## **MCNP™ ENDF/B-VI IRON BENCHMARK CALCULATIONS**

**J. David Court and John S. Hendricks**

**Los Alamos National Laboratory**

Four iron shielding benchmarks have been calculated for, we believe the first time, with MCNP4A<sup>1</sup> and its new ENDF/B-VI library.<sup>2</sup> These calculations are part of the Hiroshima/Nagasaki dose re-evaluation for the National Academy of Sciences and the Defense Nuclear Agency. We believe these calculations are significant because they validate MCNP and the new ENDF/B-VI libraries. These calculations are compared to ENDF/B-V, experiment, and in some cases the recommended MCNP data library (a T-2 evaluation) and ENDF/IV.

The first iron shielding benchmarks are the Livermore pulsed sphere experiments<sup>3,4</sup> from the 1960's. These consist of a 14-MeV pulsed D-T neutron source in spheres of different materials and thicknesses and measured with time-of-flight detectors. The iron experiments were for iron spheres of 0.9 and 4.8 mean free paths. In addition to comparing the detailed energy spectrum from 2-MeV to 16 MeV, the integrals of emerging neutrons are tabulated in two bins: 2 - 16 MeV and 12 - 16 MeV. These data are presented in Table 1.

The second benchmark experiment is the Oak Ridge fusion shielding benchmark devised by Santoro in the early 80's.<sup>4,5</sup> The experiment consists of a monodirectional 14-MeV D-T neutron source impinging upon three configurations of steel shielding. Concrete and borated polyethylene are also important shielding

materials in the problem. Detectors are located both on and off-axis from the incident beam. The different data libraries used in the calculation and the different shielding configurations and detector locations provide a large number of spectra to compare. The spectra for ENDF/B-VI, configuration 1, and the on-axis detector is shown in Fig. 1, coplotted against experimental upper and lower energy. The agreement between all data versions and the experiment are within 50% which is excellent for deep penetration problems. Note that agreement is always bad in the 7.5 to 9.5 MeV energy range where the computational unfolding routines that were used to process the experimental data produce a nonphysical dip in the neutron spectra.

The third shielding benchmark experiment is a 76-cm diameter iron sphere with a Cf-252 fission source in the 15.3 cm diameter cavity in the center.<sup>6</sup> These results are consistent with the Livermore Pulsed Spheres.

The fourth and final shielding benchmark experiment is the Oak Ridge iron benchmark with a fission source.<sup>7</sup> A reactor beam port emits neutrons in the range thermal - 10 MeV which impinge on iron thicknesses up to 92 cm (13 mean free paths) thick. Detectors are placed about a meter behind the iron slabs at various angles relative to the incident neutron beam. For the most part the calculations are within the quoted 15% experimental uncertainty.
