Concordant ^{241}Pu - ^{241}Am Dating of Environmental Samples: Results from Forest Fire Ash

Steven J. Goldstein, Warren J. Oldham, Michael T. Murrell, and Danny Katzman

We have measured the Pu, ^{237}Np , ^{241}Am , and ^{151}Sm isotopic systematics for a set of forest fire ash samples from various locations in the western U.S. including Montana, Wyoming, Idaho, and New Mexico. The goal of this study is to develop a concordant ^{241}Pu ($t_{1/2} = 14.4$ y)- ^{241}Am dating method for environmental collections. Environmental samples often contain mixtures of components including global fallout. There are a number of approaches for subtracting the global fallout component for such samples. One approach is to use ^{242}Pu / ^{239}Pu as a normalizing isotope ratio in a three-isotope plot, where this ratio for the non-global fallout component can be estimated or assumed to be small. This study investigates a new, complementary method of normalization using the long-lived fission product, ^{151}Sm ($t_{1/2} = 90$ y). We find that forest fire ash concentrates actinides and fission products with $\sim 1\text{E}10$ atoms $^{239}\text{Pu}/\text{g}$ and $\sim 1\text{E}8$ atoms $^{151}\text{Sm}/\text{g}$, allowing us to measure these nuclides by mass spectrometric (MIC-TIMS) and radiometric (liquid scintillation counting) methods. The forest fire ash samples are characterized by a western U.S. regional isotopic signature representing varying mixtures of global fallout with a local component from atmospheric testing of nuclear weapons at the Nevada Test Site (NTS). Our results also show that ^{151}Sm is well correlated with the Pu nuclides in the forest fire ash, suggesting that these nuclides have similar geochemical behavior in the environment. Results of this correlation indicate that the $^{151}\text{Sm}/^{239}\text{Pu}$ atom ratio for global fallout is ~ 0.164 , in agreement with an independent estimate of 0.165 based on ^{137}Cs fission yields for atmospheric weapons tests at the NTS. ^{241}Pu - ^{241}Am dating of the non-global fallout component in the forest fire ash samples yield ages in the late 1950's-early 1960's, consistent with a peak in NTS weapons testing at that time. The age results for this component are in agreement using both ^{242}Pu and ^{151}Sm normalizations, although the errors for the ^{151}Sm correction are currently larger due to the greater uncertainty of their measurements. Additional efforts to develop a concordant ^{241}Pu - ^{241}Am dating method for environmental collections are underway with emphasis on soil cores.

Concordant ^{241}Pu - ^{241}Am Dating of Environmental Samples: Results from Forest Fire Ash

^{241}Pu - ^{241}Am Age Dating of Environmental Samples

- ^{241}Pu ($t_{1/2} = 14.4$ y) \longrightarrow ^{241}Am ($t_{1/2} = 432.7$ y)
- Environmental samples often contain mixtures of components
 - Global Fallout
 - Well mixed stratospheric component
 - Peak in middle 1950's-early 1960's
 - Regional Fallout
 - Mixture of global fallout with poorly mixed tropospheric component.
 - Local Component
 - Sample of interest to identify Pu isotopic signature of source and age-date.

An Illustrative Example: NIST SRM 4350B & $^{242}\text{Pu}/^{239}\text{Pu}$ Corrections

