The US HEDP Program has three major facilities for HED science experiments

Omega

30 kJ

ZR (2007)

2700 kJ

NIF (2010)

1800 kJ

ZR: Refurbishment of the **Z** Pulsed Power Generator

Cost of the refurbishment of the Z facility will total \$90.4M – \$61.7M for engineering, design and hardware, and \$28.7M for R&D, installation and testing.

The Z facility gives us several methods of achieving high energy density conditions

High Current

Z-pinch x-ray source

Magnetic pressure

Wire array

Current

B-Field

$J \times B$ Force

Fusion

Radiation Science

Material Properties

Increased current on refurbished **Z** will increase capability for multiple applications

| Capability | Z Today | After Refurbishment* |
|--------------------------------------|-------------------|----------------------|
| Power Radiated (Nested Arrays) | 230 TW | 350 TW |
| Energy Radiated (Single Array) | 1.6 MJ | 2.7 MJ |
| T_r for Radiation Physics VH / DH | 140 / 215 eV | 165 / 260 eV |
| T_r for ICF VH / DH | 70 / 215 eV | 85 / 260 eV |
| P_{pk} for ICE (Cu) | 3.25 Mbar | 10 Mbar |
| Flyer Plate Velocity | 34 km/s | > 40 km/s |
| In band energy 1 keV / 5 keV / 8 keV | 450 / 100 / 18 kJ | 900 / 300 / 72 kJ |

VH = Vacuum Hohlraum DH = Dynamic Hohlraum ICE = Isentropic Compression Experiments

*The ZR project will deliver 26 MA into baseline z-pinch load with pulse shaping capability for ICE and flyers. ZR full capability will be achieved by the program.

The Z-Petawatt Laser System will provide new capability for radiography and fast ignition research

View of ZBL HiBay

Z/ZR

Z-Beamlet Laser

- Currently, the terawatt-class Z-Beamlet Laser (ZBL) creates a backlighting x-ray source in the 1-10 keV range on Z
- A petawatt-class enhancement, referred to as the Z-Petawatt (ZPW), is being constructed for:
 - New radiography options (X-ray radiography in the 10-100 keV range; Proton radiography)
 - Fast Ignitor fusion research on Z/ZR
- The 2 kJ/1 ps system will begin operation in 2007

Techniques have been developed on Z for accurate EOS studies—both major advances

Isentropic Compression Experiments (ICE)

Magnetically produced Isentropic Compression Experiments (ICE) to provide measurement of continuous compression curves to ~3 Mbar
- previously unavailable at Mbar pressures

Magnetically launched flyer plates

Magnetically driven flyer plates for shock Hugoniot experiments at velocities to ~ 34 km/s
- exceeds gas gun velocities by ~ 4X and pressures by ~ 7-8X with comparable accuracy

Data to 1.8 Mbar has been obtained on liquid D₂ to help resolve discrepancy in high-pressure response

Sandia was asked to quantify Be & diamond melt for the National Ignition Campaign (NIC)

300 eV graded-doped Be design:

Sputtered Be has Grains

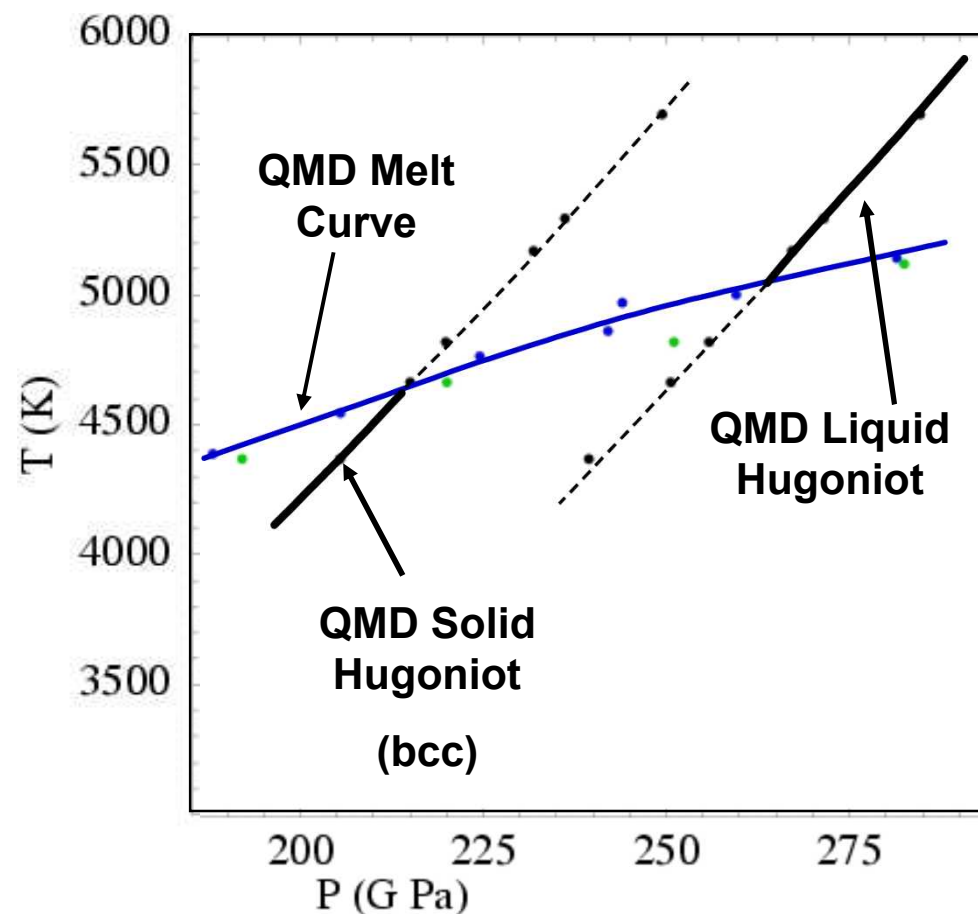

This is predicted to be of no consequence when the Be melts

- Risk reduction strategy
 - Ensure Be capsules melt
 - Measure melt properties of Be on the Hugoniot
 - Compare measurements with QMD modelling
- Determine melt properties of pure, polycrystalline Be samples from Brush-Wellman
- Success of the beryllium experiments led to experiments to investigate the melt properties of diamond
 - CVD grown, polycrystalline diamond samples supplied through LLNL (both microcrystalline and nanocrystalline)
- Diamond studies resulted in a delay in the shutdown of Z for the upgrade

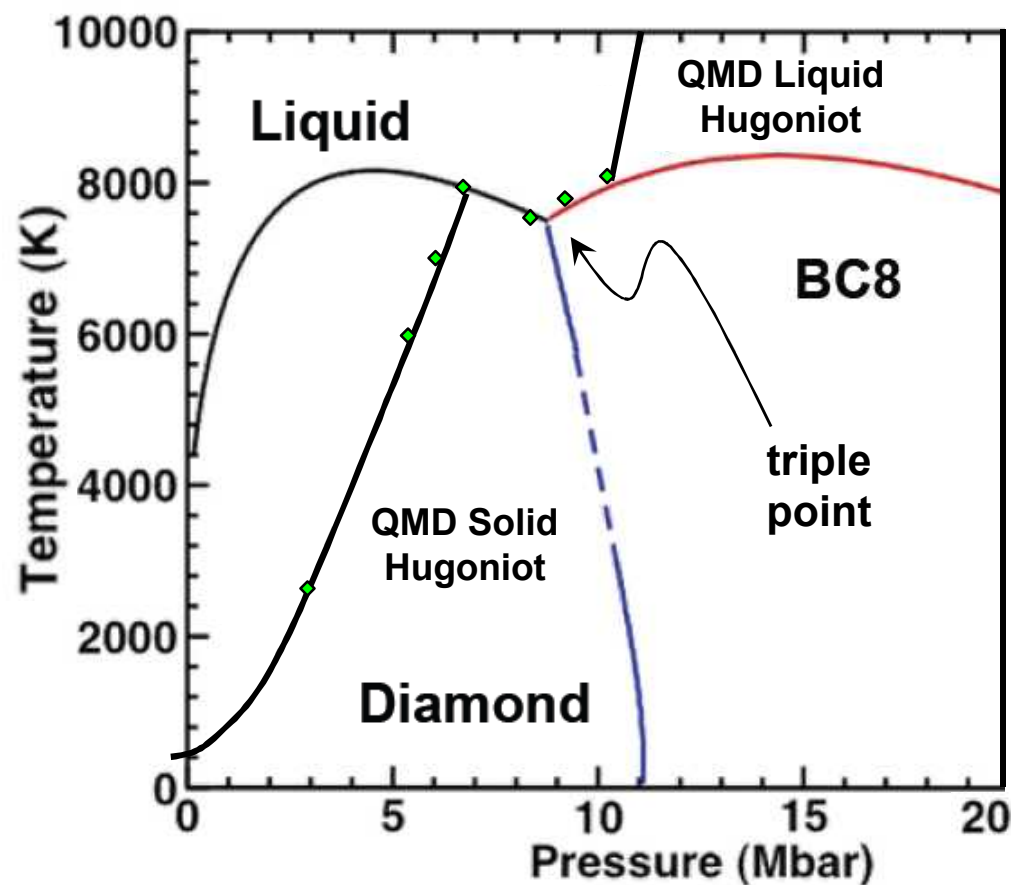

QMD calculations were critical in providing estimates of the stress regime of interest

