1.0 Purpose

AET-1 was tasked by ADEM with determining the temperature rise in the drum contents of drums stored in the Dome 375 Perma-Con® at TA-54 given a wildland fire. The wildland fire causes radiative and convective heating on the Perma-Con® exterior. The wildland fire time histories for the radiative and convective heating environment were provided to AET-1 by EES-16. If the calculated temperature rise results in a drum content temperature over 40 °C, then ADEM desires a design solution to ensure the peak temperature remains below 40 °C.

2.0 Methodology

Microsoft Excel spreadsheets with time history columns for gas temperature (the air temperature around the Perma-Con®), convective heating environment and radiative heat flux were generated by EES-16. Three separate time histories were provided, with each being seen as having the potential to be a worst case wildland fire scenario. AET-1 then generated a Finite Element (FE) model using ANSYS Workbench 17.0. The time history information was input into the FE model as transient boundary conditions on the Perma-Con® exterior and the FE model was solved. The temperature results of the drum contents were then checked to see if temperatures exceeded the 40 °C limit.

3.0 Acceptance Criteria

ADEM required that the post wildland fire temperature results of the drum contents remain below 40 °C. If that temperature is exceeded, a design solution that ensures the peak temperature remains below 40 °C is required.

4.0 Open Items

None.

5.0 Assumptions

The following assumptions were made to simplify this analysis:

a. The Perma-Con®, drum, drum contents and concrete floor slab can be modeled using axi-symmetry.
    i. This is a conservative assumption as the axi-symmetric geometry limits the distance between the drum and the Perma-Con® interior wall as well as reduces the thermal mass associated with an array of drums and the thermally radiative area of the concrete floor slab.
b. The initial temperature used for the analysis is 23.89 °C (75 °F).
    i. This is the maximum allowable temperature of the drums per AREAG-ESS-14-002-R5 (Reference 1).
c. The exterior emissivity of the Perma-Con® is taken as 1.
    i. This is a conservative assumption as the calculated blended (panel, steel frame, door, etc.) emissivity of the Perma-Con® exterior is 0.393. The reasoning is that the Perma-Con® is covered in dust, ash and soot which has an emissivity near 1.
d. The drum is not in physical contact with the concrete floor slab.
    i. This is a conservative assumption as physical contact between the drum and floor slab would allow the concrete floor slab to cool the drum by conduction.
e. Free air is not modeled inside the Perma-Con®.

   i. The inclusion of free air inside the Perma-Con® would allow for conduction from the Perma-Con® wall to the drum and would allow for convective heat transfer to/from the drum by the temperature gradient driven buoyancy of the air. The thermal properties (conductivity and specific heat) of air are orders of magnitude less than those of the other materials (steel and concrete) present in the analysis. That fact, coupled with the short time duration of the wildfire induced heating of the Perma-Con®, render the inclusion of air in the model unnecessary.

f. Natural convection of the drum air is not modeled.
   i. The thermal properties (conductivity and specific heat) of air are orders of magnitude less than those of the other materials (steel and concrete) present in the analysis. That fact, coupled with the short time duration of the wildfire induced heating of the Perma-Con®, render the inclusion of natural convection of the drum air in the model unnecessary.

g. After the wildfire event has passed a natural convection coefficient, h, value of 5 W/m^2*K is assumed on all Perma-Con® exterior surfaces to simulate buoyancy driven cooling on the surfaces.
   i. This is considered conservative as there would be some wind (forced convection) and depending on the temperature rise of the Perma-Con®, the value for h could be as high 7 W/m^2*K.

h. After the wildland fire, a 2,000 W/m^2 radiative flux is assumed as a residual heat flux from the environment for an additional 91 seconds. The total duration of the wildland fire from when the peak flux rises beyond 2,000 W/m^2 and then declines down to 2,000 W/m^2 is 91 seconds.
   i. This is considered a conservative assumption since the majority of fuel near the Perma-Con® location is grass, which is not cable of producing long lasting embers.

