MCNPX Simulation of a Passive Gamma System to be Used in a Spent Fuel Plutonium Assay Strategy

Jack Douglas Galloway

Michael Lorne Fensin

Abstract

MCNPX has been used to simulate the response of a passive gamma system used in the assay of spent nuclear fuel. This talk, presented for the Next Generation Safeguards Initiative (NGSI) review committee, first addresses source set-up and transport simulation challenges and methods, and then examines how signal emission ratios from fission products can be used to quantify attributes of spent nuclear fuel. Specifically examined in this presentation are $^{134}\text{Cs}/^{137}\text{Cs}$ as well as $^{154}\text{Eu}/^{137}\text{Cs}$ ratios from specific spent nuclear fuel assembly burnups, initial enrichments and cooling times. Results show that ratios can be used to effectively ascertain state-point information.

Passive Gamma

- Spent fuel assemblies (actinides and fission products), among numerous radioactive releases, also emit:
 - Spontaneous, delayed and (α, n) neutrons
 - Gamma rays during the decay of fission product
- These assemblies are termed as a "source" of neutrons and gammas for further transport calculations
 - Active interrogation: exposing the fuel to some external source of particles and analyzing the resultant spectra
 - Provide a snapshot in time
 - Passive interrogation: particles and interactions that occur as a result of radioactive decay of the assembly and analyzing the resultant spectra
 - Provide time integrated effects up to snapshot
- Passive gamma (PG) is the detection and interpretation of gamma lines emitted spent nuclear fuel (SNF)

SNF Source Characteristics

- SNF gamma emission signal is dependent upon the spatial and temporal behavior of the radioactive constituents within the fuel
 - This behavior is dictated by fission yield, capture cross section, activity and branching ratio
 - Energy emission affects attenuation
 - ^{134}Cs (795.8 keV), ^{137}Cs (661.7 keV), ^{154}Eu (1274.4 keV)
- Leverage the N-4 SNF library

PG Source Generation

- The count time is relatively short compared to the prior decay time leading to the count (S.S. picture)
- Only the most significant lines are important
 - FPs from SNF that have large signal to background ratio

NASA

PG Simulations

- ~100 PG cases run to quantify capability of PG to detect fissile mass
 - ~33 diversion cases
 - 64 non-diversion cases
 - Unique combination of
 - Burnup: 15, 30, 45 and 60 GWd/MTU
 - Initial enrichment: 2, 3, 4, and 5%
 - Cooling time: 1, 5, 20 and 60 years
- Gamma transport dependent upon linear attenuation coefficient of transporting medium
 - Borated H₂O used

UNCLASSIFIED

NASA

PG Results – Fission Yields

- For a given atomic mass:
 - Isotopic fission yields can vary drastically
 - 6 orders of magnitude from Z=51 to Z=53
 - Hump due to metastable isotope

UNCLASSIFIED
Generated by Los Alamos National Security, LLC for the U.S. Department of Energy/NNSA

NASA

PG Results – Fission Yields

- Drastic difference in isotopic fission yield for a given fission product

Mass yields for ²³⁵U and ²³⁹Pu with respect to A=154 are quite similar, yet isotopic fission yields for ¹⁵⁴Eu are drastically different

Isotope	Yield (235U)	Yield (239Pu)
¹⁵⁴ Eu	3.86E-08	3.35E-06
¹⁵⁴ Tb	6.00E-04	5.97E-03
¹⁵⁴ Dy	9.70E-10	1.40E-03

PG Next Steps

- Increase the number of lines tracked to ensure all important lines are included
- Tally only gamma flux at detector surface planes
 - These will lead to increased computational effort
 - Significant cluster upgrades since initial work afford resources for these calculations
- Assess ability to infer
 - Burnup
 - Initial enrichment
 - Cooling time
- Excel macro converted to Perl script
 - One script execution generates detector response – a 'go' button!

UNCLASSIFIED

Operated by Los Alamos National Security, LLC for the U.S. Department of Energy's NNSA

PG Next Steps

- Spectra comparison
 - 'Original' refers to the results from the 1E-4 threshold simulation approach initially adopted
 - 'Modified' refers to the no threshold version of initial approach, including significantly more energy lines
 - Still executes source generation quite efficiently (time required for source generation << time required for MCNP execution)
- Comparison with old method used to validate
 - Comparison spectra determined with simulation approach developed by V. Mozin for DG research

PG Next Steps

UNCLASSIFIED

Operated by Los Alamos National Security, LLC for the U.S. Department of Energy's NNSA

Conclusions

- Use of PG for determination of burnup, initial enrichment, and cooling time ...
 - Has been assessed for infinitely reflected assembly
 - Something on transport/source generation method
 - Something on fission yields (look at independent yield)
 - Something on ratios: flux dependence/ integrated fission dependence
- Being evaluated for asymmetrically burned assembly
 - Improvements due to increased computer resources ...
 - Still allows for efficient source determination
 - Includes greater number of gamma lines
- Continuity of knowledge maintained through contact with Mike Fensin

Par = sp Limitations**■ MCNPX 2.7.A new passive gamma feature**

- Generates a spontaneous photon source based on cell activity
- Source sampling → activity*emission for a time integrated decay
- Linked to delayed gamma capability

■ Caveats

- Delayed gamma capability calculates the multi-group emission spectra for both neutrons and photons regardless
- All CDFs are not banked in MCNPX 2.7.A
 - CINDER90 is run for every source particle
 - Only certain FP decay chains are prebanked

Simple multi-cell lattice test with actinides took too long for practical use!!!
These limitations were fixed in MCNPX 2.7.D