Be Phase Diagram

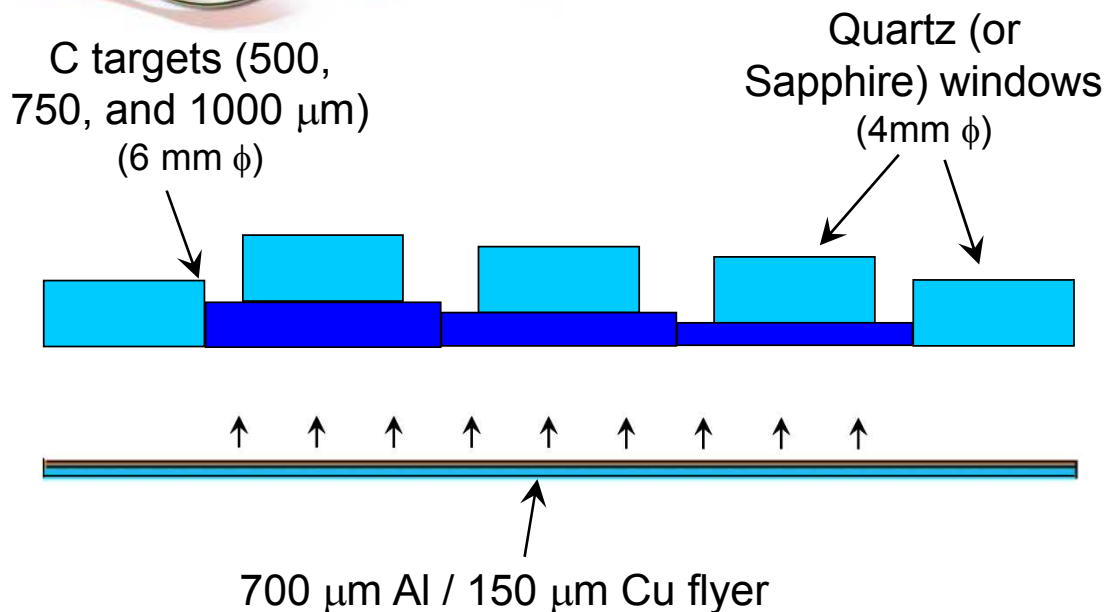

Diamond Phase Diagram

MHD simulations were critical in providing load geometries to achieve desired flyer velocities

- Experiments required an Al/Cu flyer with peak velocities in the range of 7-24 km/s
- Four asymmetric loads were designed to produce 2 flyers per shot with $\sim 10\%$ difference in peak velocity
- ALEGRA 2D MHD was used to set flight distances and to set charge voltages on Z

