

Development and Validation of a Two-phase, Three-dimensional Model for PEM Fuel Cells

Ken S. Chen (PI)

Sandia National Laboratories

May 12, 2011

FC027

Overview

Timeline

- Project start date: **10/1/09**
 - DOE Kickoff meeting held 9/30-10/1/09
- Project end date: **9/30/13**
- Percent complete: **~38%**

Budget

- Total project funding (over 4 years)
 - DOE share: **\$4,292,000**
 - Contractor share: **\$1,200,000**
- Funding received in **FY10**:
\$232,000
- Funding for **FY11**:
\$986,000

Barriers

- Barriers addressed
 - **Performance**
 - **Cost**

The validated PEM fuel cell model can be employed to **improve** and **optimize** PEM fuel cells **design** and **operation** and thus address these two barriers.*

Partners

- Direct collaborations with Industry, University and other National Labs:
Nissan (no cost), **Ballard**
Penn State University
LANL, LBNL.
- Project lead: **Sandia** National Labs

* PEM refers to polymer electrolyte membrane

Objective/Relevance

- The project objective is twofold:
 - 1) to **develop** and **validate** a **two-phase, three-dimensional** transport **model** for simulating **PEM fuel cell** performance under a wide range of operating conditions;
 - 2) to **apply** the validated PEM* fuel cell **model** to **improve fundamental understanding** of key phenomena involved and to **identify performance-limiting phenomena** and **develop recommendations** for improvements so as to **address technical barriers** and **support DOE objectives**.
- The **coupled DAKOTA/PEMFC model** computational capability can be employed to **improve** and **optimize PEM fuel cell design** and **operation**. Consequently, the project helps **address** the **performance** and **cost** technical barriers since **improving performance** will **reduce cost**, for example, by **using less materials** such as catalyst or membrane or hydrogen fuel or **minimizing operation cost** (e.g., reduce pumping power).

* PEM refers to polymer electrolyte membrane

Approach

Our approach is both **computational** and **experimental** with active **participation from industrial partners**:

- Numerically, develop a **two-phase, 3-D, transport model** for simulating PEM fuel cell performance under a wide range of operating conditions.
- Experimentally, measure **model-input parameters** and generate **model-validation data**.
- **Perform model validation** using experimental data available from the literature and those generated from team members.
- Apply the validated transport model **to identify performance-limiting phenomena** and **develop recommendations** for improvements.

What distinguishes the present work and previous efforts?

- Couple the **PEMFC model** with **DAKOTA** (toolkit for design/optimization) to perform **computational DOE** (design of experiments) and **3-D detailed probing, sensitivity** and **variability** analyses, and **parameter estimation**.
- **Collaboration** with and **participation** by industry partners, **Ballard & Nissan**, **ensure** that the PEMFC model can be used as a **practical design tool**.

Approach:

FY10 & FY11 Milestones, and Current Status

| Month/Day/Year | Milestone Descriptions |
|----------------|--|
| 09/30/2010 | Develop a three-dimensional, <i>partially two-phase</i> , single-cell model and demonstrate model utility in case studies with acceptable numerical convergence measured by absolute residuals of 10^{-5} or less and mass/charge balance error of 2% or less. Status: completed. |
| 09/30/2010 | Measure model-input parameters related to operating cell design (Cell/Component dimensions, Component Physical/Transport Properties, Catalyst Loadings, etc.) and generate model-validation data by measuring Performance Polarization Curves, HFR and AC Impedance for single cells operating at 100% RH and 50% RH. Status: completed. |
| 03/31/2011 | Measure 10×10 current distribution performance data for model validation for 4 different operating conditions (RH = 25%, 50%, 75% and 100%). Status: completed. |
| 06/30/2011 | Develop a three-dimensional, <i>fully two-phase</i> , single-cell model and demonstrate model utility in case studies with acceptable numerical convergence measured by absolute residuals of 10^{-5} or less and mass/charge balance error of 2% or less. Status: near completion. |
| 09/30/2011 | Perform validation of the 3-D, partially two-phase, single cell model by comparing computed and measured polarization curves, and current distributions with reasonable agreement (errors fall into the 99% confidence interval or within +/-15%). Status: on track. |

Technical accomplishment: Demonstration of fully two-phase PEMFC model – effect of stoich

