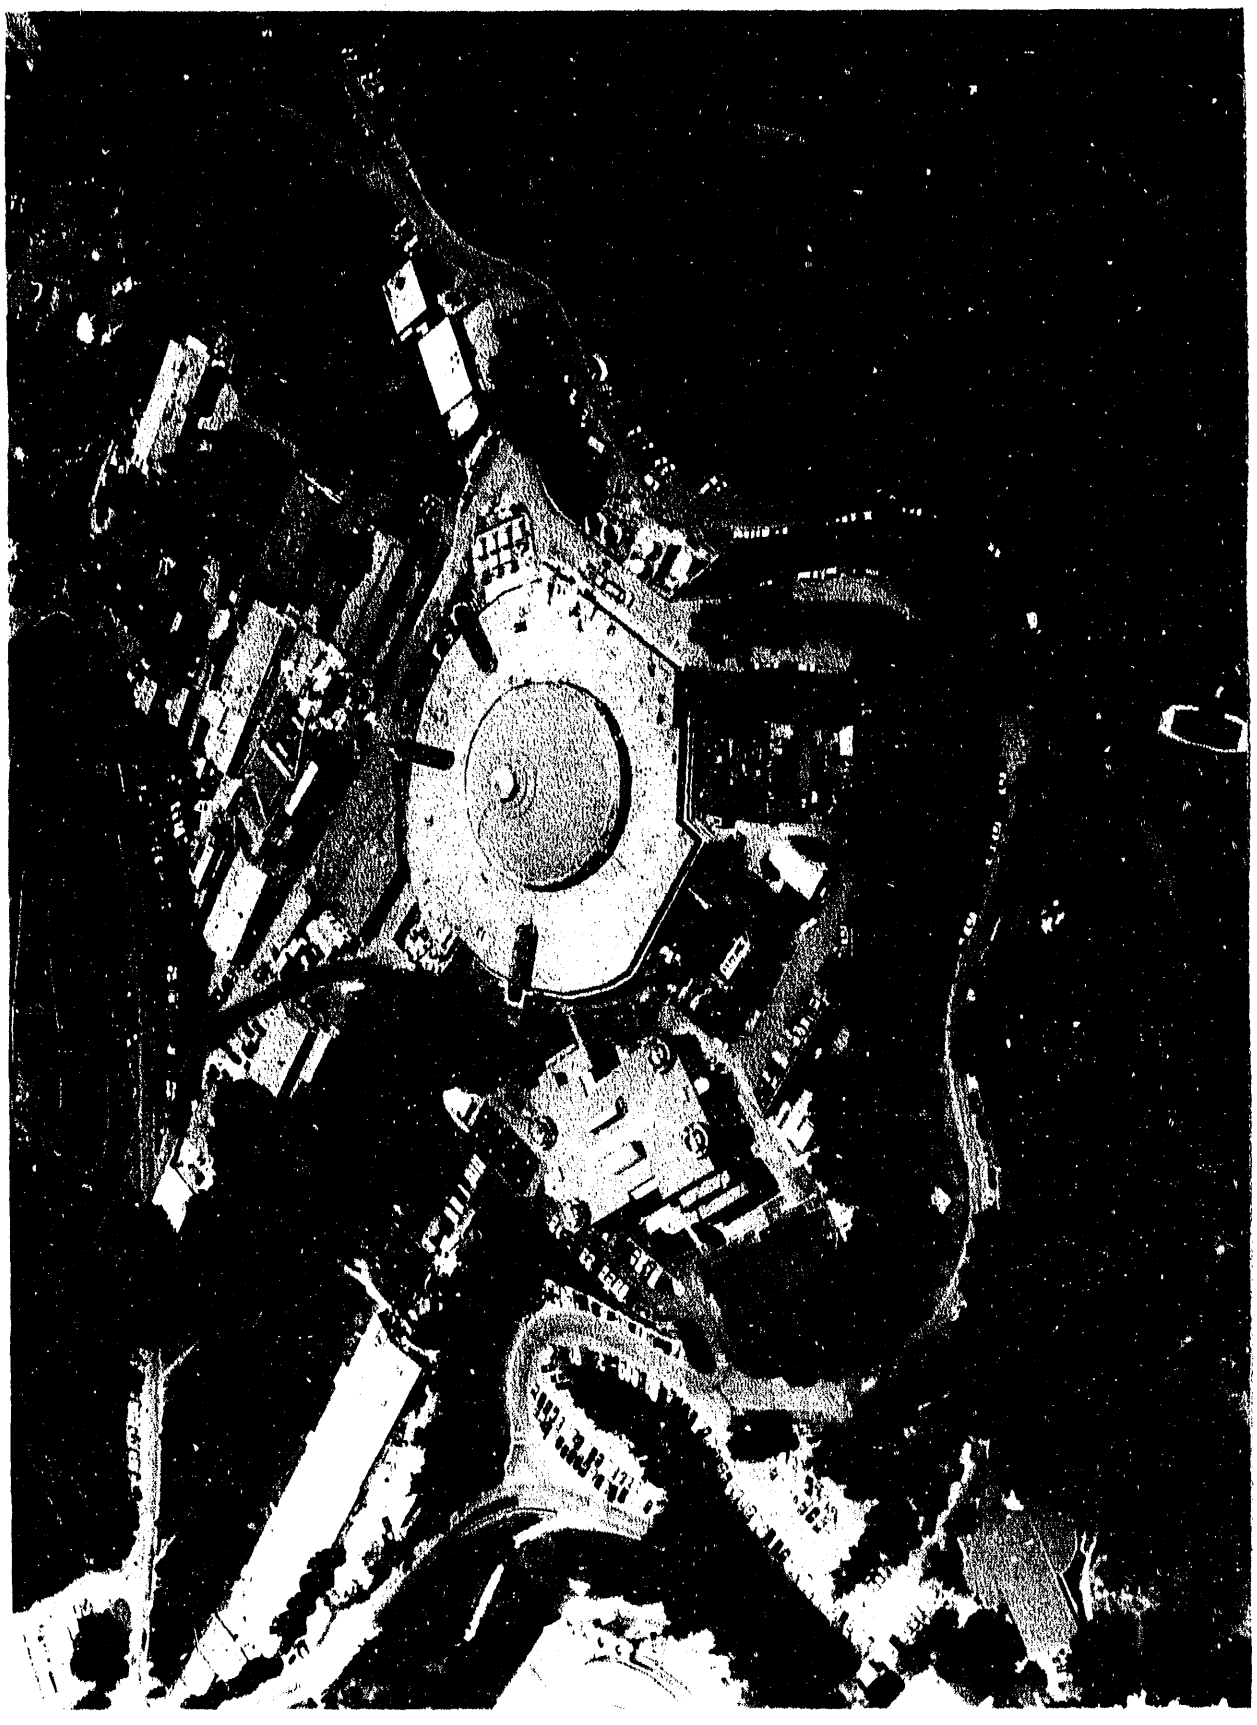
THE ADVANCED LIGHT SOURCE: X-RAY BEAMS OF UNPRECEDENTED BRIGHTNESS

從未有過的量亮度的X光束

Fred Schlachter
University of California
Lawrence Berkeley Laboratory
Berkeley, California
USA

THE ADVANCED LIGHT SOURCE: OVERVIEW

- National user facility
- Provides UV and soft x-ray beams of unprecedented brightness:
  - Broadly tunable with narrow spectral features
  - Partially coherent
  - 35 psec time structure
- Utilized by researchers from industry, academic, and national laboratory communities:
  - Materials and surface science
  - Atomic and molecular physics
  - Chemistry
  - Life sciences
  - Technology
- Construction project began in late 1986
- Begin operations in spring 1993
- Construction cost — $99.5 million



THE ALS WILL BE THE FIRST THIRD-GENERATION SYNCHROTRON-RADIATION SOURCE

ALS

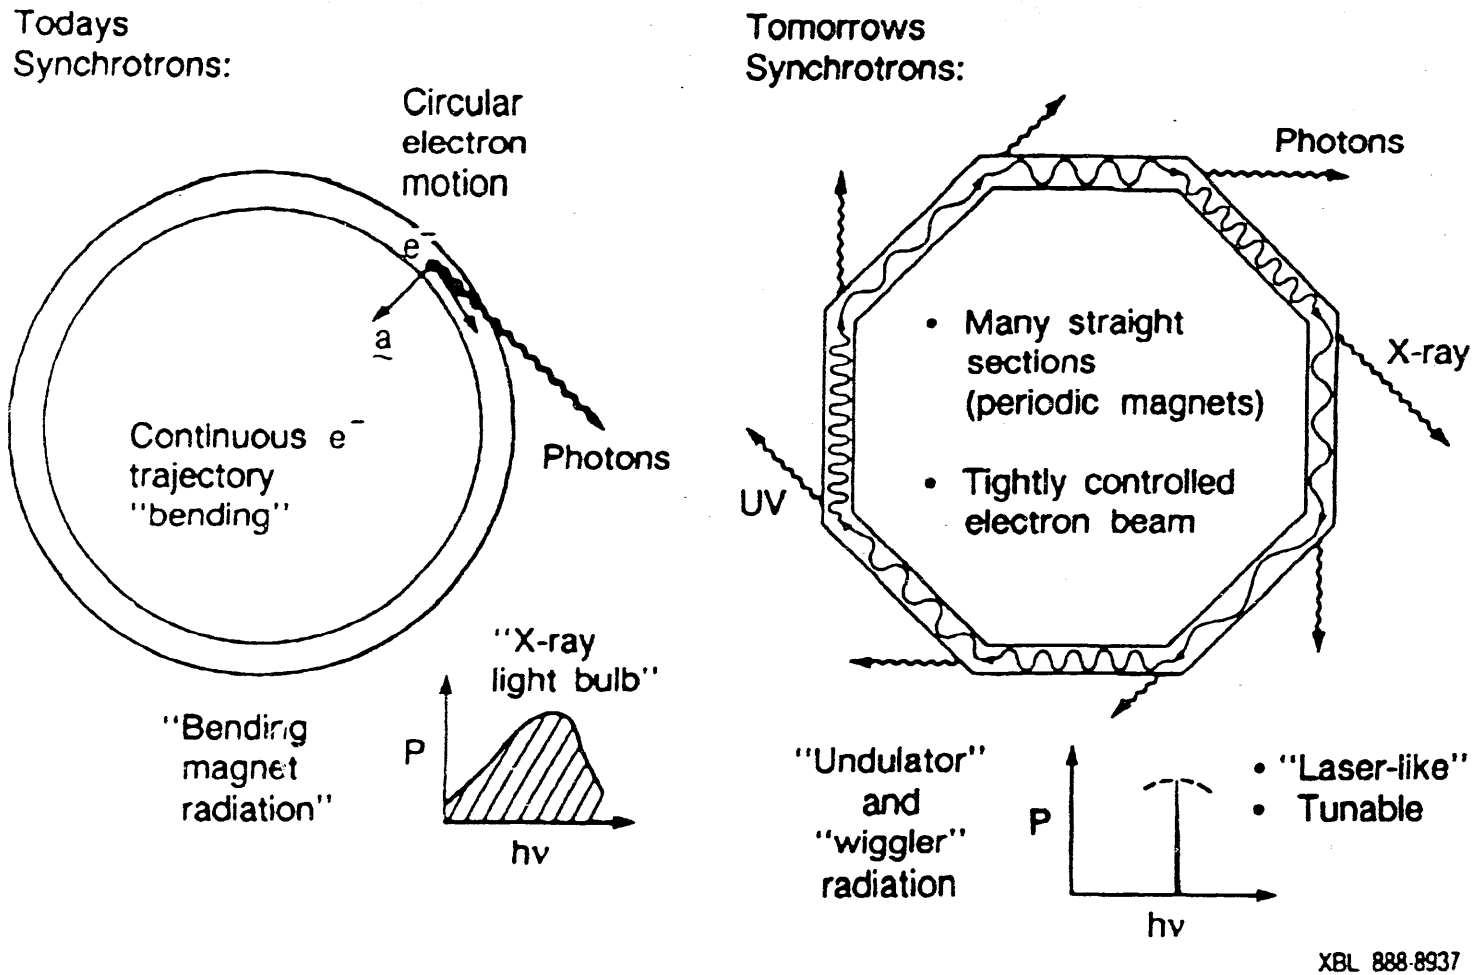
- **First generation: parasitic operation at high-energy physics facilities (e.g., SSRL)**
- **Second generation: dedicated to synchrotron radiation (e.g., NSLS)**
- **Third generation: high brightness (e.g., ALS, APS)**

  - low emittance

  -long straight sections

  -permanent-magnet undulators

EVOLUTION OF SYNCHROTRON RADIATION



An Undulator Produces a Very Bright Beam of VUV or X Rays

- Coherent superposition of radiation from electrons bent many times in periodic permanent-magnet structure

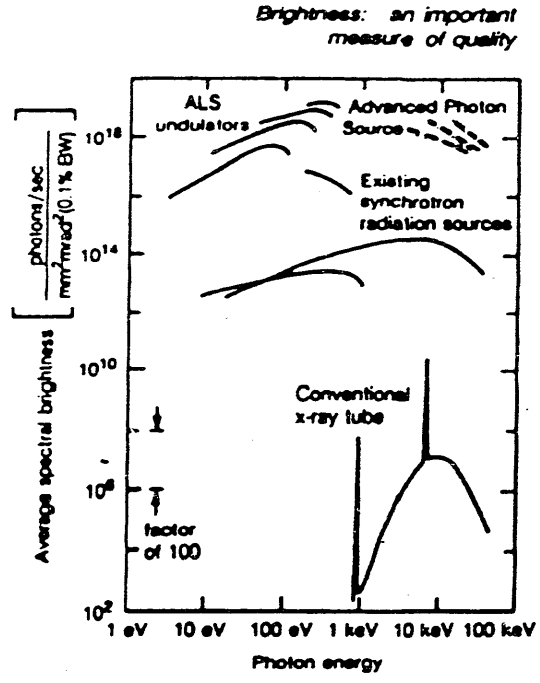
- Properties of undulator radiation:

  — High brightness
  — Tunable photon energy
  — Partial coherence
  — High linear polarization
  — Picosecond time structure

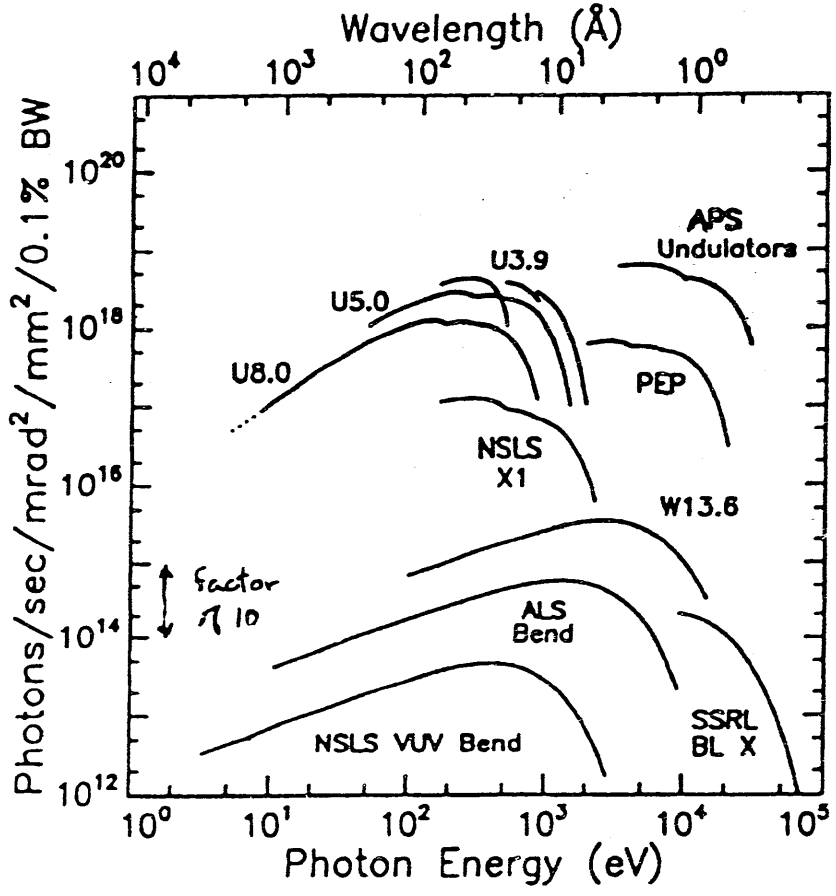
An undulator is a tunable soft-x-ray picosecond strobe light with laser-like properties

HIGH BRIGHTNESS IS THE MAIN FEATURE OF THE ALS

- High intensity
- Ease of focussing ⇒ microscopy
- Study of tenuous targets ⇒ atomic physics, chemistry
- Element-specific sensitivity
- Coherence
- Broad tuning range
- Short pulses



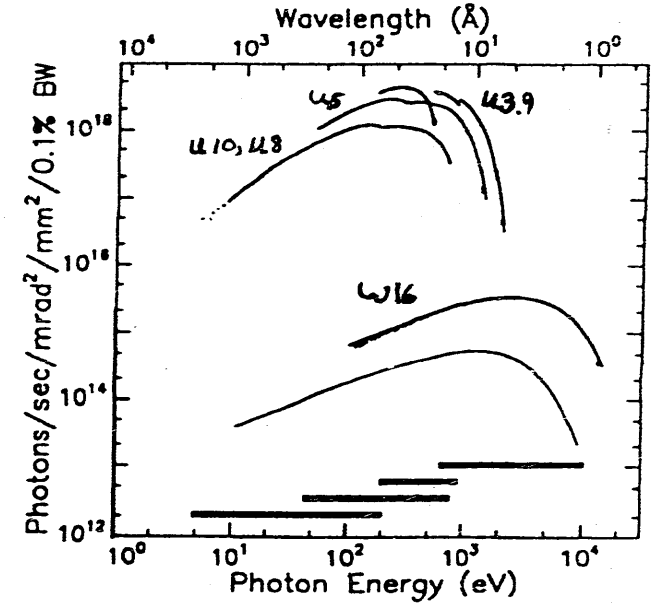
THIRD-GENERATION SYNCHROTRON-RADIATION SOURCES HAVE HIGH BRIGHTNESS



- **ALS undulators produce a beam which is a factor of 10,000 brighter than that from bend magnets**

INITIAL SCIENTIFIC PROGRAM

- Broad program
  - Photon energy: 5 eV – 10,000 eV
  - Many research disciplines
  - Researchers from many institutional settings



- Insertion-Device Program
  - 1 x U10 Combustion Dynamics
  - 2 x U8 Chemistry and Atomic Physics
  - 2 x U5 Surface and Materials Science
  - 1 x U3.9 X-ray Imaging and Optics
  - 2 x W16 Materials Science/Life Science

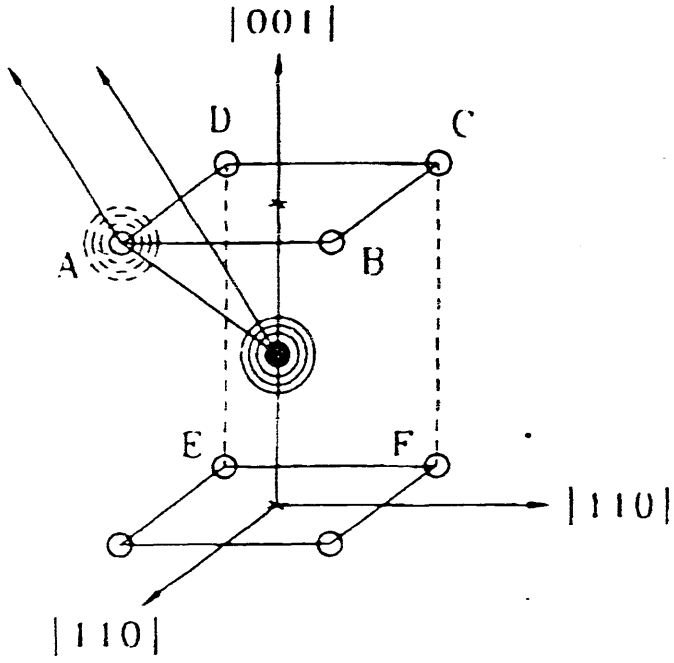
- This program will require substantial user funding to supplement ALS project funds.

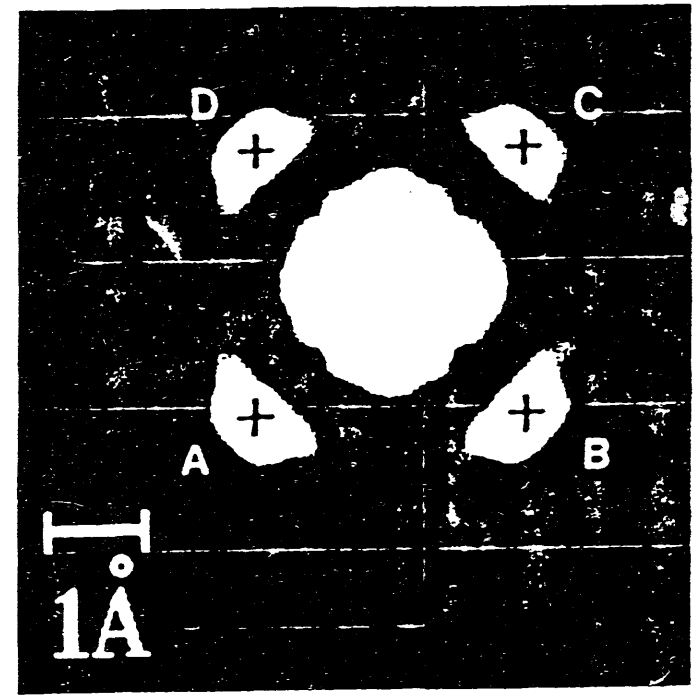
- Bend-Magnet Program
  - IDTs will utilize 3 bend-magnet lines
  - Bend-magnet teams to have been approved for 4 bend-magnet lines
    - infrared
    - optics development
    - materials science
    - circularly polarized radiation

January 1896 Röntgen/Wurzburg

ATOMIC-RESOLUTION ELECTRON HOLOGRAPHY

- Image near-neighbor environment of specific chemical species in three dimensions
- Measure photoelectron diffraction pattern produced by x ray to select chemical species
- High resolution needed to resolve chemical shifts





Holographic reconstruction of Cu (001)

Chocolate holograms

The choice of which chocolate bar to choose may soon become more difficult with the advent of edible chocolate holograms.

Dimensional Foods, Inc., of Boston is exploring techniques to apply holograms to food, under a patent issued to company founder and president Eric Begleiter in 1987, the year the company was established.

According to *Holography News*, one technique being considered is a thermal transfer process. That process is suitable for foods such as chocolate, that may be injection-molded or poured into a mold. A reverse hologram is built into the mold as a minute relief structure resembling an embossed hologram shim. The chocolate is pressed into the relief, resulting in a hologram on the reflective surface of the chocolate.

Another technique involves a dehydration process for candy coatings. This technique reproduces diffraction grating spectral colored sugar called "Sparkle," that is under consideration for coating breakfast cereals. Other candidates are lollipops and hard candies.

If DFI's product is successful, the company is interested in licensing the technology to food manufacturers. Although initial markets are child-oriented, dealing with candy, DFI is investigating application for pressure-formed tablets produced by the pharmaceutical industry.

