Outline

- **Introduction**
- **Combustion research at the ALS**
- **Future ideas**
- **Conclusions and Summary**

Introduction

- Detailed knowledge of combustion chemistry crucial for predictive control of combustion behavior
- Combustion Systems highly complex analytical problems
 - High number of Species
 - Instable species
 - Mixing gradients
 - Low concentrations
 - Harsh environments (high p and T)
- Use of simplified model systems to analyze different aspects

Instrumental setup

- Molecular beam sampling time-of-Flight Mass Spectrometry
- Offers rapid data collection and universal species overview

Model Flames

- laminar and premixed (oxygen + fuel)
- flat flame
 - one dimensional ➔ Distance from burner resembles reaction progress
 - low pressure ➔ higher spatial resolution

Other Model systems

- Atmospheric and low pressure counter flow flames
- Observation of soot growth

- Atmospheric pressure Jet Stirred Reactor
- Studies of low temperature oxidation

Isomer selective Ionization

- Ionisation by Synchrotron Radiation at the Advanced Light Source
- Typical energy resolution (0.05 eV)
- Mass resolution limited by continuous ionization
- Distinction between isobaric species with similar ionization energy challenging

Updated mass spectrometer

- Orthogonal time of flight
 - Decoupling of ionization and extraction region
 - 2 stage extraction
 - Reflectron
 - High mass resolution at continuous ionization ($R = 3000$)