Geometry and Mesh

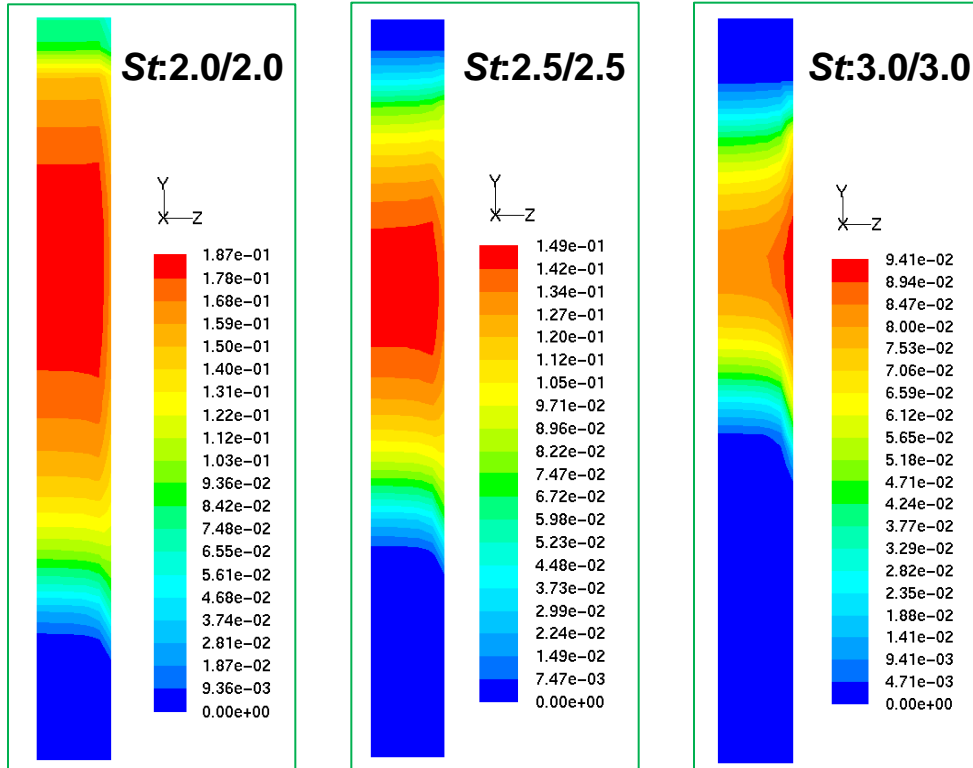

Cell Geometry:

Membrane: 30 μm CL(a/c):
10/10 μm MPL: 40 μm
 GDL: 160 μm GFC:
1 \times 0.5mm Land: 0.5mm
 Cell length (y direction): 0.1 m Cell
 height (z direction): 2.0 mm

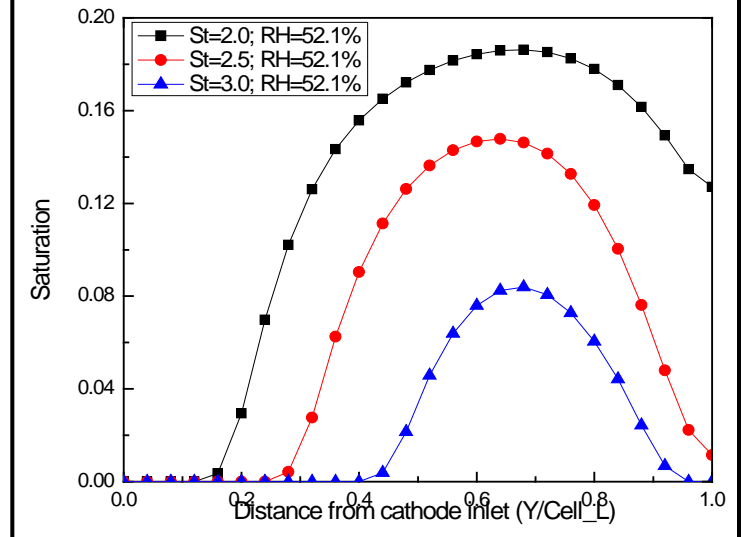

Operating Conditions: (Counter flow)

$I = 0.2 \text{ A/cm}^2$ $T_{\text{cell}} = 80 \text{ }^\circ\text{C}$ $P_a = P_c = 200 \text{ kPa}$
 Inlet %RH(a/c) = 52.1/52.1
 $St(a/c)$ (H_2/air) = 2.0/2.0 ; 2.5/2.5 ; 3.0/3.0

Liquid saturation at cathode GFC/GDL interface

Liquid saturation along cathode channel with different stoichiometric flow ratio

❖ **Liquid saturation at the cathode GFC/GDL interface and along gas flow channel decreases with increasing stoichiometric flow ratio!**

Technical accomplishment: Demonstration of fully two-phase PEMFC model – effect of inlet RH

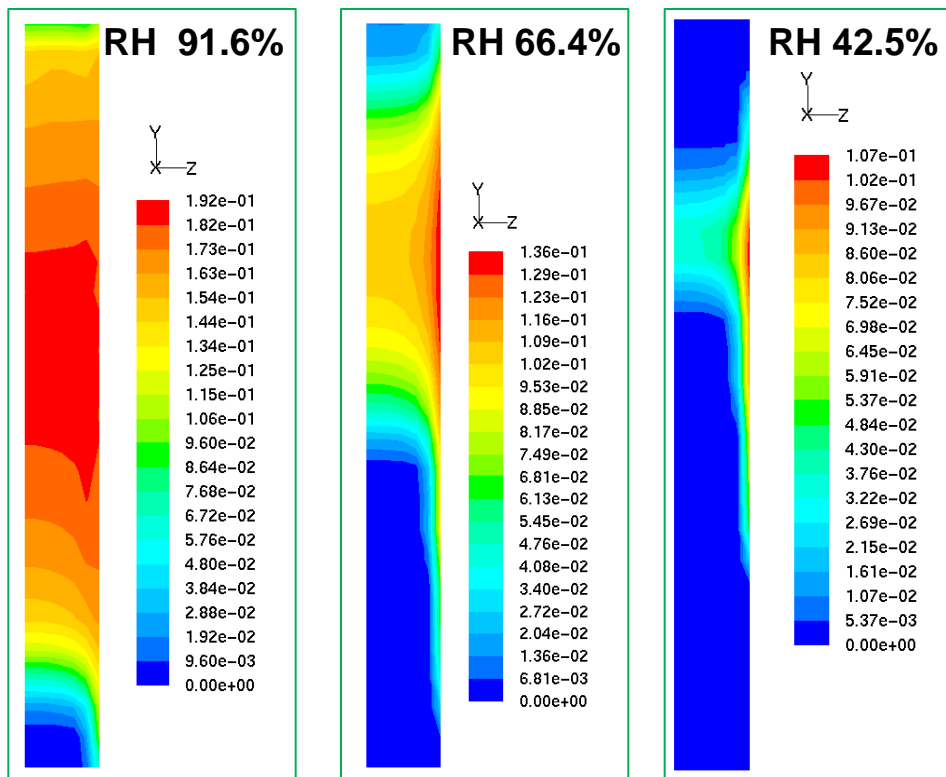

Operating Conditions: (Counter flow)

