Abstract

The Matter-Radiation Interactions in Extremes project will build the experimental facility for the time-dependent control of dynamic material performance. An x-ray free electron laser at up to 42-keV fundamental energy and with photon pulses down to sub-nanosecond spacing, MaRIE 1.0 is designed to meet the challenges of time-dependent mesoscale materials science. Those challenges will be outlined, the techniques of coherent diffractive imaging and dynamic polycrystalline diffraction described, and the resulting requirements defined for a coherent x-ray source. The talk concludes with the role of the MaRIE project and science in the future.

UNCLASSIFIED

MaRIE is the experimental facility for the time-dependent control of dynamic material performance

The Mission Need

Develop flexible and low-cost product-based solutions to materials problems in the stockpile through accelerated qualification, certification, and assessment.

What It Is: The Capability Gap

MaRIE fills the gap with:

- 42-keV XFEL for coherent, brilliant, repetitive x-rays; and
- Multiple simultaneous probes (x-ray, proton, electron, optical); and
- Close linkage to synthesis, fabrication and characterization facility; and
- Full integration with advanced theory, modeling, and computing.

The Challenge

Interfaces, defects, and microstructure between atomic scale and engineering continuum determine time-dependent material properties.

How It's Done

After time-dependent control of process, structure, and properties during synthesis of materials at the mesoscale, MaRIE will subject them to extreme environments and use both imaging and diffractive scattering to connect to the product performance.

UNCLASSIFIED

MaRIE responds to the NNSA Tri-lab Facility Roadmap Gap of “predict and control from materials and devices to manufacturing processes”

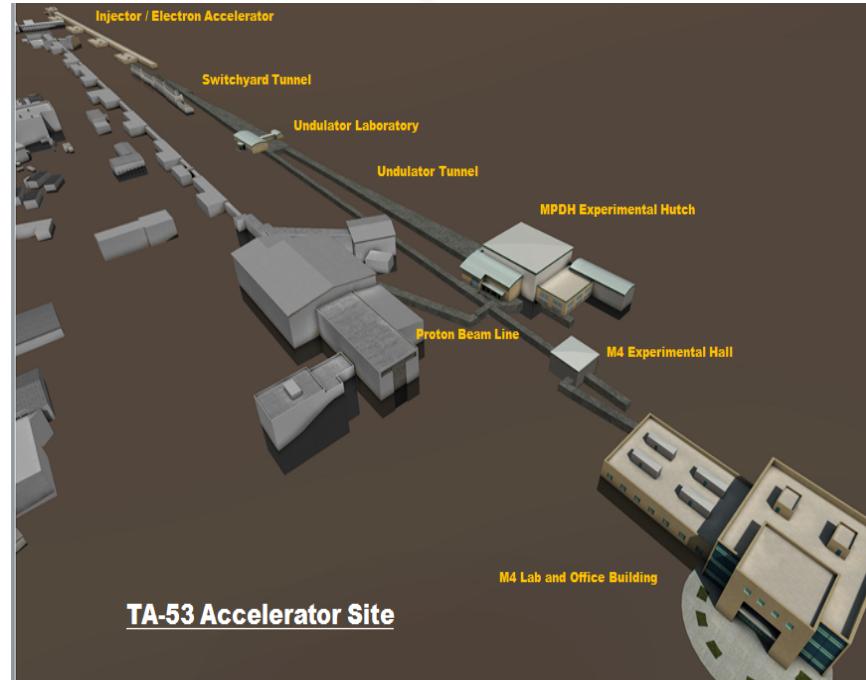

Production

Button

Boom

Disposition

- MaRIE will provide the world's first very-hard (42-keV) **XFEL** with GHz (few pulses) repetition;
- **A Making, Measuring, and Modeling Materials (M4) Facility** for materials synthesis and characterization with high-performance computational co-design focused on the mesoscale; and
- **A Multi-Probe Diagnostic Hall (MPDH)** coupling hard, coherent, brilliant x-ray photons with 12-GeV electron and 0.8-GeV proton radiographic tools in time-dependent extremes.

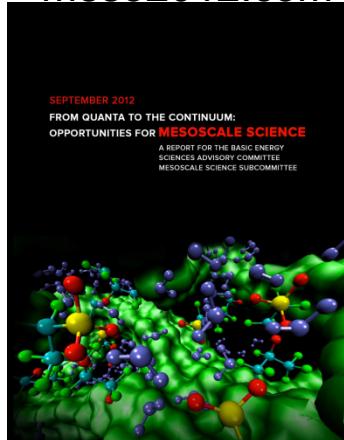

MaRIE facility definition derives from “First Experiments” functional requirements and identified performance gaps.

UNCLASSIFIED

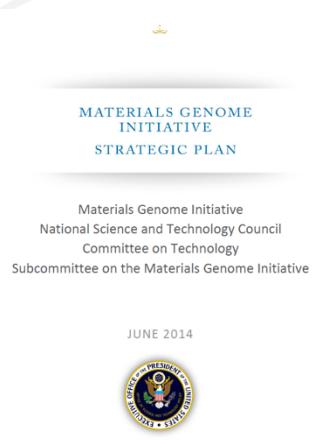

LANL-led efforts with the Scientific Community ~2006-2012 defined the Grand Challenges