Identifying the Flame Components

Mass separation by peak fitting

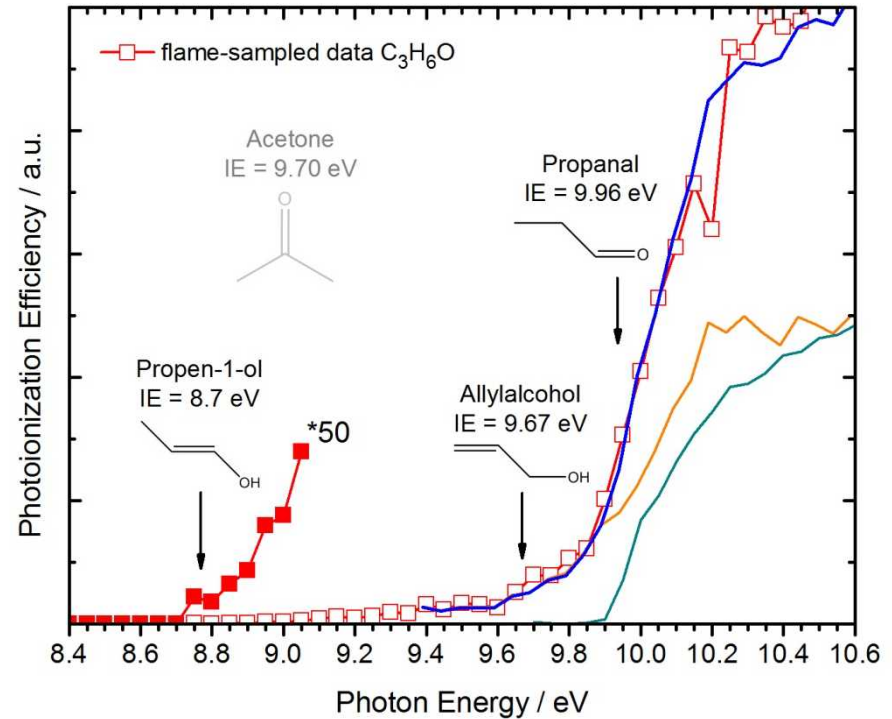

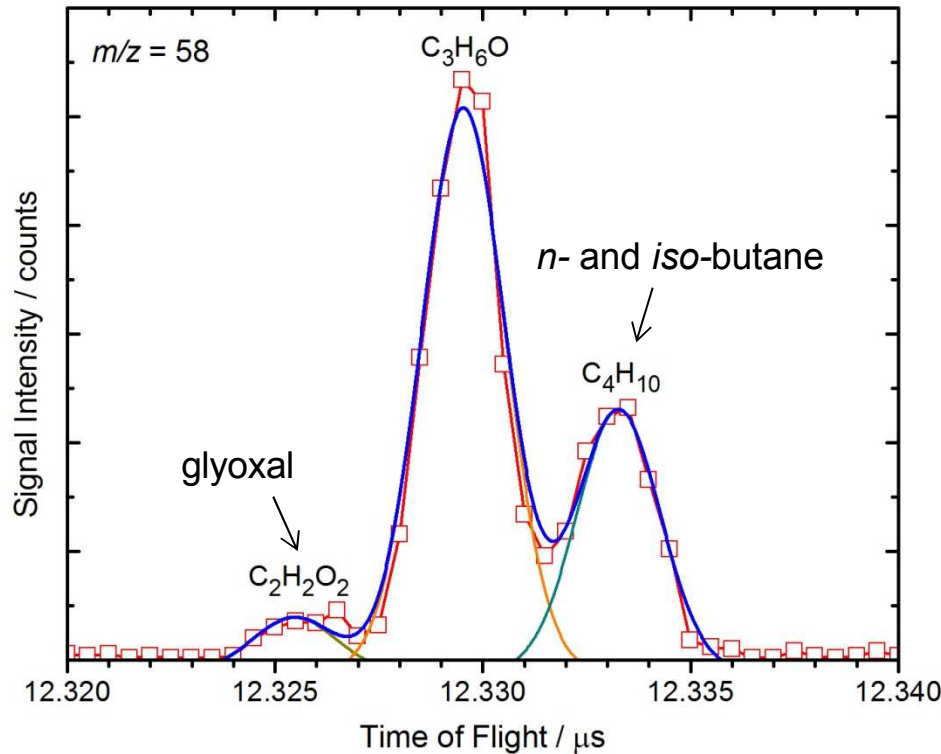

Mass separation by peak fitting

Mass separation by peak fitting

Identifying the Flame Components

- Multiple isomers at exact mass
- Distinction by ionization energies and photoionization efficiency curves

A total of 6 species can be identified at $m/z = 58$,

Identifying the Flame Components

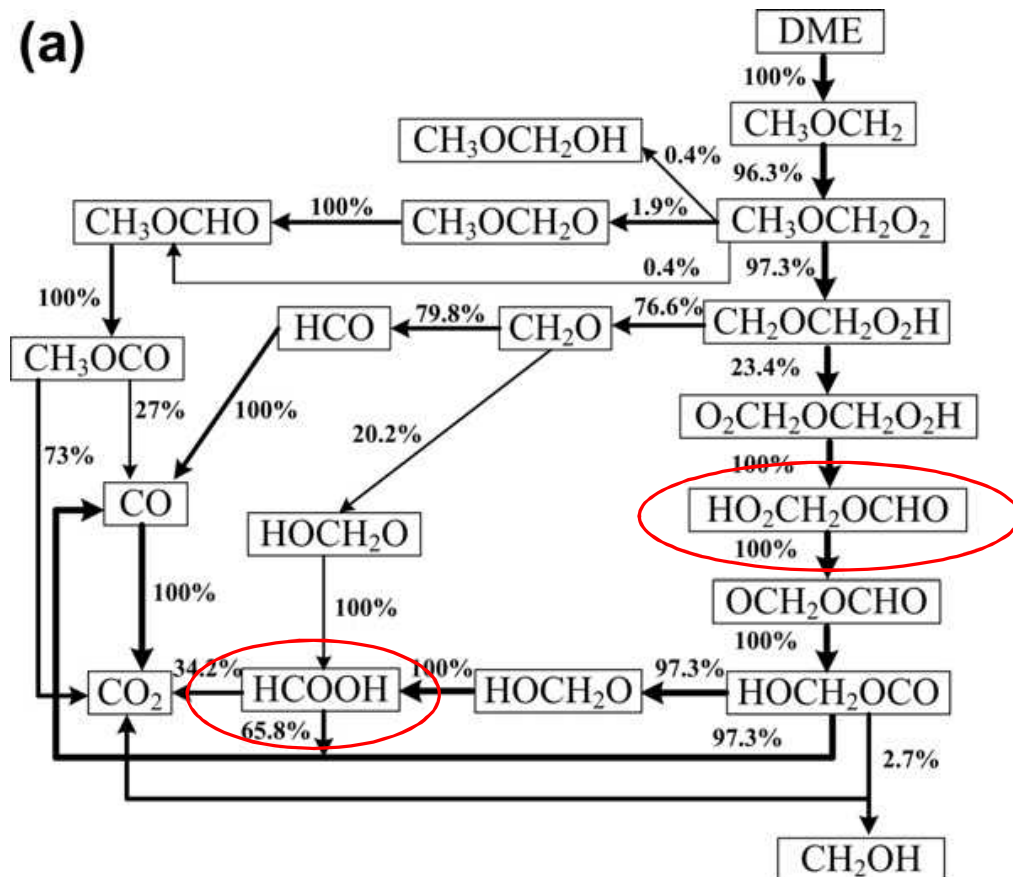

Challenges:

- Number of possible isomers increases with molecular size
- Smaller differences in heats of formation and similar structural features result in almost identical IE's and indistinguishable PIE curves
- IE's and PIE curves may not be known and need to be measured/calculated

Low temperature oxidation

- Investigation of Ketohydroperoxid formation and destruction in lean mixtures of oxygenated and hydrocarbon fuels

(a)

Fuel nitrogen conversion

- High resolving power crucially needed because of the additional elemental compositions possible.
- HCN plays an important part in the fuel nitrogen conversion
 - Very high intermediate concentrations
 - Slow decomposition