$I = 0.8 \text{ A/cm}^2$ $T_{\text{cell}} = 80 \text{ }^\circ\text{C}$ $P_a = P_c = 200 \text{ kPa}$

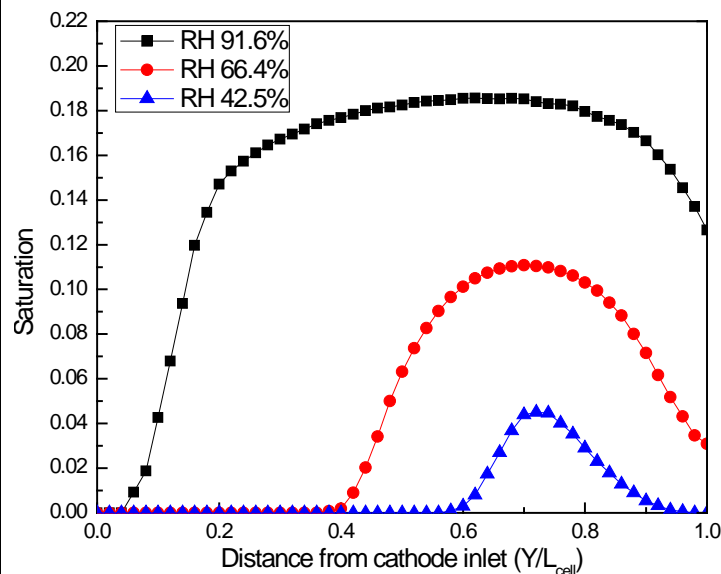

$St(a/c) (\text{H}_2/\text{air}) = 1.8/2.0$

Inlet %RH(a/c) = 91.6/91.6 ; 66.4/66.4 ; 42.5 /42.5

Liquid saturation at cathode GFC/GDL interface

Liquid saturation along cathode channel with different anode and cathode RH

- ❖ More liquid water is accumulated in the cathode gas channel as anode/cathode inlet RH is raised.
- ❖ Liquid saturation near cathode outlet increases with increasing inlet RH, indicating that water transport from cathode to anode decreases.

Technical accomplishment: Demonstration of fully two-phase PEMFC model – effect of current density

Operating Conditions: (Counter flow)

Inlet %RH(a/c)= $\frac{66.4}{66.4}$ $T_{cell} = 80\text{ }^{\circ}\text{C}$

$P_a = P_c = 200\text{ kPa}$ $St(a/c) (H_2/air) = \frac{1.8}{2.0}$

$I = 0.1\text{ A/cm}^2$; 0.2 A/cm^2 ; 1.0 A/cm^2 ; 1.5 A/cm^2

Liquid saturation at cathode GFC/GDL interface

Liquid saturation along cathode channel with various current densities

- ❖ Cathode gas channel has **more liquid water at low current densities** than at high current densities – this most likely is due to that sufficiently large drag force is required to remove liquid water from the channel.
- ❖ Cathode gas channel has the **most liquid water** at current density of 0.2 A/cm^2 for the four cases studied.
- ❖ **As current density is reduced**, the **wet region** in the cathode gas channel **enlarges** gradually in both downstream and upstream direction, due to the smaller drag force of gas flow.

Technical accomplishment: Demonstration of fully two-phase model – PEMFC with Chevron flowfield

Operating Conditions and geometry (Counter flow)

$i = 1 \text{ A/cm}^2$ $St(a/c) = 2.0/2.0$ (H_2/air) $T_{\text{cell}} = 80 \text{ }^\circ\text{C}$
 $P_a = P_c = 200 \text{ kPa}$ Inlet $\%RH(a/c) = 81.4/81.4$
 $w = 5 \text{ mm}$, $h = 1 \text{ mm}$, Membrane: $50 \text{ }\mu\text{m}$, GDL: $150 \text{ }\mu\text{m}$

PEMFC with complex Chevron flowfield

Computed current density at mid-plane of membrane (A/m^2)