6.0 Limitations

1. The input time histories for the radiative and convective heat transfer were provided to AET-1 by EES-16 (References 2, 3, 4 and 5). Any questions about how these time histories were derived should be directed towards Rod Linn and Eunmo Koo of EES-16. The values used in this calculation are included as Appendix B.
2. The property values for the drum contents were determined by Southwest Research Institute and documented in a report dated September 23, 2015 (Reference 6). This report is included as Appendix C.
3. The emissivity values for the Perma-Con® were measured by Bob Reid of AET-1. These values were documented in Memo #: AET-1-16-003 (Reference 7) and are included in Appendix D.
4. All emissivity values used in the calculation are room temperature values and do not vary with temperature.

7.0 Calculation Inputs

The axi-symmetric FE model geometry, dimensions and boundary conditions are shown in Figure 1.

Overall Drum Height = 34.9 in
Drum Air Height = 26.2 in
Drum Contents Height = 8.7 in

Drum OR = 12.0 in
Drum Wall Thickness = 0.05 in

SWB Height = 35.4 in
SWB OR= 12.26 in

SWB Wall Thickness = 10 GA (0.134 in)

Perma-Con® Height = 144 in
Perma-Con® Wall Thickness = 0.25 in

Concrete Height = 6 in
Concrete OR = 51.3 in

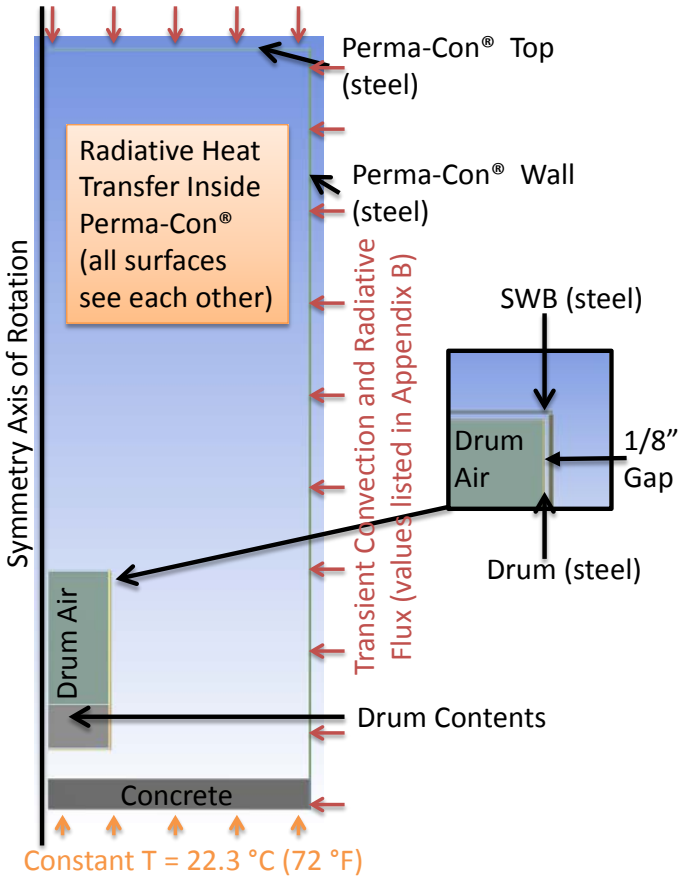

Figure 1: FE Model Geometry and Dimensions

The initial temperature for all objects in the model is 23.89 °C.

The material properties used in the model for air, steel (Permacon, drum and SWB), concrete and the drum contents are shown in Figure 2. The drum content material properties were taken from Reference 5.

Figure 2: Material Properties

The transient wildland fire boundary conditions are provided in Appendix B. These values include air temperature, convection coefficient and radiative flux, which are all boundary conditions applied to exterior of the Perma-Con® as shown in Figure 1.

Emissivity values for the white paint on the drum/SWB and the concrete were taken from Reference 8 and were input as the constant values shown in Figure 3.

Surface	Emissivity
Drum & SWB (white paint)	0.9
Concrete	0.93
Perma-Con® (interior)	0.393
Perma-Con® (exterior)	1

Figure 3: Emissivity Values

Emissivity values for the Perma-Con® exterior were measured as documented in Reference 7. As mentioned in Section 5 above, the emissivity of the Perma-Con® exterior was conservatively assumed to be 1 due to dust and ash covering the Perma-Con® exterior. For the interior a blended emissivity was calculated to avoid creating a 3-D model of the Perma-Con®. The blended emissivity was calculate to be 0.393. This calculation is included as Appendix E.

