$\text{CeCu}_2\text{Ge}_2$  orders antiferromagnetically,  $T_N \sim 4\text{K}$ , and  $\gamma(T) \sim 200 \text{ mJ/K}^2 \text{ mole}$  near  $0.5\text{K}$  and  $P=0$ . A pressure of 9.5 kbar has no measurable effect on  $T_N$ ; reduces slightly the specific-heat anomaly at  $T_N$ ; and reduces slightly  $\gamma(T)$  below  $0.7\text{K}$ . These effects of pressure are in striking contrast to the much stronger effects on other heavy-fermion compounds, e.g.,  $\text{CeAl}_3$ ,  $\text{URu}_2\text{Si}_2$  and  $\text{CeCu}_2\text{Si}_2$ .

$\text{CeCu}_2\text{Ge}_2$  is isostructural with  $\text{CeCu}_2\text{Si}_2$ , the first heavy-fermion superconductor [1]. Although  $\text{CeCu}_2\text{Ge}_2$  is not superconducting at zero pressure ( $P$ ), it is superconducting for  $P > 70$  kbar [2]. Previous specific-heat ( $C$ ) measurements [3] for  $P=0$ ,  $0.05 \leq T \leq 30\text{K}$ , and magnetic fields ( $H$ ) to  $8\text{T}$ , showed antiferromagnetic ordering at  $T_N = 4.2\text{K}$ , and an anomaly in  $C$  at  $0.45\text{K}$  and  $H=0$  that was interpreted as a maximum in  $\gamma(T)$ . The anomaly was suppressed, but not shifted in temperature, with increasing  $H$  and disappeared at  $H=8\text{T}$ . This paper reports new data for  $C$ ,  $0.35 \leq T \leq 20\text{K}$  and  $P=0$ ; and also data obtained at 9.5 kbar, the first for  $P \neq 0$ . The  $P=0$  data are in excellent agreement with the earlier work [3] suggesting that the features observed are intrinsic properties and not subject to the uncertainties related to sample dependence that are associated with some heavy-fermion compounds.

In Fig. 1,  $C$  vs  $T$ , the solid line represents an estimate of the lattice specific heat ( $C_\ell$ ) obtained for  $T > 14\text{K}$ . The corresponding Debye temperature and  $\gamma$  are  $\sim 240\text{K}$  and  $10 \text{ mJ/K}^2 \text{ mole}$ , respectively. There are substantial uncertainties in these estimates, but it is clear that  $C_\ell$  is a negligible contribution for  $T < T_N$ , and  $\gamma$  is not large for  $T > 14\text{K}$ . It follows that the quasiparticles acquire high mass only at lower temperatures.

Figure 2, a plot of  $C/T$  vs  $T$ , shows the antiferromagnetic transition centered at  $T_N = 4.3\text{K}$ , and the anomaly. Relative to the  $P=0$  data, there are small decreases in  $C/T$  just below  $T_N$

and in the vicinity of 0.45K, but with no measurable change in  $T_N$ . The entropy (S) in Fig. 3 approaches  $R\ln 2$  at higher temperatures consistent with a doublet ground state for  $Ce^{3+}$ .

To separate the 0.45K anomaly from that associated with antiferromagnetic ordering, the procedure described in Ref. 3 was used: The low-temperature antiferromagnetic magnon contribution,  $\beta_3 T^3$ , was derived from a plot of  $C/T$  vs  $T^2$ , which is linear for  $0.85 \leq T \leq 1.5K$ . Subtraction of that contribution, which is pressure independent, gives the "0.45K anomalies" shown in Fig. 4. Both the position and magnitude of the maximum for  $P=0$  are in good agreement with those of Ref. 3. In 9.5 kbar, however, the maximum is shifted to 0.5K, and reduced in magnitude for  $T < 0.7K$ , by  $\sim 30\%$  at 0.35K.

The weak  $P$  dependence of  $C$  near  $T_N$  is in sharp contrast to the relatively large change of  $C$  with  $P$  for, e.g.,  $URu_2Si_2$  [4] for which  $T_N=18K$ .  $CeAl_3$  also shows a maximum in  $C/T$  near 0.4K, but it is rapidly suppressed with increasing pressure, disappearing completely for  $P < 0.4kbar$ , and at  $P=8.2 kbar$   $C/T$  at 0.4K is reduced to less than one third of its  $P=0$  value [5].  $CeCu_2Si_2$  also shows a large change of  $C$  with  $P$  [6].

The work at LBL was supported by the Director, Office of Energy Research, Office of Basic Energy Sciences, Materials Sciences Division of the U.S. Department of Energy under contract number DE-AC03-76SF00098. NEP is grateful to the Alexander von Humboldt Foundation for an award that facilitated his collaboration with the Darmstadt group.