Computed liquid-water saturation along gas flow channel

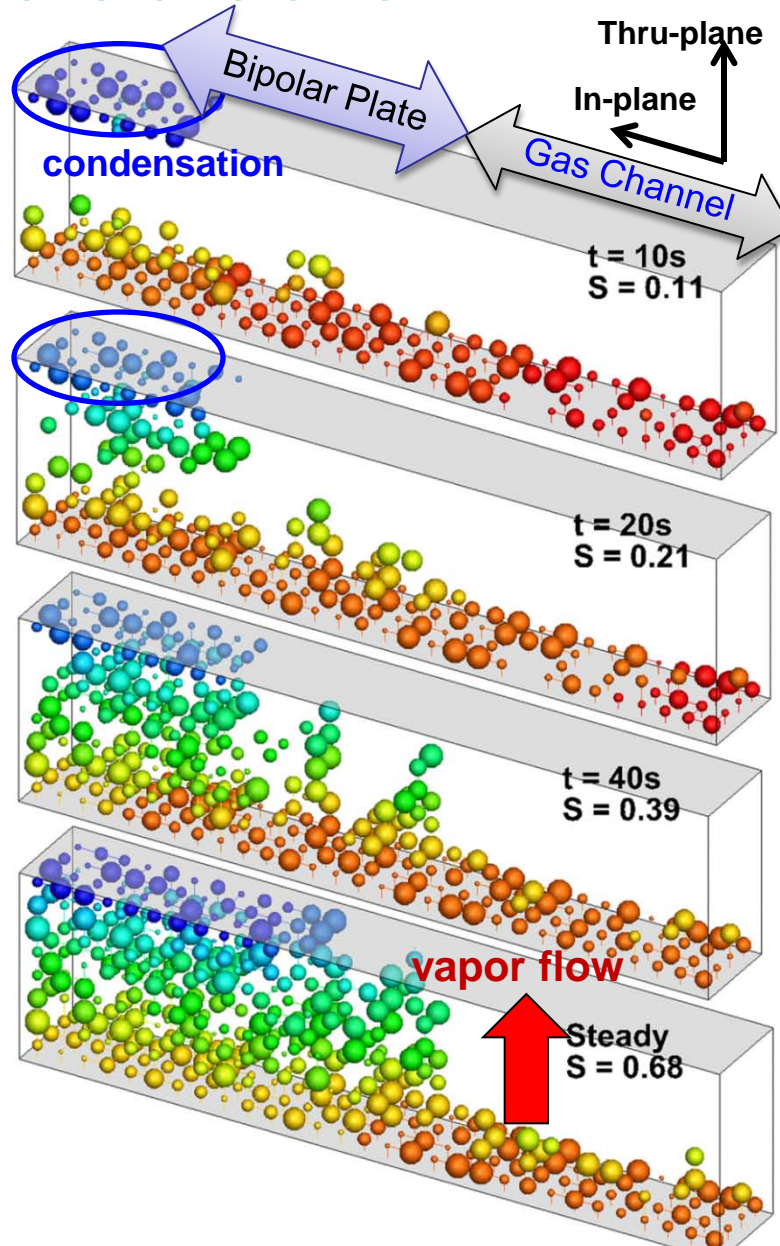

- The present model is capable of simulating PEMFC with complex flowfield!

Technical accomplishment: Nonisothermal pore network modeling: Saturation and temperature evolution

Parameters:
 $I=1\text{A/cm}^2$,
 $RH=75\%$,
 $k_{thru}=0.5\text{W/mK}$,
 $k_{in}=5k_{thru}$

- Model Capabilities:
- ◆ Heat transfer in pores & solid matrix
 - ◆ Water vapor diffusion in the pores
 - ◆ Phase change rates (diffusion limited) & location
 - ◆ Capillary dominated drainage (invasion & condensation)
 - ◆ Capillary dominated imbibition (evaporation)

Technical accomplishment: Sandia National Laboratories

3-D CFD verification of simplified analytical model for predicting water-droplet detachment

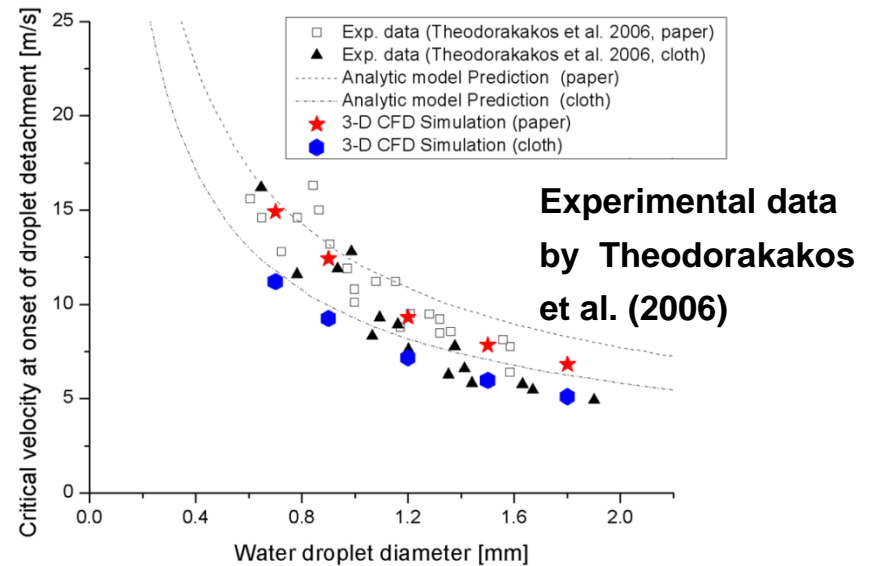

Model geometry for 3-D CFD simulation

Analytical model: detachment velocity as a function of droplet size (Chen 2008)

$$V_c = \left[\frac{H_c}{\rho\mu} \right]^{1/3} \left[\frac{\pi\gamma \sin^2 \theta_s \sin \frac{1}{2}(\theta_a - \theta_r)}{5(\theta_s - \sin \theta_s \cos \theta_s)d} \right]^{2/3}$$