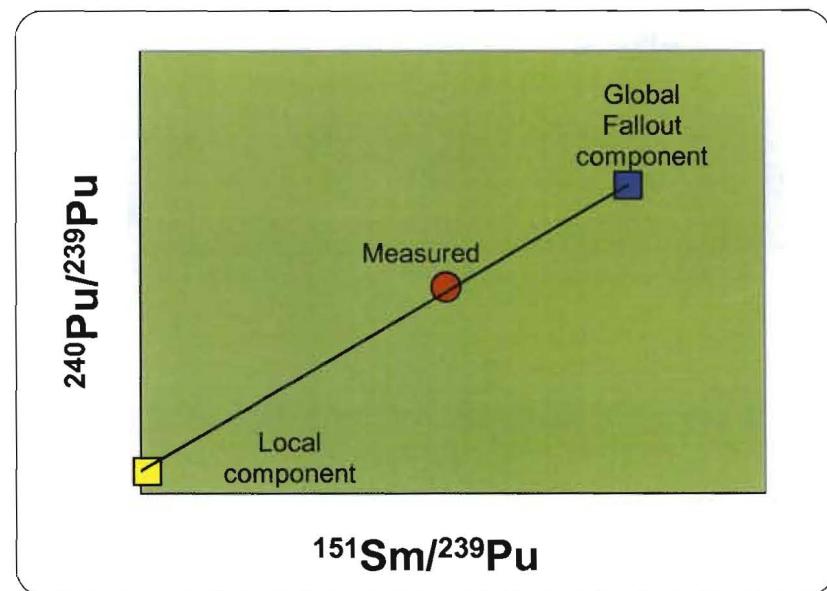

- NIST SRM 4350B: Columbia River sediment near Hanford, WA
- Typically use $^{242}\text{Pu}/^{239}\text{Pu}$ to correct for global fallout component, but need to know $^{242}\text{Pu}/^{239}\text{Pu}$ of local component.

$^{240}\text{Pu}/^{239}\text{Pu}$ Measured	+/- (%)	$^{240}\text{Pu}/^{239}\text{Pu}$ Local Component	+/- (%)	Local Component Age (cy)	+/- (y)
0.117	0.6	0.013	25	1945	11

Hypothetical Mixing of Local and Global Components: ^{151}Sm Normalization

- Can we use other fallout nuclides for normalization which may behave geochemically similar to Pu such as ^{151}Sm ?
 - ^{151}Sm ($t_{1/2} = 97$ y): Long-lived lanthanide fission product produced by weapons testing.
 - Evaluate concordance of ages and Pu isotope ratios for local component from multiple approaches.
 - Based on concordance of two approaches, determine $^{242}\text{Pu}/^{239}\text{Pu}$ and $^{151}\text{Sm}/^{239}\text{Pu}$ of local component.