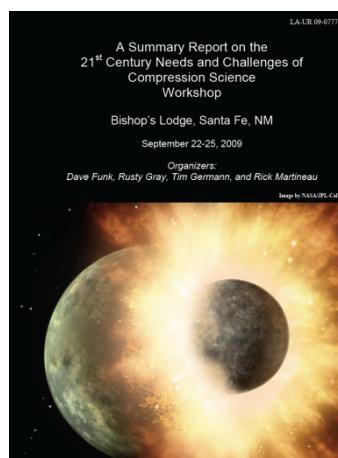

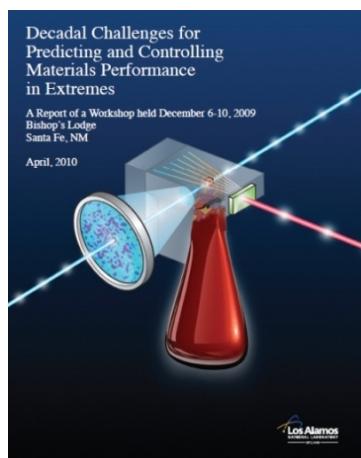

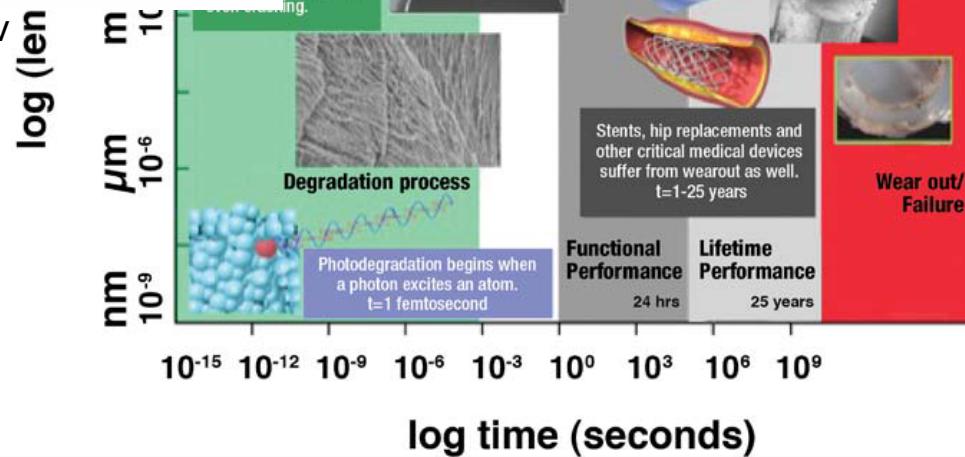

meso2012.com Materials Genome Advanced Manufacturing

science.energy.gov

Whitehouse.gov

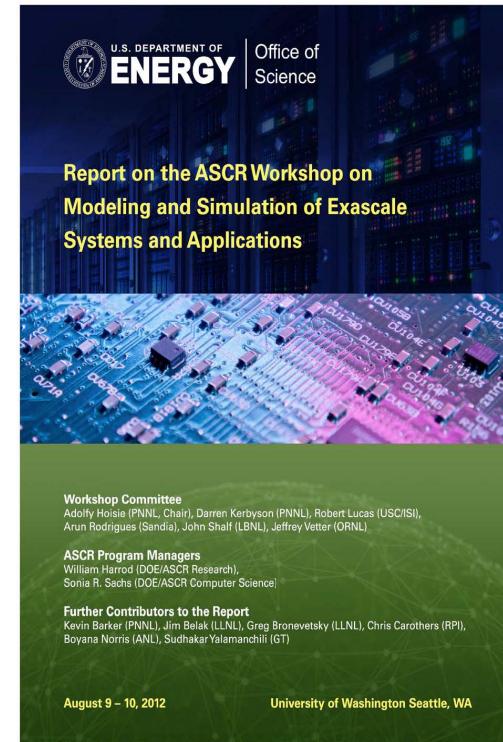

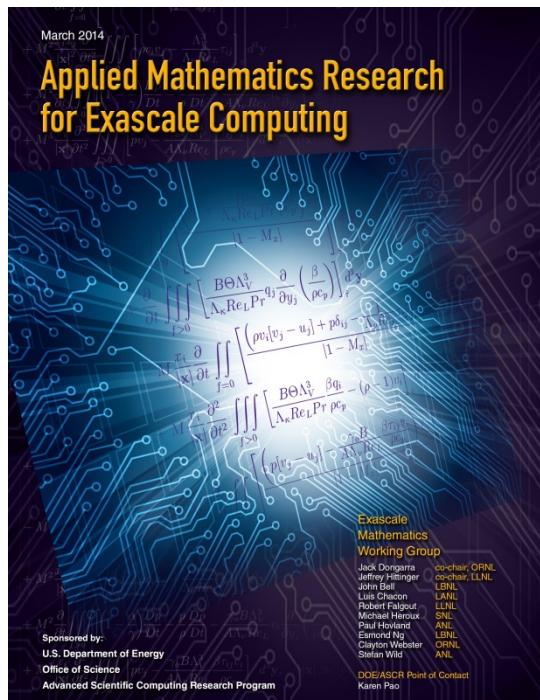

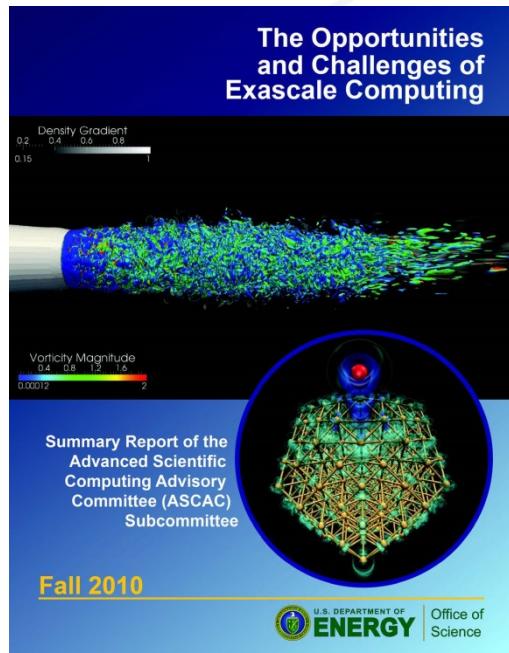

Requirements:
Sub- μm space resolution
100's – 1000's- μm samples
Sub-ns time resolution,
~30 frames in
1–10- μs duration

Slide 5

The challenge is to observe the dynamic evolution of polycrystalline materials at the granular and inter-granular level (the mesoscale)

MaRIE will be operating in an environment of exascale computing and future codes

Experimental Facilities are needed to Discover mechanisms, Validate and Calibrate sub-grid models

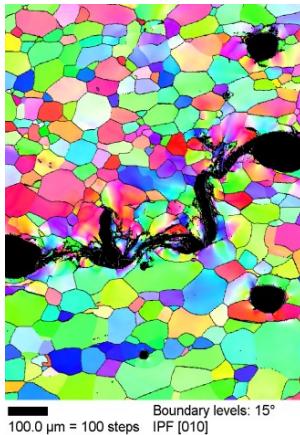

UNCLASSIFIED

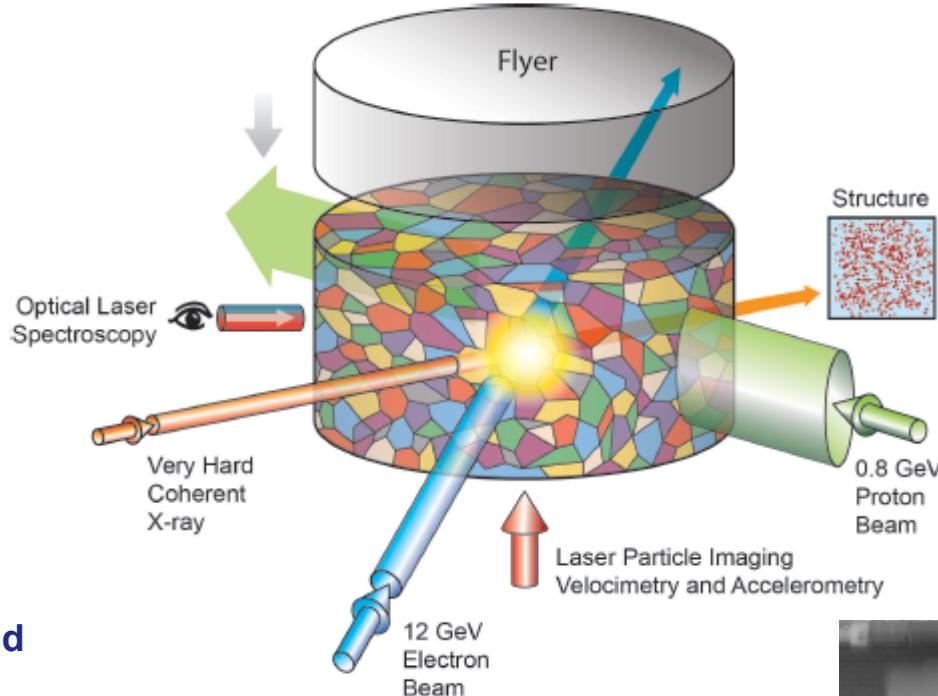

Operated by Los Alamos National Security, LLC for the U.S. Department of Energy's NNSA

The challenge is to observe the dynamic microstructure and phase evolution in materials down to the sub-granular level while connecting to the macroscale

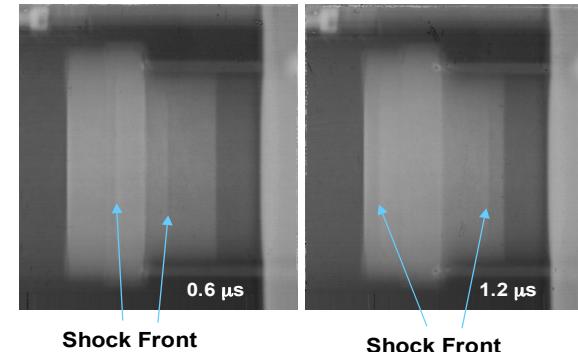

The goal
Predict dynamic microstructure and damage evolution

Requirements:
Sub- μ m space resolution
100's – 1000's- μ m samples
Sub-ns time resolution,
~30 frames in
1–10- μ s duration

The model:
Accurate sub-grain models of microstructure evolution coupled to molecular dynamics

The first experiment

Multiple, simultaneous dynamic *in situ* diagnostics with resolution at the scale of nucleation sites (< 1 μ m; ps – ns)

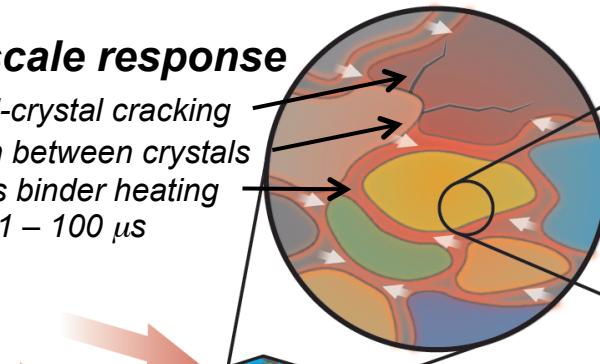

MarIE allows us to break apart the problem

MaRIE allows *in situ* study of hot spot formation and other microstructural phenomena

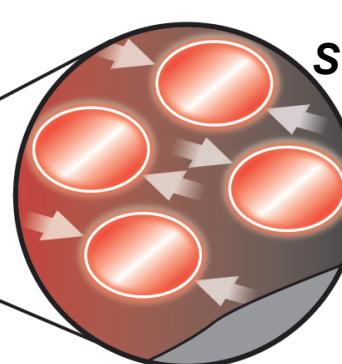

Grain scale response

Crystal-crystal cracking
Friction between crystals
Viscous binder heating
0.1 – 100 μ s

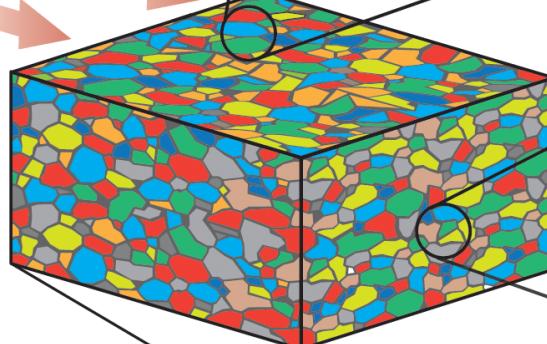

Sub-grain response

Void collapse
Localized heating
Phase transformation
10 – 1000 ns

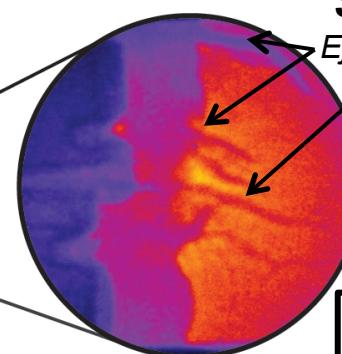

PBX sample

Heterogeneous
Multiple grains
Prill or pellet
1 – 1000 grams
0.5 – 500 cm^3

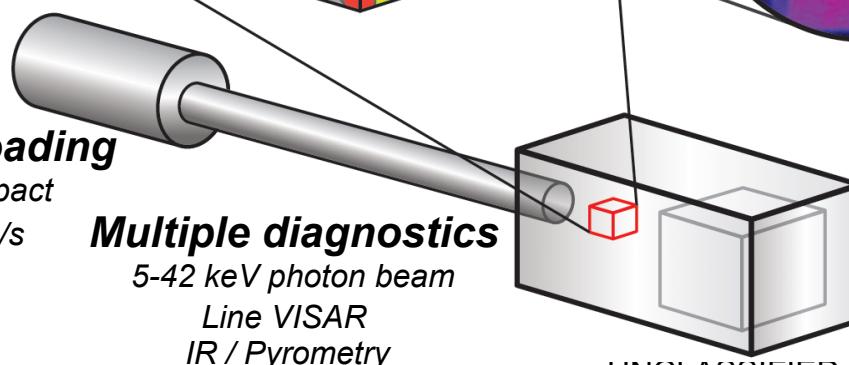

Surface response

Ejecta from machining defects
Ejecta from cracks
Material strength
Complex shock interactions
10 – 1000 ns