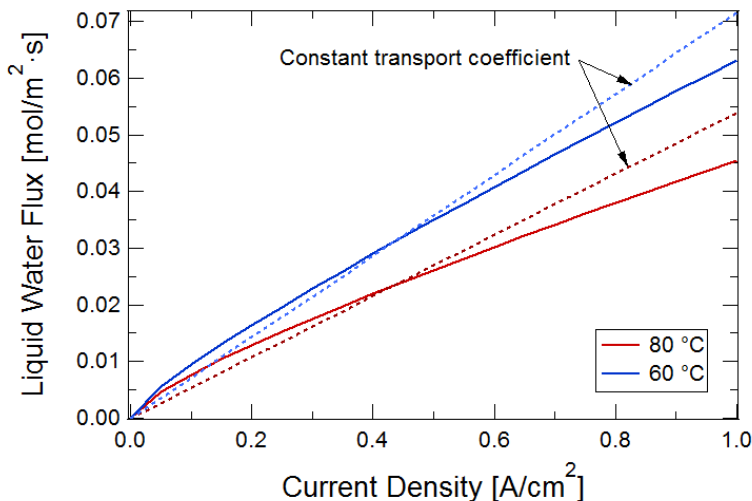

3-D CFD verification and experimental validation of analytical droplet-detachment model

• Agreements between analytical model prediction, 3-D CFD simulation, and experimental data are reasonably good!

Estimating Liquid Water Flux at GDL/channel interface

1. Calculate the critical pore radius based on force balance
2. Calculate the liquid-water flux out of the GDL/channel interface:

3. Integrate GDL pore-size distribution to obtain number of pores of each size at the GDL/channel interface
4. Determine flow rate through each pore size (assume largest to smallest in terms of filling)
5. Correlate droplet growth and detachment with the liquid water flux and flow rate

| Parameters | Values |
|------------------------------------|--------------------------------|
| Cell size | 50 [cm ²] |
| Channel height | 1 [mm] |
| Temperature, T | 60 [°C] |
| Flow velocity, u | 10 [m/s] |
| GDL contact angle, θ_s | 120 [°] |
| Net-transport coefficient, β | 0.3 |
| Water vapor fraction, α [1] | 0.56 at 80 °C 0.22 at 60 °C |
| Critical droplet size [2] | 1 [mm] |
| GDL surface tension | 0.072 [N/m] |

$$N_w = \frac{i}{F} \left(\beta + \frac{1}{2} \right) - \frac{i}{2F} \alpha$$

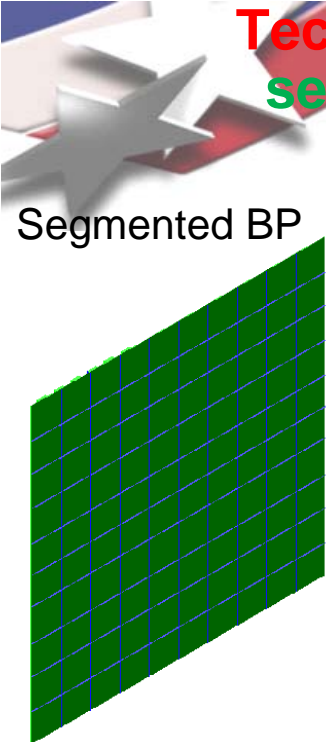

$$\beta = 0.2191 i^{-0.374}, \text{ where } i \text{ is in } \text{A/cm}^2 \text{ [3]}$$

Technical accomplishment: Computed effect of cell segmenting on current distribution measurement

Questions:

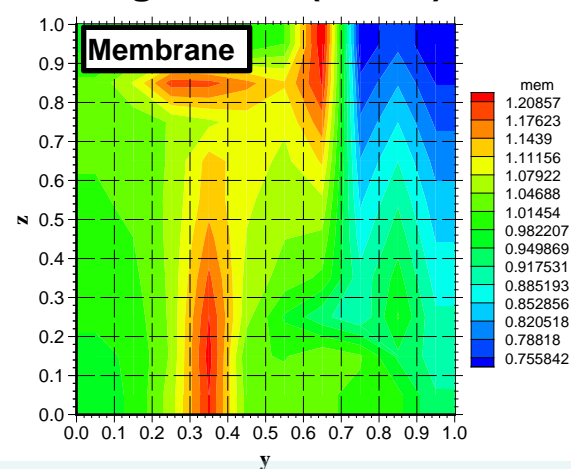

1. Are we measuring the right thing?
2. What is the best practice of cell segmenting?

Current density distribution

Non-segmented

Segmented (10x10)

➤ **Difference in current distribution between non-segmented and segmented cells < 4%!**

- ❖ Bipolar plate segmentation has negligible effect on current distribution in the membrane when done properly.
- ❖ To reduce discrepancy, some guidelines need to be followed:
 - 1) Segmentation along the flow direction
 - 2) Large errors seen mostly in U-turn regions where a segment contains mixed and irregular types of regions with flow channels and lands.
 - 3) Cutting through channels or land non-symmetrically in segmentation yields unacceptable errors in current distribution measurements.