Photoelectron Holography and Quantitative X-Ray Photoelectron Diffraction of Surfaces and Ultrathin Films

Structure of metal surfaces and thin-films by Fourier-transform Photoelectron Diffraction[†]

S. Hardcastle, Z.-L. Han, G. R. Harp, J. Zhang, X.-D. Wang, D. K. Saldin, and B. P. Tonner

- What is new about photoelectron holography?
- Physical interpretation of "images".
- Improved 'deconvolution' methods of direct imaging.
- Quantitative structure determination.

[†]Supported by NSF DMR-88-05171

Features of Photoelectron Holography

- Easily interpreted chemical-state information
- Three-dimensional "image" of atomic structure with 0.5 A resolution (direct) and 0.05 A resolution (modelled)
- Can image atoms below the surface
- Long-range order is not required
- Applies to metals, semiconductors, insulators

Method

1. Isolate region of sample by focussed X-rays or selected-area diffraction.
2. Measure 2π steradian angular-distribution of photoelectron diffraction, or *hologram*.
3. Normalize hologram to extract anisotropy function $I_{\hat{K}}$.
4. Phased two-dimensional Fourier-transform of data produces 3-dimensional structure.

$$I_K(\theta,\phi) = I_o(\theta,\phi)(1+\chi(\theta,\phi)). \tag{1}$$

$$\phi(\mathbf{r}) = \int \chi(\hat{\mathbf{K}})\, e^{i\mathbf{K}\cdot\mathbf{r}} d\hat{\mathbf{K}}. \tag{2}$$

Image function: $|\phi(\mathbf{r})|^2$

Radial image function: $|\phi(r,\hat{\mathbf{r}})|^2$

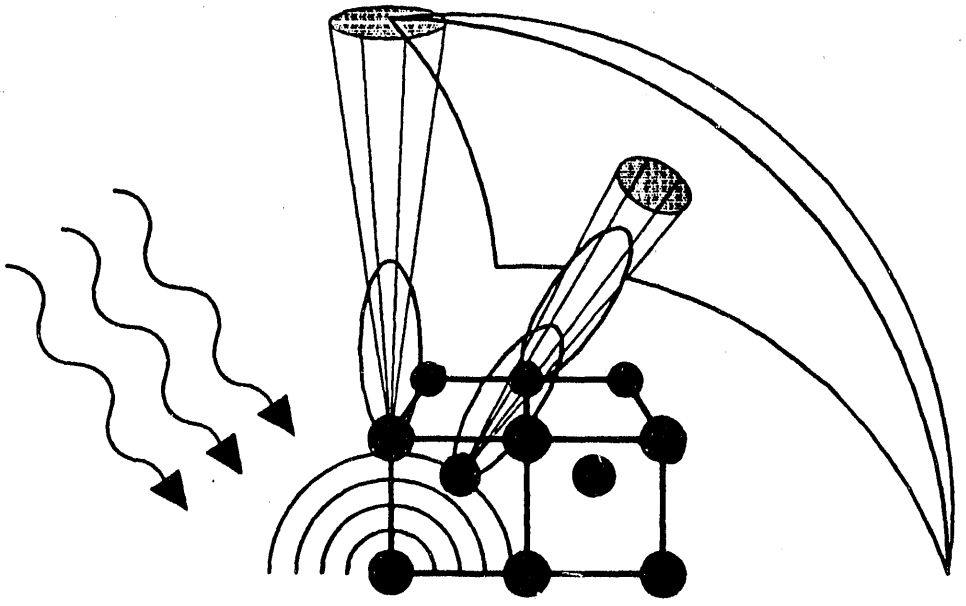
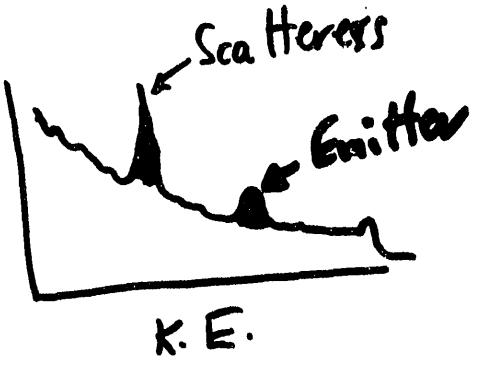
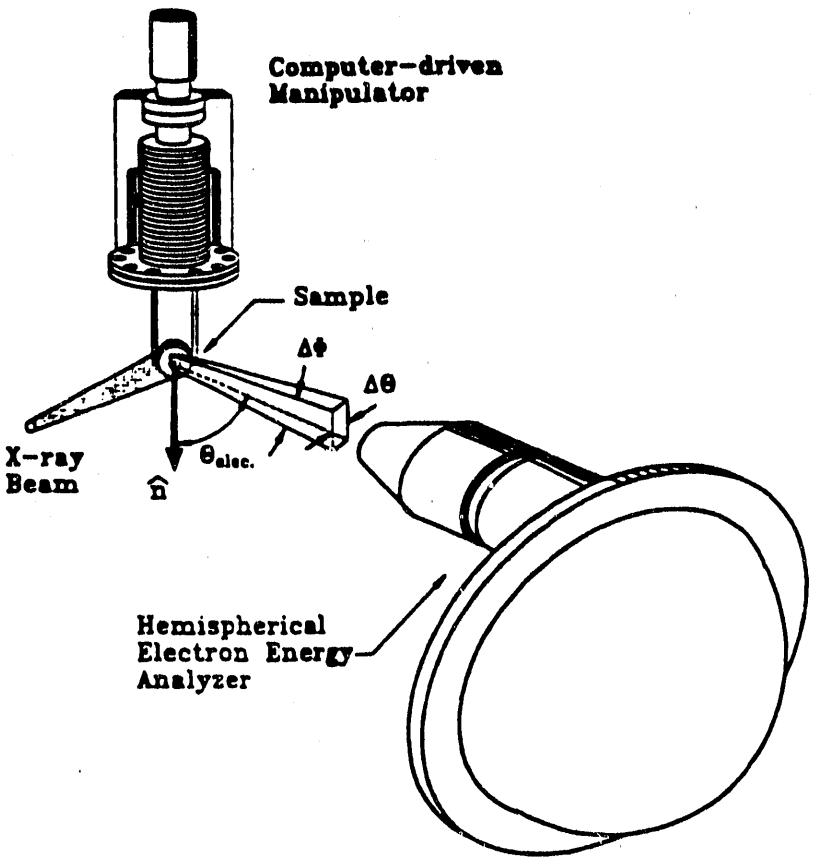
Photoemission Holography
in
Forward-scattering Geometry



- Buried atoms
- Probes the "core"
- Distinguish emitter by chemical state





Idealization of the experimental geometry, which maintains a fixed angle between the incident X-ray beam and the ejected electron ($\Theta_{photon}+\Theta_{electron} = \Gamma = const$). For each crystal azimuth (Φ), the electron polar angle (Θ_{el}) is scanned by rotating the sample normal ($\hat{n}$). In practice, the incident X-ray beam illuminates the entire sample surface, and the detector accepts a small solid-angle ($\Delta\Theta\Delta\Phi$) around the emission direction (see text for details).

Real-space interpretation of x-ray-excited Auger-electron diffraction from Cu(001)

H. Li and B. P. Tonner*
Department of Physics and Laboratory for Surface Studies, University of Wisconsin—Milwaukee 1900 E. Kenwood Blvd., Milwaukee, Wisconsin 53211
(Received 17 August 1987)

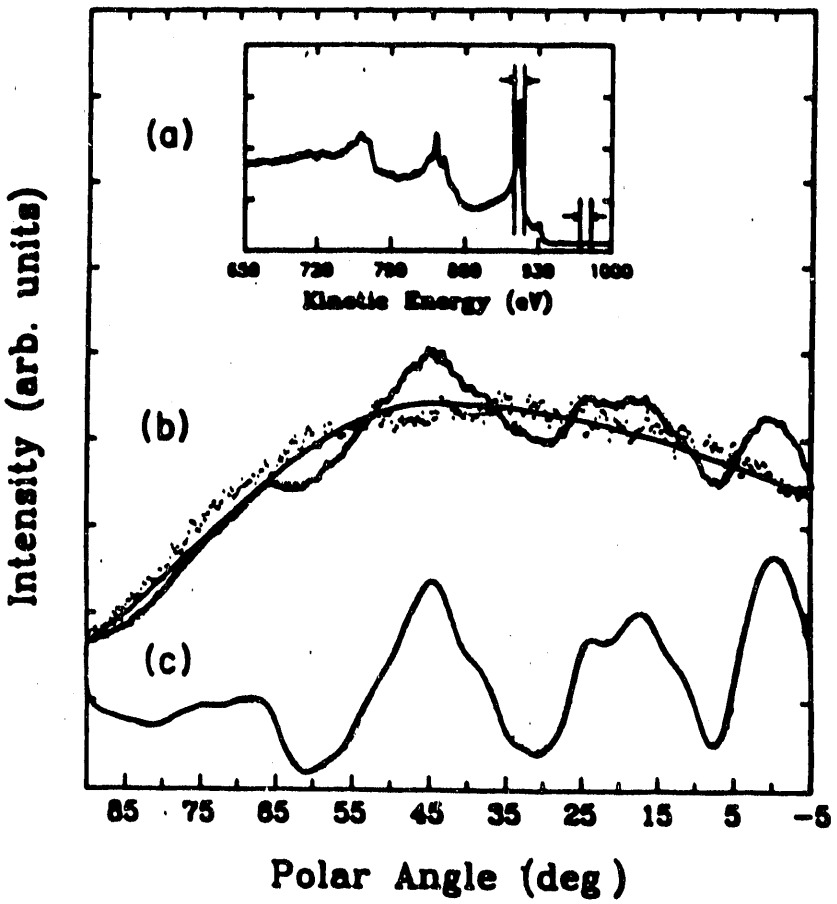


FIG. 1. Illustration of data acquisition and analysis of Auger-electron diffraction along the Cu(001) [100] azimuth. (a) Kinetic energy distribution of x-ray-excited *LVV* Auger electrons from Cu(001). The energy windows used to monitor AED at 917 eV and the background at higher energy are shown. (b) The dotted curve is the experimental background, the smooth solid curve is a theoretical fit to the experimental background. The modulated solid curve is the emission intensity from the Auger electrons. (c) Background-subtracted Auger-electron diffraction intensity, smoothed over a range of ±1.5° in polar angle.

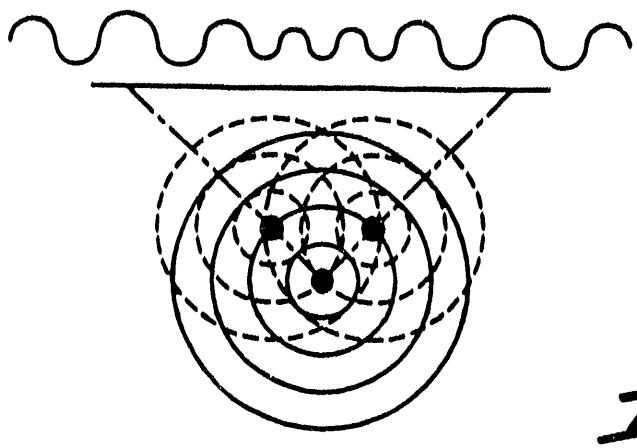
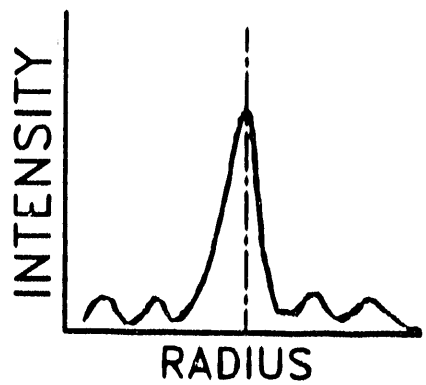
High-resolution Photoelectron Holography

- High kinetic energy ($\approx 1keV$), $\lambda \leq 0.4\mathring{A}$.
- (Near) full hemispherical pattern.
- High angular resolution ($\approx 1^{o}$).
- Multiple energies (to suppress artifacts).
- Improved algorithms (Scattered-Wave Included F-T, SWIFT).



s-wave emitter,
s-wave scatterers

(a)



Scattered-Wave Included Fourier Transform

$$I(\vec{r}) = \int K(\vec{k}, \vec{r})\, \chi(\vec{k})\, d\vec{\sigma}$$

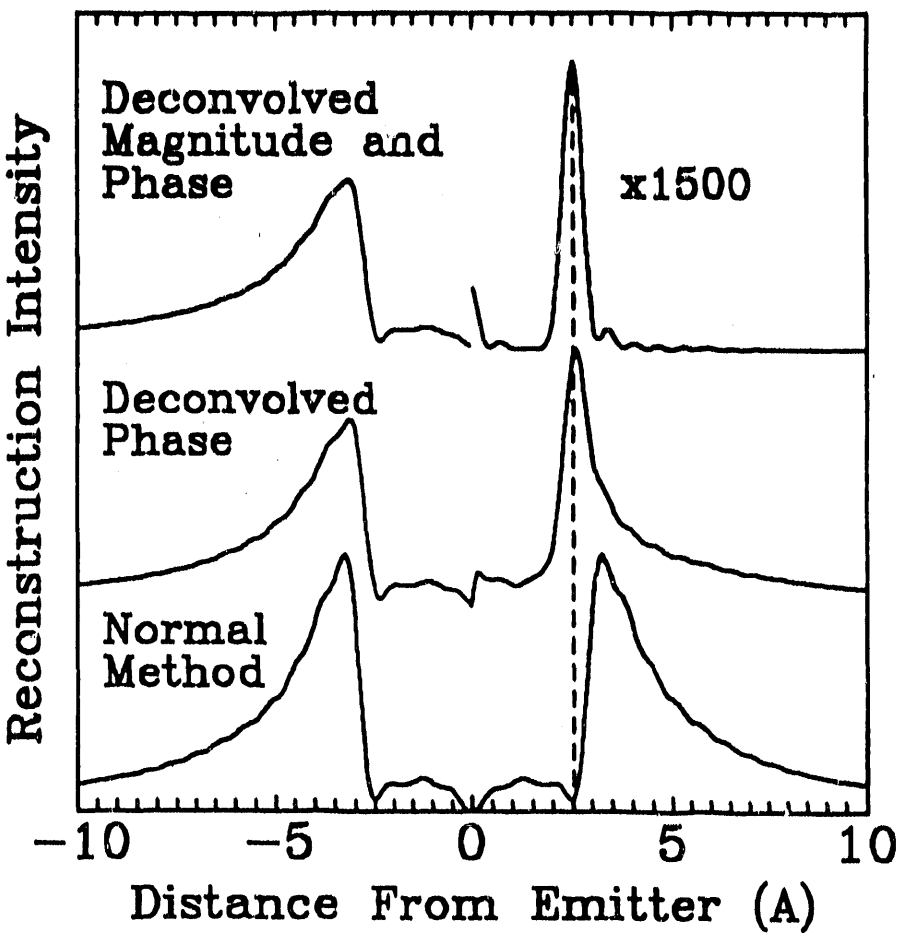
Derived from scattered wave

$$\psi_s(\vec{k}, \vec{r}_j) = F_k(\vec{r}_j)\, e^{i\vec{k}\cdot\vec{r}_j} e^{-i\vec{k}\cdot\vec{r}}$$

Deconvolution of Atomic Scattering Factor: Modified Fourier-transform Algorithm

$$\tilde{\phi}(\mathbf{r}) = \int \frac{1}{|f(\theta)|e^{i\psi(\theta)}} \chi(\hat{\mathbf{K}})\, e^{i\mathbf{K}\cdot\mathbf{R}} d\Omega. \qquad (10)$$

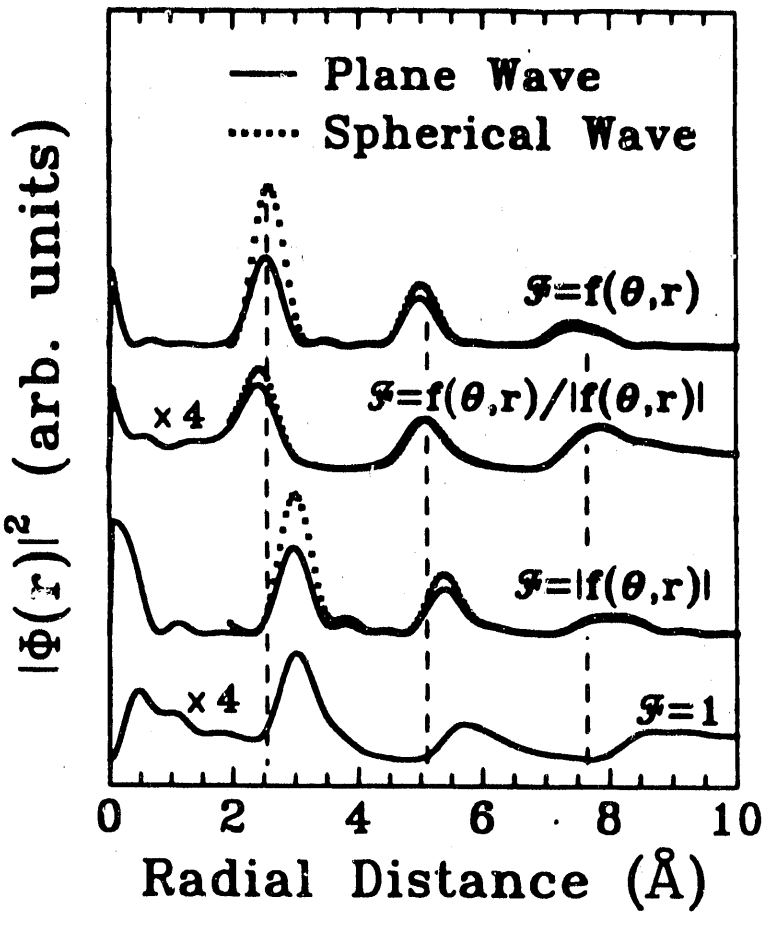
- Deconvolving only the phase removes some of the atom-shift, but leaves a large anisotropy in the atom-image intensity.
- Deconvolving both the phase and the amplitude corrects for both the atom-shift and the asymmetry, but increase the twin-image amplitude (a lot).



$\frac{\chi}{|f|e^{i\psi}}e^{i\vec{K}\cdot\vec{R}}$

$\frac{\chi}{e^{i\psi}}e^{i\vec{K}\cdot\vec{R}}$

$\chi e^{i\vec{K}\cdot\vec{R}}$



$$\Phi(\vec{r}) = \int \frac{\chi(\vec{k})}{\mathcal{F}(\vec{k},\vec{r})} e^{i\vec{k}\cdot\vec{r}}\, d\vec{k}$$

Photoemission Diffraction and Holographic Imaging

Characteristics:

- Chemical-state specific
- Surface and sub-surface atoms
- 3D atomic coordination and sites by holographic reconstruction
- Below 0.05 Angstrom accuracy with structure refinement (modelling)

Developments:

- Need high flux/small bandwidth radiation in 100-1500 eV range
- Need more efficient detectors

* Combine with SPEM

Needs for Next-generation X-ray Photoelectron Diffraction

Energy resolution of 0.1 eV	**Chemical state**
Photon energy range to 1000 eV	**Multi-energy holography**
Angular resolution of 0.1 degree	**Resolve high-frequency fringes**
Angular range of 2-pi steradian	**High accuracy in hologram**
Small spot size (few micron or less)	**Isolate small chemical domains**
High count rates	**Reduce sample exposure**

Some Aspects of X-Ray and Electron Holography

A. Szoke

Lawrence Livermore National Laboratory

SOME ASPECTS OF X-RAY AND ELECTRON HOLOGRAPHY.

ABRAHAM SZOKE

LAWRENCE LIVERMORE NATIONAL LABORATORY
AND
ROWLAND INSTITUTE FOR SCIENCE.

I./ A short historical overview.
II./ Some thoughts on the reconstruction of holograms.

A VERY SHORT HISTORICAL NOTE. (1)

HOLOGRAPHY. Gábor invented it before there were lasers.

1./ Coherent superposition of wavefronts has (most of) the missing information.
2./ Illumination with the reference beam reconstructs the object by "deconvolution".

Problems: Ordinary sources have short coherence length.
Fringes are small, of the order of λ.
Limited magnification, accompanied by distortion.

PHOTOELECTRON DIFFRACTION. Liebsch, 1974.

He realized that the first (odd) order scattering of a photoelectron contains information about the emitting atom's environment.

(Even order scattering that interferes with the photoemission produces EXAFS.)

MORE HISTORICAL NOTES. (2)

HOLOGRAPHY WITH A LOCAL REFERENCE BEAM. Szöke, 1975, 1985.

1./ The emission of a characteristic X-ray, or a potoelectron, or an Auger electron can serve as a reference beam in holography.
2./ The elastically scattered waves from neighboring objects interfere to give a hologram.

This method corrects Gábor's problems and has some more advantages.
The objects are close, no long coherence length needed.
The recorded interference fringes are large, $>>\lambda$.
Great magnification is inherent in the process.
Many similar objects, similarly oriented, (but not necessarily ordered in space) give a single hologram.

MORE HISTORICAL NOTES (3)

Methods of producing holograms (From Szöke, 1985)

	RECORDING MEDIUM	
	X-rays	electrons
Local source	Characteristic radiation	Photoelectron or Auger electron diffraction.

Electrons backscattered from the lattice acting as reference.
(B. Tonner, et al., 1989)

RECONSTRUCTION OF HOLOGRAMS AND MULTIPLE SCATTERING. (1)

With acknowledgement to the work of Barton, Tong, Rehr.

1./ Single scattering, general (angle dependent, complex) scattering amplitude. We will follow Barton's derivation.

The "useful" part of the hologram is

$$\chi(\theta) = \frac{\exp(ikR)}{4\pi R} \{f_o(\theta) + \sum_n f_n(\theta)\exp[-ikr_n(1-\cos\theta)]\}$$

Using the Helmholtz - Kirchhoff intergal theorem, we get

$$U(r) = \frac{1}{2\pi R^2} \sum_n \int_S \{[f_o^*(\theta)f_n(\theta)\exp(ikr_n - ik.r_n) + cc.] \exp(-ik.r)\}$$

The reconstructed object will in general be of weird shape. If the angular dependence of $f_n(\theta)$ is known, the hologram can be corrected by multiplying it with $1/f_n(\theta)$. (This is my interpretation of the proposal by Barton and by Tong.)

An alternative interpretation is a two step process. In the first step the weird shape is reproduced, in the second the result is interpreted as a superposition of known weird shapes.

RECONSTRUCTION OF HOLOGRAMS AND MULTIPLE SCATTERING. (2)

2./ Multiple scattering, general considerations.

The propagation of the electron, or the X-ray in the medium can be described by an integral equation.
In X-ray diffraction it is called the dynamical theory. (Darwin, Ewald, Laue, beginning cca. 1915.)
In quantum mechanics it is called the Lippmann - Schwinger equation.
For discrete scatterers the integral reduces to a sum.

3./ Multiple scattering, isotropic (s-wave) point scatterers.