Gas gun loading

Projectile impact
0.05 – 5 km/s

Multiple diagnostics

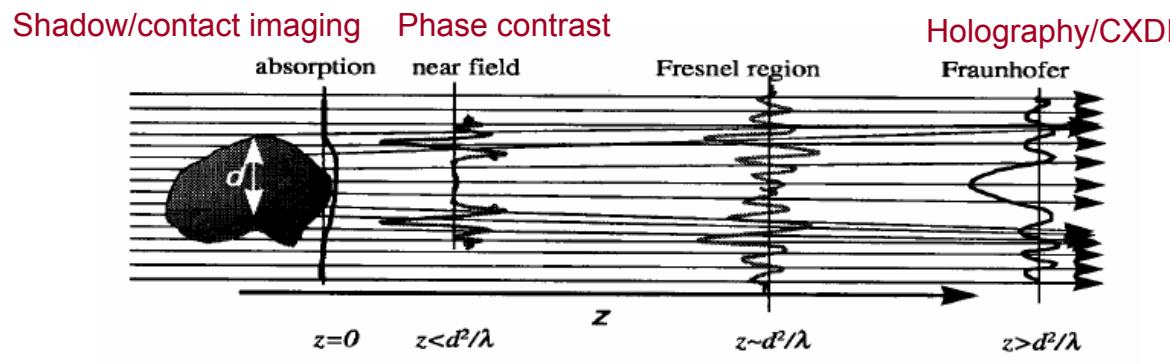

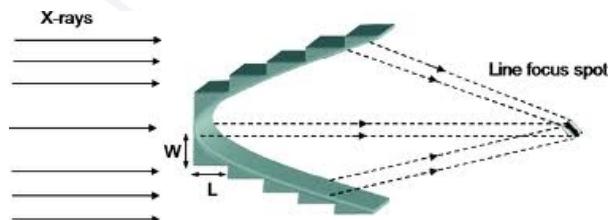

5-42 keV photon beam
Line VISAR
IR / Pyrometry

MaRIE will directly observe hot spot formation and mesoscale deformation mechanisms within insensitive PBX materials during dynamic loading.

X-ray Imaging Techniques Can Give Sub-micron Resolution

- **Traditional Imaging (think lens)**
 - Fresnel, Kirz, Laue, Kinoform lenses for hard x-rays (up to 0.5 MeV)
 - Resolution: down to ~100's nms
- **Radiography Approaches (Line-projection, tomography, PCI and divergent beam PCI)**
 - Resolution typically scales with pixel size (max $r \sim \text{pixel}/100 > 100 \text{ nm}$, typically 1 μm)
- **Coherent Approaches (Holography, PCI, CXDI)**
 - Resolution: down to <10 nm

CXDI can provide 3D information, but has only been demonstrated for softer x-rays (<1 keV) and small samples (few micron)

The Far Field

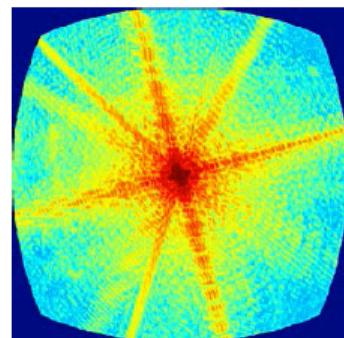

Define the Fresnel number, $Fr \equiv \frac{a^2}{\lambda z}$. When $Fr \ll 1$:

$$\vec{E}(\vec{r}) \propto \int d\vec{r}' \rho(\vec{r}') e^{-i\vec{q} \cdot \vec{r}'} = \text{FT} \{ \rho \}$$

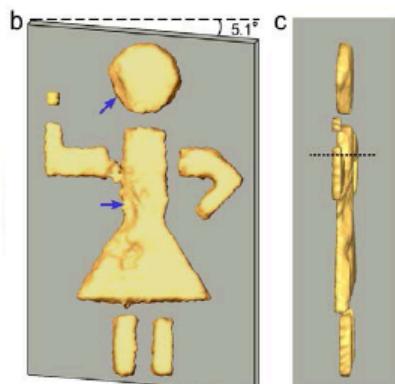

where $\vec{q} = \vec{k}_f - \vec{k}_i = k\hat{r} - \vec{k}_i$ is the *scattering vector*. Since \vec{q} is a 3D vector, 3D imaging is possible in the far field*:

Sample (SEM image)

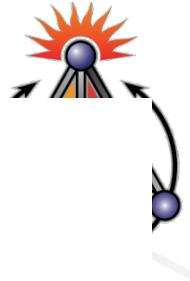

Scattering Pattern

Reconstruction

For “MaRIE-like” imaging problems, achieving $Fr \ll 1$ requires prohibitively-large values of z (100s to 1000s of meters) due to the high photon energies (and low wavelengths λ) required to penetrate a sample of dense material.

* “Three-dimensional structure determination from single view,” Raines, et al. *Nature* **463**, 214-217 (2010).

The Fresnel Regime

Define the “Small angle number” $An \equiv \frac{D^4}{8 \lambda z^3}$. When $An \ll 1$:

$$\vec{E}(\vec{r}) \propto \int d\vec{r}' \rho(\vec{r}') e^{i\frac{k|\vec{r}'|^2}{2z}} e^{-i\vec{K}\cdot\vec{r}'} = \text{FT} \left\{ \rho e^{i\frac{k|\vec{r}'|^2}{2z}} \right\}$$

where $\vec{K} = k_z \vec{r} - \vec{k}_i$.

It can be shown that \vec{K} is a purely two-dimensional vector, i.e. it lies on a 2D manifold. This means that in the Fresnel regime, the scattered and diffracted field encodes only 2D information about the sample, and **3D imaging is not possible in the usual experimental setup***.

Nevertheless, the condition $An \ll 1$ is often much less stringent than the far-field condition $Fr \ll 1$. For fixed detector size $D \sim 2.8$ cm (a typical value), values for z of 10s of meters to 100 meters are sufficient to ensure that $An \ll 1$.

Coherent X-ray Diffractive Imaging

Detector preserves intensity – but not phase – of scattered field:

$$I(\vec{r}) \propto \left| \vec{E}(\vec{r}) \right|^2 \propto \left| \int d\vec{r}' \rho(\vec{r}') e^{-i\vec{q} \cdot \vec{r}'} \right|^2 = |\text{FT} \{ \rho \}|^2 = |\hat{\rho}(\vec{q})|^2$$

Provided additional information about the support of the sample/beam intersection is available in the form of an oversampling condition, these missing phases can be recovered via a process of *iterative phase retrieval* (Fienup 1978).

Transverse imaging resolution:

$$\frac{\Delta x}{\lambda} = \frac{1}{D} \sqrt{\left(\frac{D}{2}\right)^2 + z^2} \approx \frac{z}{D} \quad \text{Far-field}$$

$$\frac{\Delta x}{\lambda} = \frac{z}{D} \quad \text{Fresnel}$$

Longitudinal imaging resolution:

$$\frac{\Delta z}{\lambda} = \frac{1}{2} \left(1 - \frac{z}{\sqrt{\left(\frac{D}{2}\right)^2 + z^2}} \right)^{-1} \approx \frac{4z^2}{D^2} \quad \text{Far-field}$$

$$\frac{\Delta z}{\lambda} = \infty \quad \text{Fresnel}$$

Energy = 50 keV
 $An \sim 10^{-3}$

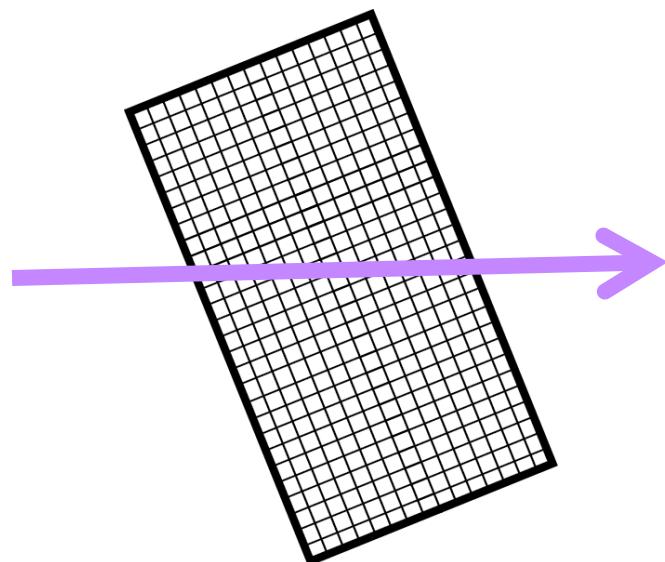

$\Delta x \sim 200 \text{ nm}$

UNCLASSIFIED

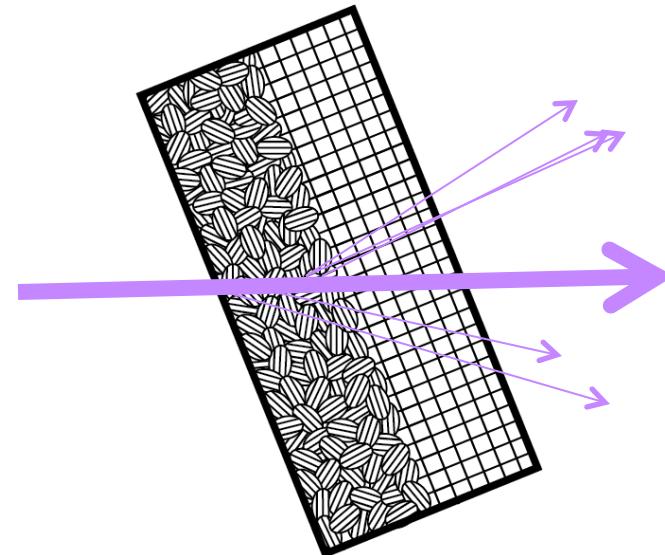

Techniques for probing shocked single crystals on MaRIE are being developed at LCLS