9.0 Summary and Conclusions

An axi-symmetric FE simulation was completed to determine the peak temperature of the contents of a drum stored in the Dome 375 Perma-Con® during a wildland fire event. Three wildland fire time histories for the radiative and convective heat transfer were provided by EES-16 and were inputs for the FE simulation. The maximum drum content temperature reached was found to be 110 °C while using inputs from the SiteG_2ms_4ign_wind_from_west.xlsx time history input and not including the SWB in the model. Including the SWB in the results in a peak drum content temperature of 61 °C for the SiteG_2ms_4ign_wind_from_west.xlsx inputs. EES-16 decided that by using fuel mitigation efforts, such as mowing the grass and shrubs near the Perma-Con® they could reduce the shrub/grass fuel loading near the Perma-Con® from 1.46 kg/m^2 to 0.146 kg/m^2 and by using a less conservative fuel loading for the debris field inside the Dome 375 perimeter, reducing it from 0.58 kg/m^2 to 0.058 kg/m^2 in their model. They also greatly increased the resolution of their radiation model and increased the accuracy of their model's required convergence value. Using this refined input the maximum drum content temperature was found to be 28 °C with no SWB present in the model. Additionally, this refined input model was modified to include worst case emissivity values for the concrete, drum and Perma-Con® interior, along with adding a 91 second long residual radiative heat flux of 2,000 W/m^2 to the end of the refined wildland fire input. For this case the maximum drum content temperature was found to be 32 °C. For Rev. 2 of this calculation and additional simulation was run that included a cable fire heat flux on the exterior of the Perma-Con® that was calculated by FP-DO. Including the cable fire heat flux in the model without the SWB resulted in a peak drum content temperature over time of 43 °C. Including the SWB in the simulation with the cable fire heat flux resulted in a peak drum content temperature over time of 35 °C.

11.0 Calculation

The entirety of the output reports for each FE analysis completed for this calculation is included in Appendix A. These reports contain the detailed setup information for the calculations and can be used to recreate the calculations from scratch. The highlights of the results are discussed in more depth below.

Figure 4 shows the transient peak temperature of the drum contents resulting from the three wildland fire time histories for the radiative and convective heat transfer provided by EES-16. This model did not include the SWB and the interior of the Perma-Con® radiates directly to the drum. The file SiteG_2ms_4ign_wind_from_west.xlsx produced the maximum drum content temperature, which was 110 °C.