The Green's function for the propagation of the electron is

$$G(\mathbf{R},0;E) = \frac{\exp(ikR)}{4\pi R} + \sum_{n\neq 0} \frac{\exp(ik|\mathbf{R}-\mathbf{r}_n|)}{4\pi R} V_n \frac{\exp(ik|\mathbf{r}_n|)}{4\pi|\mathbf{r}_n|}$$

$$+ \sum_{n\neq m \; m\neq 0} \frac{\exp(ik|\mathbf{R}-\mathbf{r}_n|)}{4\pi R} V_n \frac{\exp(ik|\mathbf{r}_n-\mathbf{r}_m|)}{4\pi|\mathbf{r}_n-\mathbf{r}_m|} V_m \frac{\exp(ik|\mathbf{r}_m|)}{4\pi|\mathbf{r}_m|} + \ldots$$

The series can be resummed by singling out the last scatterer

$$G(\mathbf{R},0;E) = \frac{\exp(ikR)}{4\pi R}\left[1+\sum_{n\neq 0}\frac{\exp(-ik|r_n|)}{4\pi|r_n|}V_n\frac{\exp(ik|r_n|)}{4\pi|r_n|} + \sum_{n\neq m\neq 0}\frac{\exp(-ik|r_n|)}{4\pi|r_n|}V_n\frac{\exp(ik|r_n-r_m|)}{4\pi|r_n-r_m|}V_m\frac{\exp(ik|r_m|)}{4\pi|r_m|}+\ldots\right]$$

$$+\sum_{n\neq 0}\frac{\exp(ik|\mathbf{R}-r_n|)}{4\pi R}V_n\left[\frac{\exp(ik|r_n|)}{4\pi|r_n|}+\sum_{m\neq n\ m\neq 0}\frac{\exp(ik|r_n-r_m|)}{4\pi|r_n-r_m|}V_m\frac{\exp(ik|r_m|)}{4\pi|r_m|}+\ldots\right]$$

The general form of the series is the same as for single scattering

$$G(\mathbf{R},0;E) = \frac{\exp(ikR)}{4\pi R}\{f_o(\theta) + \sum_n f_n(\theta)\exp[-ikr_n(1-\cos\theta)]\}$$

The first term, $f_o(\theta)$, is the angle, and energy dependent factor for EXAFS. The second term changes the phase, and intensity of atom n in its reconstruction, but it does not move its position.

This is the "theory of fog". The first layer of scatterers is seen clearly, the images of the deeper layers are attenuated severely even if there are no losses.

RECONSTRUCTION OF HOLOGRAMS AND MULTIPLE SCATTERING. (4)

4./ Discrete scatterers, but general scattering.

Rehr has derived a formula that treats this case. It is also similar in form to the single scattering case, but both $f_0(\theta)$ and $f_n(\theta)$ depend strongly on the scattering by the other atoms.

The only real hope I have that an iterative algorithm will converge to the correct solution.

Recent work by Barton and by Tong propose to use holograms at various electron energies to arrive at better estimates. These can also be used the same way.

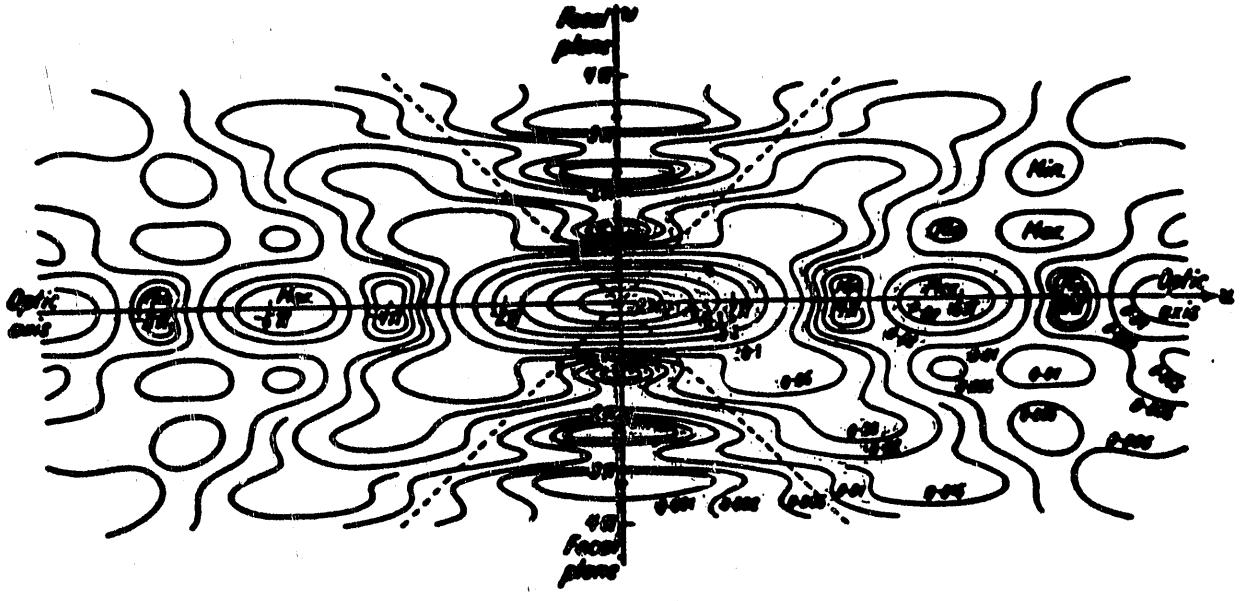
$\int_A e^{ikk\cdot r} dr$ is peaked at $r=0$



Isophotes [contour lines of the intensity $I(u,v)$] in a meridional plane near focus of a converging spherical wave diffracted at a circular aperture. The intensity is normalized to unity at focus. The dotted lines represent the boundary of the geometrical shadow. When the figure is rotated about the u-axis, the minima on the v-axis generate the AIRY dark rings.

[Adapted from E.H. LINFOOT AND E. WOLF, Proc. Phys. Soc. B 69, 823 (1956).]

Born & Wolf

	Experiment	Stationary Phase Integral	Peak
1D	ARPEFS	$\int dk\, e^{ik(a-\vec{a}\cdot\hat{k})}e^{-ikr'}$	$P[r' - \lvert a - \vec{a}\cdot\hat{k}\rvert]$
2D	Holography	$\iint dk_x dk_y\, e^{ik(a-\vec{a}\cdot\hat{k})}e^{ik\vec{r'}\cdot\hat{k}}$	$e^{ika}P[\vec{r'} - \vec{a}]$
3D	Inverse Diffraction	$\int dk \iint dk_x dk_y\, e^{ik(a-\vec{a}\cdot\hat{k})}e^{-ik(r'-\vec{r'}\cdot\hat{k})}$	$P'[r' - a]P[\vec{r'} - \vec{a}]$

$\iint I(\vec{k})\, dk_x dk_y\, e^{ik\vec{r}\cdot\hat{k}}$ extracts all $\vec{a}$ oscillations

1) Too many
   - twins
   - ghosts
   - multiple
2) Direct!

Inverse Diffraction from Multiple Wavenumber Photoelectron Holography

	Experiment	Stationary Phase Integral	Peak
1D	ARPEFS	$\int dk\, e^{ik(a-\vec{a}\cdot\hat{k})} e^{-ikr'}$	$P[r' - \lvert a - \vec{a}\cdot\hat{k}$
2D	Holography	$\iint dk_x dk_y\, e^{ik(a-\vec{a}\cdot\hat{k})} e^{ik\vec{r'}\cdot\hat{k}}$	$e^{ika} P[\vec{r'} - \vec{a}]$
3D	Inverse Diffraction	$\int dk \iint dk_x dk_y\, e^{ik(a-\vec{a}\cdot\hat{k})} e^{-ik(r'-\vec{r'}\cdot\hat{k})}$	$P'[r' - a]P[\vec{r'} -$

$\int dk \iint dk_x dk_y\, I(\vec{k})\, e^{-ik(r'-\vec{r'}\cdot\hat{k})}$

extracts oscillations with $\vec{a}$ and $|\vec{a}|$.

1) Single Scattering!
   - No Twins
   - Less Ghosts
   - Less Multiple Scat.

2) Direct!

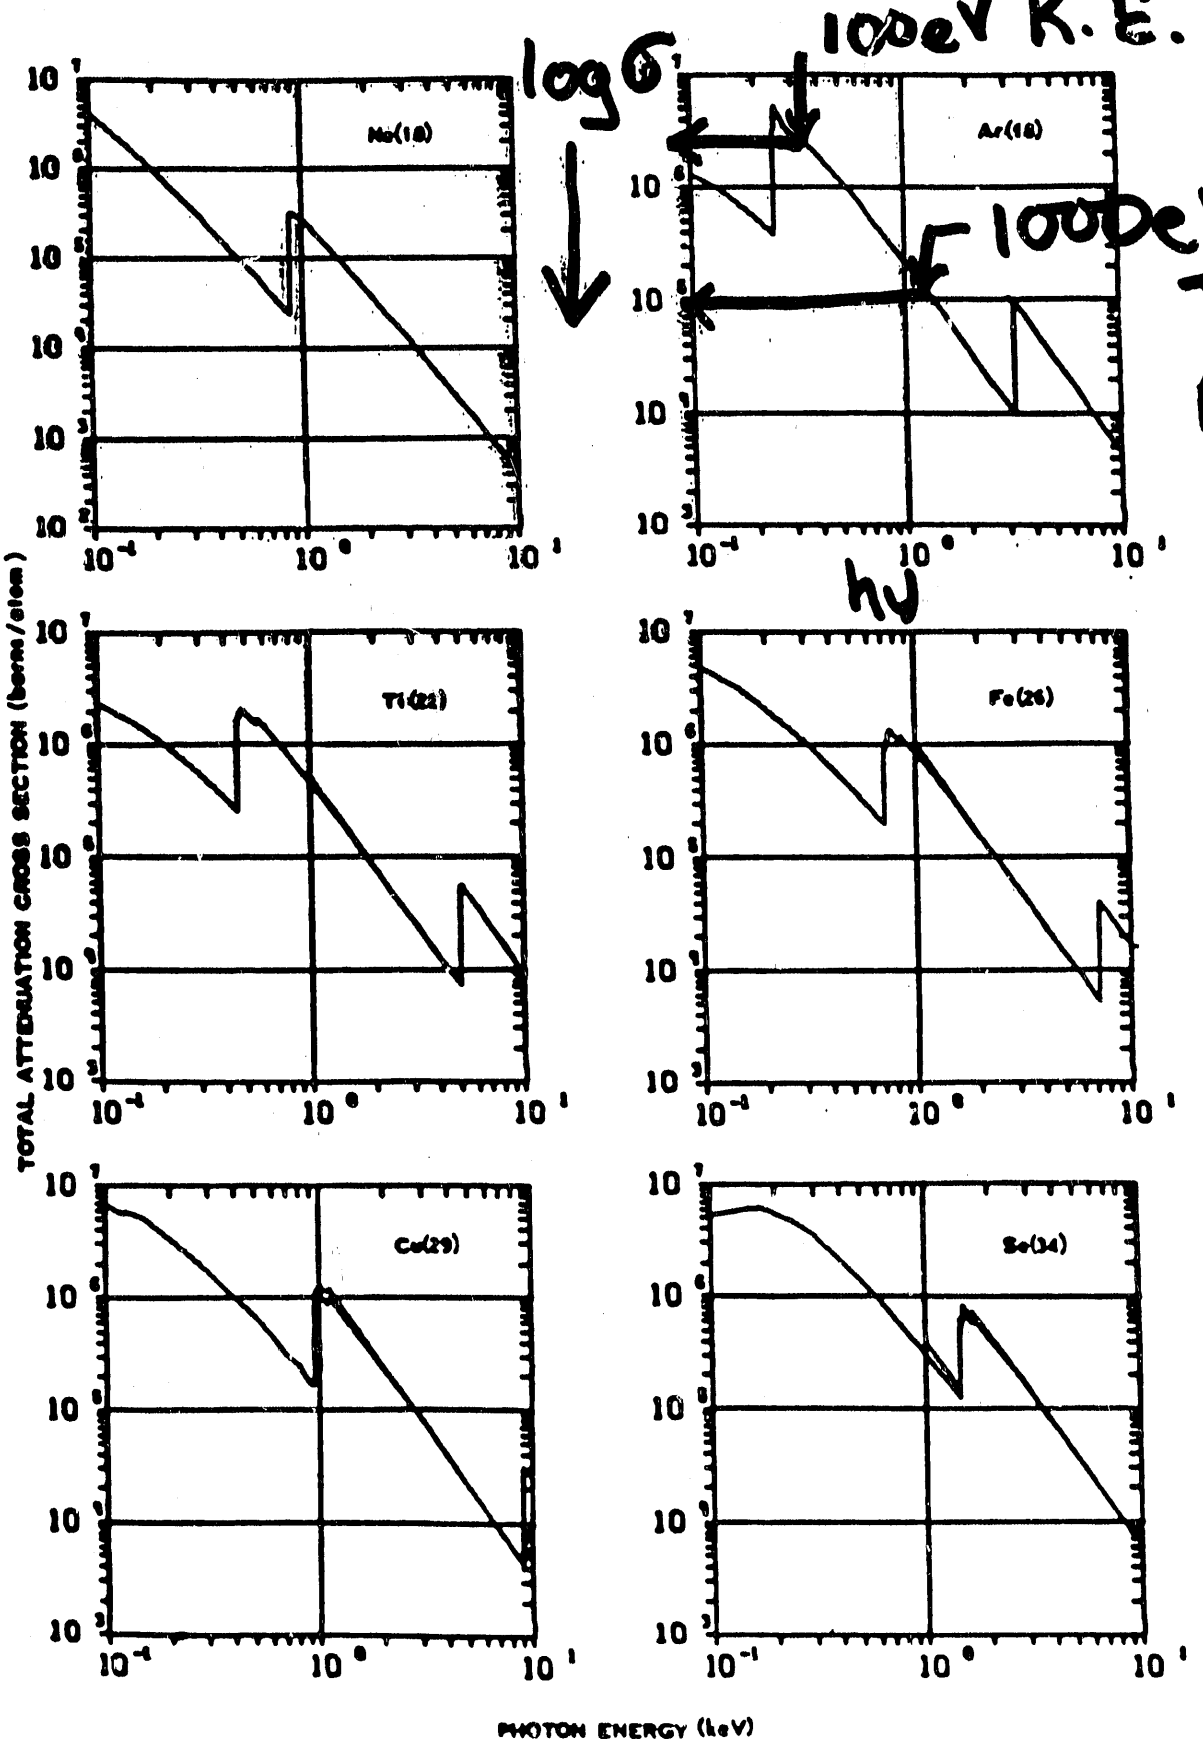
Experimental Design Issues

Goals:

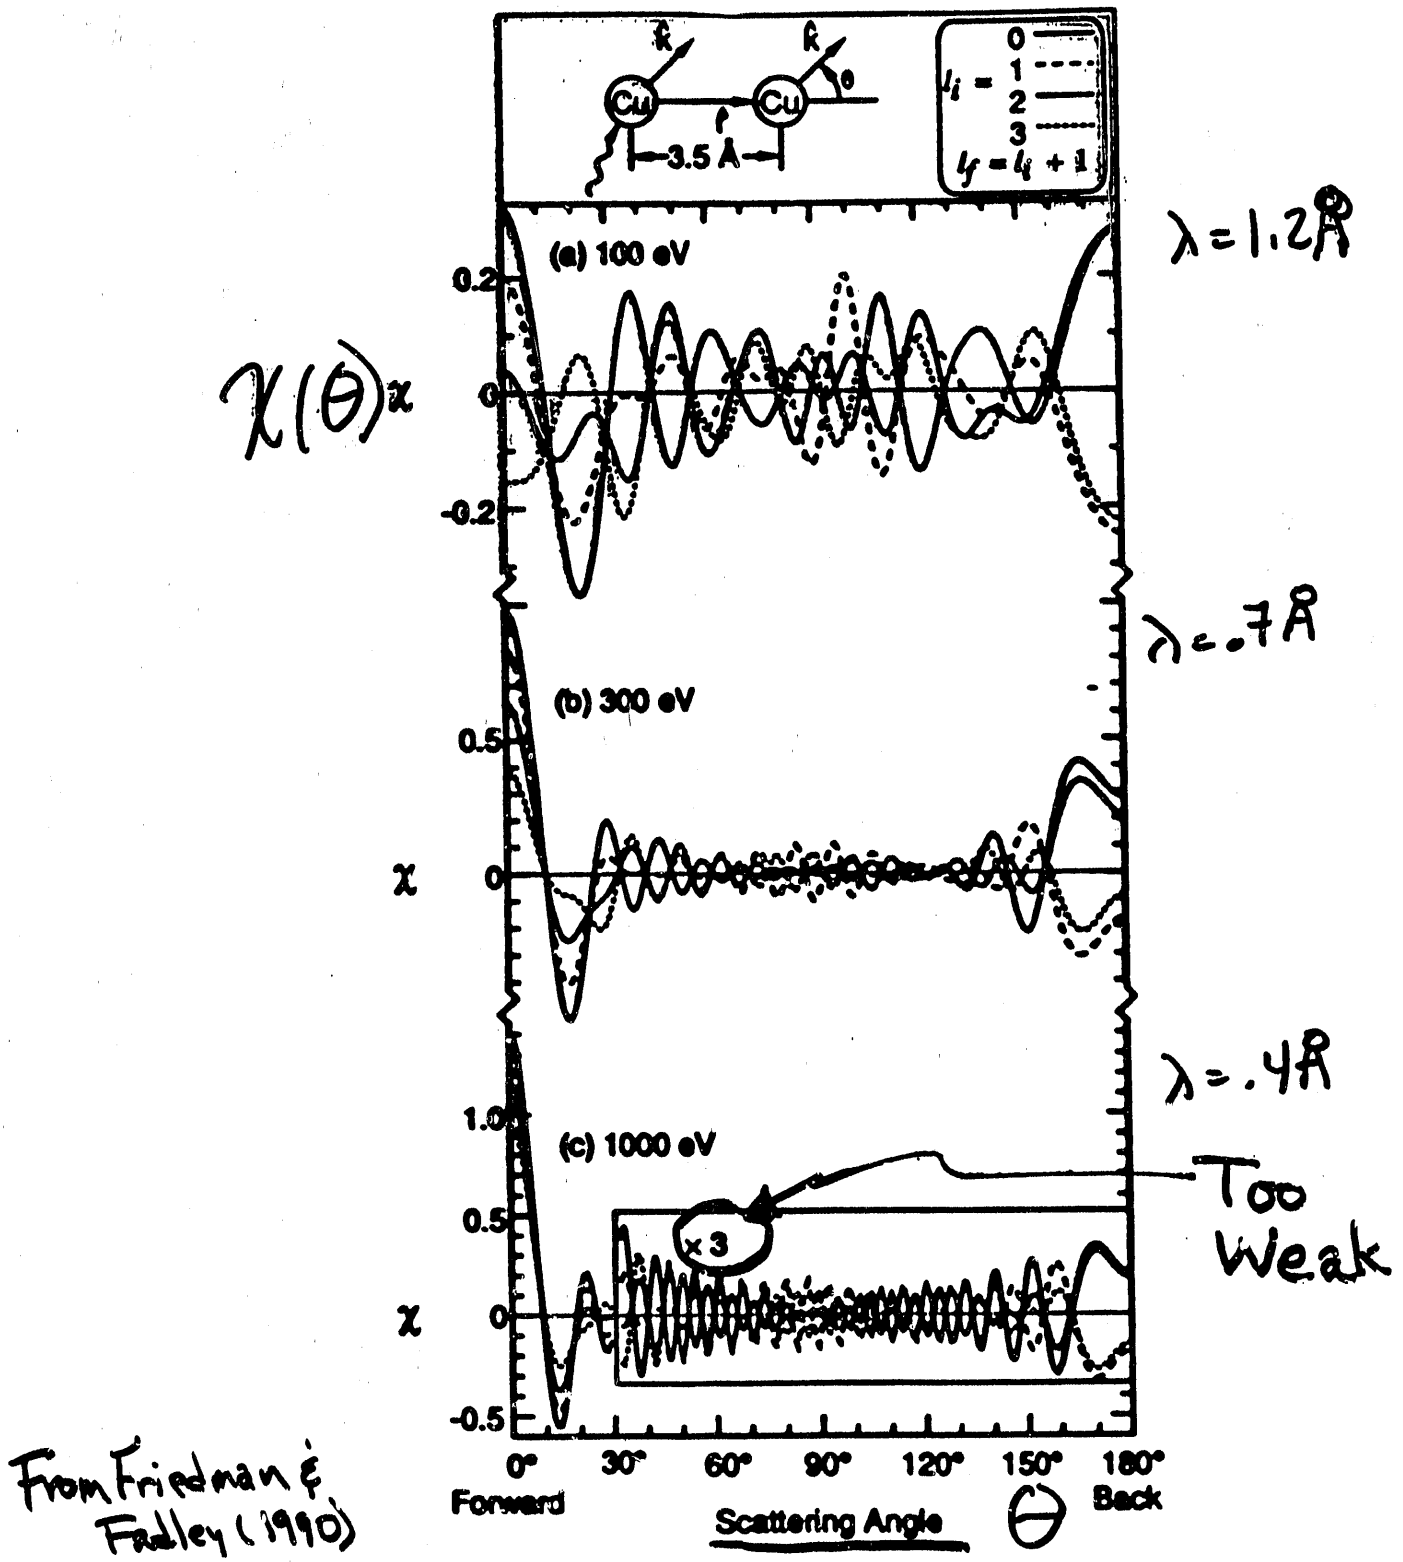
- **Direct → Site.**
- **Accurate → 0.02Å.**

Requirements:

- **Measureable**
  - **Low or Medium Energies** 100 - 300eV
  - **Simultaneous 2D**
- **Resolvable Site (2Å)**
  - **Multiple Medium Energies**
- **Accurate (0.02Å)**
  - **Precise relative emission angles.**
  - **Precise relative amplitudes.**
  - **More accurate theory.**



APHS. Computer plots. 0.1 keV $\leq h\nu \leq$ 1 – 10 keV from theory; 1 keV $\leq h\nu \leq$ 10 keV from least-squares fit to experimental data. In regions of overlap the calculated curves are to be preferred.



From Friedman & Fadley (1990)

The photoemission intensity calculated for a Cu-Cu photoemitter-scatterer system as a function of scattering angle. The radiation is unpolarized (sum of two perpendicular polarizations) and incident perpendicular to the $\hat{k}, \hat{r}$ plane. Curves are shown for initial-state angular momentum l_i ranging from $l_i = 0$ to 3, and electron kinectic energies of 100 eV, 300 eV, and 1000 eV. Only the $l_i \rightarrow l_i + 1$ channel is included. The intensity I is normalized to the primary-wave intensity I_0 as the quantity $X \equiv (I - I_0)/I_0$.