- Matching the Bragg condition for ambient single crystal diffraction creates signal that is too strong for detector
- Set up experiment for no diffraction from the ambient single crystal
- Diffraction signal occurs when Bragg condition is satisfied for transformed phase

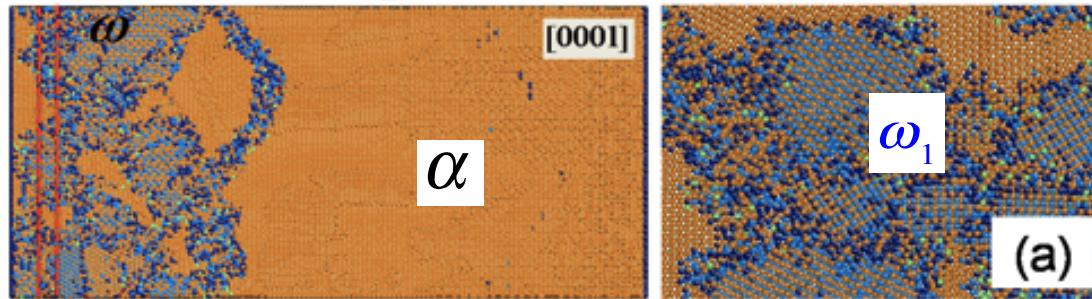

Bragg condition is not satisfied for ambient single crystal

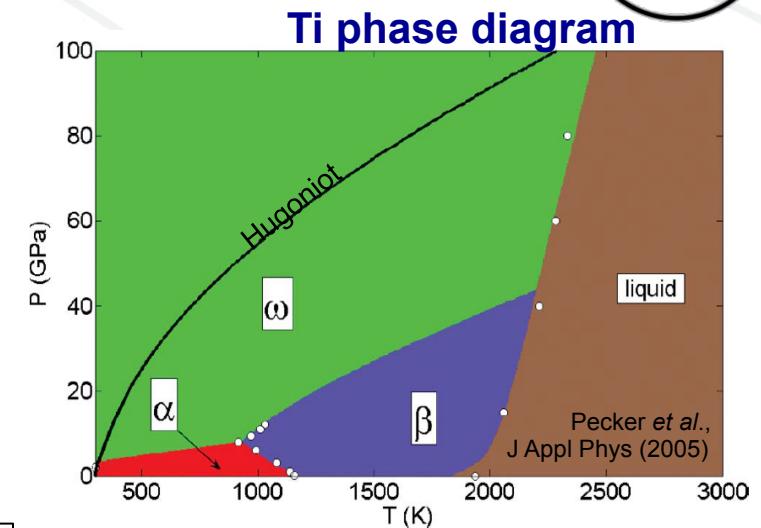

Some crystals of the shock transformed phase satisfy the Bragg condition, causing diffraction

UNCLASSIFIED

Experiments at LCLS on phase transformation dynamics demonstrate utility of MaRIE

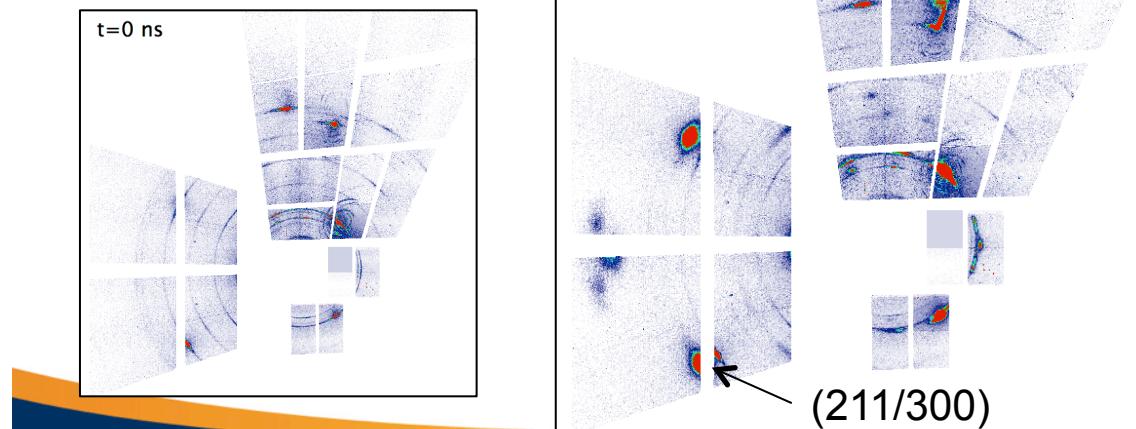

Large dependence of the evolving structure on the crystallographic shock direction in MD calculations