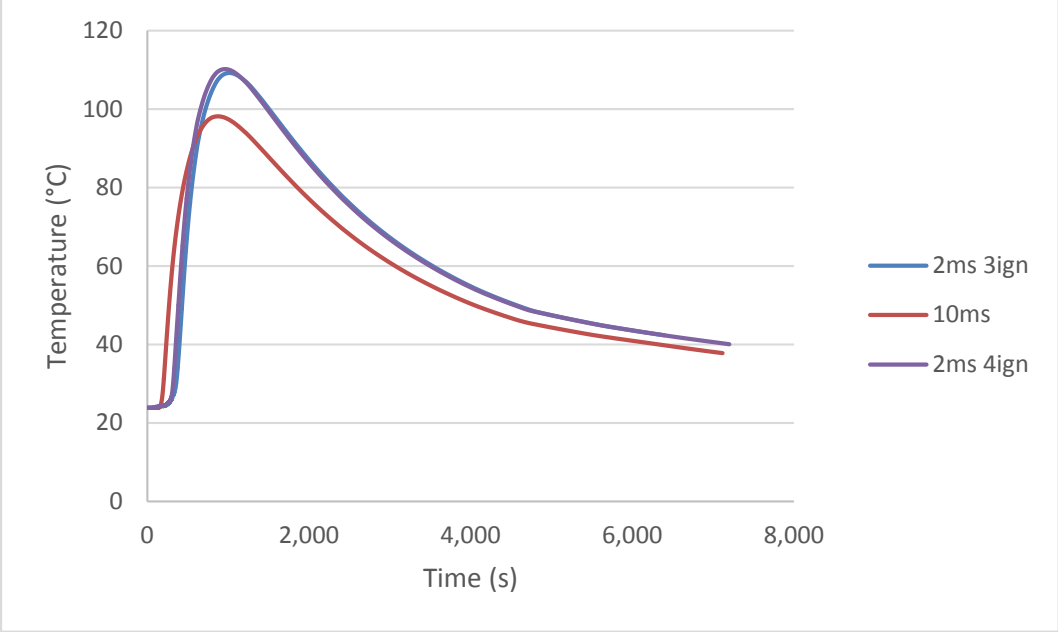

Figure 4: Maximum drum content temperature results for the three wildland fire inputs, no SWB

Since the maximum drum content temperature was over 40 °C, the SWB was added to these models, as shown in Figure 1. The Perma-Con® now radiates to the SWB which, in turn, radiates

to the drum. With the SWB included, the file SiteG_2ms_4ign_wind_from_west.xlsx produced the maximum drum content temperature, 61 °C. These results are shown in Figure 5.

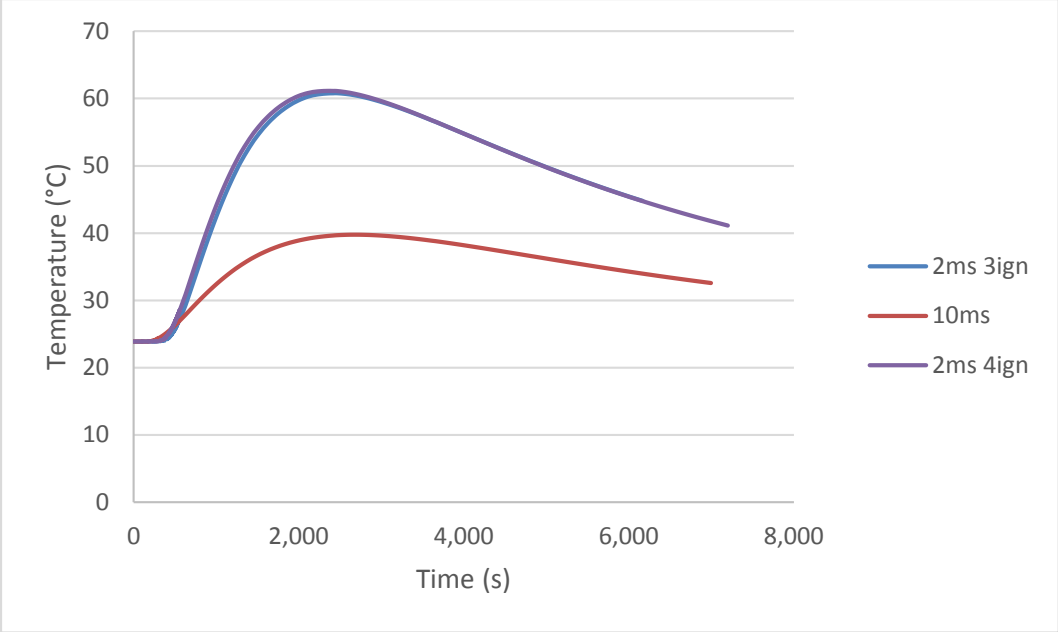

Figure 5: Maximum drum content temperature results for the three wildland fire inputs, with SWB

Adding the SWB did not result in keeping the drum content temperature below 40 °C. Therefore EES-16 looked at what could be readily accomplished to mitigate the fire loading near the Perma-Con®. Risk mitigation experts have now scheduled periodic mowing of the grasses near Dome 375. This will reduce the grass fuel load near the Perma-Con® from 0.146 kg/m^2 to 0.146 kg/m^2. Additionally, a decision was made to use a less, but still, conservative loading for the debris within the perimeter of Dome 375, reducing the load from 0.58 kg/m^2 to 0.058 kg/m^2. This resulted in the Reference 4 output file. As part of this effort EES-16 refined their radiation model resolution as well. The required accuracy for the convergence criteria of their model was also increased. Figure 6 shows the results for the solid parts in the FEA model using this input file. The maximum temperature of the drum contents for this case is 28 °C.