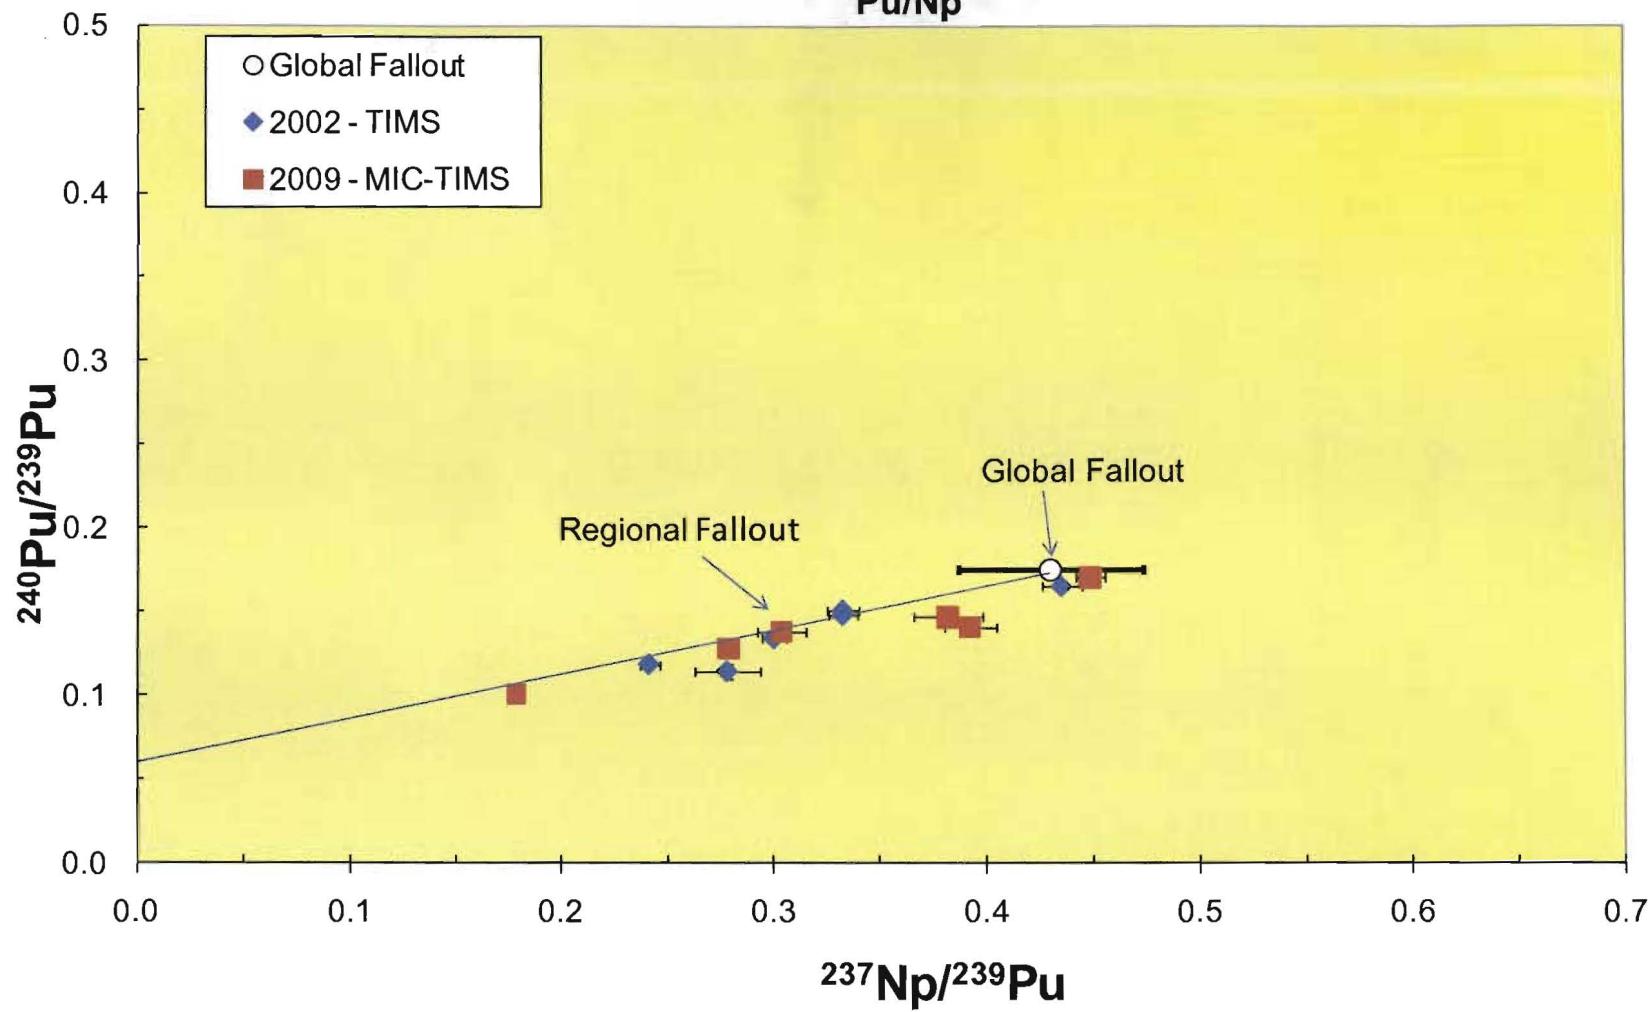

Forest Fire Ash

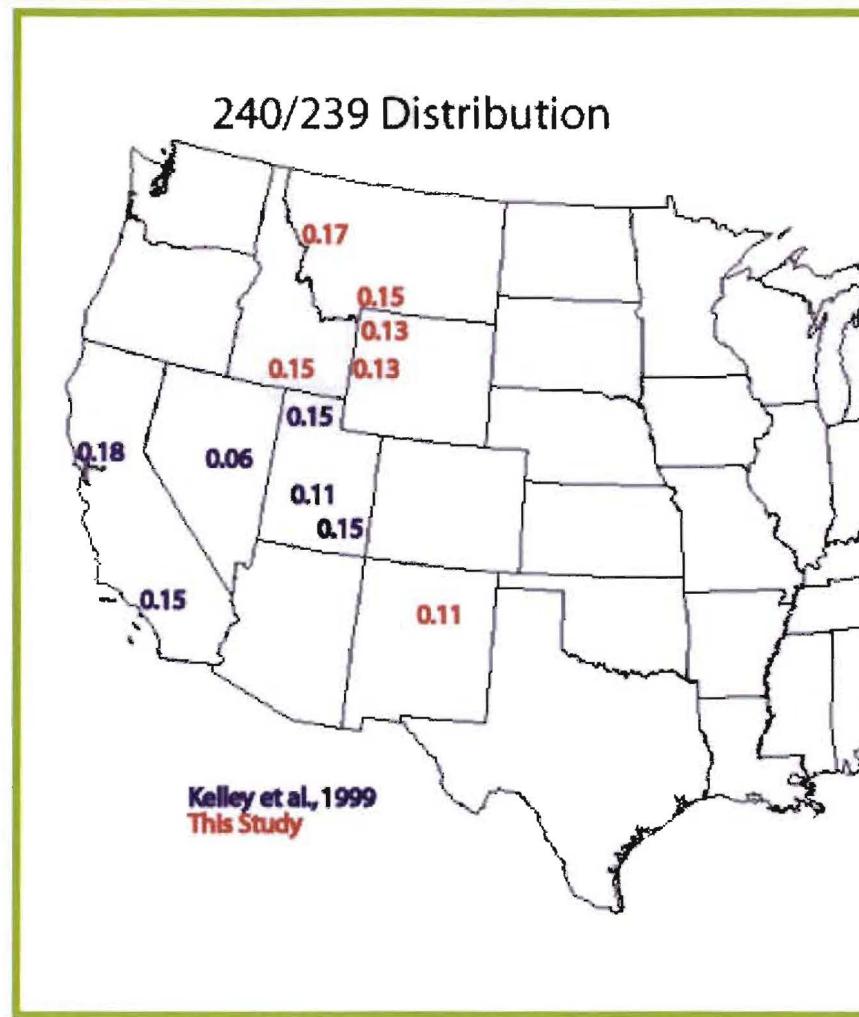

- Samples from 2000 Cerro Grande Fire near Los Alamos, New Mexico, along with other contemporary western U.S. fires in Idaho, Montana, and Wyoming.
- Concentrates actinides and fission products, so good way to determine regional and global $^{151}\text{Sm}/^{239}\text{Pu}$ systematics
 - Pu $\sim 1\text{E}10$ atoms/g, measureable by MIC-TIMS
 - Am $\sim 1\text{E}8$ atoms/g, measureable by MIC-TIMS or alpha spectrometry
 - $^{151}\text{Sm} \sim 1\text{E}8$ atoms/g, measureable by liquid scintillation counting

Americium – Age Dating of Non-Global Fallout Component in Forest Fire Ash

Sample ID	Age (²⁴² Pu Corrected)	+/- (y)	Age (¹⁵¹ Sm Corrected)	+/- (y)
CABG-01-0091-04 Wyoming	1960	+ 6 - 4	1960	+ 28 -10
CABG-01-0064-04 Idaho	1954	+ 9 - 6	1953	+ 25 -9

Summary

- Forest fire ash samples have Pu-Np-Am-Sm isotopic systematics consistent with a regional western U.S. fallout signature.
- ^{151}Sm and Pu are correlated in forest fire ash samples, suggesting similar geochemical behavior in the environment.
- $^{151}\text{Sm}/^{239}\text{Pu} = 0.0164$ in global fallout presently.
- Concordant ages (middle 1950's-early 1960's) are obtained for two forest fire ash samples, corresponding to a peak in above ground weapons testing at that time.