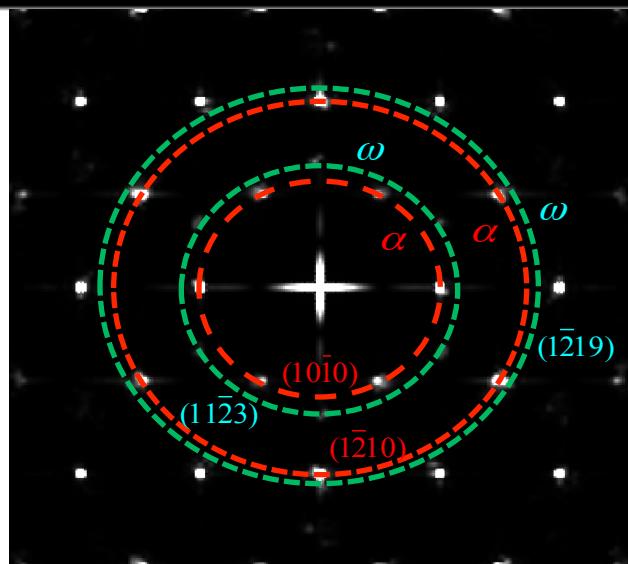

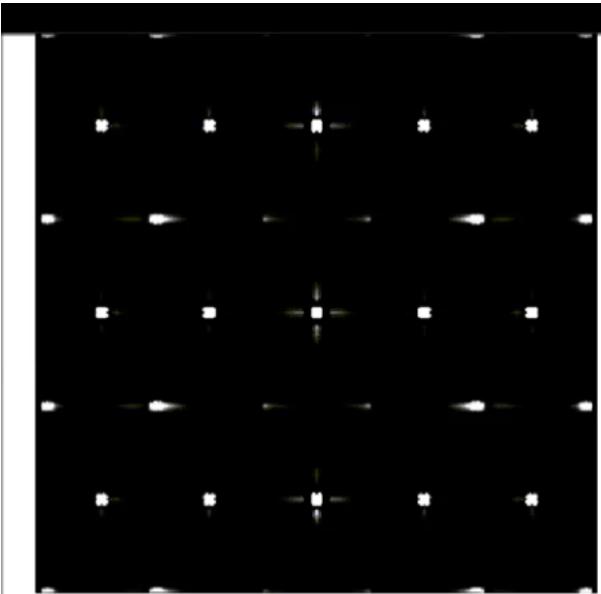

Goal: Determine the mechanisms of plasticity and phase transformation

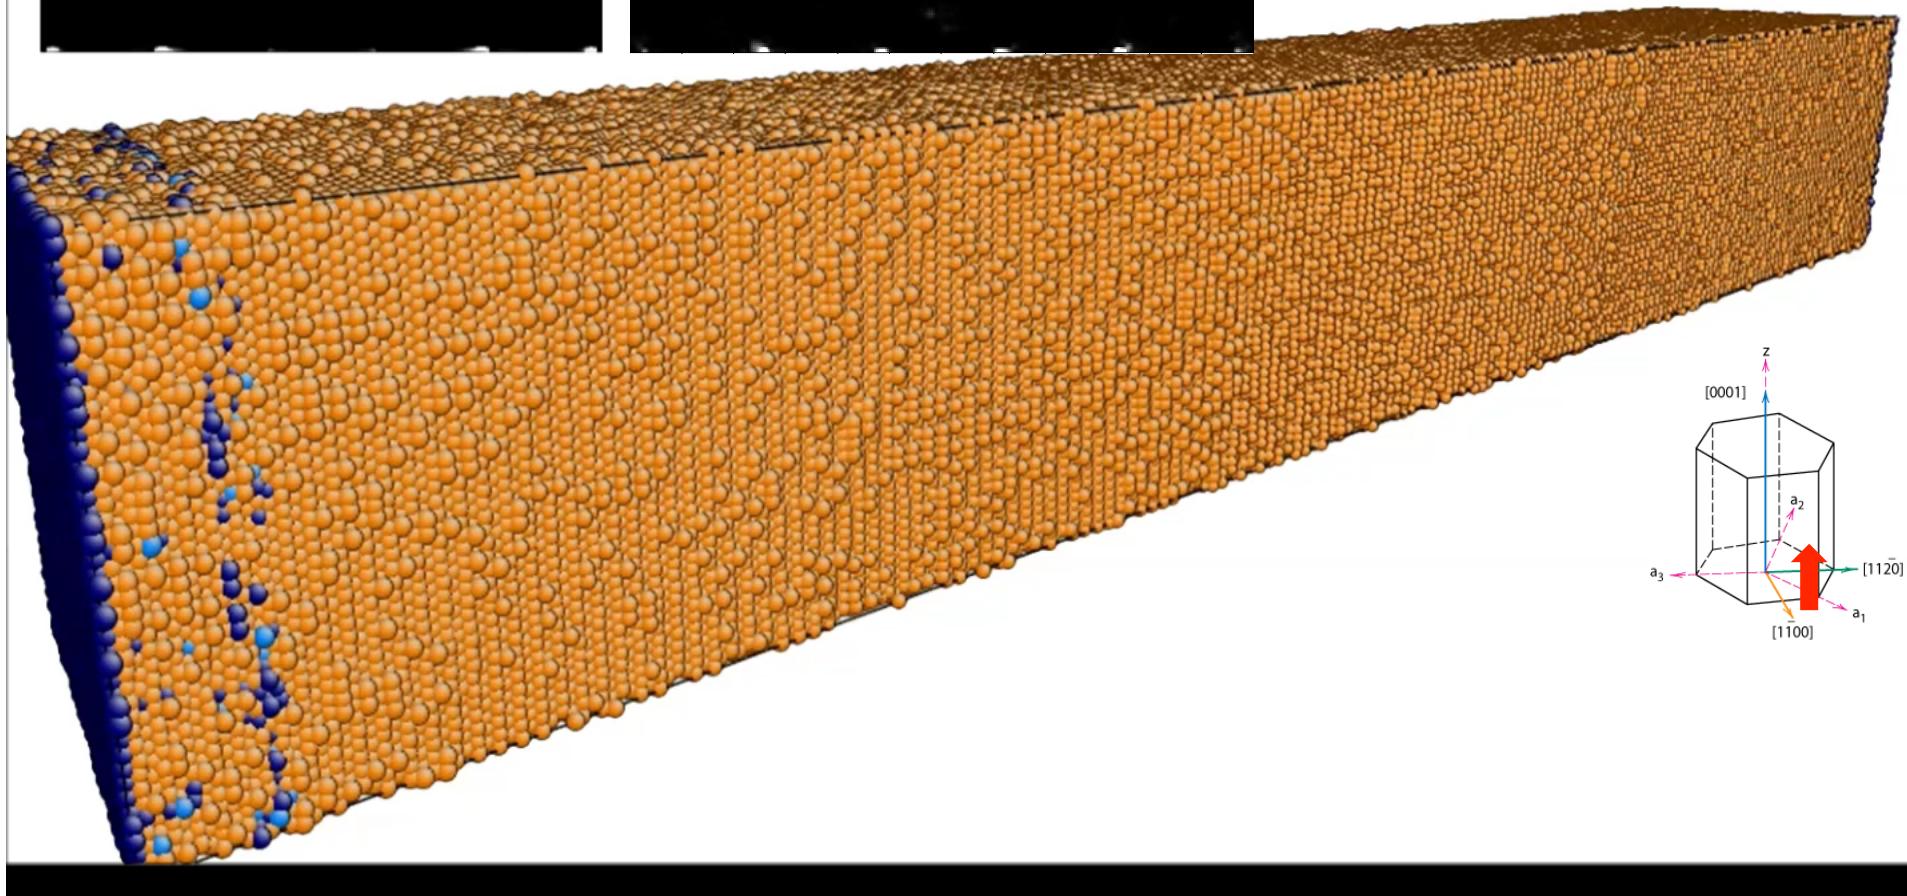

Ti [10-10]

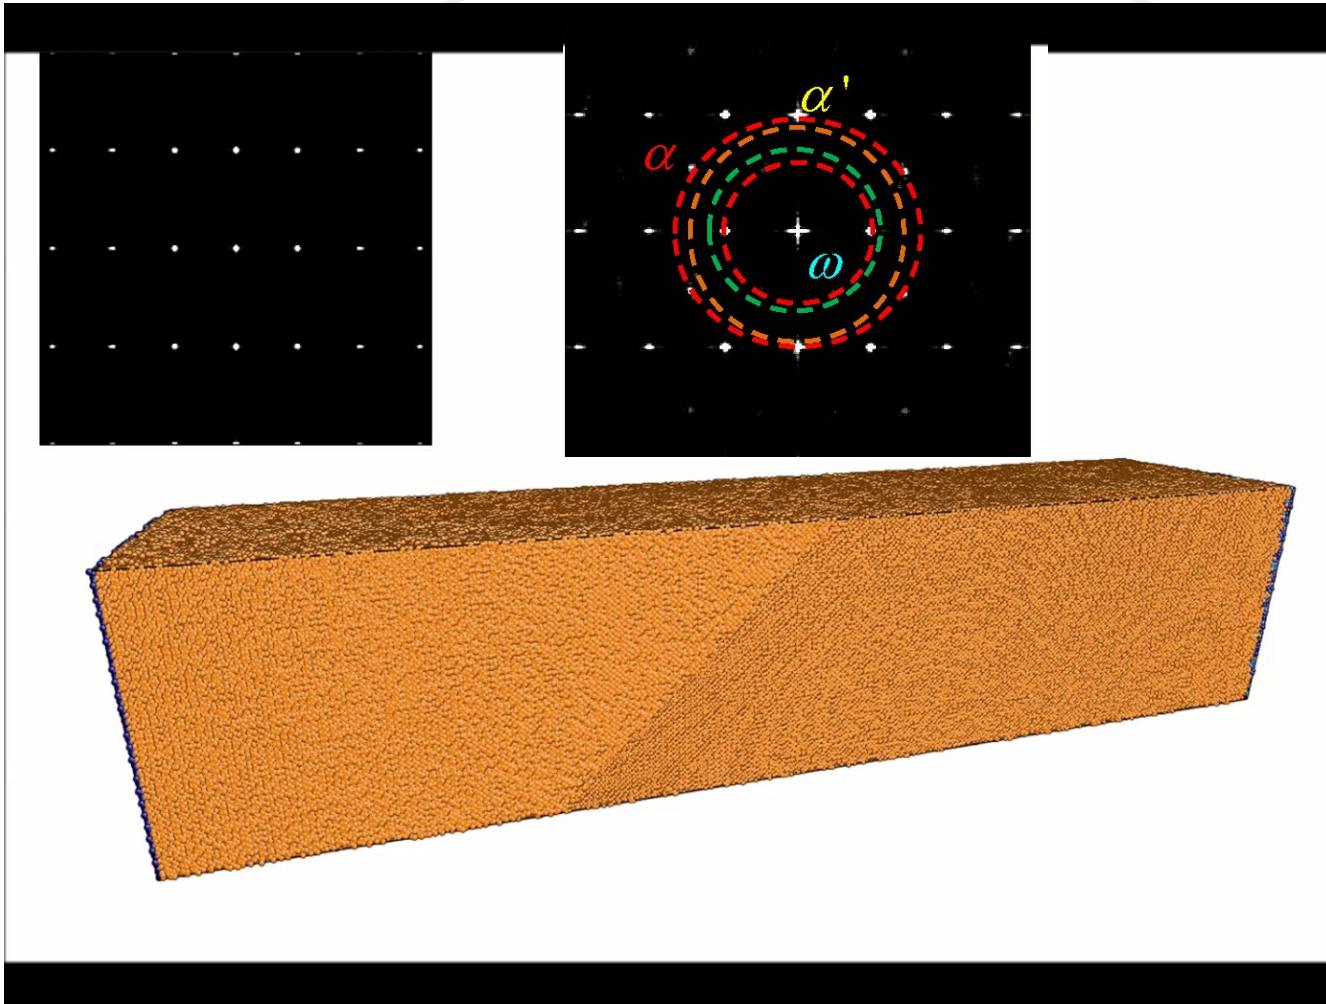

Kinetics of α - ω shock-driven phase transformation were observed

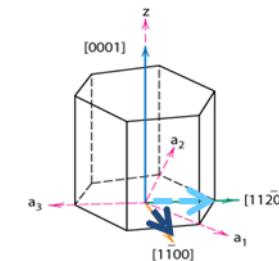

Simulated diffraction patterns show clear phase transformation

Movies allow probing new mechanisms in Ti single crystal under shock: 90° rotation PRECEDES phase transformation!