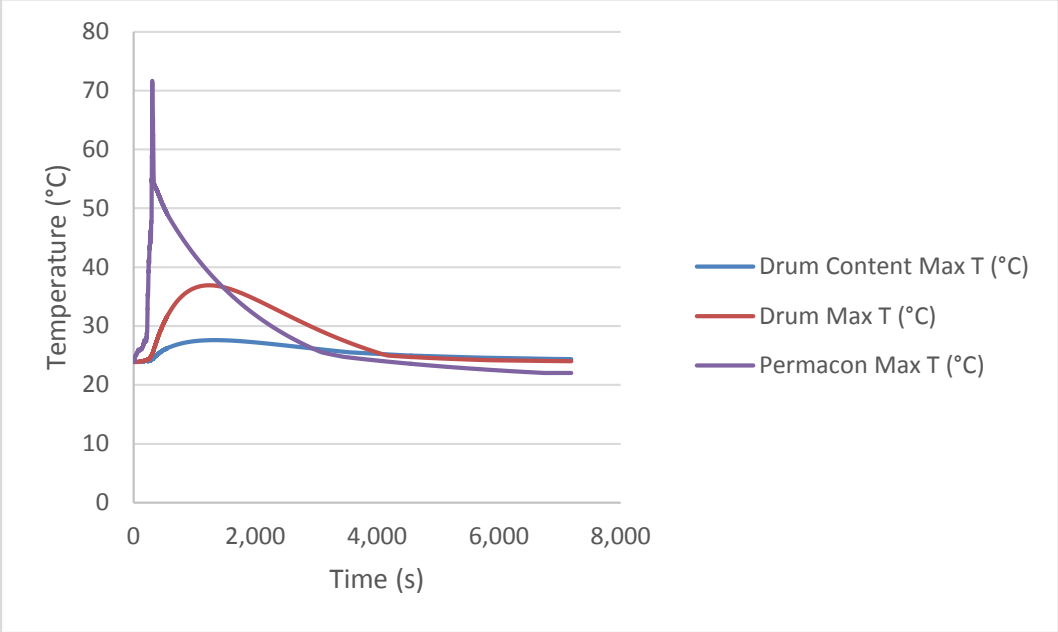

Figure 6: Maximum temperature results for the refined radiation inputs (Reference 4)

A mesh study was completed on the FE model for which the results were shown in Figure 6. The number of elements in the model was increased from 982 to 3,928 elements. The peak temperature of the drum contents remained at 28 °C.

To determine if these results were overly sensitive to emissivity measurements, which may vary with temperature, the FE model used for the Figure 6 results was altered to have a concrete emissivity of 0.0001 and the interior Perma-Con® emissivity and drum emissivity were set as 1. Reducing the emissivity of the concrete, reduced the amount of heat energy from the drum and Perma-Con® that could radiate to the cooler concrete. Likewise raising the emissivity of the Perma-Con® and drum increased the heat transfer between them, since with the reduction of the emissivity of the concrete, there is no substantial heat sink. Additionally, the residual flux of 2,000 W/m^2 was added to the back end of the wildland fire transient radiative flux for 91 seconds (see

Section 5 of this calculation). For this case the maximum temperature of the drum contents was found to be 32 °C.