Experimental apparatus and setup at LANL for polarization & current distribution measurements

Fuel Cell Assembly 50 cm²

- Current and T Distribution (10 x 10 segments)
- Varying Compression

Assembled fuel cell
w. segmented current collector

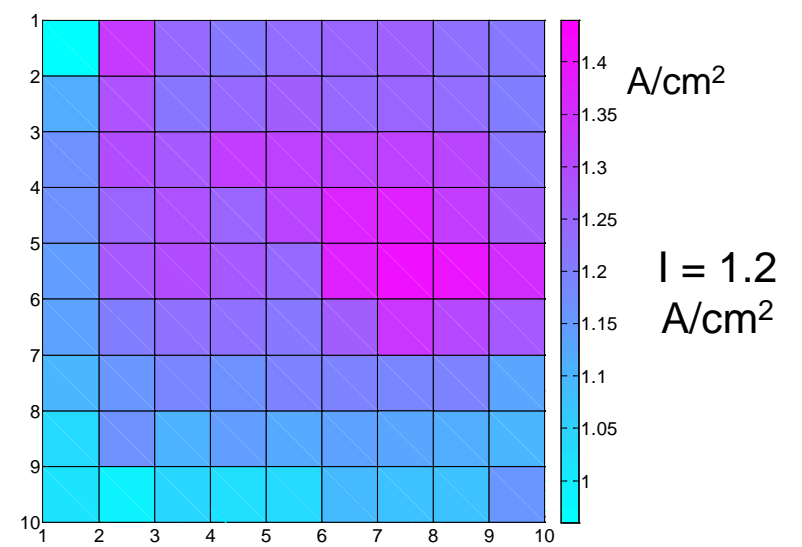

Assembled cathode side:
flow field + frame + current collector

Technical accomplishment: Current distribution maps obtained using LANL's 10x10 segmented cell

Cell Area = 50 cm², Flow Field = 5-pass serpentine with manifolds, Segmented Current Collector = 10 x10 segments
MEA (catalyst coated membrane) = A510.2/M710.18/C510.4 (by W. L. Gore), GDL = SGL24BC (by SGL Carbon)
GDL – 200μm, MPL – 50μm, cathode CL – 20μm, anode CL – 10μm, membrane – 18μm.

Technical accomplishment: Simultaneous current & temperature distribution measurements

Ballard's current and temperature mapping tool

Sample current/temperature distribution obtained by Ballard's mapping tool

Technical accomplishment: Polarization curves with upper and lower bounds (Ballard)

Sample polarization curve with upper and lower bounds

Temperature sensitivity

RH sensitivity

Validation Procedure

- Data collection milestone (led by LANL)
 - 80C, 100-75-50-25RH, 0.1-0.4-0.8-1.0-1.2 A/cm²
 - 60C, 100-50RH, 0.1-0.4-0.8-1.0-1.2 A/cm²
 - uncertainty quantification (error bars on the data)
- Mesh and model generation based on LANL experimental setup
 - Generate sequence of meshes
- Verification:
 - Geometric and model input parameters
 - Mesh convergence
- Initial calculations (no parameter adjustments)
- Sensitivity analysis (determine key model parameters)
- Calibration using subset of data – 80°C/50 RH/0.8 A/cm²
- **Validation** against remaining LANL data
- Uncertainty quantification (error bars on the simulations)
- Summer 2011: testing and **validation** against Ballard data

Predicted membrane current distribution

Operating conditions:

Stoich(a/c): 1.2/2

Pressure(a/c): 1.95 atm

Materials/geometry:

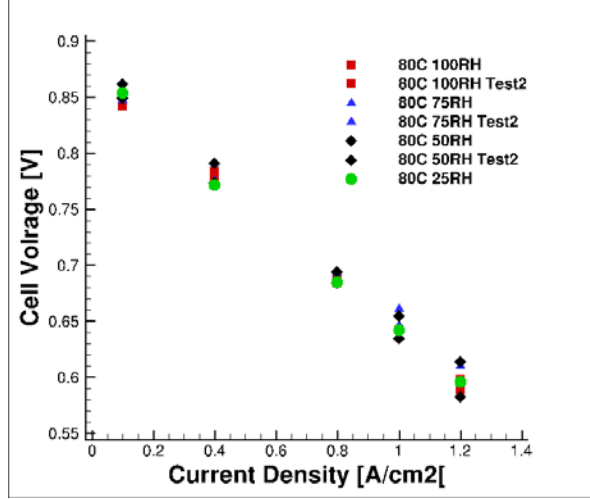

Gore MEA (18 μm mem.)

Pt (a/c): 0.2/0.4 mg/cm²

Cell area: 50 cm²

Technical accomplishment: Model Validation: I-V Curves

Experimental data from LANL at 80°C and 60°C (note variability)

- Model calibration at 80°C and prediction at 60°C are **within uncertainty** of the experimental data!

Technical accomplishment: Validation: Current Distribution

Detailed **model prediction** of current density (0.5mm grid gives 140x140 resolution)

Current density map of **segmented cell data** obtained by LANL (10x10 cell)

Operating Conditions:
(Case 1)
80° C
50% RH
0.8 A/cm²

Model prediction

- Agreement between computed and measured current density distribution is good with RMS error < 11.3%!

PEMFC Model Demo: Overview of code and files

Setting input parameters

- The code is based on FLUENT with extensive user-defined functions (UDF) to provide additional capability.
- Prerequisites for the code are
 - the *.cas file (“Sample.cas”)
 - the UDF library (“libudf”)
 - an installation of FLUENT and C compiler
- Contents of the Sample.cas file
 - The computational mesh (including boundary/volume/interface zones)
 - Material and boundary condition specifications
 - Solver parameters

Collaborations:

How team partners work together to achieve project objective?