Fresnel number ~ 5 : same as 4 x 4 x 15 μm sample and 7 x 7 cm panel at 4 cm
~Near-field conditions: diffraction peaks reflect crystal shapes
Intensity: log scale spanning 4 orders of magnitude
Crystals undergo initial elastic compression, followed by plastic deformation and phase transformation
Brown = non-bcc atoms; green = twin planes

UNCLASSIFIED

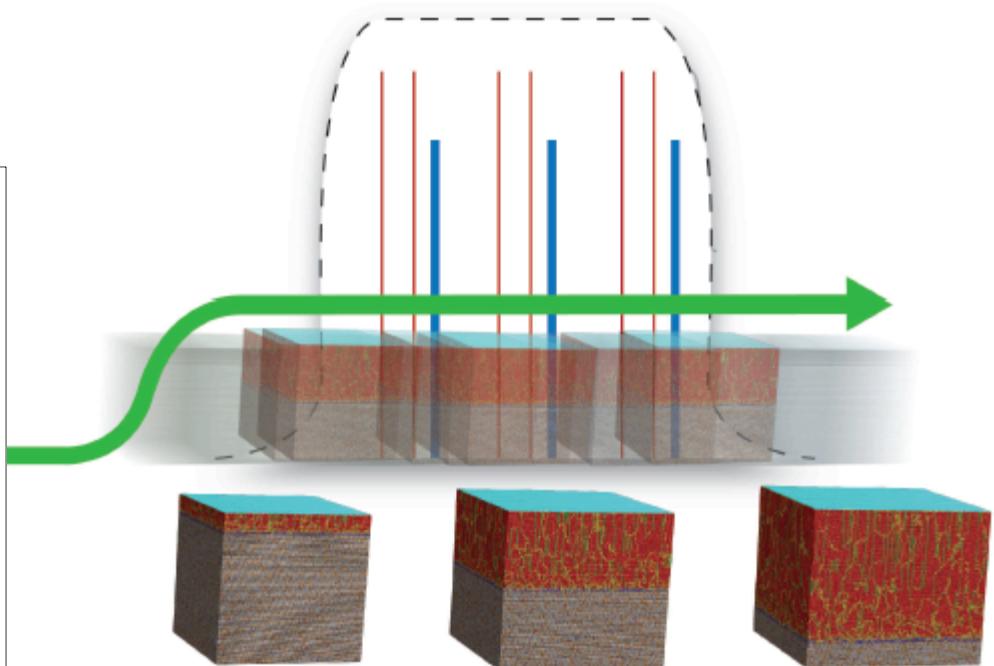

To see with time-dependence into and through the mesoscale requires: x-rays; coherent; brilliant and high repetition-rate; of sufficient high energy; and multiple probes at multiple scales

The MaRIE XFEL is harder and higher repetition rate than peer photon sources

MaRIE multiplexes 42-keV x-ray photons (red), 12-GeV electrons (blue), and 0.8-GeV protons (green) during a single dynamic event

Slide 23

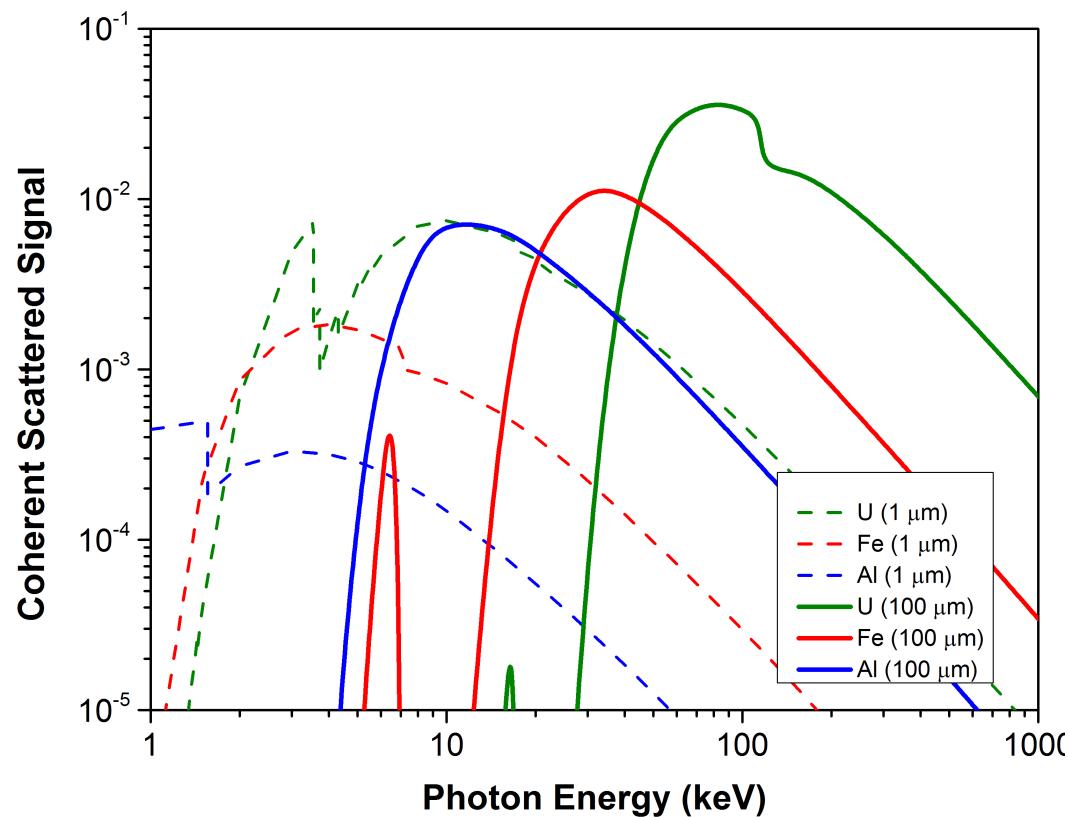

Optimizing the Coherently-Scattered Signal

N_0 = # of photons incident upon the sample

$N_U(t)$ = # of unscattered / unabsorbed photons in the beam at a depth t into the sample

$N_{1C}(t)$ = # of singly-coherently-scattered photons in the beam at a depth t into the sample.

$$\frac{N_{1C}(t)}{N_0} = \mu_C t e^{-\mu_T t}$$

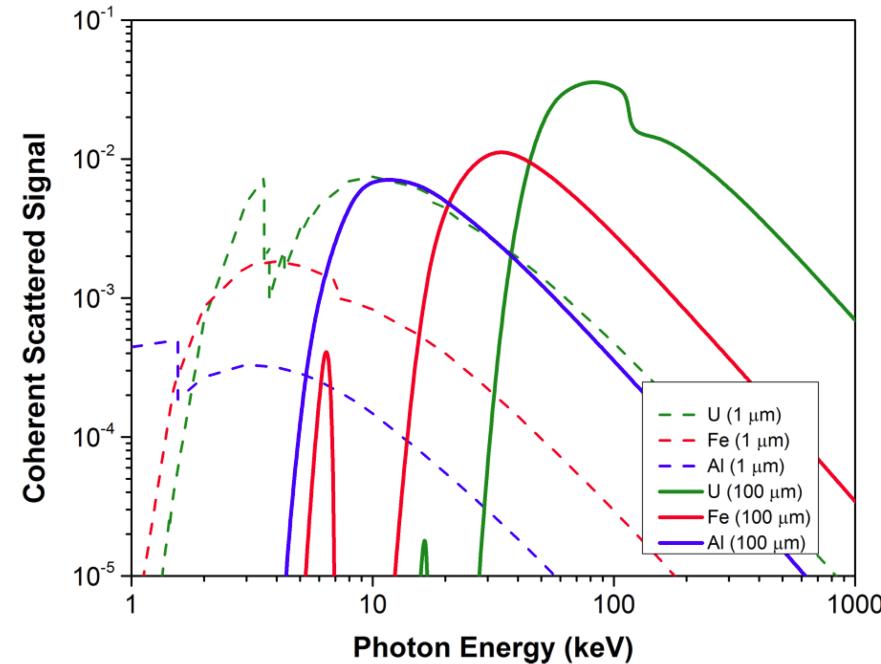

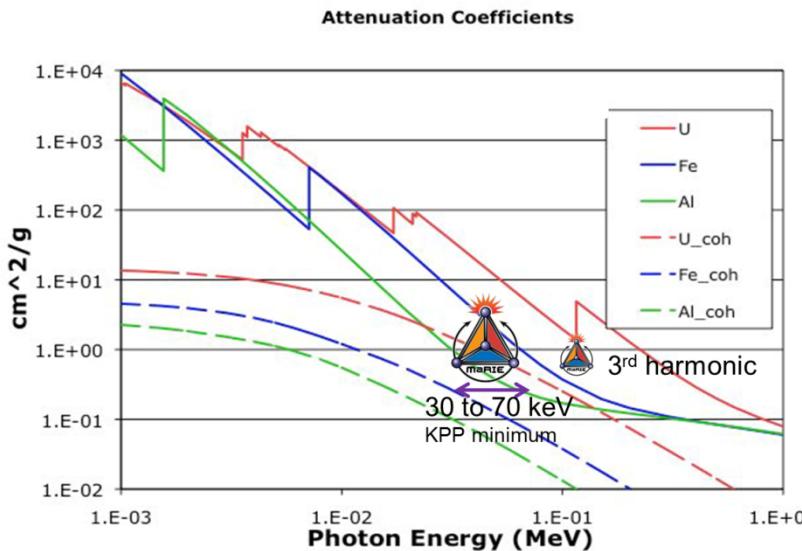

Note: It can be shown that for CXDI the rule of thumb for required coherence is that

$$\frac{\Delta\lambda}{\lambda} < \frac{2}{N_p} \sim 10^{-3}$$

where N_p is number of usable pixels on the detector.