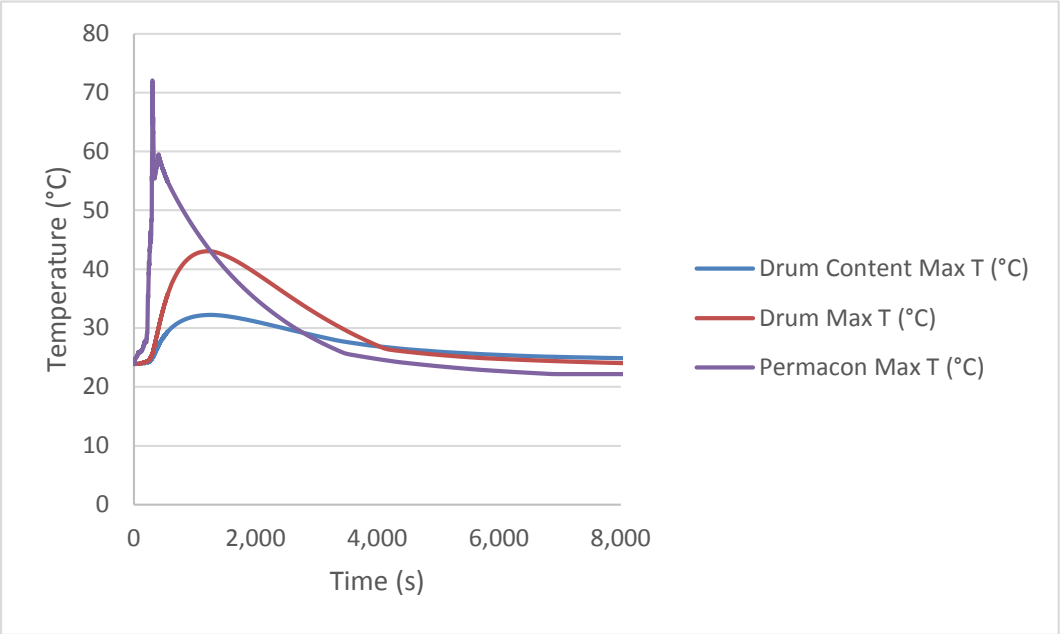

Figure 7: Maximum temperature results for the refined radiation inputs (Reference 4) with concrete emissivity set to 0.0001 and interior Permacon and drum emissivity set to 1

EES-16 provided an additional heat flux that was calculated through an under resolved Monte Carlo calculation (red smoothed curve in Figure 7). This artificially-high heat flux was approximately seven times greater than the refined radiant heat flux calculation described above. This curve was used to test the sensitivity of the FE model to uncertainty in the wildland fire model calculations. Figure 7 shows this bounding case in bold red line which envelopes all the higher resolution radiative heat fluxes which converge as convergence criteria is decreased and Monte Carlo ray numbers are increased. Note that this red line is a only used for sensitivity testing and that the results presented in Figure 6, which correlate to the purple line in figure 7, represent the results of what EES-16 considers the worst case wildland fire inputs.

