Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Little Grand Wash Fault, Crystal Geyser, Utah

- Observations along the surface exposure of the Grand Wash fault indicate alteration zones of 10-50 m width with spacing on the order of 100 m
- Locations of conduits controlled by fault-segment intersections and topography
- Sandstone permeability reduced by 3 to 4 orders of magnitude in alteration zones by carbonate cementation

Reactive Transport Modeling Framework

- Pore scale reactive transport model can provide a tool to develop functional forms of reaction rates for CaCO_3 precipitation and dissolution as a function of system parameters based on fundamental principles without model assumptions
- Pore-scale modeling results will be able to develop the response functional forms of permeability, porosity, and surface area changes as a function of pore structures, volume, Pe, Da number, mineral types, and influent solution chemistry
- Response surface results can be used as input for continuum scale reactive transport modeling

System parameters

Flow rate, Mineral type

Chemistry (e.g., pH & CO_3 conc)

Not far from equilibrium ($\log Q = \sim 0.7$)

Far from equilibrium ($\log Q = \sim 3.7$)

Pore Scale Model Framework

Lattice Boltzmann Method:
Velocity field (u) at pore scale

Velocity at 1 micron resolution

Finite Volume Method: Reactive transport at pore scale

Δt

$\Psi_j = C_j + \sum_{i=1}^{N_{eq}} v_{ji} C_i$ Chemical equilibrium in bulk fluid (e.g., H^+ , HCO_3^- , ...)
Extended Debye-Hückel Equation for activity coefficients

$$D \frac{\partial \Psi_j}{\partial \mathbf{n}} = -I_m \quad \text{on reactive surface}$$

$$I_m = k_{cc} \left([\Omega]^n - 1 \right)^m \quad \Omega = \frac{Q_{cc}}{K_{sp}} \text{ or } \ln \left(\frac{Q_{cc}}{K_{sp}} \right)$$

Update of $CaCO_3$ volumetric content (V_m)

$$\frac{\partial V_m}{\partial t} = \overline{V}_m s_m k_{cc} \left(\left[\frac{a_{Ca^{2+}} a_{CO_3^{2-}}}{K_{sp}} \right]^n - 1 \right)^m$$

Functional Relationships based on Pore Scale Simulations

- Pe & Da numbers

$$Pe(uL/D) = 0.08, 0.8, 8$$

$$Da(kL/(K_{sp}^{0.5} \times D)) = 0.002, 0.02, 0.1$$

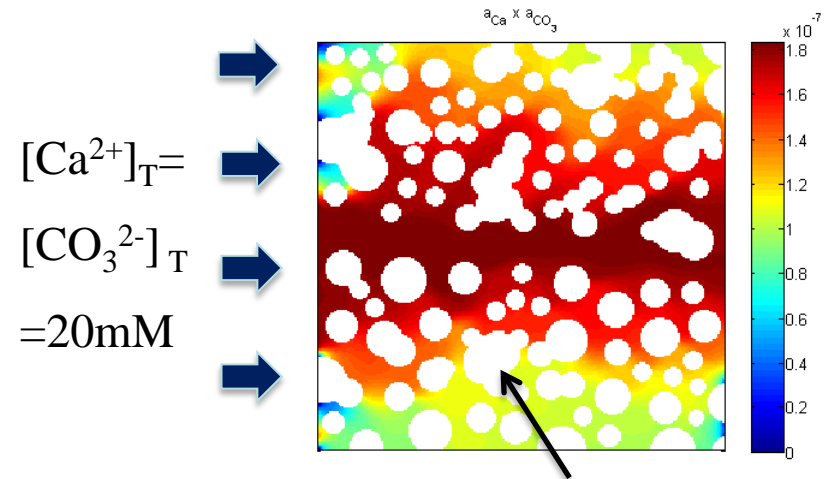

$$(K_{sp, \text{calcite}} = 3.3 \times 10^{-9} \text{ M}^2)$$

- Chemical speciation

Speciation: Ca^{2+} , H^+ , CO_3^{2-} , HCO_3^- , H_2CO_3

No speciation: Ca^{2+} , CO_3^{2-}

- Pore structures

Direction of precipitation and pore clogging

Medium Pe & High Da

Flow

High Pe & Low Da

Flow

- Simulation results under two different Pe and Da regimes show fast precipitation from the top – this example show multiple possible pathways for field observations

High Pe & High Da

CaCO₃ volumetric content

↑ $[Ca^{2+}]_T = [CO_3^{2-}]_T = 20\text{mM}$

- Precipitation occurs near the main fault and clogging of fracture networks moves away from the main fault conduit as observed in the outcrop

Summary

- Fault-controlled CO₂ leakage conduits are sites of preferred carbonate pore and fracture cementation
- Carbonate cementations significantly increases caprock sealing capacity
- Vigorously tested pore-scale model was used to develop a permeability and porosity (k - ϵ) relationship for continuum-scale model
- Pore scale model was able to qualitatively capture pore clogging patterns in a simple fracture network model mimicking the Little Grand Wash fault
- An adaptive strategy to couple pore- and continuum scale will be tested against cement precipitation patterns observed in the Little Grand Wash fault
- Algorithms developed in this work will be implemented into a continuum scale reactive transport model

Simple chemistry & mineralogy

- Spring water: Low temperature and Mg concentrations; high concentrations of dissolved CO_2 ($p\text{CO}_2 = \sim 100 \text{ kPa}$)
- Aragonite precipitation indicates large, sudden increase of supersaturation with respect to CaCO_3 in solution \rightarrow high CO_2 degassing rate
- Both calcite and aragonite are present

Continuum Scale Reactive Transport Modeling

- Simplified, two-dimensional response surface
- Permeability reduction due to CaCO_3 precipitation is a function of cumulative pore volume (Q) of groundwater and fluid pressure (P)
- Fluid pressure is taken as a gross proxy for chemical conditions in which higher CaCO_3 solubility is associated with higher fluid pressure (greater depth)

Crystal Geyser Site: Grand Wash Fault Modeling

- Unconditional geostatistical simulation
- Initial simulated steady-state flow pattern is qualitatively similar to the spacing of seeps along the Grand Wash fault (~100's of m between locations of groundwater discharge)
- Transient flow simulation includes explicit updating of permeability (k) at each time step using the response surface (FEHM)
- k is reduced by several orders of magnitude by calcite precipitation, primarily in the shallower high-flow channels
- Evolution of the flow field results in more dispersed groundwater discharge at the surface

Functional relationships based on Pore Scale Simulations

- Vigorously tested pore-scale model can be used to develop a response function (or dimension reduction model) for continuum-scale permeability and porosity (k - ε) relationships
- k - ε and surface area- ε relationships will be developed over a range of solution chemistry, chemical reaction, and pore structure configurations in addition to Pe and Da numbers

Changes in porosity due to precipitation ~tortuosity and permeability by phenomenological power law relations

$$\tau(\varphi) = \tau_0 \left(\frac{\varphi}{\varphi_0} \right)^n \quad k(\varphi) = k_0 \left(\frac{\varphi}{\varphi_0} \right)^n \quad a_{cc} = a_{cc}^0 \left(\frac{\varphi}{\varphi_0} \right)^{2/3}$$