Asymmetric Flyer Load for Be Melt Experiment

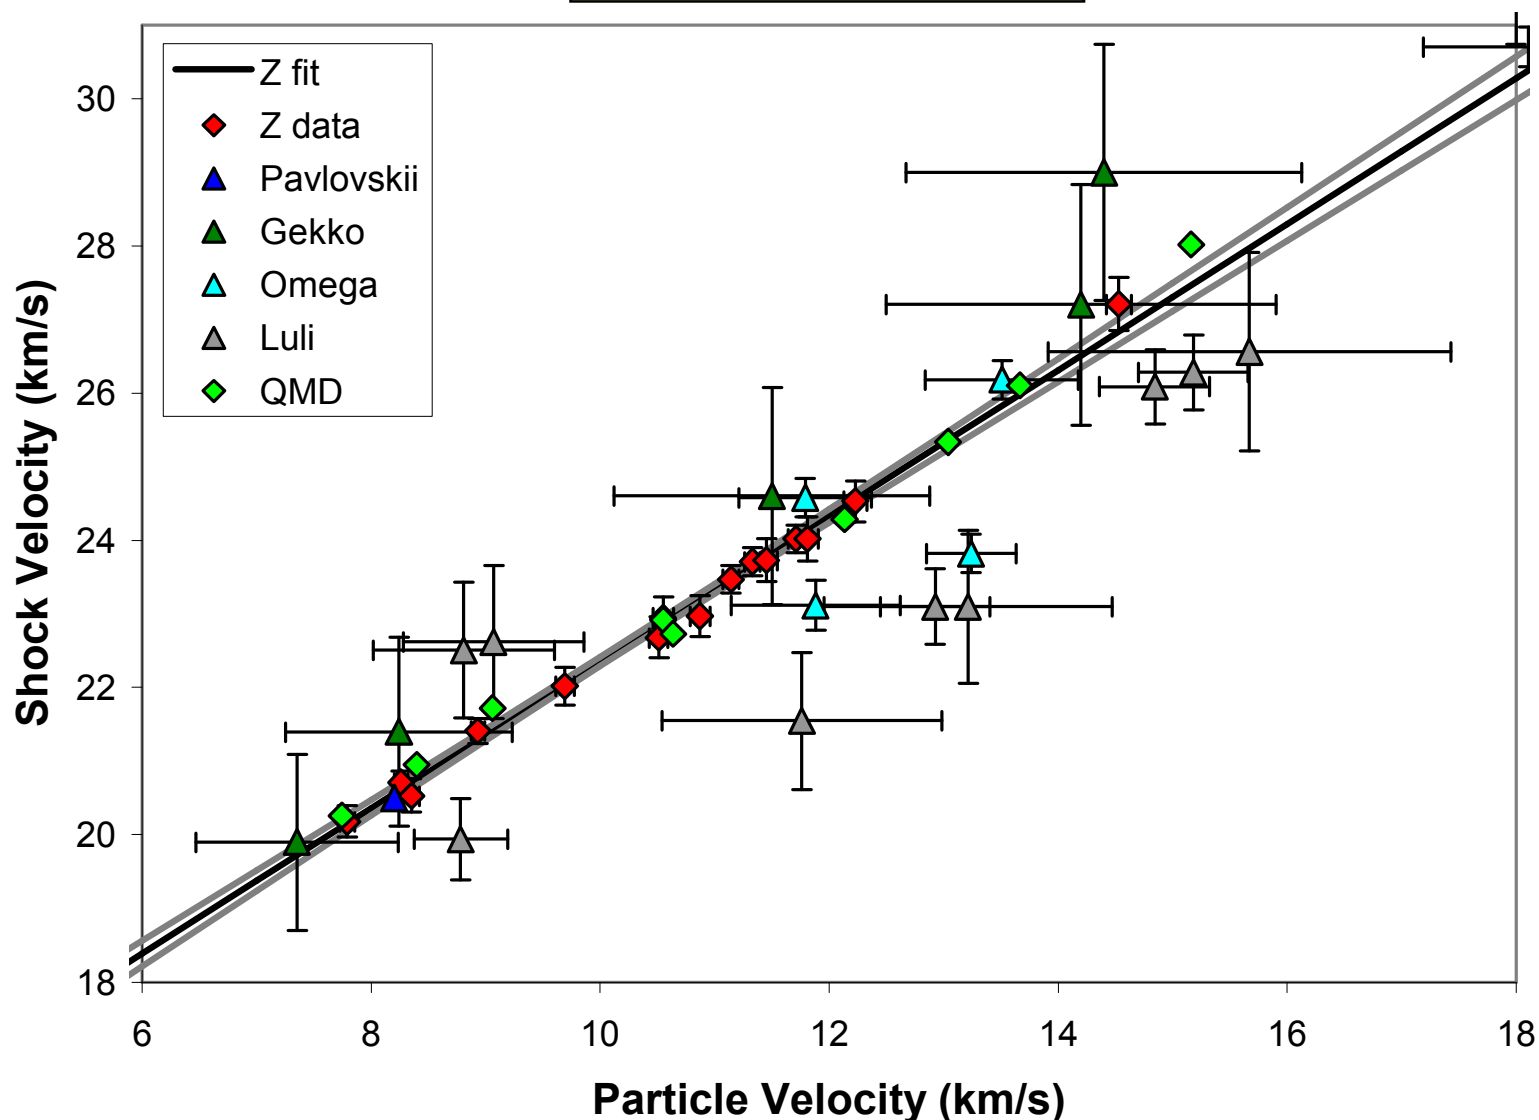

Predicted / Measured Flyer Velocities z1624

Experimental geometry enabled very precise Hugoniot measurements at multi-Mbar stresses

$U_s - u_p$ Hugoniot

- Sub-percent measurement of U_s and u_p
- Each point is a weighted average of 2 or 3 individual measurements (3 samples per panel)
- Significant benefit in being able to measure flyer plate velocity for impedance match

Experimental geometry enabled very precise Hugoniot measurements at multi-Mbar stresses

$\sigma - \rho$ Hugoniot

- Density precision of ~1% on average, as low as 0.67%
- High precision allows for quantitative comparison with theory
- These are by far the most accurate Hugoniot measurements of diamond in the multi-Mbar stress regime