The 42-keV design energy is a trade-off between maximizing elastic scattering for diffraction, minimizing absorptive heating, and sample thickness

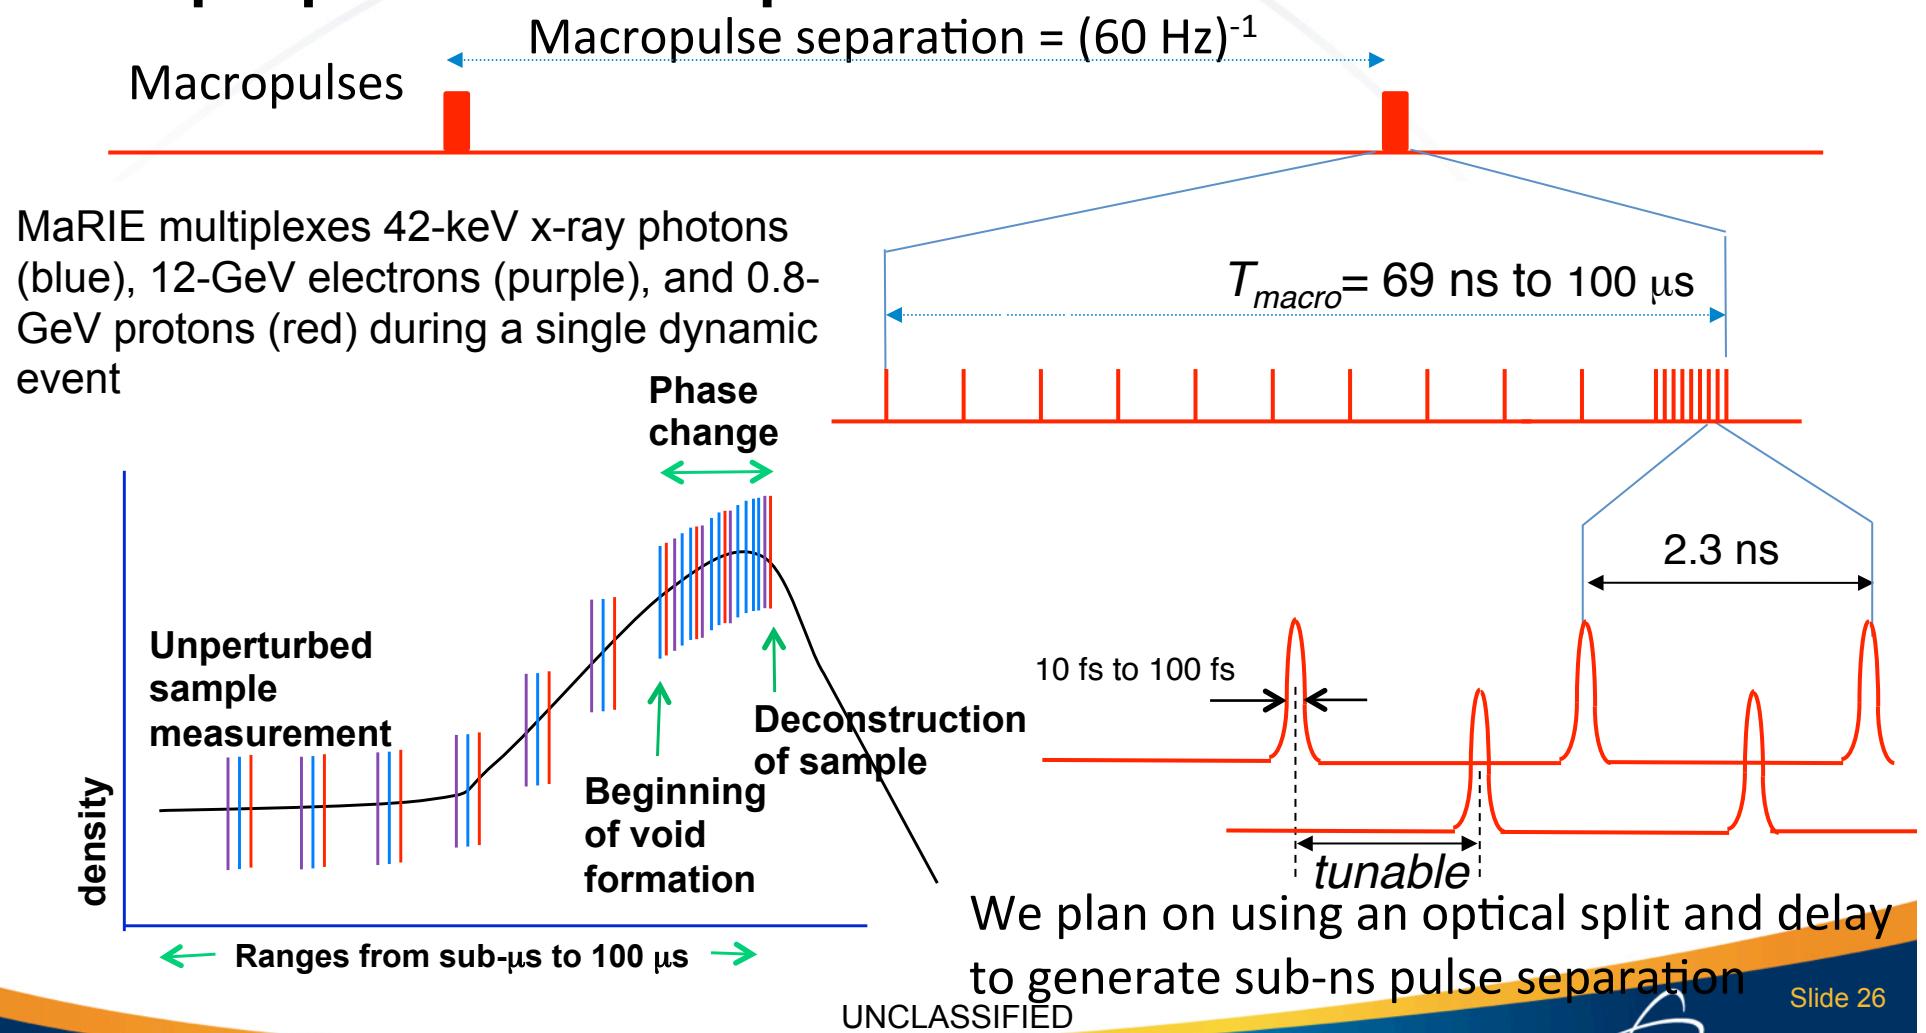

A high resolution image requires a minimum number of coherently scattered photons per sub-ps pulse. This sets the incident number of photons on a sample of $\sim 2 \times 10^{10}$.

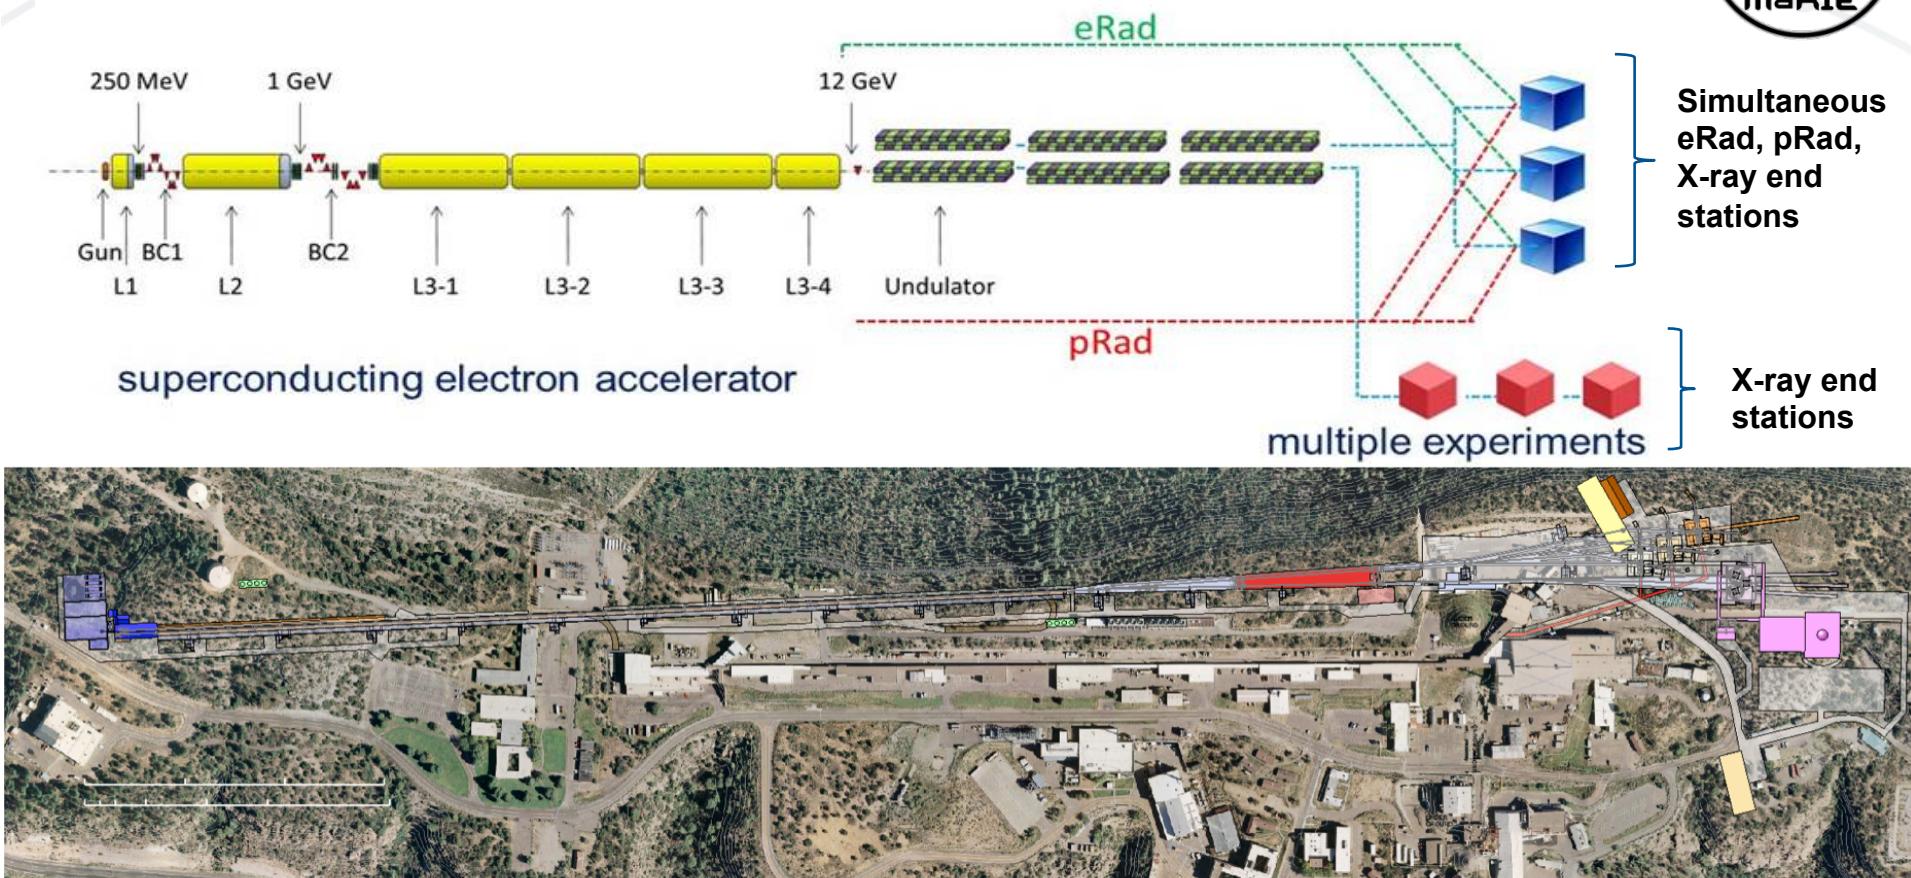

The fraction of incident photons coherently scattered just once, the coherent scattering signal, as a function of incident photon energy for various materials at thicknesses of 1 μ m (dashed lines) and 100 μ m (solid lines)