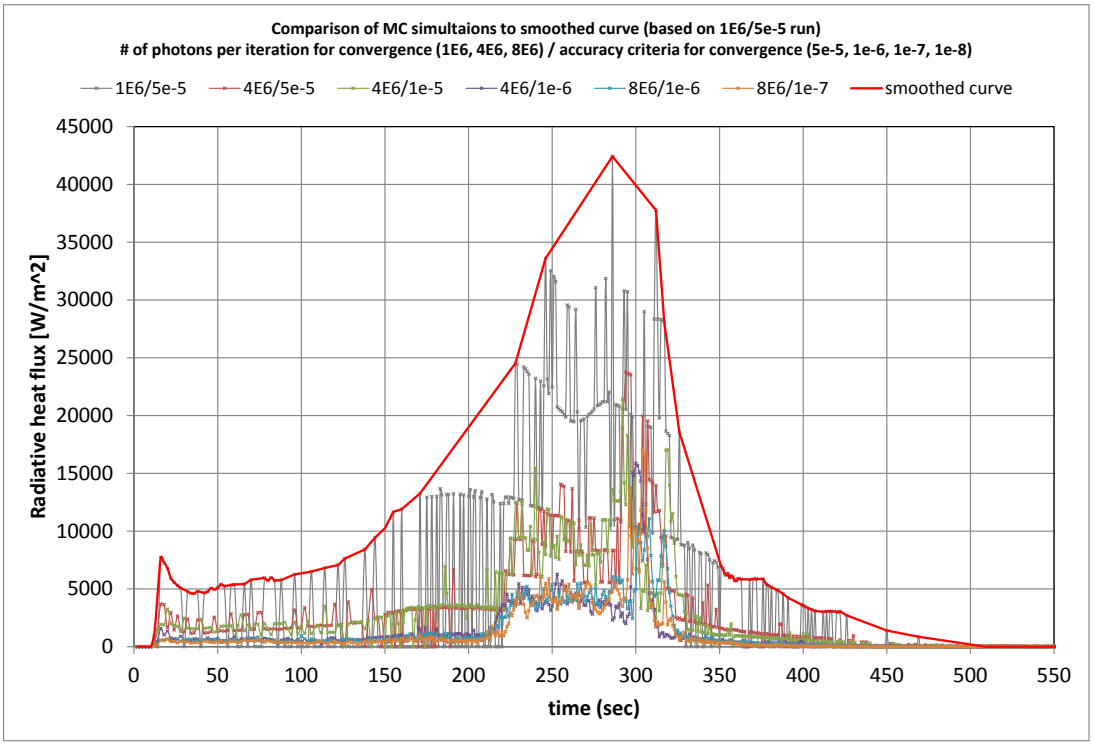

Figure 7: Bounding curve for higher resolution radiative heat flux inputs

Inputting this seven times higher total radiative heat flux input into FEA model (with SWB) yields the results shown in Figure 8. For this case the maximum temperature of the drum contents is 61 °C. A seven times increase in the radiative flux that heats the Perma-Con® exterior results in a 2.2 times increase in drum content temperature.

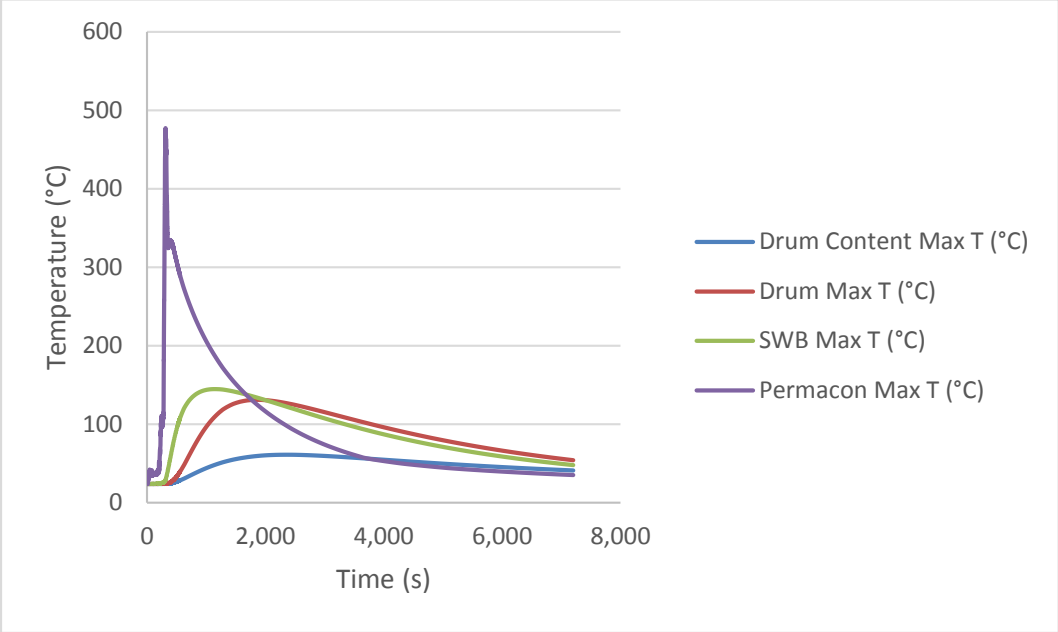

Figure 8: Maximum temperature results using the bounding radiative flux input

Additionally, a simple ODE was solved to compare the FE results to as a sanity check. This calculation is included as Appendix F and the results show that if the Perma-Con® is at 72 °C (the maximum temperature of the Perma-Con® for the case shown in Figure 6 is 72 °C) it would take over three hours for the average bulk temperature of the thermal mass equivalent (as opposed the maximum at any point in the drum contents, which is what the FE results show for maximum temperature) of the drum contents to reach 40 °C. By comparison the longest wildfire event provided by EES-16 is less than ten minutes.