Summary of Results

Beryllium Conclusions

- Be melts on the Hugoniot at ~210 GPa
- Be coexistence ~50 GPa
- Be melts directly from hcp (not bcc)
 - Caused us to revisit the phase diagram
- Be exhibits significant yield strength near melt, ~3.5 GPa

Diamond Conclusions

- Extremely precise Hugoniot measurements obtained for diamond at multi-Mbar pressures
- Diamond melts on the Hugoniot at ~650 GPa
- Diamond coexistence is large, ~400 GPa
- There appears to be a diamond-liquid-bc8 triple point along the coexistence curve at ~850 GPa
- Diamond exhibits an extremely large yield strength near melt, ~50-80 GPa
 - It appears there is negligible shear stress in the shocked state
- Nano- and Micro-crystalline samples appear to behave similarly

Understanding the dynamics of wire array z-pinches is critical for optimizing radiation sources

Goal: Validate an ablation model for simulating wire array z-pinches using Z data; design & predict shots on ZR

Wire Array Z-Pinch

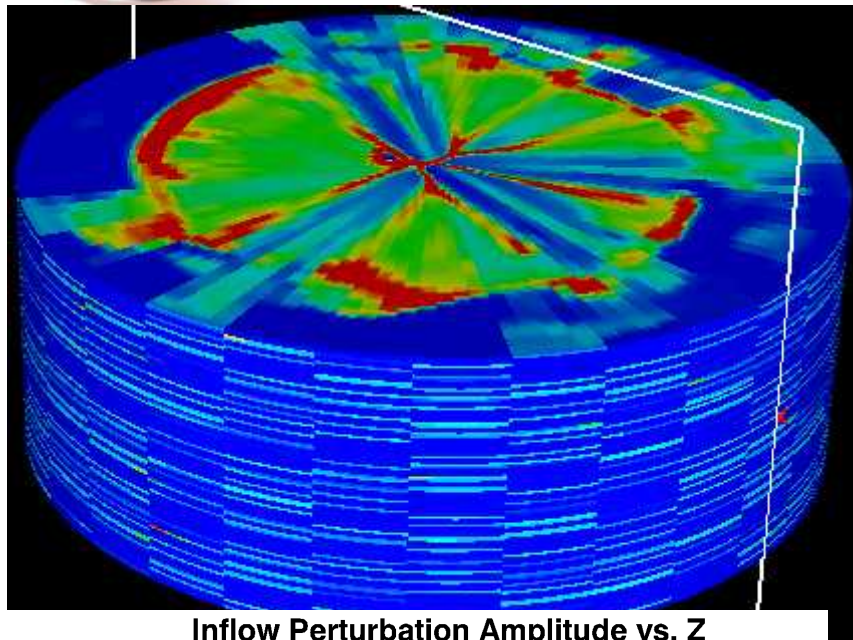

Radiograph $t = -5$ ns (D. Sinars)

We are studying 3-D wire array z-pinch implosions using a mass ablation model

Inflow Perturbation Amplitude vs. Z

$$\dot{m} = \dot{m}_0 I^{1.4}$$

E.P. Yu, B.V. Oliver, P.V. Sasorov, et. al.,
Phys. Plasmas 14, 022705 (2007)

Spectrum Axial Perturbation

Z1611 stack voltage & current, mitl & load B-dots used to obtain $V(t)$ & $Z_{flow}(t)$ for simulation

$$Z_{flow}(t) = \Delta V / \sqrt{I_u^2 - I_d^2}$$

See Z circuit analysis in E. M. Waisman, et al., Physics of Plasmas 11(5), 2009-2013 (2004), in which the 4 MITL levels are accounted for.

3-D simulations show azimuthal correlation of plasma structure grows with time & depth

R=10 mm surface (entire pinch)

R=9.5 mm surface

R=8 mm surface

Z-pinch dynamics are 3-dimensional: current can flow around axial gaps in the plasma

60 Degree Periodic Wedge with Cylindrical Cut Surface through Tungsten Plasma

Current Density Vectors Superimposed on Cylindrical Cut Surface

Radial & azimuthal currents create $j \times B$ forces that modify plasma structure

We are using this ablation model to guide the design for initial wire array shots on ZR

- Perturbation is fixed from experimental data, but we believe we will understand this theoretically soon.
- Mass ablation rate is constrained by the implosion time.
- Energies and powers then agree well with experiments, and partially validate ablation model.
- We are designing ZR shots to validate our understanding of how the model parameters scale.

Data: D. B. Sinars et al, Phys. Plasmas 13, 042704 (2006).