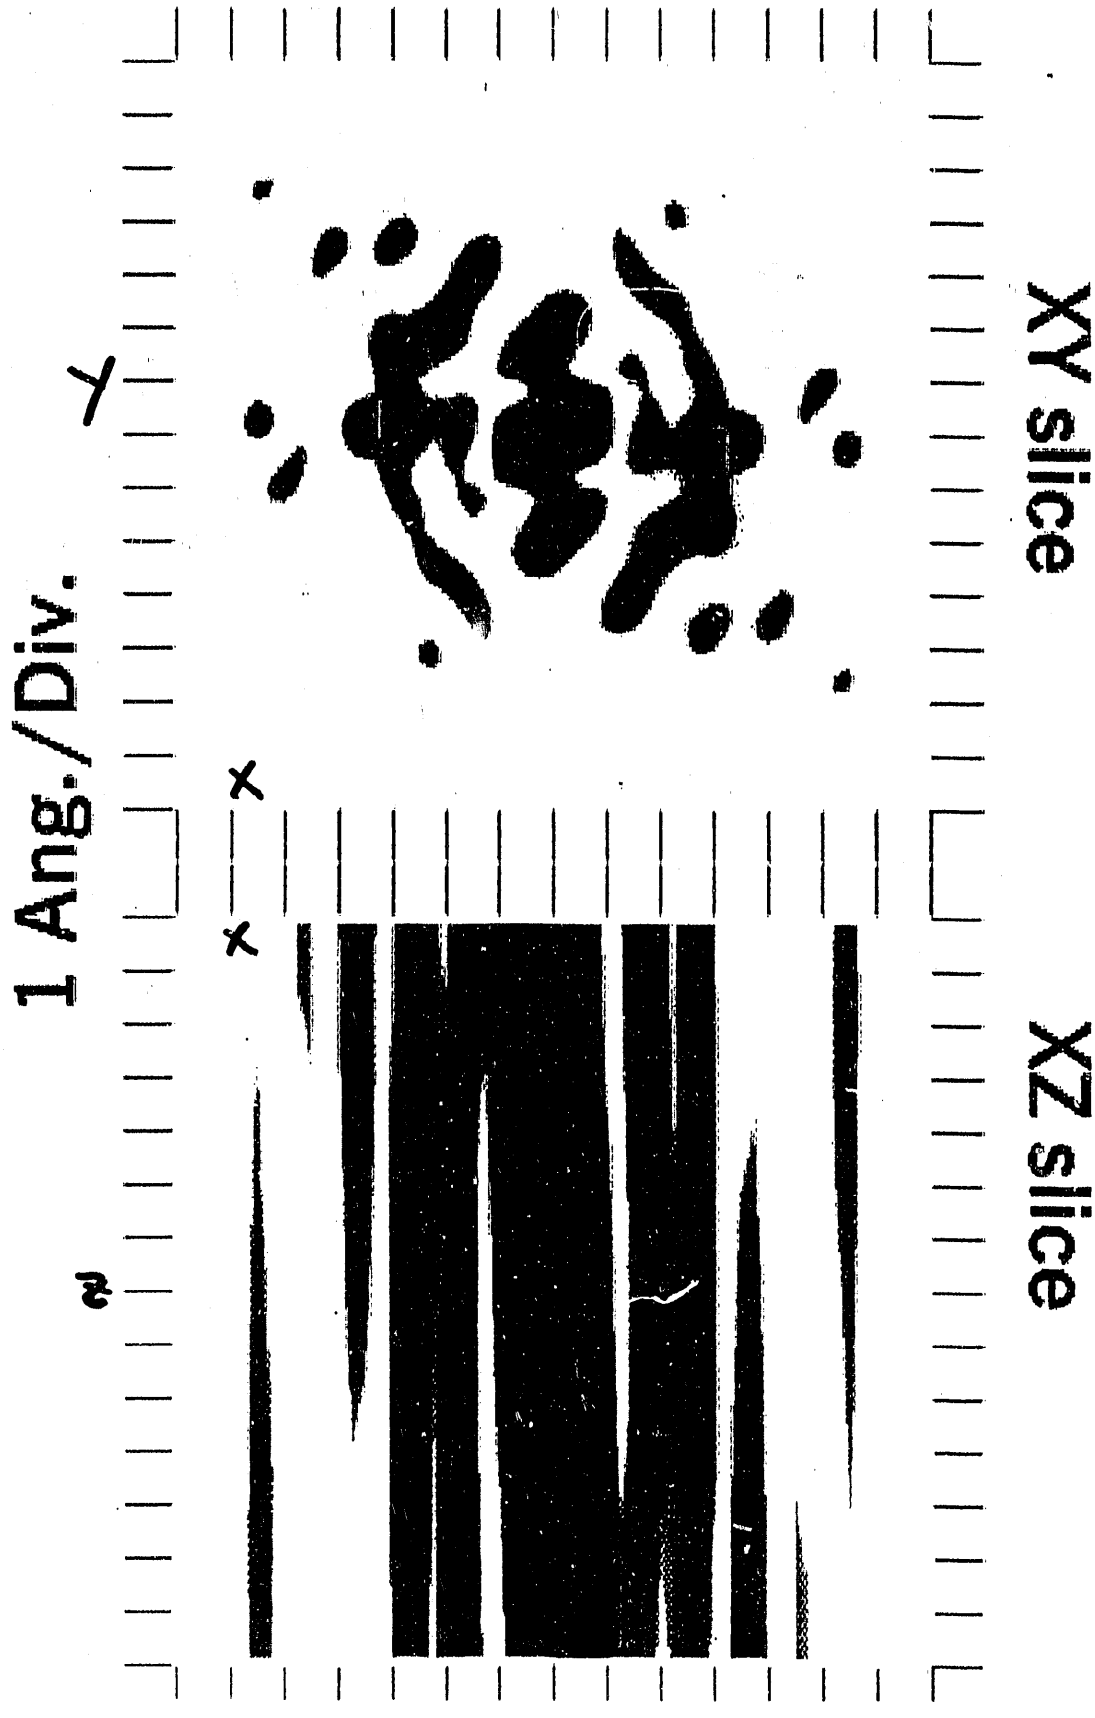
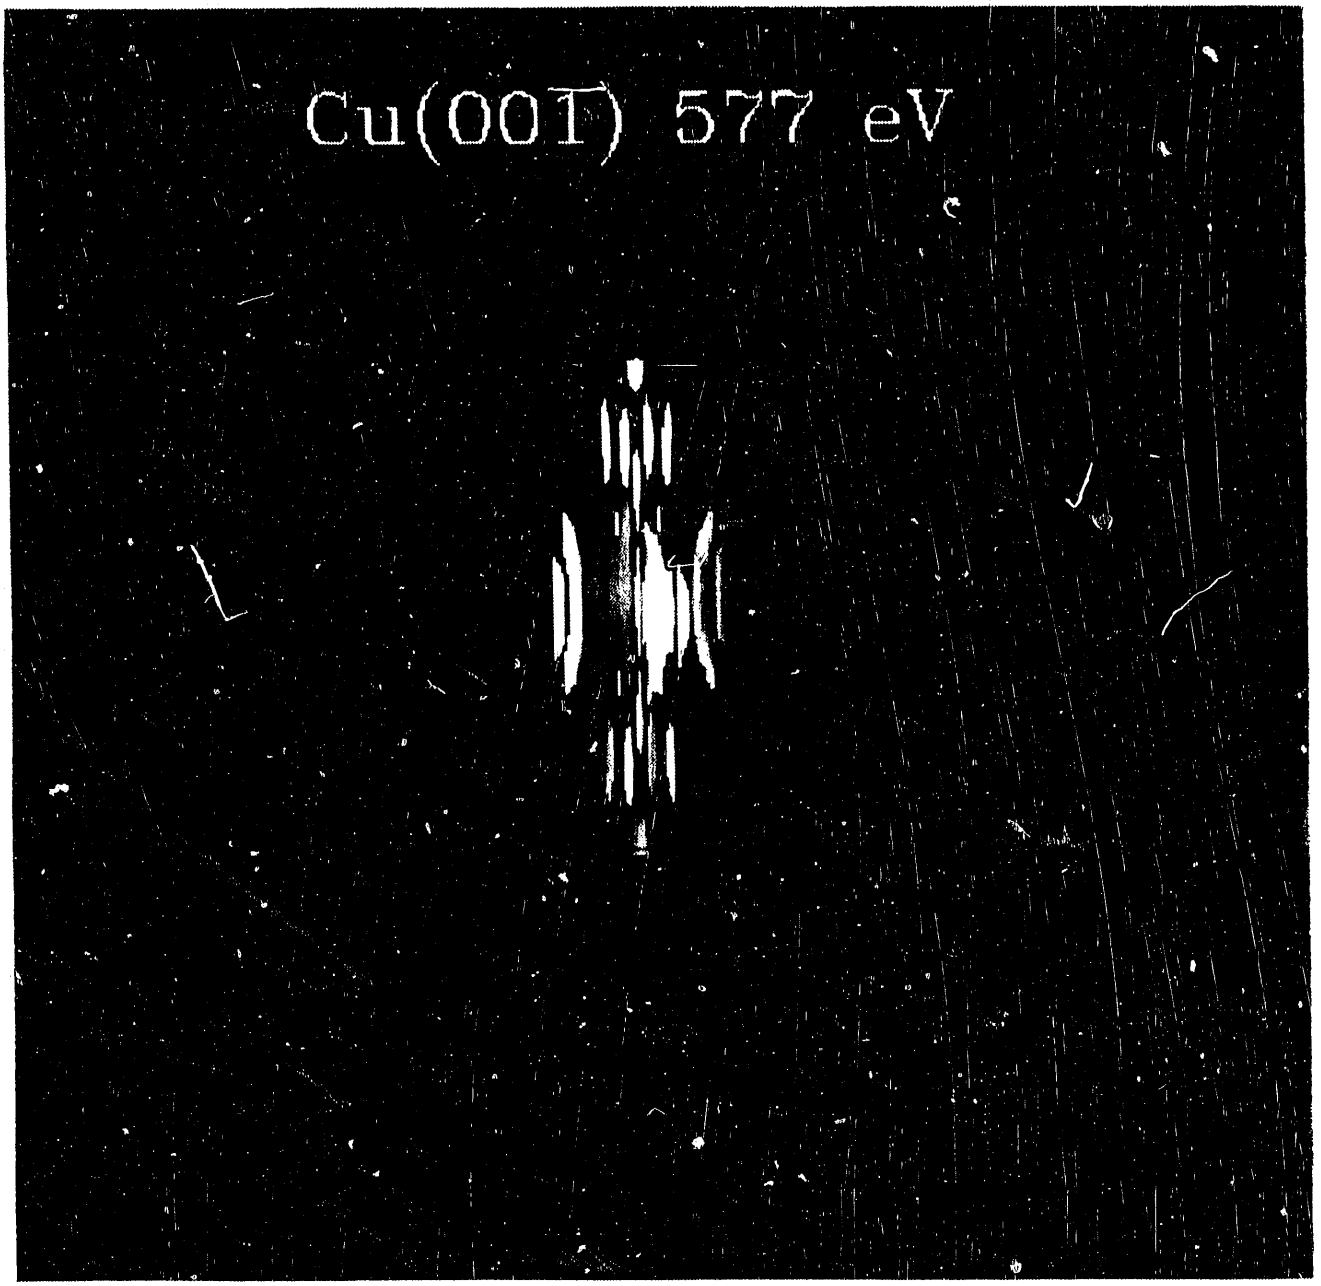
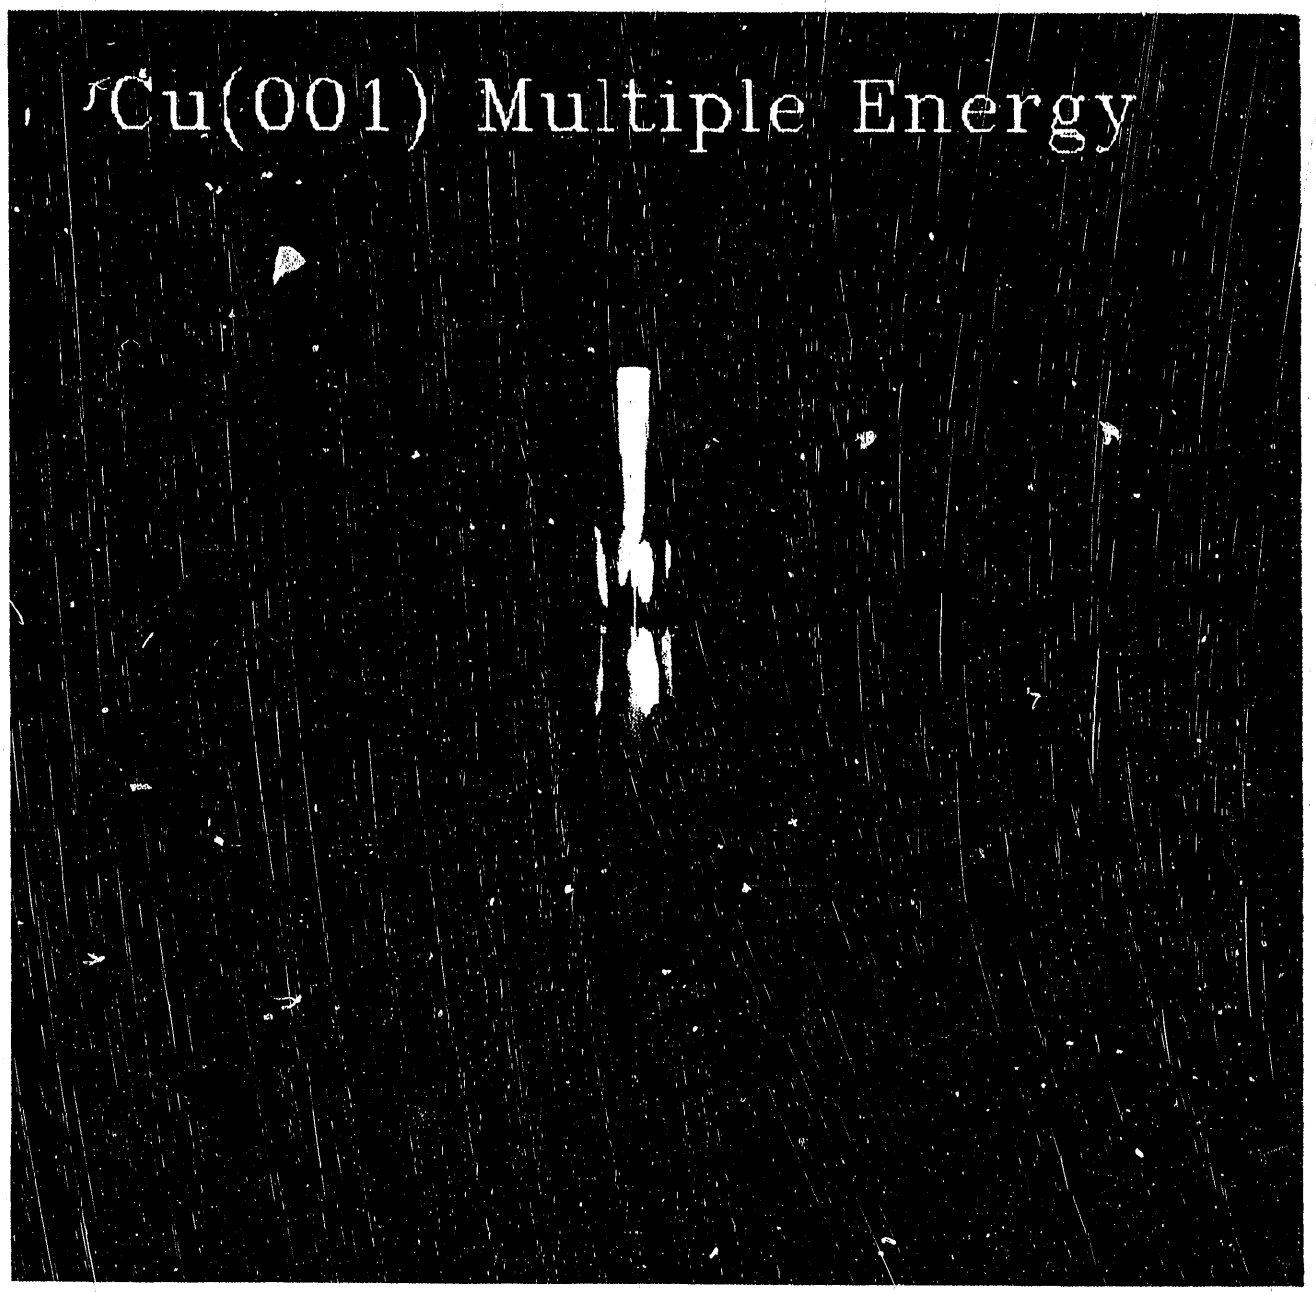
Cl/Cu(001)FFT





Cu(00$\bar{1}$) 577 eV



Cu(001) Multiple Energy

Experimental Prognosis

Setup Complicated:

- Synchrotron Radiation.
- 2D Analyzer.
- Angle Calibration.
- High-Capacity Computing System.
- 3D Data Analysis Software.

Use Straightforward:

- No time-dependent calibration.
- No mechanical motions.
- Electron energy only variable.
- Insensitive to macroscopic vibration.
- Insensitive to sample position.
- Ten holograms at 1/10 as much time.
- Direct analysis to 3D images of surface sites!

Will It Work?

Cannot just "Try It and See"

- Accuracy Criterion?
- Limitations Intrinsic?

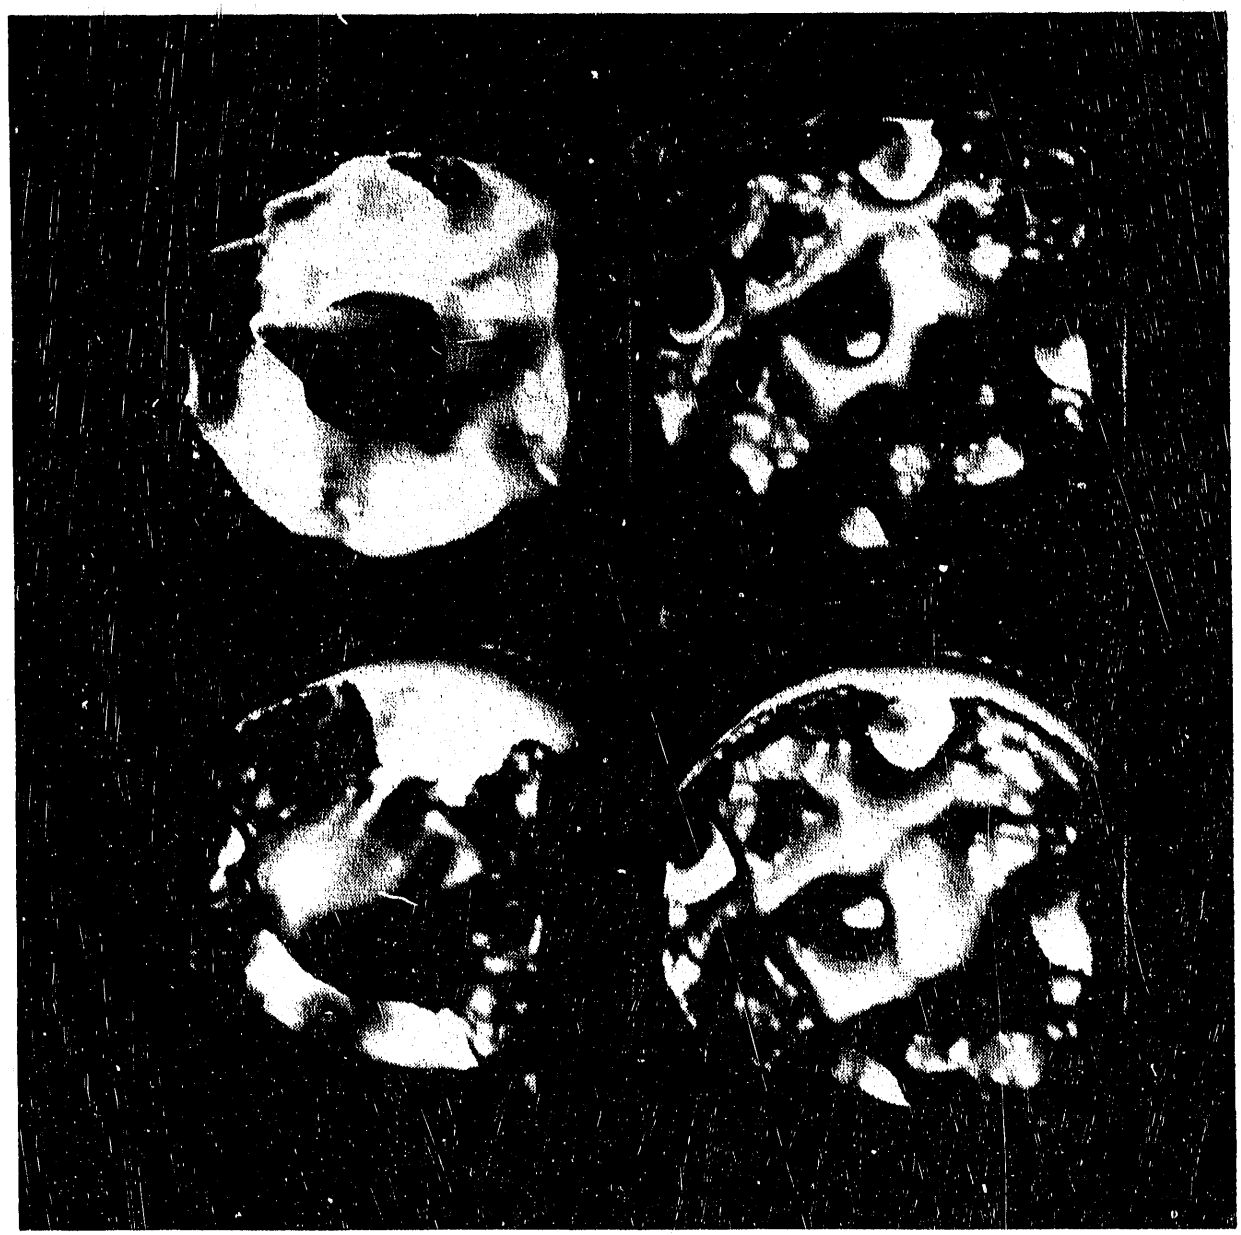
Do We Understand Electron Scattering?

- Yes, but...
- Problem of the Auger Holes (D. Frank, A. Hubbard, et al.).

Theoretical Best Inversion.

- Inverse Diffraction.
- Angular Spectrum of Plane Waves.

Cu(100) 56 eV



Curved Source Waves.

- Effects appear when $l(l+1)/kr$ is not small.
- Photoemission selection rules:

$$\begin{aligned} l_{\max} &= l_i + 1 \\ l_f &= l_{\max}, l_{\max} - 2 \end{aligned}$$

For example, Cu 3p, $l_f = 2, 0$.

- Auger selection rules:

$$\begin{aligned} l_{\max} &= l_i + l_1 + l_2 \\ l_f &= l_{\max}, l_{\max} - 2, \ldots \qquad (l_f > 0) \end{aligned}$$

For example, Cu 3p3d3d ($M_{23}N_{45}N_{45}$), $l_f = 5, 3, 1$.

$l=0$ vs $l=3$

Detected Intensity

$$I(\underline{k}) = \left| 1 + \sum_i f(\hat{\underline{k}}.\hat{\underline{r}}_i) \exp\{i(kr_i - \underline{k}.\underline{r}_i)\}/r_i \right|^2$$

$$= 1 + \sum_i |f(\underline{k}.\hat{\underline{r}}_i)|^2/r_i^2 + \sum_i f^*(\hat{\underline{k}}.\hat{\underline{r}}_i) \exp\{(\underline{k}.\underline{r}_i - kr)\}/r_i$$

$$+ \sum_i f(\underline{k}.\hat{\underline{r}}_i) \exp\{-i(\underline{k}.\underline{r}_i - kr_i)\}/r_i + \cdots$$

Helmholtz-Kirchoff algorithm

$$A(\underline{r}) = \int I(\underline{k}) e^{-i\underline{k}.\underline{r}} d\hat{\underline{k}}$$

the terms linear in f^* and f give:

$$A(\underline{r}) = \cdots + \sum_i \frac{e^{-ikr_i}}{r_i} \int f^*(\underline{k}.\hat{\underline{r}}_i) e^{i\underline{k}.(\underline{r}_i - \underline{r})} d\hat{\underline{k}}$$

$$+ \sum_i \frac{e^{ikr_i}}{r_i} \int f(\underline{k}.\hat{\underline{r}}_i) e^{-i\underline{k}.(\underline{r}_i + \underline{r})} d\hat{\underline{k}} + \cdots$$

This gives peaks at $r = \pm r_i$ only if $f(\underline{k}.\hat{\underline{r}}_i)$ is slowly varying with $\hat{\underline{k}}$.