Team partners: SNL(prime), PSU(sub), LBNL(sub), LANL(sub), Ballard(sub), Nissan(no cost)

Future Work

Remaining FY11:

1. Complete development and testing of the **3-D, fully two-phase, single-cell model**
Milestone M3: Develop a 3-D, *fully two-phase*, single-cell model and demonstrate model utility in case studies with acceptable numerical convergence measured by absolute residuals of 10^{-5} or less and mass/charge balance error of 2% or less. **Due: 6/30/2011**
2. Complete **model validation** in the single-phase and partially two-phase regimes using **LANL** data from **segmented cell experiments**.
3. Perform **model validation** in the single-phase and partially two-phase regimes using **test data** from **Ballard** (polarization, current/temperature maps, etc.).
Milestone M5: Perform validation of the 3-D, partially two-phase, single-cell model by comparing computed and measured polarization curves, and current distributions with reasonable agreement (errors fall into the 99% confidence interval or within $\pm 15\%$). **Due: 9/30/2011**

FY12:

4. Complete **sub-model** and **algorithm development**, and **numerical implementation**.
5. Develop a 3-D, two-phase, **short stack** model.
6. Obtain **water profiles** in the through-plane using **neutron radiography** setup at NIST.
7. Perform **model validation** in the **fully two-phase** regimes using **neutron imaging data** obtained by **LANL** at NIST, and **test data** from **Nissan** and **Ballard**.

FY13: **Exercise model** to identify performance-limiting phenomena and **develop recommendations** so as to **address technical barriers** and **support DOE objectives**.

Summary of Technical Accomplishments

- Year 2 **experimental milestone M4** (“Measure 10×10 current distribution performance data for model validation for 4 different operating conditions (RH = 25%, 50%, 75% and 100%)”) was successfully **completed**.
- A 3-D, **fully two-phase**, single-cell **model** was **developed** and **demonstrated** in parametric studies; the Year 2 **modeling milestone M3** (“Develop a 3-D, fully two-phase, single-cell model”) is **near completion**.
- **Significant progress** has been **made** in model **validation** using polarization and **current distribution data** obtained by LANL using a 10×10 segmented cell. Year 2 **model-validation milestone M5** is **on track**.
- Other accomplishments include:
 - Demonstrate the **fully two-phase model** by simulating a PEMFC with a **Chevron flowfield**.
 - A **nonisothermal pore network model** was developed and demonstrated.
 - **3-D CFD simulation** was performed to **verify** the analytical **model** for **droplet detachment**.
 - Simplified calculations were performed to **estimate water flux at GDL/channel interface**.
 - Effect of cell segmenting was investigated and **segmentation guidelines** were **developed**.
 - **Current/temperature maps** and **polarization curves** with upper/lower bounds were **obtained**.
- 3 journal publication, 3 proc. papers and 6 conference presentations were generated.

Technical Back-Up Slides

An approximate but robust approach for accounting for MPL effect

Motivation: to eliminate the need for numerically treating the MPL/GDL interface with steep saturation jump.

Approach: treat MPL/GDL as a composite component with effective properties (ε , K , θ_c).

From pore volume being additive:

$$\varepsilon_{MPL-GDL} = \varepsilon_{MPL} \frac{H_{MPL}}{H_{MPL} + H_{GDL}} + \varepsilon_{GDL} \frac{H_{GDL}}{H_{MPL} + H_{GDL}}$$

From flow resistance being additive:

$$K_{MPL-GDL} = \frac{1}{\frac{1}{K_{MPL}} \frac{H_{MPL}}{H_{MPL} + H_{GDL}} + \frac{1}{K_{GDL}} \frac{H_{GDL}}{H_{MPL} + H_{GDL}}}$$

From capillary-pressure being additive:

$$\cos \theta_{c,MPL-GDL} = \cos \theta_{c,MPL} \left(\frac{\varepsilon_{MPL}}{\varepsilon_{MPL-GDL}} \frac{K_{MPL-GDL}}{K_{MPL}} \right)^{1/2} \frac{H_{MPL}}{H_{MPL} + H_{GDL}} + \cos \theta_{c,GDL} \left(\frac{\varepsilon_{GDL}}{\varepsilon_{MPL-GDL}} \frac{K_{MPL-GDL}}{K_{GDL}} \right)^{1/2} \frac{H_{GDL}}{H_{MPL} + H_{GDL}}$$

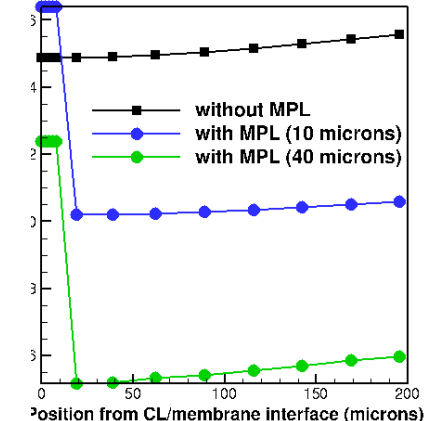

Parameters: $\varepsilon_{GDL} = 0.6$, $K_{GDL} = 10^{-12} \text{ m}^2$, $\theta_{c,GDL} = 92^\circ$, $\varepsilon_{MPL} = 0.4$, $K_{MPL} = 10^{-13} \text{ m}^2$, $\theta_{c,MPL} = 150^\circ$, $H_{GDL} + H_{MPL} = 200 \text{ } \mu\text{m}$

Computed effect of MPL on cell performance

• MPL improves cell performance slightly when it is thin but hurts performance when sufficiently thick!