UNCLASSIFIED

To see with time-dependence into and through the mesoscale requires: x-rays; coherent; brilliant and high repetition-rate; of sufficient high energy; and multiple probes at multiple scales

MaRIE 1.0 will enable us to observe and ultimately control the time-dependent properties of materials that affect materials performance

MaRIE 1.0: A Flagship Facility for Predicting and Controlling Materials in Dynamic Extremes

A proposal submitted by Los Alamos National Laboratory in response to the NNSA call for New Flagship Experimental ST&E Facility Concepts.

A mission need exists for a facility focused on predicting and controlling materials in extreme environments, exploiting *in situ* transient measurements on real materials in relevant dynamic extremes to **address national security challenges through accelerated qualification, certification, and assessment.**

Achieving controlled functionality at the mesoscale through co-design is the **frontier of materials research.**

MaRIE 1.0 meets this need with a robust preconceptual reference design that is grounded in **community-defined mission and scientific requirements.**

Slide 32

MaRIE 1.0 is about *both* time-dependent control of making materials, and measurements of their time-dependent performance

- Materials Design is the integration of **structure** and **processing** to achieve a desired **property** of a material, all of which determines the **performance** of an engineering system with the intent to
 - (A) develop new materials and properties,
 - (B) select functions of materials for applications, or
 - (C) optimize performance of a given material.

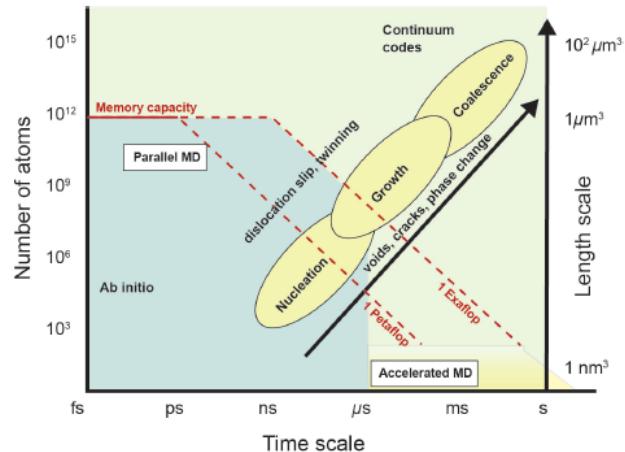

Vision: MaRIE provides process-aware manufacturing R&D capability that integrates in-situ diagnostics with real-time adaptive modeling for concurrent feed-back control at the mesoscale for "born-qualified" materials.

Some parameters from a few example experiments*:

Quantity	Description	Example 1	Example 2	Example 3
Z	Sample atomic number	26 (Fe)	92 (U)	92 (U)
λ	Source wavelength (\AA)	0.25	0.25	0.3
E_γ	Photon energy (keV)	50	50	41.3
d	Spot size (μm)	100	100	120
t	Sample thickness (μm)	500	100	200
iFOM	Imaging figure-of-merit	400	500	120
O_\perp	Transverse oversampling factor	2	2	2
p	Pixel size (μm)	12.5	12.5	12.5
$D = O_\perp \text{ iFOM } p$	Detector size (cm)	1.0	1.25	0.3
L	Sample-detector distance (m)	100	100	100
$\phi_{\max} = \tan^{-1}(D/2L)$	Maximum scattering angle (rad)	5×10^{-5}	6.3×10^{-5}	1.5×10^{-5}
$\Delta x = L\lambda/D$	Transverse image resolution (nm)	250	200	1000
$\Delta z = 4\lambda L^2/D^2$	Longitudinal resolution (cm)	1.0	0.64	13
$\text{Fr} = d^2/\lambda L$	Fresnel number	4.0	4.0	5
$\text{An} = D^4/\lambda L^3$	Small angle number	4×10^{-4}	1×10^{-3}	3×10^{-6}
η_{QE}	Detector quantum efficiency	90%	90%	90%
P	Average photons per pixel	400	100	100
$1/\sqrt{P}$	Average-per-pixel noise-to-signal	5%	10%	10%
N_0	Required incident photons for imaging [Eq. (33)]	1.3×10^{10}	6.4×10^9	1.5×10^{10}
N_{1C}	Coherently-scattered photons for imaging [Eq. (31)]	2.8×10^8	1.1×10^8	6.4×10^6
N_{1C}/N_0	Fraction coherently scattered	2.3%	1.7%	0.04%
ΔT	Average temperature rise (K) [Eq. (35)]	3.4	27	23

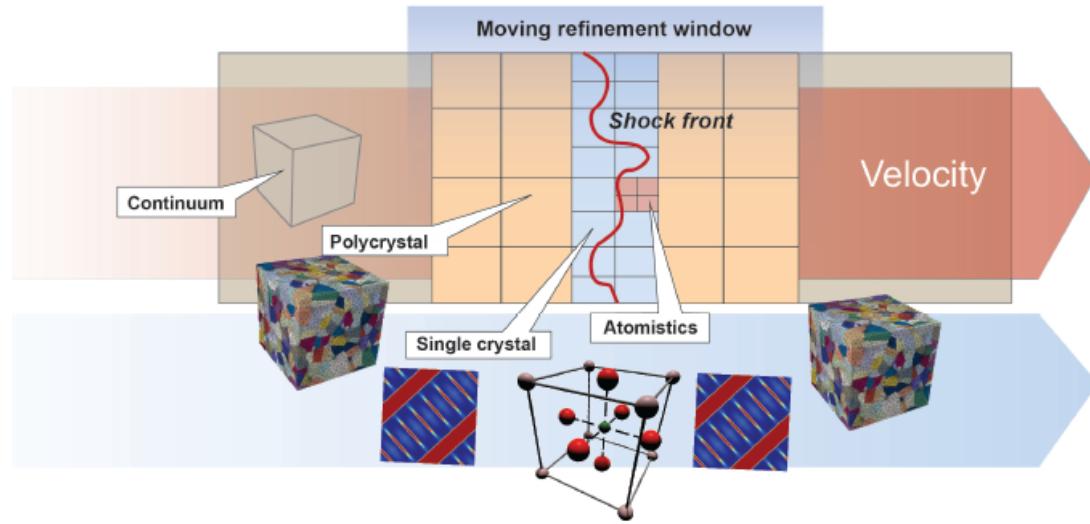

* Taken from PRB 89 184105 (2014).

The coupling of multi-scale theory and multi-probe experiments on next-generation computing architectures for future integrated codes is key to our success.

Mesoscale materials phenomena need extreme-scale computing

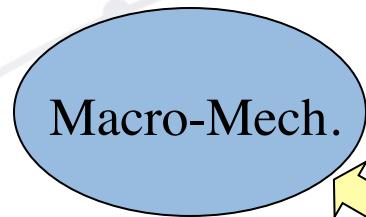

Variable-resolution models are synergistic with multi-probe, *in situ*, transient measurements

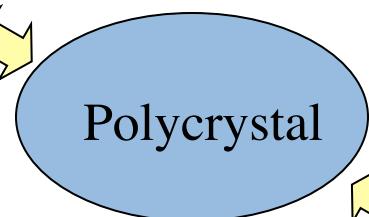

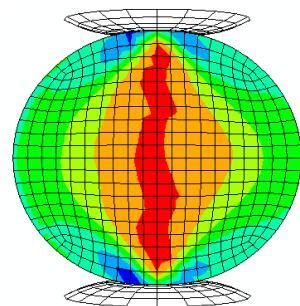

The development of MaRIE-validated models will **reduce uncertainty** in integrated codes and provide **predictive descriptions of materials & components** during **manufacturing** and **in dynamic extremes**

Experimental ties to Theory for both manufacture and performance is critical

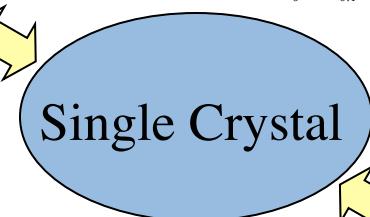

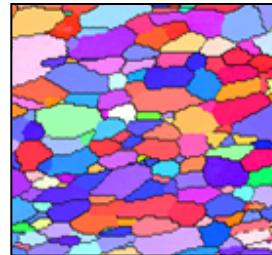

A number of codes are used