Scattering factor deconvolution

$$A(\underline{r}) = \int \frac{I(\underline{k})}{f^*(\underline{k}.\underline{r})} e^{-i\underline{k}.\underline{r}} d\hat{\underline{k}}$$

THIS GIVES GOOD STATIONARY PHASE CONDITION AT $\underline{r} = \underline{r}_i$ but not at TWIN, $\underline{r} = -\underline{r}_i$

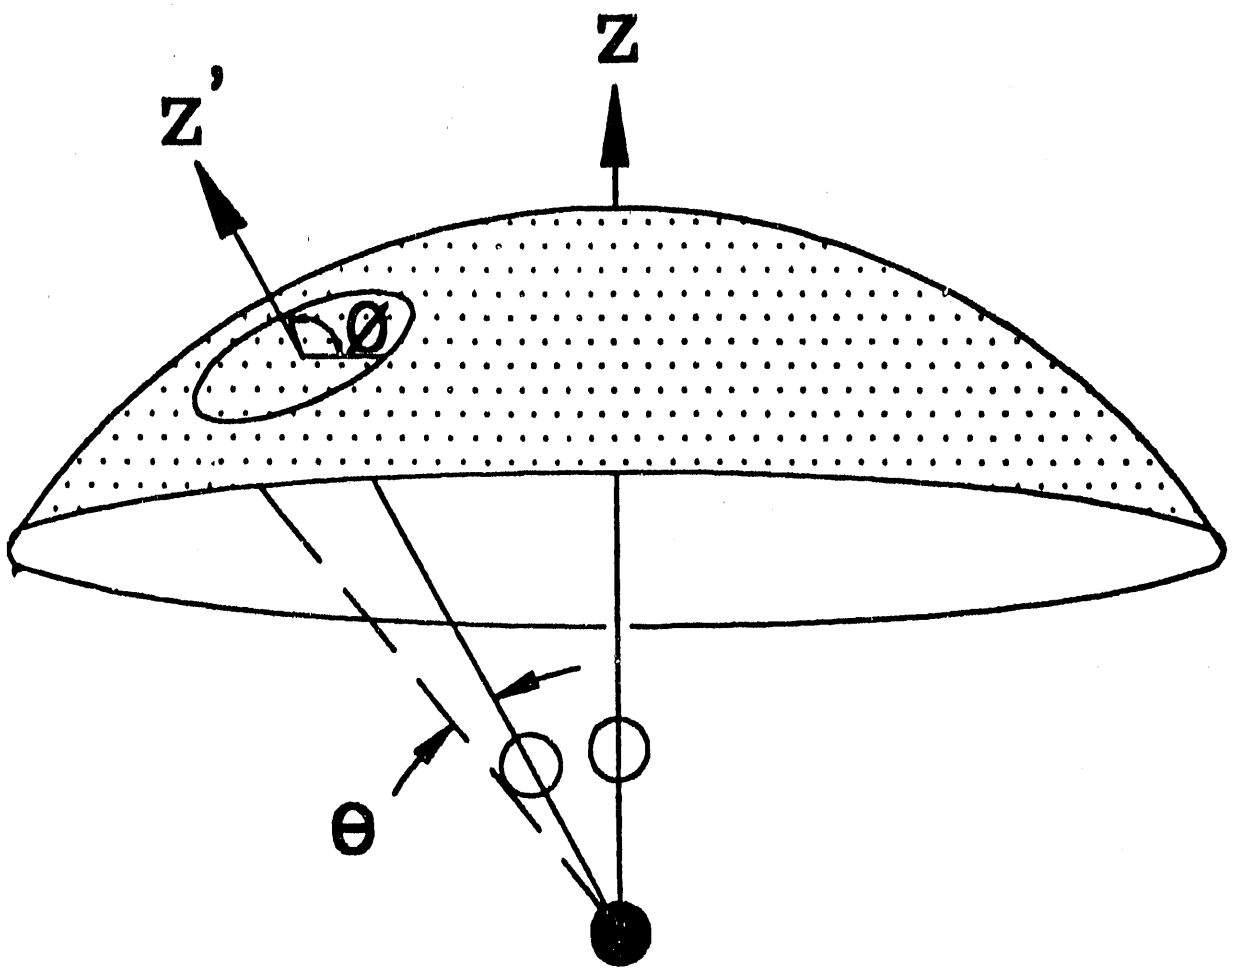
Distance From
Emitting Atom (Å)

Rotating polar axis



Radial image function (RIF)

In general, a polar axis (z') may be chosen in the direction of the RIF currently being considered.

From $A(\underline{r}) = \iint I(k_x, k_y)\, e^{-i \underline{k} \cdot \underline{r}}\, dk_x\, dk_y$

$$A(z') = -\int \{ I(k_{z'}, \phi)\, d\phi \}\, e^{-i k_{z'} z'}\, dk_{z'}$$

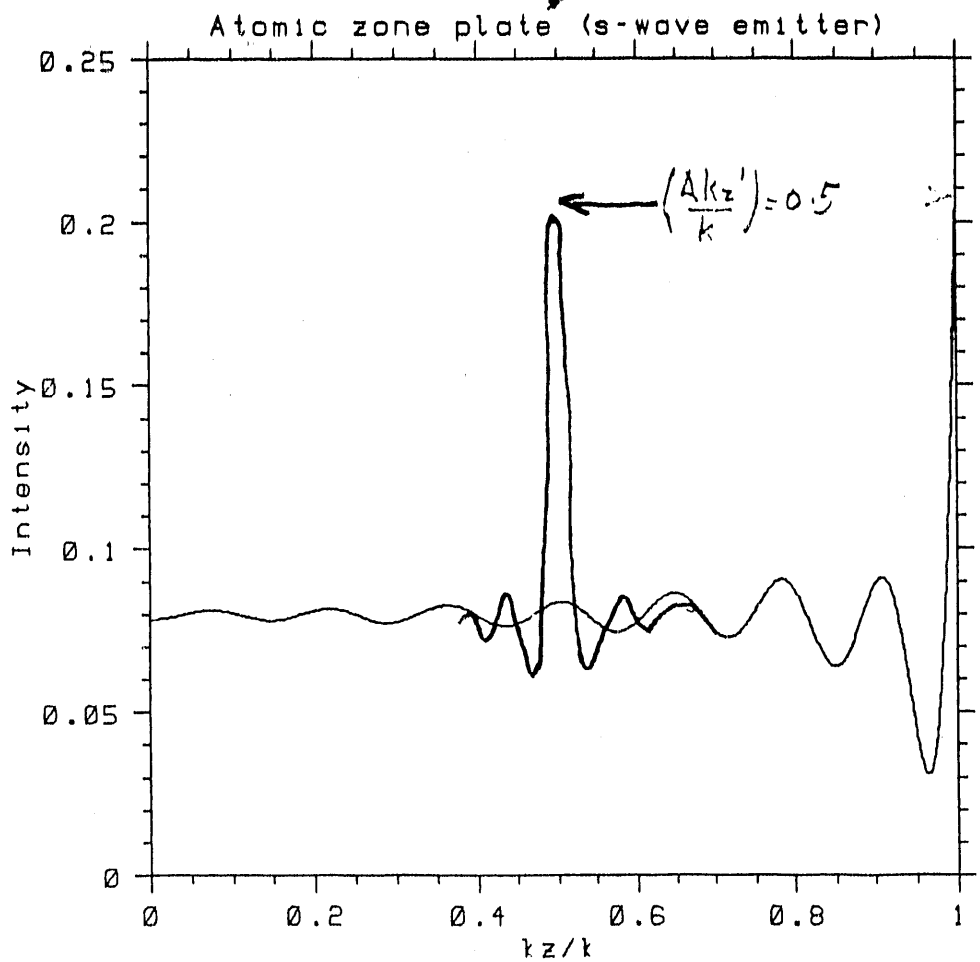
$$= -\int J(k_{z'})\, e^{-i k_{z'} z'}\, dk_{z'}$$

where $J(k_{z'}) = \int I(k_{z'}, \phi)\, d\phi$

Thus the RIF is a 1-D F.T. of the azimuthally integrated intensity as a function of $k_{z'}$.

Cu(100) 2-layer film

Neighboring forward scattering peak.



$$A(z') = \int I(k_z') e^{-i k_z' z'} dk_z'$$

"Frequency" $= z_a = \frac{2\pi}{\Delta k_z'} = \frac{2\pi}{(0.5)k}$

$$= \begin{cases} 1.2\,\text{Å} & \text{for } E = 400\text{ eV} \\ 0.8\,\text{Å} & \text{for } E = 914\text{ eV} \end{cases}$$

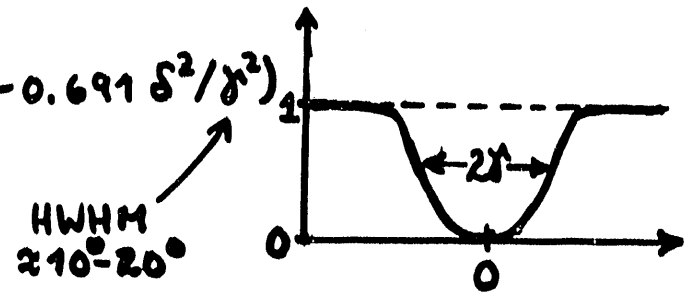
- IMAGE IMPROVEMENT BY:
  - CUTTING FULL HOLOGRAM ANGLE α ($\leq 180°$) TO ELIMINATE FORWARD SCATT. PEAKS

  - ELIMINATING FORWARD SCATT. PEAKS BY GAUSSIAN FACTOR:

$$1 - \exp(-0.691\,\delta^2/\gamma^2)$$



HWHM ≈ 10°-20°

- USE OF SCATTERED-WAVE INTEGRAL FOURIER TRANSFORM (SWIFT) METHOD OF SALDIN ET AL.:

$$|SWIFT| = W'(x,y,z) = \left| \iint \frac{[\chi(\vec{k}) e^{ik_z z}]}{F(k, \hat{k}\cdot\hat{r}, v)} e^{ik_x x} e^{ik_y y} dk_x dk_y \right|,$$

// SPHERICAL-WAVE $f_{sw}(k, \hat{k}\cdot\hat{r}, v)$ FOR NOW,

WITH REQUIREMENT THAT $|f_{sw}|$ NOT GO BELOW SOME THRESHOLD (= SWIFT') AS % OF $|f_{sw}|_{MAX}$ FOR PROBLEM

ARE POSITIONS, PEAK SHAPES IMPROVED WITH SWIFT' CORRECTIONS?

- USING ONLY PART OF FULL HOLOGRAM TO ISOLATE CERTAIN ATOMS AND REDUCE REAL/TWIN OVERLAP.

  IS SWIFT' CORRECTION MORE EFFECTIVE?

- DOING PHASED SUMMATION OF IMAGES AT SEVERAL ENERGIES (BARTON) WITH AND WITHOUT SCATTERED-WAVE CORRECTION:

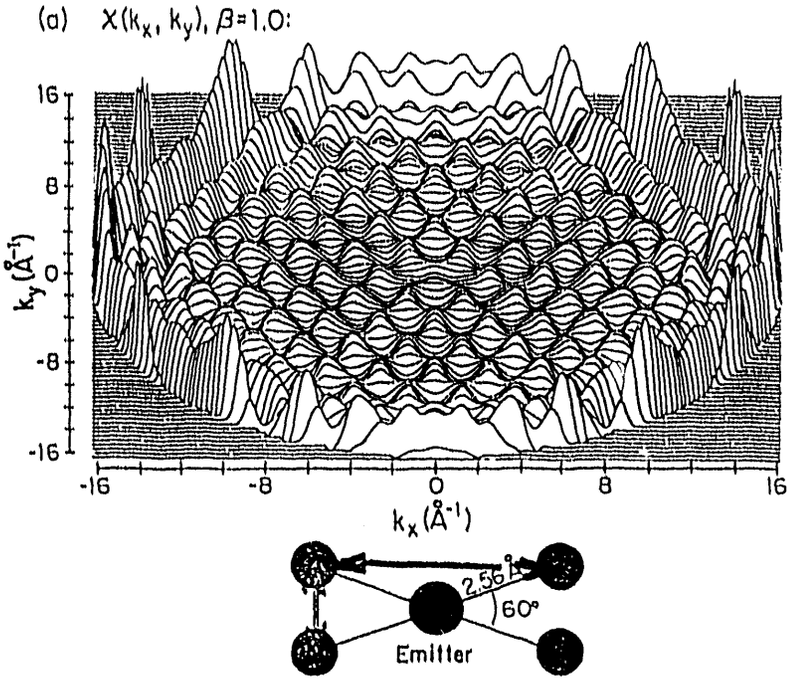
$$U''(x,y,z) = \left| \sum_i e^{-ik_i r} (FT)_i \right|, \quad i = 1,2,\ldots n \text{ ENERGIES}$$

OR

$$U'''(x,y,z) = \left| \sum_i e^{-ik_i r} (SWIFT')_i \right|.$$

ARE TWINS + MS EFFECTS REDUCED?

SELF-INTERFERENCE EFFECTS:



$$\Psi = \Phi_0 + \beta \sum_j \Phi_j$$

CONCLUSIONS / FUTURE PROSPECTS

ϕ BARTON
* TONNER, SALDIN ET AL
+ OUR GROUP

- HOLOGRAPHIC FOURIER TRANSFORMS[ϕ] OF EXPERIMENTAL DATA FOR Cu(001)[*], Cu(111)[*], c(2×2)S/Ni(001)[+], Si(111)[+], & Ge(111)[+] SHOW PEAKS ~ AT NEAR-NEIGHBOR POSITIONS, BUT SHIFTED OUTWARD AND ELONGATED ALONG SCATTERING DIRECTIONS, AS EXPECTED FROM THEORY
  THEORETICAL SS + MS SIMULATIONS SHOW THAT:
- FOR HIGHER ENERGIES ≳ 500 eV ⇒ STRONG FORWARD SCATTERING:
  - HIGHER-ORDER DIFFRACTION FEATURES VERY KINEMATICAL[+]
  - MS ALONG ATOMIC CHAINS SUPPRESSES SCATTERING ANISOTROPY ⇒ BETTER IMAGES[+]
- SELF-INTERFERENCE EFFECTS MAY BE PRESENT AT ~15-20% OF NEAREST-NEIGHBOR PEAKS[+] REMOVING FWD. SCATT. PEAKS IMPROVES IMAGE CONTRAST + PEAK SHAPE IN BOTH EXPT. + THEORY[+]: REDUCE OPENING ANGLE OR USE GAUSSIAN ELIMINATION
- SCATTERED-WAVE INCLUDED FOURIER TRANSFORM (SWIFT') METHOD[*] WORKS WELL, BUT TWIN OVERLAP PROBLEM: USE PART OF HOLOGRAM?[+]
- SUMMING IMAGES AT SEVERAL (~10) ENERGIES[ϕ] WITH SWIFT' IMPROVES PEAK POSITIONS,[*†] AND FOR SOME GEOMETRIES/LOWER ENERGIES, ALSO REMOVES TWINS (…AND MS?)[ϕ+]
- PHOTOELECTRON ANISOTROPY IN $\phi_0 = \phi_{REF}$ AND $\phi_j = \phi_{OBJECT}$ YIELDS WORSE IMAGES THAN ISOTROPIC "AUGER-LIKE" EMISSION ⇒ SWIFT" CORRECTION NEEDED?
- ENCOURAGING, BUT NEED MORE EXPTS. + TESTING!

	LOW ENERGY ~100-300 eV	HIGH ENERGY ~500-1500 eV
SS vs MS	MS OVER LARGER ANGLE RANGE −	MS ALONG FWD. − CHAINS; ~SS + ELSEWHERE
SCATT. FACTOR	MORE ISOTROPIC, + MORE S-LIKE, BACKSCATT. INFORMATION +	STRONG FWD. + PEAK-USEFUL! BUT BAD IN HOLOGRAPHY −
ULTIMATE RESOLUTION	$\propto \lambda_e$ − WORSE	$\propto \lambda_e$ + BETTER
PHOTO e^- CROSS SECTION	HIGHER +	LOWER −
TOTAL SCATT. FACTOR	HIGHER→ LARGER + EFFECTS	LOWER→ LESS SELF-INT. + + MS +
INELASTIC ATTEN.	MORE SURF. SENSITIVE	MORE BULK SENSITIVE
MAGNETIC SCATT?	YES +	NO −

- PHOTOELECTRON DIFFRACTION CAN BE USED TO STUDY NEAR-SURFACE PHASE TRANSITIONS IN BOTH POSITIONAL ORDER AND SHORT-RANGE MAGNETIC ORDER (USE OF CIRCULARLY-POLARIZED RADIATION WILL PERMIT GOING BEYOND SIMPLE MULTIPLETS).

INTRODUCTION

Purpose:

summarize:

theoretical state of the art
in electron emission from surfaces

address:

some physical principles
that underlie the formation of holograms

BASICS OF ELECTRON EMISSION

Types of electron emission:

- photoelectrons

  matrix element well known (if single-channel emission)

  element specific

- Auger electrons

  matrix element poorly known,
  but approximately s-wave at E > 300 eV

  element specific

- Kikuchi (inelastic) electrons

  matrix element poorly known, except for phonon losses

  not element specific

- MEED (elastic) electrons

  matrix element well known

  not element specific

Electron energy range:

- 300 - 1500 eV

Measurement:

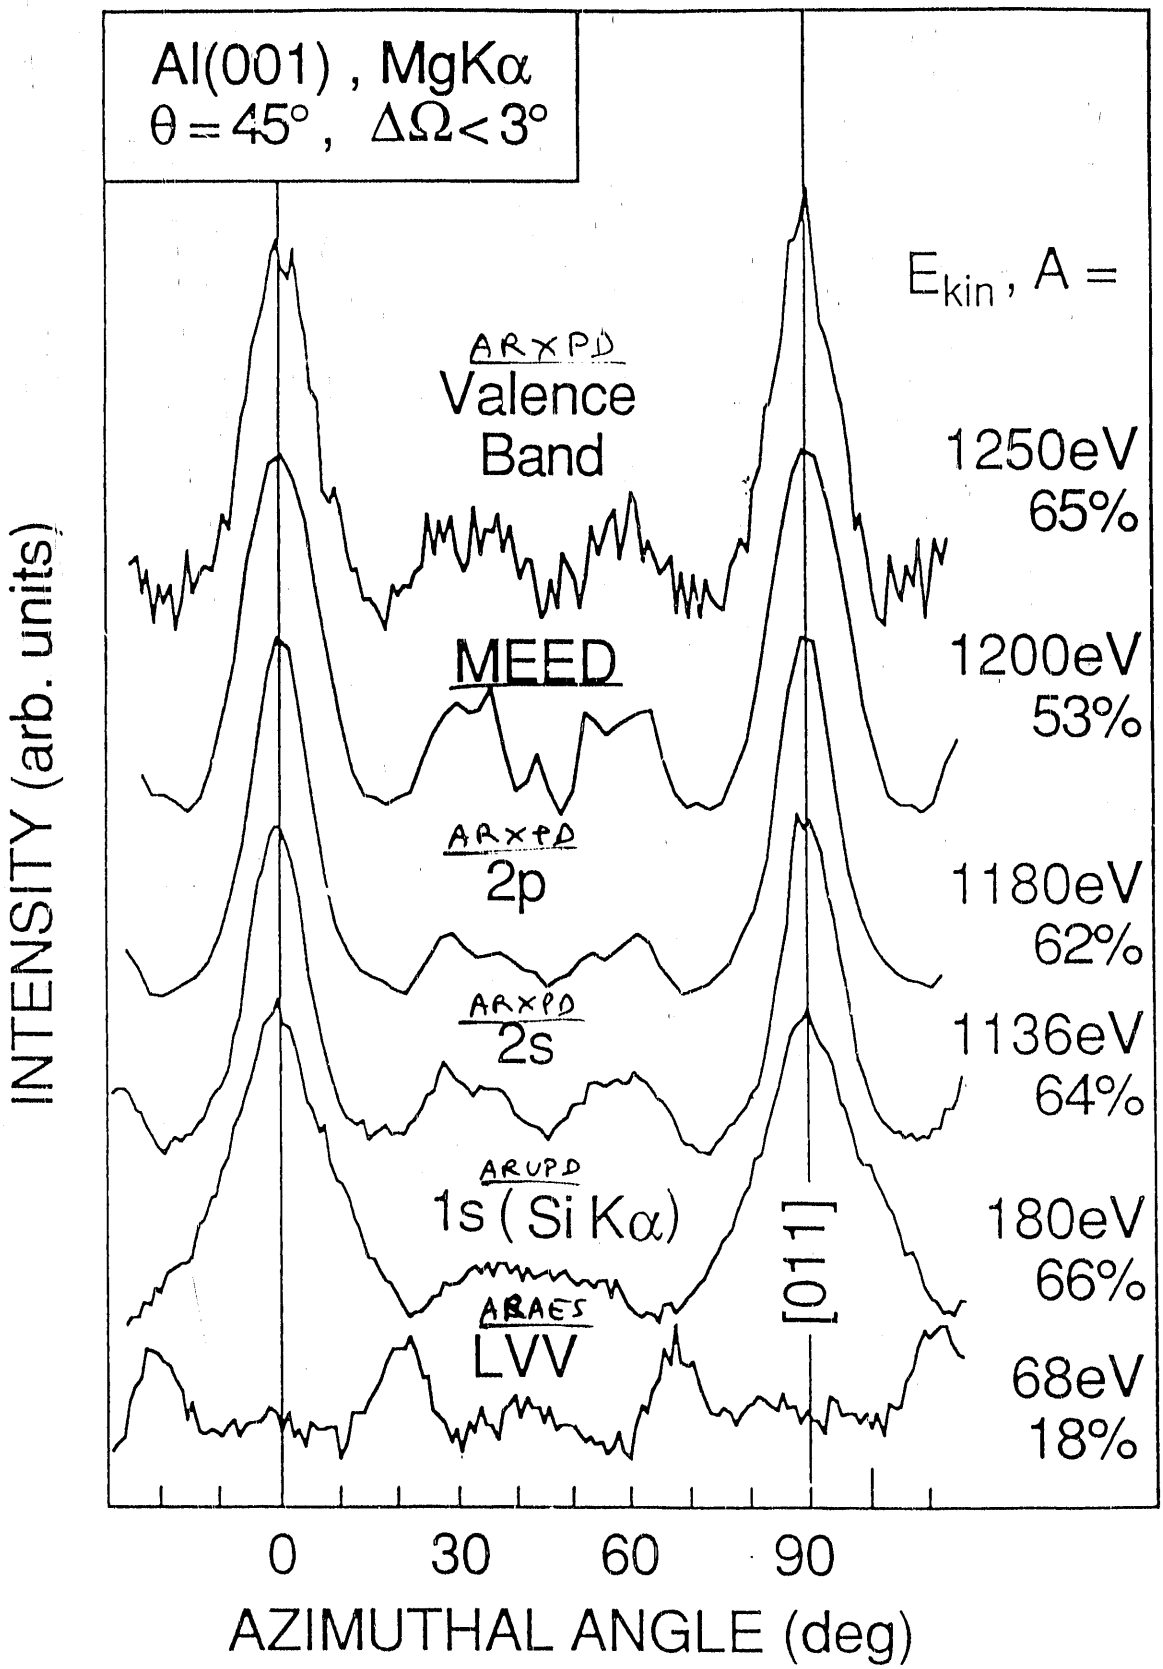
- scanned angle (ARXPD, ARAES,...)
- scanned energy (PhD, ARPEFS,...)