Computed liquid saturation across CL and MPL/GDL

• Incorporating hydrophobic MPL reduces liquid saturation in MPL/GDL, particularly under the land!

Back-of-Envelope Calculation: Droplets

- Droplet detachment
 - Gas flow velocity

- Droplets on surface

- Number of droplets

- Surface static contact angle

- Growth of droplets

Droplet Imaging Experiment

Goal: Improve models and understand droplet governing physics

- Directly measure the adhesion force instead of depending on contact-angle measurements and hysteresis
 - Measure angle at which droplet begins to move and liquid pressure
- Measure real and ideal materials with liquid water injected

- Understand the impact of pore size and injection rate of liquid supply
- Look at both ideal and real GDLs (including multiple droplets)
 - Identify droplets growth in an unit area
- Vary materials, droplet sizes, injection flow rates and sizes, existence of channels and flow

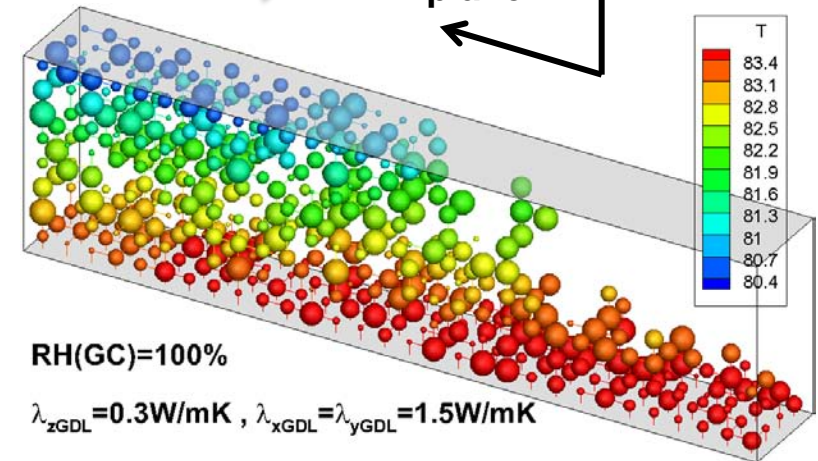

Goniometer with Tilt Stage

Pore network modeling: Effect of channel RH and GDL thermal conductivity (steady state)

λ_{GDL} decreases

Channel RH decreases

In-plane
Thru-plane

Lower thermal conductivity & channel RH result in less GDL flooding!

Sensitivity Analysis Using PEMFC/DAKOTA Coupled Model

Efficient sensitivity analysis is enabled using the PEMFC/DAKOTA coupled model.

Here we varied 22 parameters to determine the ones with greatest impact on cell voltage.

Linear regression predicts effect of parameter on performance. Positive R value indicates positive correlation.

Cathode exchange current density was most important parameter, followed by anode CL porosity.

| param | R | m | b |
|-----------|-------|-----------|------|

Reviewer-Only Slides

Addressing reviewers' comments from 2010 AMR

- **Comment:** Collaborative efforts could be a little stronger. Partners seem academia heavy.

Response: Model development involves one university (PSU) and two national labs (SNL and LBNL). Experimental and validation results come from one national lab and two industrial partners (Ballard and Nissan). We tend to believe that a strong academic presence is a good thing in that it provides a strong theoretical background which is important for such a modeling project. Lastly, the collaboration with industry will become more apparent later this year and in Years 3 and 4, when the model input data and performance data provided by Ballard and Nissan are utilized in model validation, and when Ballard and Nissan start to run the PEMFC model and the coupled DAKOTA/PEMFC model computational capability.

- **Comment:** This project obviously requires a lot of collaboration, since all of the team members must provide substantial input to generate the complex model of the sort envisioned here, especially if the model is also going to be validated (instead of just being used to "predict general trends"). It is also good that the project has an original equipment manufacturer (OEM) like Ford participating with no funding from DOE.

Response: Nissan has replaced Ford in our project. We are fortunate to have Nissan's participation in this project "with no funding from DOE". We consider Nissan's involvement, and guidance/insights and parameter ranges, etc. provided by Nissan to be very important to the success of this project.

Addressing reviewers' comments from 2010 AMR (Continued)

- **Comment:** The proposed approach of continuing to the partial two-phase model with the validation of the current model seems to be sound. The continued incorporation of the DAKOTA approach to make the model predictive and allow for uncertainty is good. I think it is important to address the water flux as described in the future work.

Response: Thanks for the positive comments. Yes, it is important to “address the water flux as described in the future work”. Specifically, Adam Weber of LBNL is leading this effort to develop a submodel for properly accounting for water flux at the GDL/channel interface.

- **Comment:** The approach of modeling the behavior and trying to build in the uncertainty is an important step. The focus on generating good data for the model, under a range of conditions, as well as gathering fundamental data on the mass transport and the effect of materials properties, is a definite strength.

Response: Thanks for the positive and encouraging comments.

- **Comment:** Validation of the modeling to date is weak.

Response: We’ve made significant progress in model validation this year. Model validation will be continued in the remaining of this year and also in Years 3 and 4. It should be noted that model validation is being carried out using data obtained by LANL on their segmented cell. In the next stage of model validation, we plan to use cell design and data provided by original equipment manufacturer (OEM) Ballard.