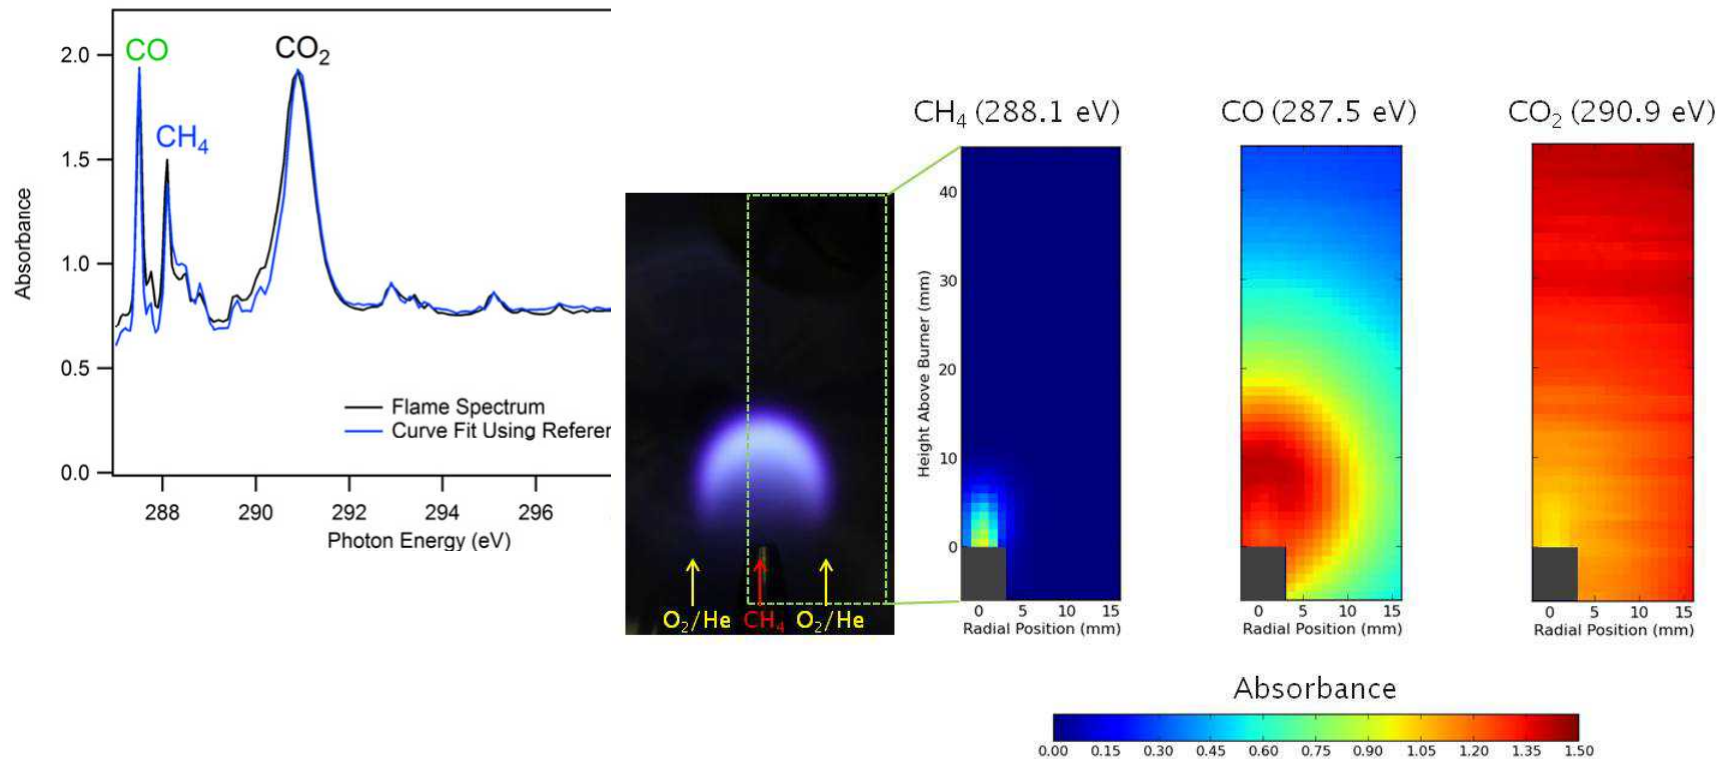

Future Prospects

- Isomer identification via post ionization dissociation
 - Spontaneous decay of metastable ions after soft ionization
 - Laser induced dissociation at turning point of reflectron
 - Laser or collision induced dissociation after linear TOF followed by reflectron TOF

X-ray techniques

➤ Soft x-ray absorption

Frank et. al. 8th US Combustion Meeting Utah 2013

Summary and Conclusions

- Orthogonal time of flight improves identification power significantly
- Isomer possibilities of larger species are still challenging
- In situ soft x-ray absorption viable option for non premixed flames
- Further enhancement possible by spontaneous or induced post ionization dissociation
- Soot formation may be possible to investigated by Small Angle x-ray scattering or x-ray Raman scattering