Structure information:

- interference between direct and scattered paths
- forward focusing (forward scattering)

  Fadley, Egelhoff, ...

Osterwalder et al



THEORY

Physical ingredients:

- **muffin-tin model**
- **inelastic mean free path**
- Debye-Waller factor ?

Form of scattering wave:

- **plane wave vs. spherical wave**

  plane wave simpler

Role of multiple scattering:

- **single vs. multiple scattering**

  single scattering much simpler

Validity of approximations:

- **single and plane-wave (SSPW) scattering valid in favorable cases**

  what is accuracy of such (non-holographic) structure determination?

- **multiple and spherical-wave (MSSW) scattering often needed**

  for aligned atoms (forward focusing)

  for interference features

  what is accuracy of such (non-holographic) structure determination?

- concentric shells (XANES-like)

  Saldin et al

<u>slab approach</u>

- layer stacking (LEED-like)

  Tong et al

AN ISSUE

Thermal vibrations:

Debye-Waller factor

distant source (MEED, LEED, XRD, etc.):
average of diffracted amplitudes over configurations

nearby point source (ARPES, ARAES, XAFS, etc.):
average of diffracted intensities over configurations

both averages give same Debye-Waller factor (Rehr - XAFS)

DW factor sharpens forward focusing peak, with no height loss;

counter to observation, e.g. Pb, CO (Bonzel et al):
peak broadens and weakens!

BUT: DW assumes:

rms vibration amplitude $\sqrt{<u^2>}$ << wavelength λ

examples:

$\sqrt{<u^2>} \approx 0.10$ Å *(bulk Ni) -* 0.25 Å *(bulk Pb, -CO) at RT*

$300 < E < 1000$ eV $\rightarrow 0.7 > \lambda > 0.4$ Å

SO: $\sqrt{<u^2>} \approx \lambda$ and DW breaks down!

EFFECT: forward focusing peak must be smeared out, not sharpened!

→ *no forward focusing in electron microscopy:*
$\lambda \approx 0.03 - 0.01$ Å $<< \sqrt{<u^2>}$

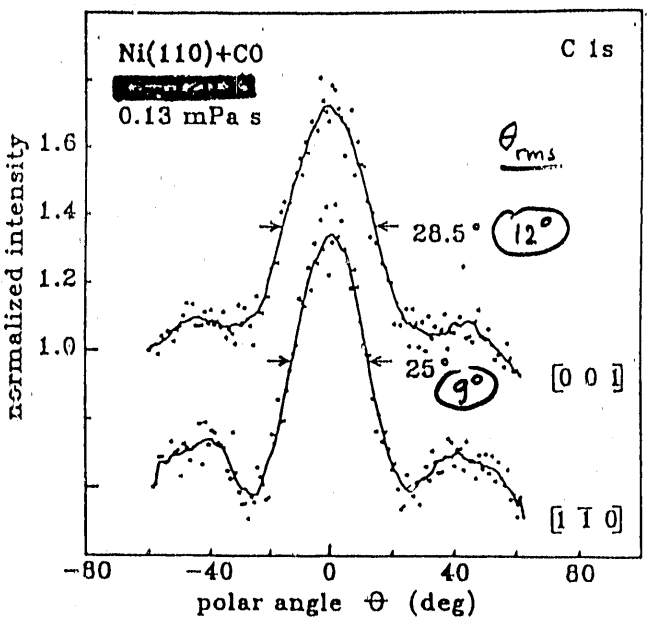
straight averaging over configurations

Fadley, Kaduwela, Van Hove: CO / Fe (100)

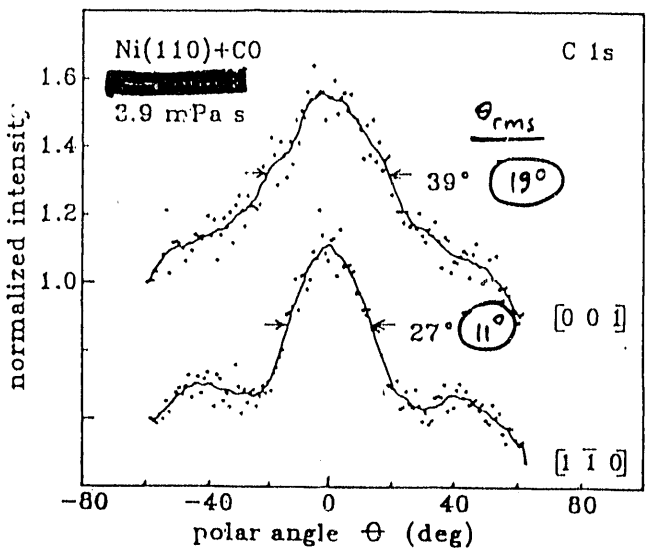
other complication: correlated vibrations

Fadley et al

Surf. Sci. 199, L419 (1988)



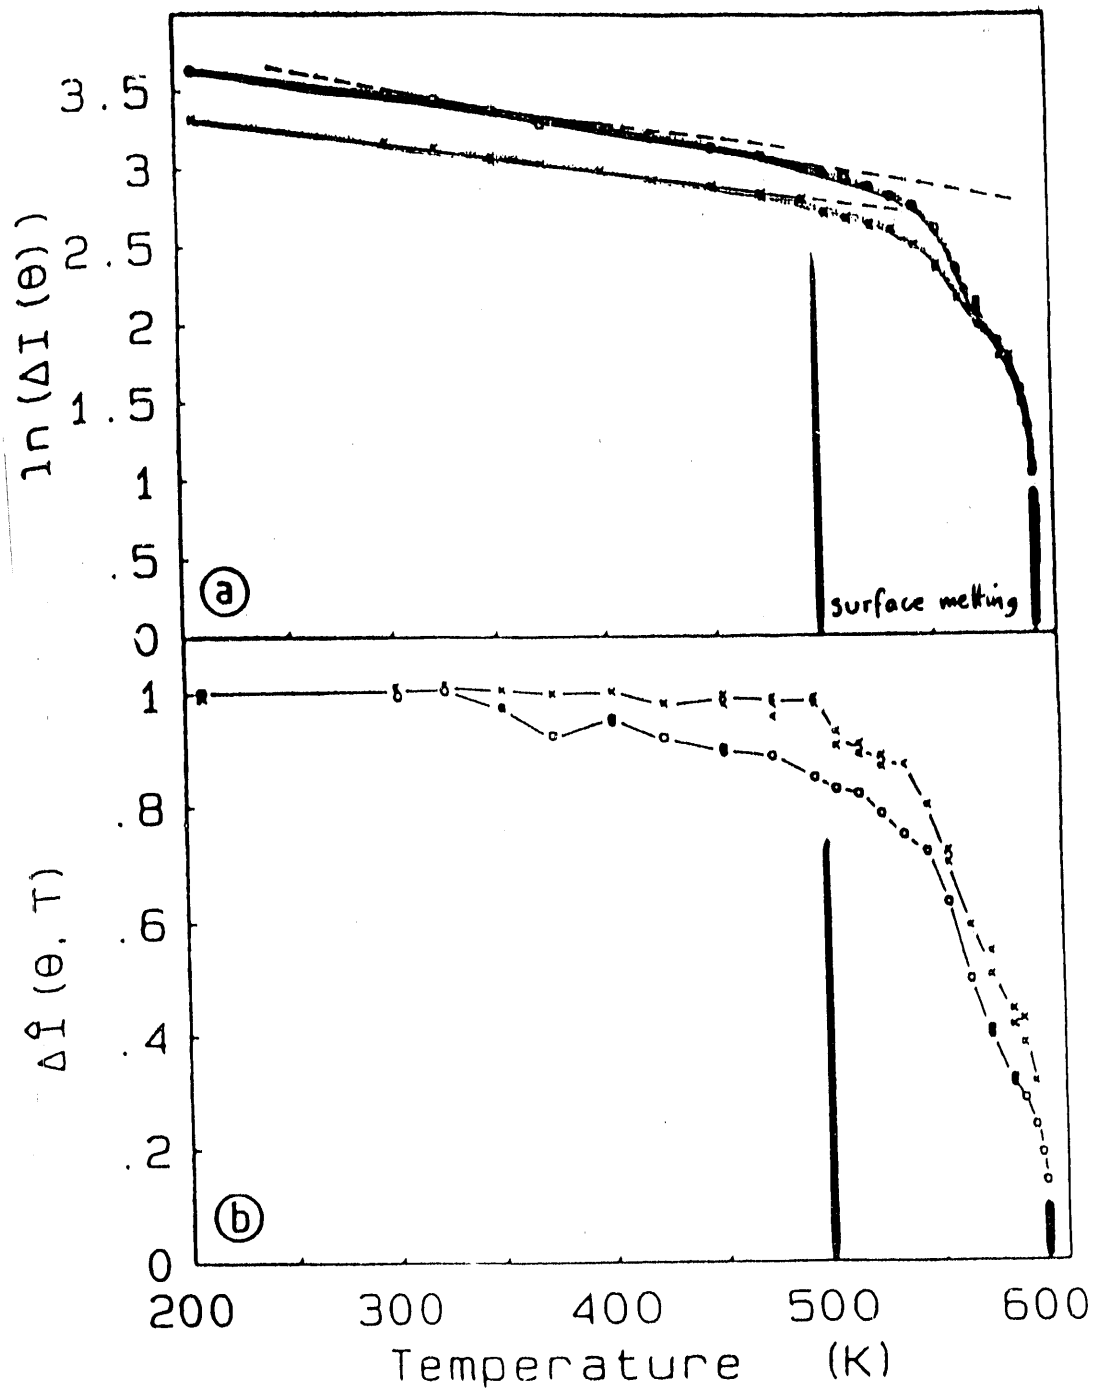
Polar angle dependence of C 1s normalized intensities for a low CO coverage on Ni(110). Two perpendicular azimuths along [001] and [1$\bar{1}$0] directions are shown. The numbers indicate the FWHM of the main forward scattering peak.



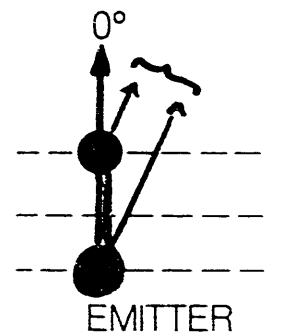
Same as in fig. 2 but for CO adsorption at 300 K.

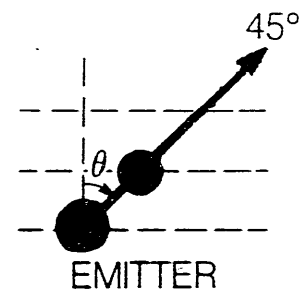
θ_{rms} from calibration by Fadley et al

JVST A8, 2489 (1990)

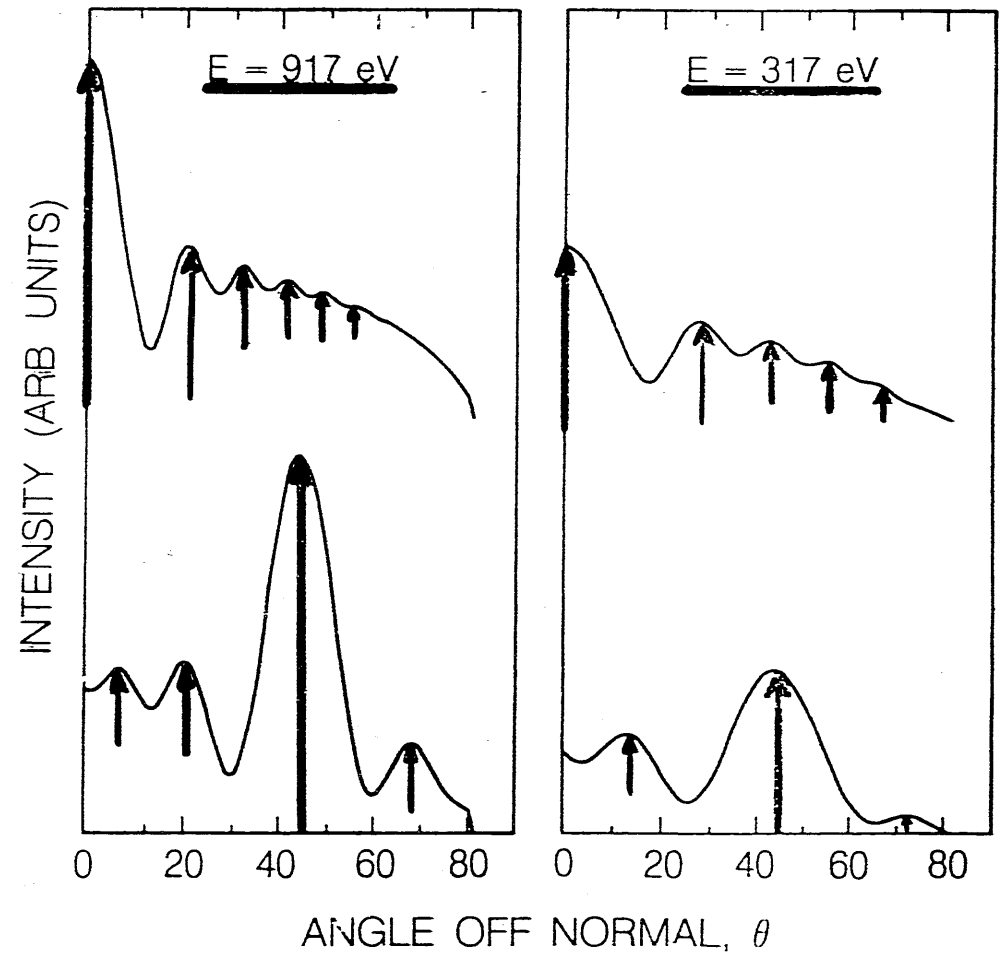


(a) Plot of ln $\Delta I(\Theta,T)$ vs temperature for the peak at $\Theta = 45°$ in [110] (□) and $\Theta = 54.7°$ in [001] direction (×). (b) For Debye-Waller effects corrected intensity distribution $\Delta\hat{I}(\Theta,T)$ vs temperature for the two peaks in (a).



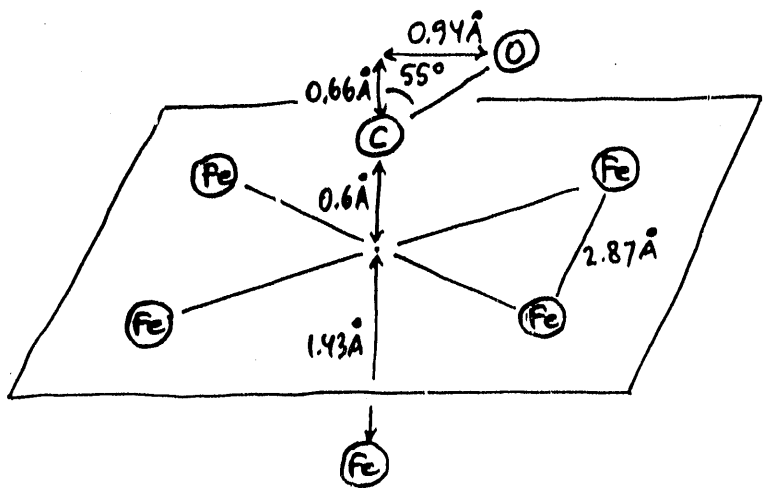


Cu ELECTRON EMISSION FROM A POINT SOURCE AT THE END OF Cu CHAIN

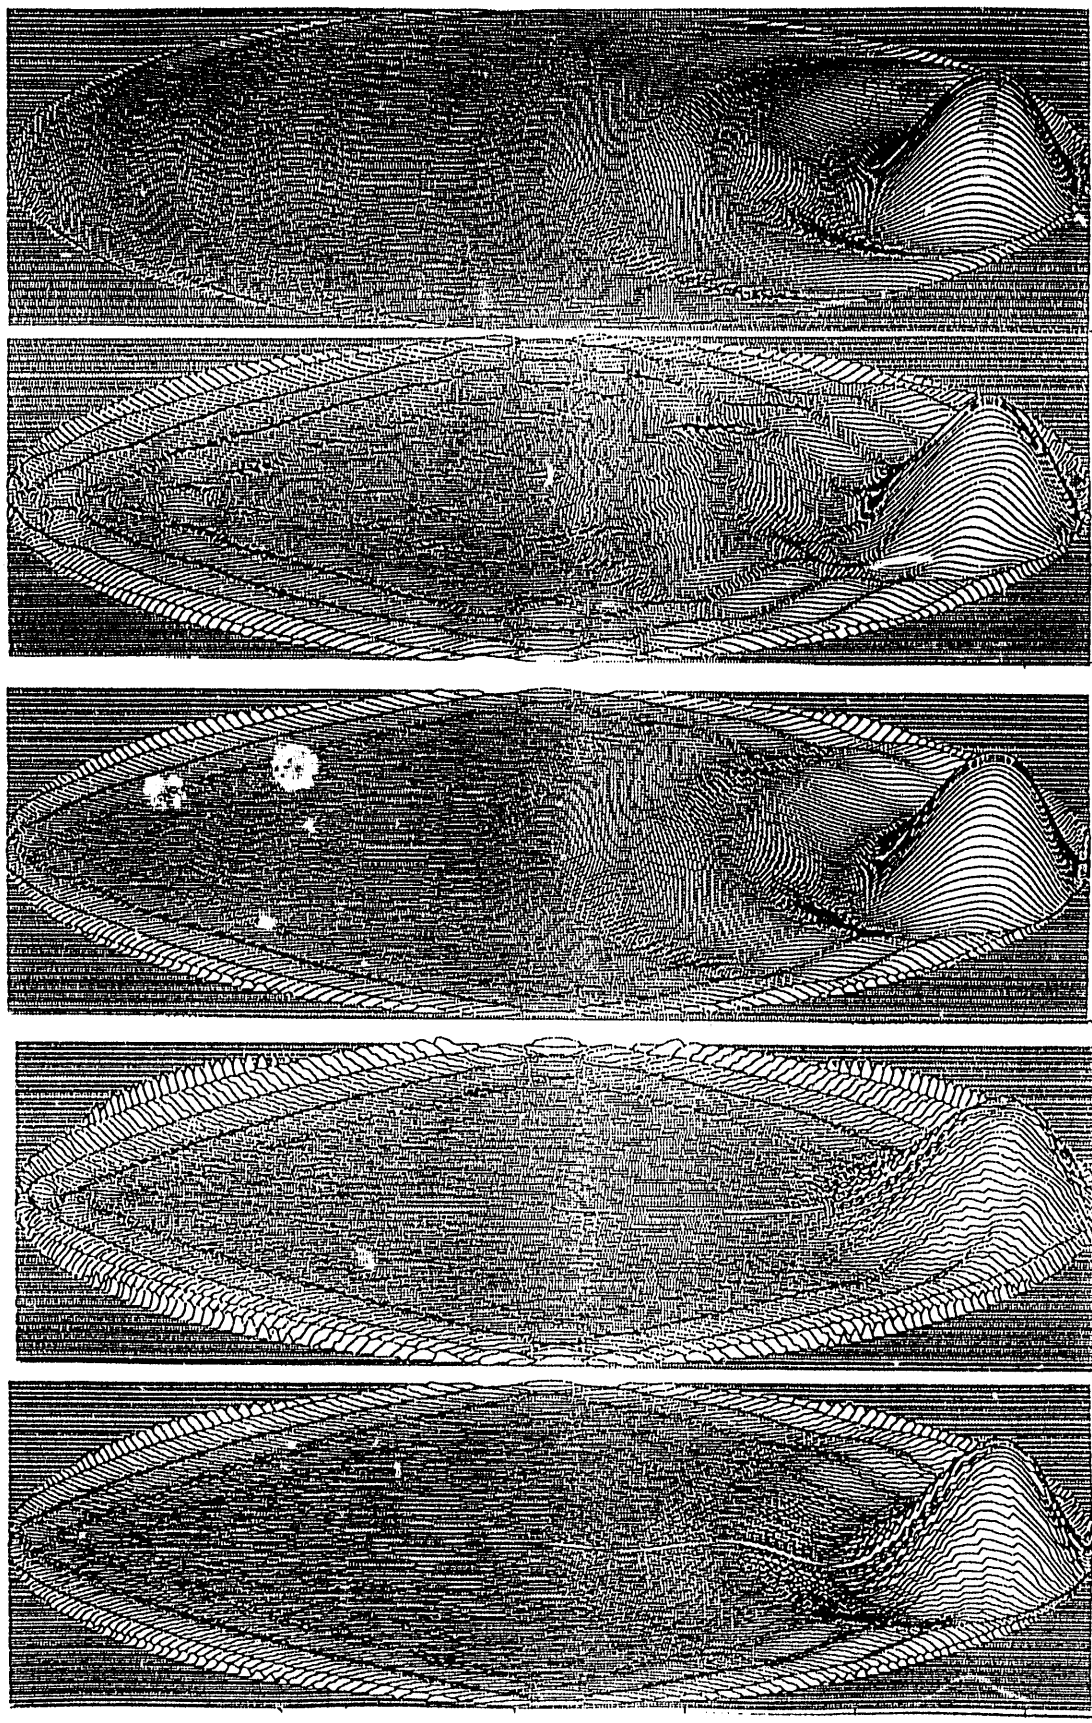


XBL 884-10189

Fe_5CO cluster



treatment of vibrations
C emission from Fe_5CO cluster



Kaduwela et al

ANOTHER ISSUE

Meaning of Fourier transform in electron holography:

assume weighted and phased distribution $S(\mathbf{R})$ of s-wave point sources, emitting amplitude $A(\mathbf{k},\mathbf{R})$ at large R, excluding all scattering:

(this mimicks multiple scattering as extra sources)

$$A(\mathbf{k},\mathbf{R}) \approx \frac{e^{ikr}}{R} \iiint d^3R\, S(\mathbf{R})\, e^{-i\mathbf{k}.\mathbf{R}}$$

then, inversely:

$$S(\mathbf{R}) \approx \iiint d^3k\, A(\mathbf{k},\mathbf{R})\, e^{i\mathbf{k}.\mathbf{R}}$$

SO: Fourier transform of non-scattered amplitude is point-source distribution

- this is ideal goal of holography

BUT: electron holography uses intensity $I(\mathbf{k},\mathbf{R})$:

$$S'(\mathbf{R}) \approx \iiint d^3k\, I(\mathbf{k},\mathbf{R})\, e^{i\mathbf{k}.\mathbf{R}}$$

i.e.:

image = effective point source distribution $S'(\mathbf{R})$,
such that $S'(\mathbf{R})$ reproduces "amplitude" $A' = I$,
where I is actual hologram

SO: electron holography yields an effective point source distribution $S'(\mathbf{R})$, that compensates for:

- using I, not A (giving twin and self-images)
- phase shifts, including forward focusing
- multiple scattering
- finite integration domain
- etc...

example:

forward focusing:

causes effective source at focus
and no image at nucleus of scatterer

Efficient Multiple-Scattering Methods in Photoelectron Diffraction and XAFS

J. Rehr

University of Washington

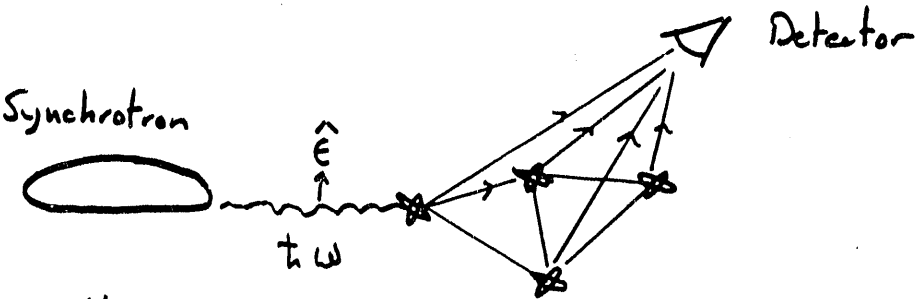
Efficient Multiple-Scattering Methods in Photoelectron Diffraction & XAFS

collaborators - R.C. Albers (Los Alamos)
- S.I. Zabinsky, Jose Mustre (UW)
- C.S. Fadley, A. Kaduwela, D. Friedman (U. Hawa

support - U.S. D.O.E.

Goal: Fast, accurate calculations of P.D., XAFS, AES, etc

PD:

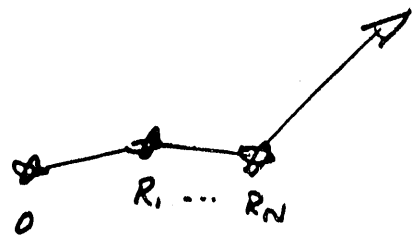


$$\frac{d\sigma}{d\Omega} \sim \left| \sum_{L,N}^{\text{paths}} G^{N}_{00,L} \langle L | \hat{\epsilon} | c \rangle \right|^2$$

Talk:
1) Introduction - "Angular Momentum Disease"
Practical IMPOSSIBILITY of calculating $G^{N}_{00,L}$
2) Approximations: (cures)
Spherical Wave Approximation SWA
Magnetic Quantum Number Expansion MQNE
Scattering Matrices SM
3) Why does it work?

1. Introduction - Multiple Scattering Expansion

$G^N_{00,L}$ N-leg propagator



$$G^N_{00,L} = G_{00,L_N}(\bar{R}_N - \bar{R}_N)\, t_{L_N}(R_N)\, G_{L_N L_{N-1}}(\bar{R}_N - \bar{R}_{N-1}) \cdots t_{L_1}(R_1)\, G_{L_1 L}(\bar{R}_1)$$

matrix product

Ingredients: — $G_{LL'}(\bar{R})$ free propagator

⊗ $t_L \delta_{LL'}$ t-matrix

$t_\ell = e^{i\delta_\ell} \sin\delta_\ell$

Angular Momentum Disease

$L = \ell, m$ $\quad \ell \tilde{<} kR_{mt}$ $\quad 2 < k < 20\,\text{Å}^{-1}$ $\quad R_{mt} \sim 1.2$ $\Rightarrow \ell_{max} \tilde{=} 25$

$-\ell < m < \ell$

Matrix Dimension: $\ell_{max} \cdot (2\ell_{max}+1) \sim 10^3$

Storage $\sim L^2 \sim 10^6$

CPU $\sim L^3 \sim 10^9 \times$ # paths

$\Rightarrow$ IMPOSSIBLE to calculate high order paths at <u>high</u> energy.

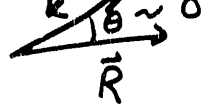
2. Approximations - CURES (?)

Spherical Wave Approximation (SWA)

J.R. - Albers - Natoli-Stern (1986)

$$G_{LL'}(\bar{R}) = c \int \frac{d^3k}{(2\pi)^3} \frac{Y_L^*(\hat{k})\, Y_{L'}(\hat{k})\, e^{i\vec{k}\cdot\vec{R}}}{E - \frac{1}{2}k^2 + i0^+}$$

LARGE # $kR \Rightarrow$ small angles



$$\cong \text{saddle-point} \quad 4\pi \frac{e^{ikR}}{kR} Y_L^*(\hat{R})\, Y_{L'}(\hat{R})\, C_\ell(kR)\, C_{\ell'}(kR)\, J_0\left(\frac{\ell\ell'}{kR}\right)$$

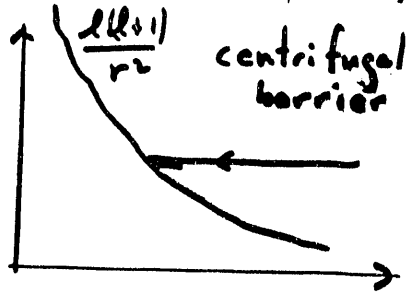
- separable! ($J_0 \approx 1$)
  ℓ, ℓ' uncoupled

C_ℓ = "spherical correction factor to Hankel fn"

$$C_\ell \cong \left(1 + \frac{\ell(\ell+1)}{2(kR)^2}\right)^{1/2} e^{i\frac{\ell(\ell+1)}{2kR}}$$

(SWA)

$$h_\ell^+ = i \frac{e^{-\ell\, ikR}}{kR} C_\ell(kR)$$



LARGE $\frac{\ell(\ell+1)}{2kR}$ phase shift due to centrifugal barrier

Result: Matrix product →

product of "curved wave scattering amplitudes"

$$G\, t_N\, G\, t_{N-1}\, G \cdots t_1\, G \rightarrow$$

$$f(\infty, R_N\, \theta_N)\, f(R_N\, R_{N-1}\, \theta_{N-1}) \cdots f(R_0\, R, \theta)$$

$$f(R\, R'\, \theta) = \frac{1}{k} \sum_{\ell}{}' (2\ell+1)\, t_\ell\, P_\ell(\cos\theta)\, \underbrace{C_\ell(kR)\, C_\ell(kR')}$$

curved wave correction

- Simplicity of PWA!
- Fair to Good approximation to full spherical-wave

SW - exact spherical wave

PW - plane wave

B. Small m- expansion — MQNE Barton Shirley
— RAMF Fritzsche
Trick rediscovered many times! etc.

Note: Only small m contribute to $G_{lm\,l'm'}(\vec{R})$
if $\vec{R} \parallel \hat{z}$. $G \sim \frac{e^{ikR}}{kR} Y^*_{lm}(\hat{R})\, Y_{lm}(\hat{R})$

∴ Rotate bonds // $\hat{z}$ axis

$$Y_L \to \sum_\mu' R^l_{m\mu}\, Y_{l\mu}$$

↑ Rotation matrix

⇒

$$G_{LL'}(\vec{R}) = \sum_\mu' R^l_{m\mu}\, G_{l\mu\,l\mu}(R\hat{z})\, R^{l'}_{\mu m'}$$

$$G_{l\mu\,l\mu'}(R\hat{z}) = \sim \frac{e^{ikR}}{kR}\, G^{\mu}_{ll'}(kR)\, \delta_{\mu\mu'}$$

"z-axis propagator"

→ ALMOST-CURE

$l(2l+1) \to l\cdot(2\mu+1) \tilde{<} 5 l_{max} \sim 10^2$

$\mu \tilde{<} 2$

Problem reduced to CRAY hours! 100×100 matrices!

Danos & Maximon (1965)

Many of our results are contained in the literature. They are, however, not easily available. As a matter of fact, we found the references only after having rederived most of them. The characteristic of being hidden was re-emphasized in that an additional genealogic tree of references was called to our attention[12] after having submitted the paper to the Editor. It is very likely that still further references exist in the literature. - going back to Rayleigh 1890's

J.R. + R. Albers (1990)

Our method is based on a new separable representation of the free Green's-function matrix elements $G_{L,L'}(\rho)=\langle L,\mathbf{R}|G|L',\mathbf{R}'\rangle$, where $\rho=k(\mathbf{R}-\mathbf{R}')$. These propagator (or translation operator) matrix elements $G_{L,L'}$ also appear in the addition formula for the translation of screened spherical waves[13-15] as well as in multiple-scattering expansions.[1-2,15] The theory of such functions has an extensive, if relatively obscure literature; a historical survey is given in Ref. 13. Like other researchers in this area, we have occasionally found some of our results in the literature only after having first worked them out independently by ourselves.

3. Why does the Separable Approximation work?

Fritzsche: - expect LARGE errors in Scattering Matrix at high energy!

- "instability"

Our analysis:

i) Fritzsche is partly right -

- terms in separable expansion converge slowly - if at all! $\sim C_\ell \frac{\ell\ell+1}{kR}$

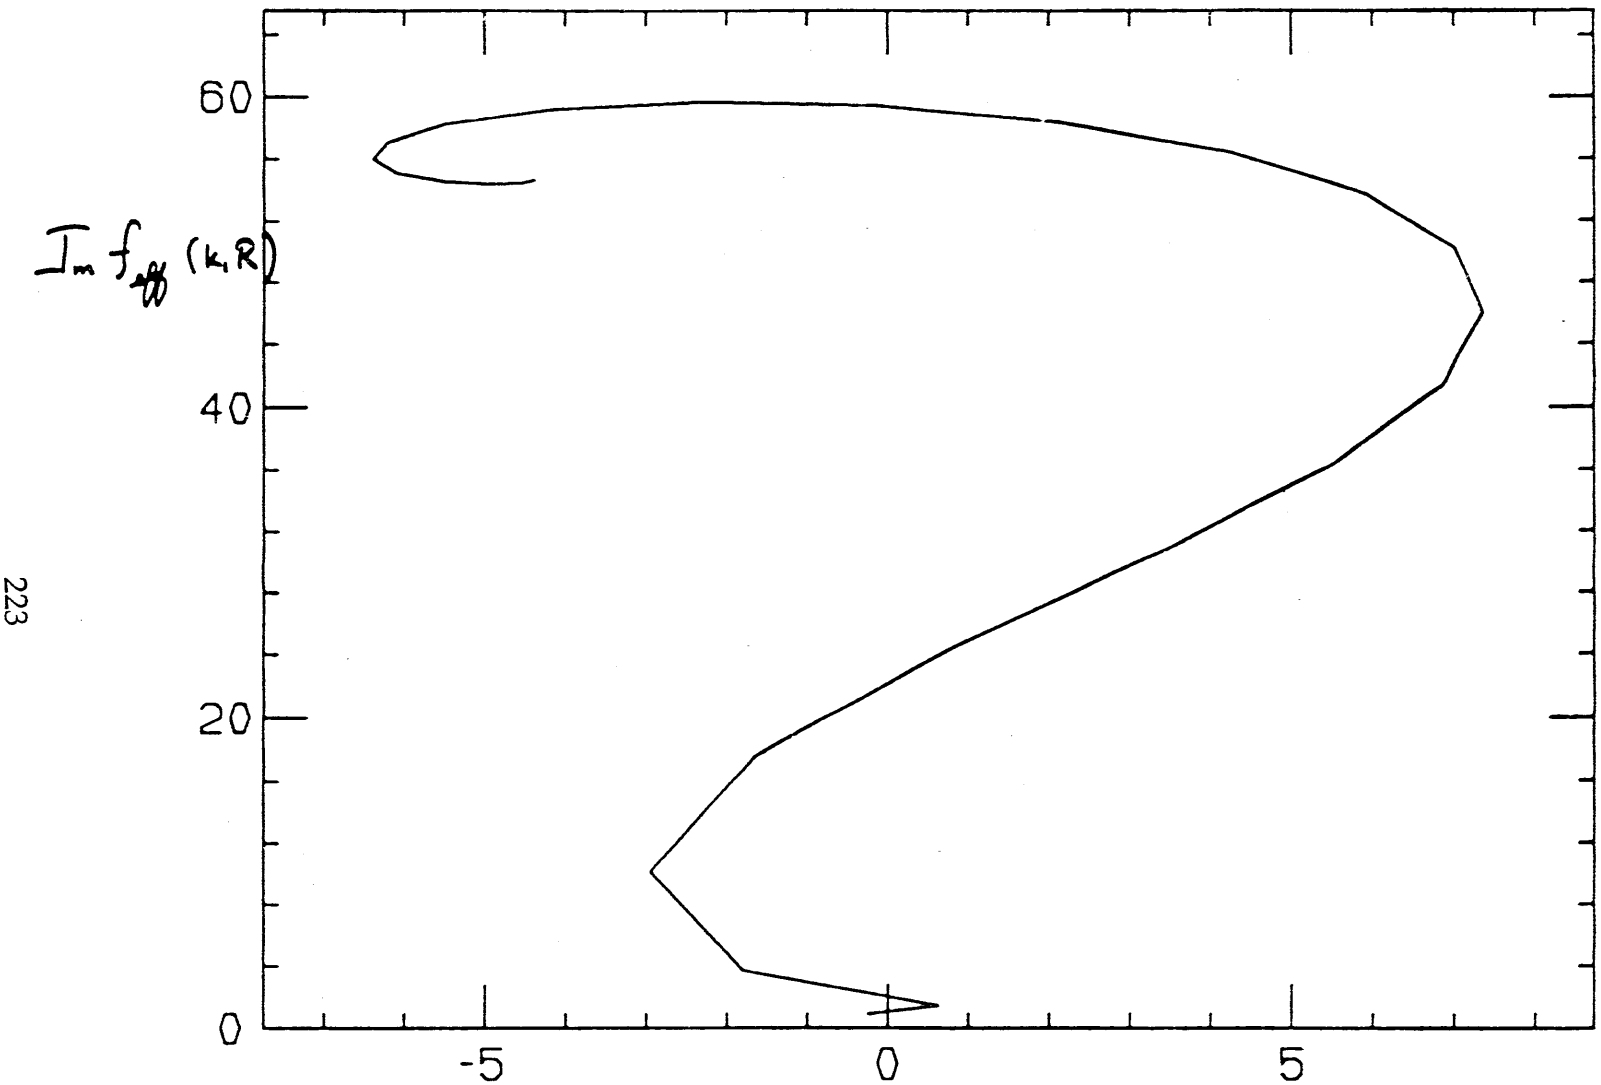
ii) Fritzsche is partly WRONG -

- C_ℓ's $\Rightarrow$ Fresnel convergence
  $\Rightarrow$ large ℓ cutoff!

Approximation gets better with increasing energy!

third shell, k=20 inv Ang

Forward scattering



Partial sums

$$f_{eff} = \sum_{l}' (2l+1)\, t_l\, C_l^2(kR), \quad 0 \le l \le 20$$

Conclusions

1) SWA — Fast ✓, fair approximation

2) MQNE — Slow, Accurate ✓

3) S-Matrix — Fast ✓, Accurate ✓ CURE!

- 6×6 matrices
- order of magnitude faster than MQNE
- 2 orders of magnitude faster than exact
- can calculate arbitrarily high order paths

" Results obtained using this new separable Green's function matrix approach are in very good agreement with other MS methods and with experiment."

A. Kaduwela Ph.D. Thesis U. Hawaii 1991

4) Fritzsche's "instability" NOT a problem.

Conclusions and Future Directions

1. Site-specific XPD works provided the sites possess different symmetries with respect to specimen crystal axes (i.e. zincblende).

2. State-specific XPD works provided the chemical shifts are large enough to be reasonably resolved.

3. State-specific XPD can be done with monochromatic lab x-ray sources, but it is very slow. High total energy resolution (~0.2-0.3 eV), high photon energy (>~ 1 keV), and high intensity (ALS!) required for more rapid data acquisition and lower statistical uncertainties in measured anisotropies.

Photoelectron Diffraction of Magnetic Ultrathin Films

J. Tobin

Lawrence Livermore National Laboratory

Photoelectron Diffraction of Magnetic Ultrathin Films

James G. Tobin
Lawrence Livermore National Laboratory

Goal: Determination of both the local Geometric and Magnetic Structures

Collaborators:

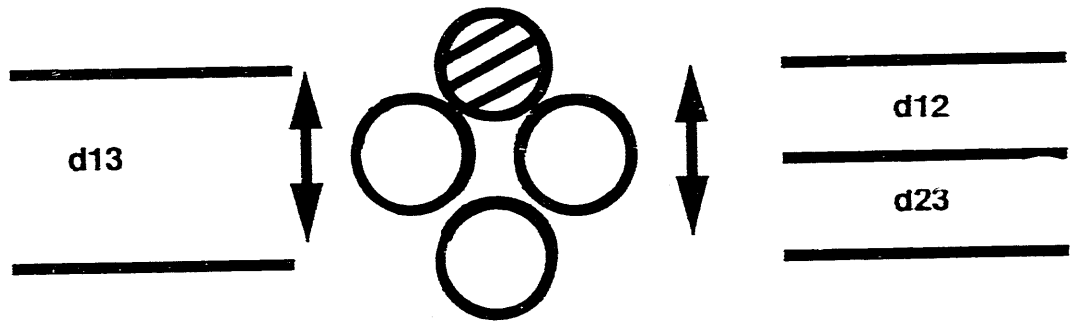
Four Fold Hollow Model FCC - (001)



d13 = d12+d23

d13 = 3.60 Å

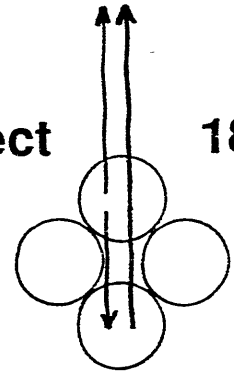
1. d_{12} uncertain

2. Composition (Fe vs. Cu) unknown

   [used monolayer, bilayer and trilayer of Fe on Cu (001)]

Fe/Cu (001) Photoelectron Diffraction

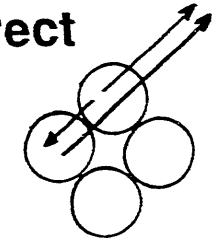
Why are we sensitive to $d_{13} = d_{12} + d_{23}$?



Direct 180° backscattered

NORMAL EMISSION

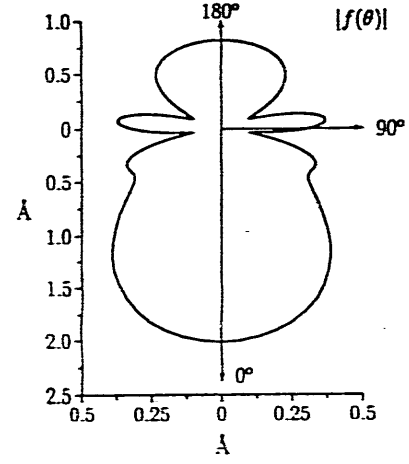
How can we measure d_{12}?



Direct 180° backscattering

OFF-NORMAL EMISSION ~45°

Scattering amplitude vs. angle, at low KE.



Fe 3p Photoelectron Diffraction

Consistent with FCC structure, d_{13} = 3.60Å

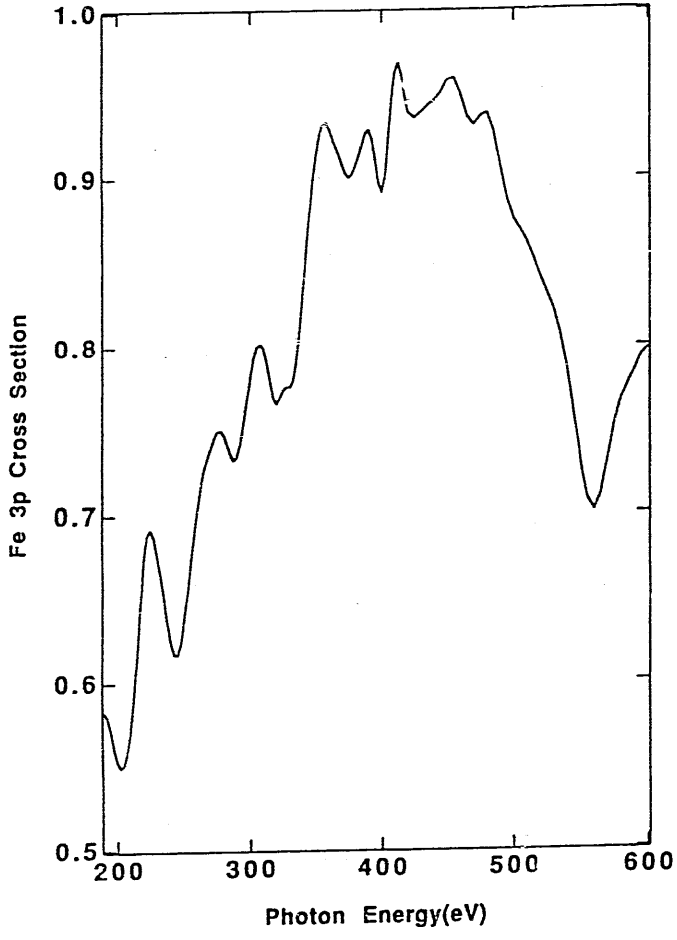
Need to determine

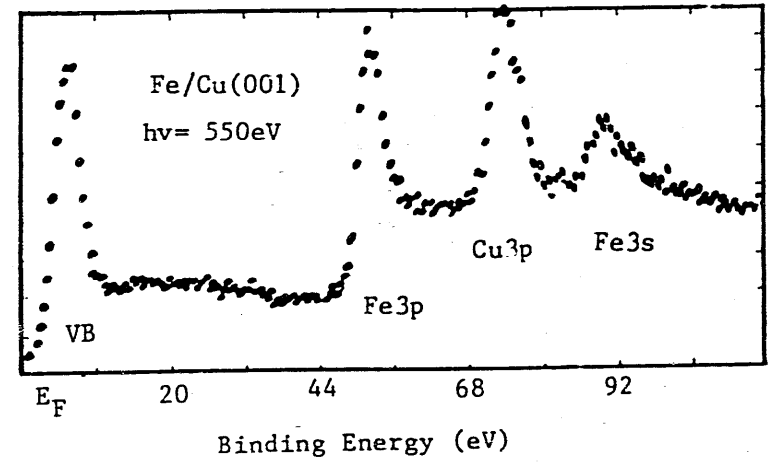
1. d_{12}
2. Elemental nature of nearest neighbors (overlayers vs. clusters vs. alloying...)
3. Accuracy to $\lesssim \pm$ .05Å

Solutions

1. Wider hν range
2. σ vs KE at 45° emission to test d12
3. Multiplet split photoelectron diffraction
   → Fe 3s ←
   Spin dependence + Local magnetic ordering

Wider Photon Energy Range: Preliminary Analysis





Magnetic Structure: Spin Dependent Photoelectron Diffraction

Transfer from source to specimen

Demagnification x 10

Monochromacy : XPEEM : 0.5 - 1 eV

AEEM : uncritical

Assumed losses : factor 10^3

Specimen

Illuminated area : 10^4 μm^2

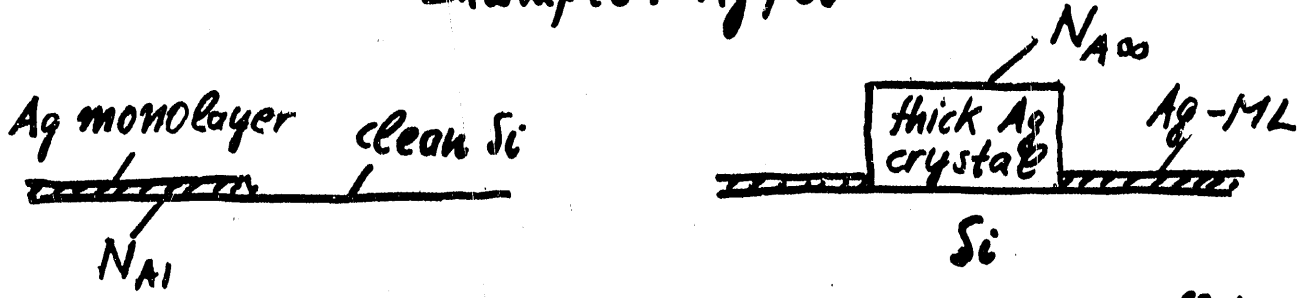
Flux density : XPEEM $\approx 10^{22}$ photons/m^{2}s

AEEM $\approx 10^{24}$ "

(10% bandwidth)

(IV) Qualitative Analysis

Example: Ag/Si



XPEEM $E_{char} = 100\,eV$ $(h\nu = 484\,eV)$ $n = 10^{22}/m^2s$

AEEM $E_{M_{45}VV} \approx 350\,eV$ $(E_p \approx 1.5\,keV)$ $n = 10^{24}/m^2s$

Feature recognition when signal difference

- $\Delta S \gtrsim 5N = 5(\overline{S+B})^{1/2}$ Rose criterion

Signal from object region with area

$r^2 = (L\delta)^2 = 500\,nm^2 \approx (22\,nm)^2$ for $T = 10^{-2}$:

- $S = n(L\delta)^2 N_A \sigma_A T$

$N_{Al} \approx 8 \times 10^{18}$ atoms/m^2

$N_{A\infty} = \dfrac{N_{Ag(111)}}{1 - \exp(-d_{111}/\ell)} \approx 40 \times 10^{18}$ atoms/m^2

$\sigma_A = 3.5 \times 10^{-22}\,m^2$

$S_{Al} \approx 1.4 \times 10^2$ e/s

$S_{A\infty} \approx 7 \times 10^2$ e/s

LEEM

I_0 5 nA in 6 µm $\phi \hat{=} \frac{36\pi}{4} \times 10^{-12}\,m^2 \approx 25 \times 10^{-4}$

$R = 60\% \rightarrow I = \frac{3 \times 10^{-9}}{1.6 \times 10^{-19}} \approx 2 \times 10^{10}$ e/s in "

$I_{in\ 500\,nm^2} = \frac{500 \times 10^{-18}}{25 \times 10^{-12}} 2 \times 10^{10}$ e/s $= 4 \times 10^5$ e/s

8 µm ϕ, 30% R $\rightarrow 1 \times 10^5$ e/s

Background

clean Si: scaled from Mg K_α (1254 eV) to 484 eV excitation via $\sigma_i(h\nu)$:

$B_{Si} \approx 1.25 \times 10^2$ e/s

Ag monolayer: $B_{Al} \approx B_{Si}$

thick Ag crystal: $B_{A\infty} \approx 0$

↓

① Ag monolayer island recognition

$\Delta S_{min} \approx 5\left[\frac{1}{2}(S_{Al} + B_{Si} + B_{Si})\right]^{1/2} \approx \underline{70}$ vs

$\Delta S_{exp} = S_{Al} + B_{Si} - B_{Si} \approx \underline{140}$

1 s → 10 s $\quad \Delta S_{exp} \approx \underline{1400}$ vs $\Delta S_{min} \approx \underline{220}$

② thick Ag crystal recognition

$\Delta S_{min} \approx 5\left[\frac{1}{2}(S_{A\infty} + S_{Al} + B_{Si})\right]^{1/2} \approx \underline{110}$ vs

$\Delta S_{exp} = S_{A\infty} - (S_{Al} + B_{Si}) \approx \underline{535}$

V. Quantitative Analysis

Detectable $\Delta N_A = N_A - N_A'$

at a given average density

$$\bar{N}_A = \frac{1}{2}(N_A + N_A')$$

in integration time τ

N_A	$N_{A'}$
S_A	$S_A' = S_A + \Delta S_A$
B	B'

assume $B = B'$

$$\Delta N_A \triangleq \Delta S_A = \Delta\theta\, S_{A1}$$

θ coverage

S_{A1} monolayer signal

Recognition condition

$$\Delta S_A \geqq k\,(S_A + B + S_A' + B')^{1/2} \longrightarrow$$

$$\Delta\theta_{min} \approx k\sqrt{2}\,\frac{\sqrt{B+S_A}}{S_{A1}}$$

$\Delta\theta_{min}$ for $S_A \approx S_{A1}$, 22×22 nm^2 pixel, $k = 5$

τ (sec)	XPEEM $S_{A1} = 140$, $B = 125$	AEEM $S_{A1} = 240$, $B \approx 900$
1	0.92	1.05
10	0.27	0.32
100	0.08	0.10
1000	0.03	0.03

↓

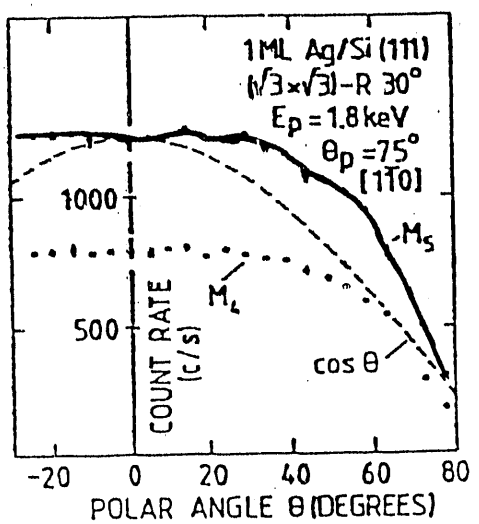
Quantitative analysis possible with

$\delta \approx 20$ nm, $\tau = 100 - 1000$ s, $\Delta\theta = 0.10 - 0.03$ ML.

Auger electron angular distributions

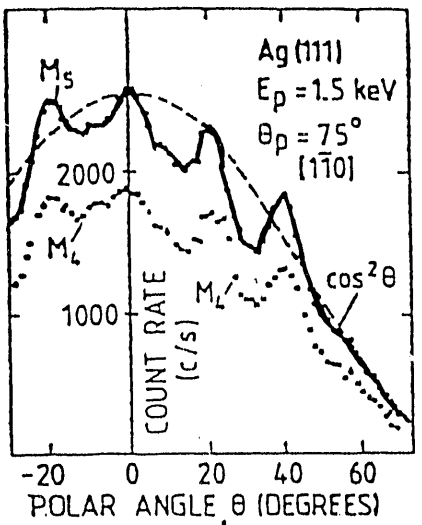
$M_{45}VV$

1 ML Ag on Si(111)

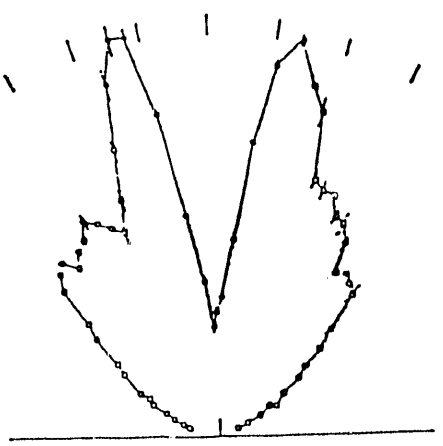


a

Ag(111)



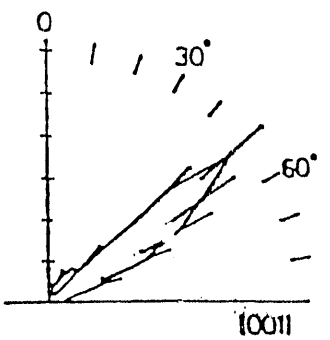
b



c

Cu (100)

$M_{23}VV$



d

½ ML Se on Ni (100)

$M_{45}VV$

Auger electron and photo electron backdiffraction can cause mayor problems because of small angular acceptance of system

Ag-ML on Si :	OK
thick Ag (111) :	≈ OK
Cu (100) :	not OK
Se ½ ML on Ni (100) :	not OK

Nevertheless

Direct chemical imaging appears very promising, in particular in combination with

LEEM
LEED
and
UV-PEEM

Outline

- Motivation for spectromicroscopy. What can we learn?
- Approaches to spectromicroscopy, microprobe devices.
- Requirements on the source.
- X1-SPEM, instrument details
- First results, present status
- Future outlook: spatial, energy, and time resolution

Why X-Ray Photoemission Microscopy?

- Photoemission/Soft X-Ray Spectroscopies are

  Very Powerful Techniques for Studying

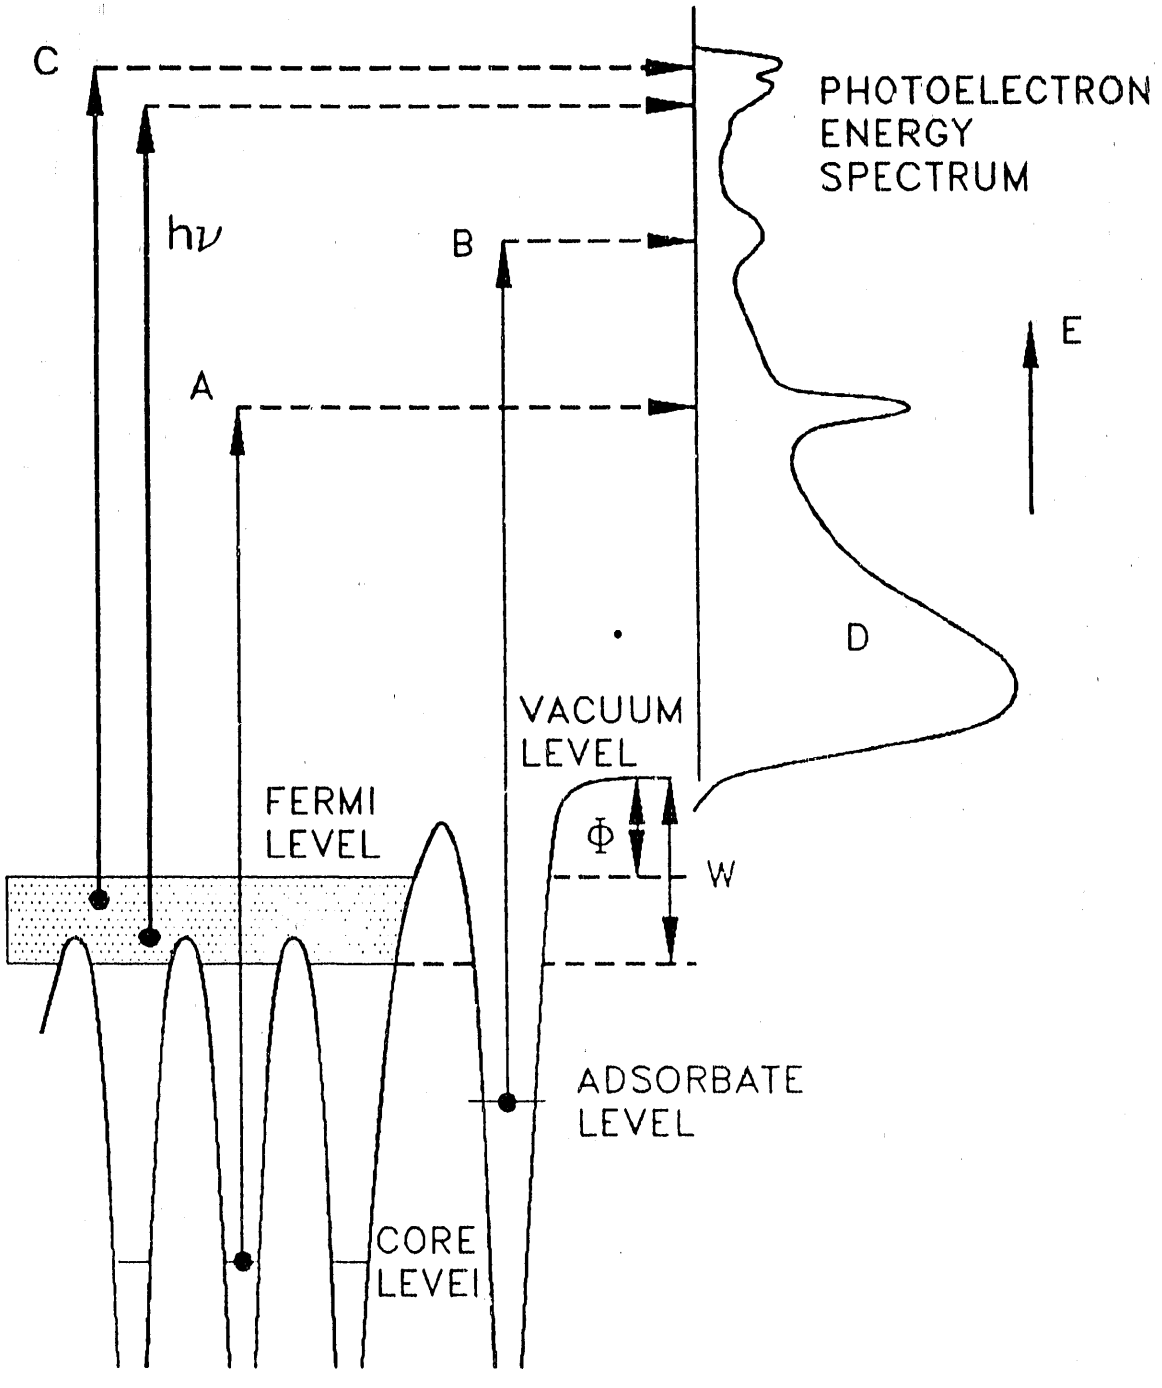
  - Chemistry at Surfaces
  - Geometric and Electronic Structure

- Until Recently, Not Much Lateral Resolution
  - Require Model System (PES)
  - Robust Systems (electron probes: SAM, STEM, etc.)

- Many Systems of Interest Are Inhomogeneous and/or e-Beam Sensitive
  - Oxides/Oxyhydroxides
  - Catalytic Systems
  - Thin Film/Thin Film Growth (polymers esp.)
  - Semiconductor Devices
  - Interfaces, Co-polymers

- PEM Contains More Information than SAM: Primary Photoelectron Peaks and AUGER Peaks (can use Auger parameter)

- XANES Mode for Certain Elements



Auger decay of core hole

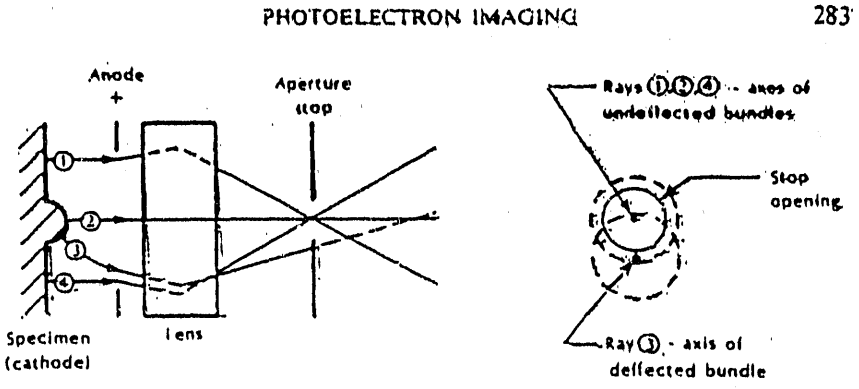
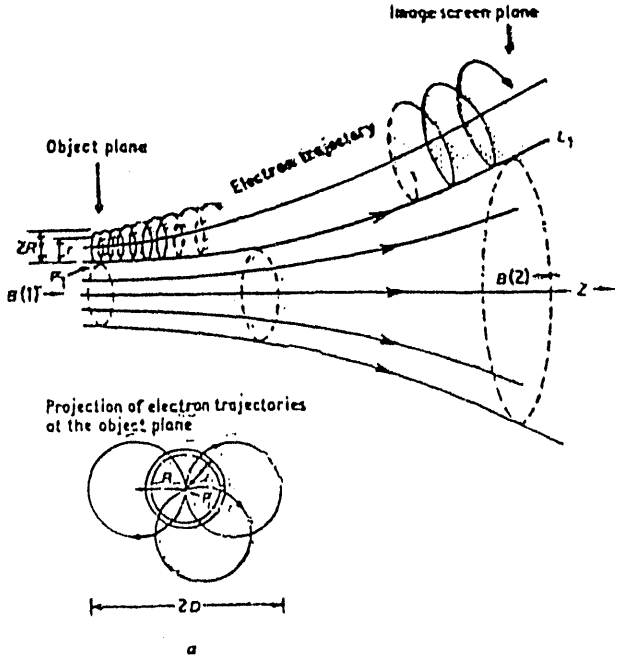
Approaches to Spectromicroscopy

Image e- (Electron Optical Instruments):

- electro-static (Bauer-Telieps, Tonner micro-XANES)



- magneto-static (Beamson, Pianetta)

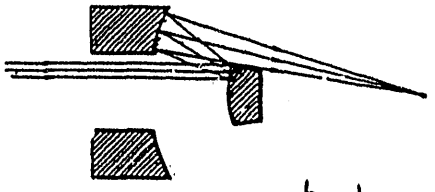


Focus X-rays (Microprobe Instruments):

- **normal incidence multilayer Schwarzschild (F.Cerrina)**

potentially very high spatial resolution

stiff limit (3mm) ≈ 6mm



f + f(λ)
WD few cm

but only few % BW tunability

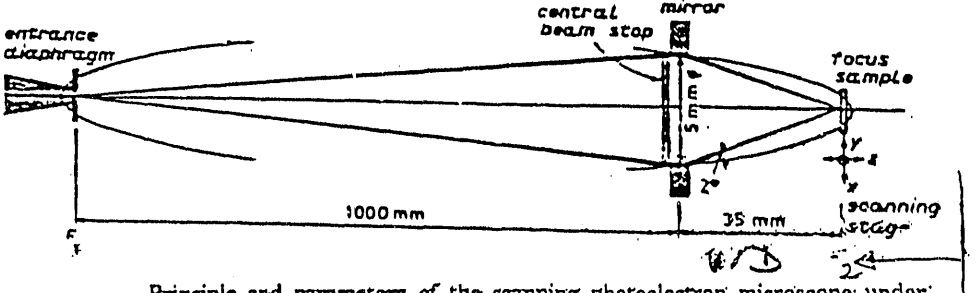
Figure 1. 0.3 N.A. Schwarzschild objective

presently hν < 280 eV

- **grazing incidence ellipsoid (Kunz)**

20 eV → 2000 eV f + f(λ)

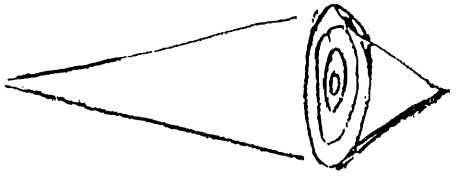
inefficient beam 95% obstructed (radius)



Principle and parameters of the scanning photoelectron microscope under construction at HASYLAB. F_1, F_2 are the foci of the elliptical mirror.

Central obstruction → more flux into outer lobes of Airy pattern

- **zone plate (SPEM)**



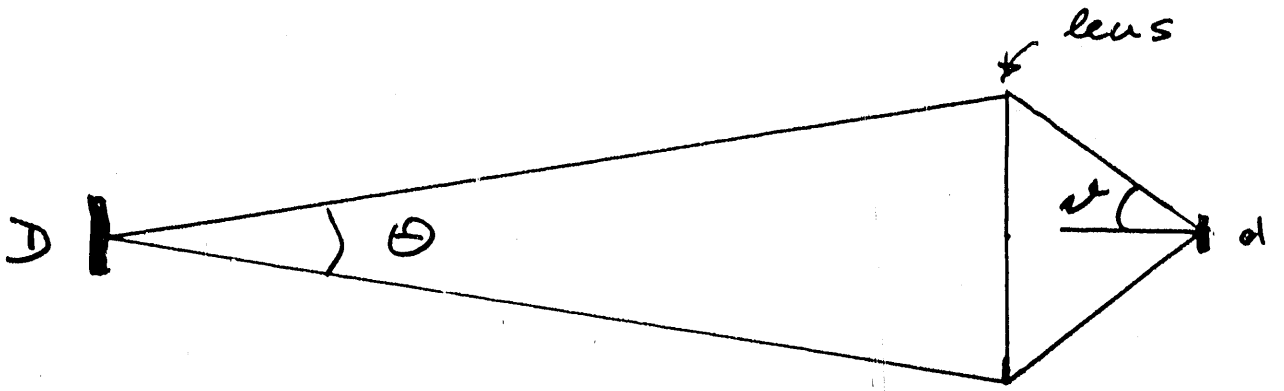
~100 eV → ~2000 eV
tunable over ~15% BW (so far)

$f \propto E \left(\propto \frac{1}{\lambda}\right)$

WD ≈ 1-2 mm

Diffraction limited resolution

$$d \propto \frac{\lambda}{2\,N.A.}$$



for small angles $\alpha \propto N.A.$

$$\xrightarrow{(1)} \quad 2\alpha d \propto \lambda$$

Liouville's Theorem (conservation of photon phase space)

$$D\theta = 2\alpha d \propto \lambda$$

∴ for smallest possible probe size need to limit the accepted source phase space to about λ i.e. need coherent illumination

Possible Experiments

- Heterogeneous Alumina ($Al_2O_3 + \varepsilon H_2O$)
  - Catalyst or used as support for catalysts
  - Surface acidity depends strongly on binding energy of hydrogen in the hydroxyl group (alumina phase, local geometry)
  - Dosing with ammonia, various alcohols, CO, and CO_2

Electron energy (eV)

Summary of Present X1-SPEM Capabilities

- First and Only Submicron Images with Primary Photoelectrons
- Spatial Resolution Approaching 100 nm
- 3–6 eV Energy Resolution with Primary Photoelectrons
- 5–9 $\times 10^8$ photons/(sec, 0.29% BW) @ 650 eV
- Simultaneous TY and CMA Images
- Feasibility Studies on Alumina Under Way

Instrumental Improvements of the X1–SPEM

- Add XANES Mode with 0.3–1.0 eV Photon Energy Resolution
- Higher Spatial Resolution (few months: sub-100 nm; one year: 50 nm; few years: 20 nm)
- More Efficient Grating (gain of 2–5 in flux)
- Ni Phase Zone Plates (gain of factor 2 in flux)
- Commercial Spectrometer (gain of >10 peak count rate, simultaneously factor 2 in energy resolution, or <1 eV energy resolution)
- Multiple Energy (16 channel) Detection over 5–20 eV Window
- Alternate Signals (PSD, fluorescence [ALS], scattering)

Comments on Scanning Versus E-Imaging

- Spatial Resolution: E-Imaging May Be the Winner (XANES)
- Energy Resolution: Scanning and Imaging at Par
- Detection Efficiency: Scanning $\Omega/2\pi > 10\%$ and Multichannel Detection, E-Imaging (XPS mode) $\Omega/2\pi \leq 0.1\%$ (depends on ∂_r)
- Time Resolution: Since Undulator Output Is Coherent, Time Resolution Determined by the Detection Efficiency (i.e., E-imaging loses its advantage as a parallel imaging system)
- Damage: If Thermal, Need E-Imaging, Otherwise Scanning (detection efficiency)

Alternate Signals:

- Scanning: Fluorescence, SA Diffraction/Scattering, Neutral Ions
- E-Imaging: Compatible with LEED, Photoelectron Holography

Both techniques have a bright future and complement each other.