For Revision 2 of this calculation, a simulation with a cable fire on the exterior of the Perma-Con® was completed. The details of how the cable fire transient heat flux was determined are included in Reference 10 and a plot of the transient heat flux for the cable fire is shown in Figure 9. Note that the heat flux calculated in Reference 10 was reduced by 50% as an input into this calculation. In reality the cables are only installed on one wall of the four sided Perma-Con®, over a maximum length of 15 feet. Since the Perma-Con® to drum heat transfer simulation uses axi-symmetry, which results in the drum being completely surrounded by the cable fire heat flux, a 50% reduction in the flux is considered conservative. Note also that the use of axi-symmetry in the model greatly reduces the thermal mass of the Perma-Con® structure and only allows for the inclusion of a single drum, a reduction in the mass of potential heat sinks. This must conservatively result in higher temperatures for the Perma-Con® and drum as compared to modeling the entire Perma-Con® and drum array.

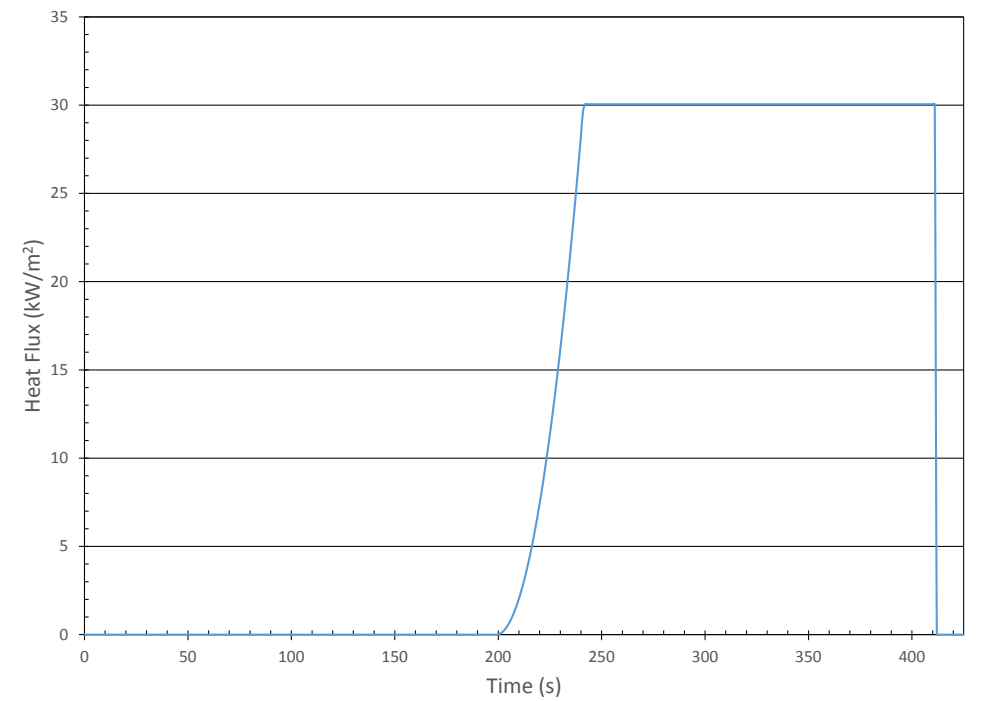

Figure 9: Cable Fire Transient Heat Flux Input

The cable fire heat flux was added as a heat flux on the boundary shown in Figure 10. ANSYS allows stacking of heat fluxes on the same surface, so the wildland fire heat flux was left unaltered and acts on all exterior Perma-Con® surfaces.

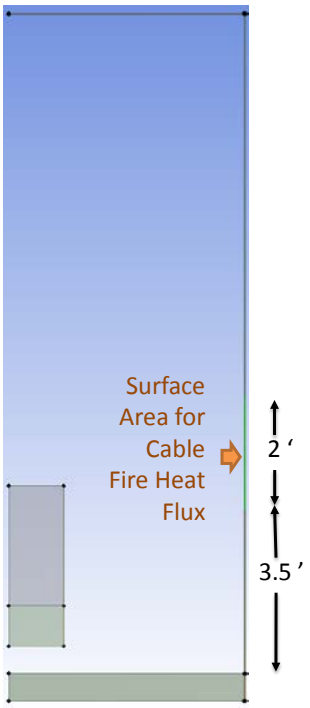

Figure 10: Cable Fire Heat Flux Location on Perma-Con® Exterior

The cable fire heat flux was added to the model with results shown in Figure 6. The maximum temperature of the drum contents with the cable fire present is 43 °C. The simulation results are shown in Figure 10.

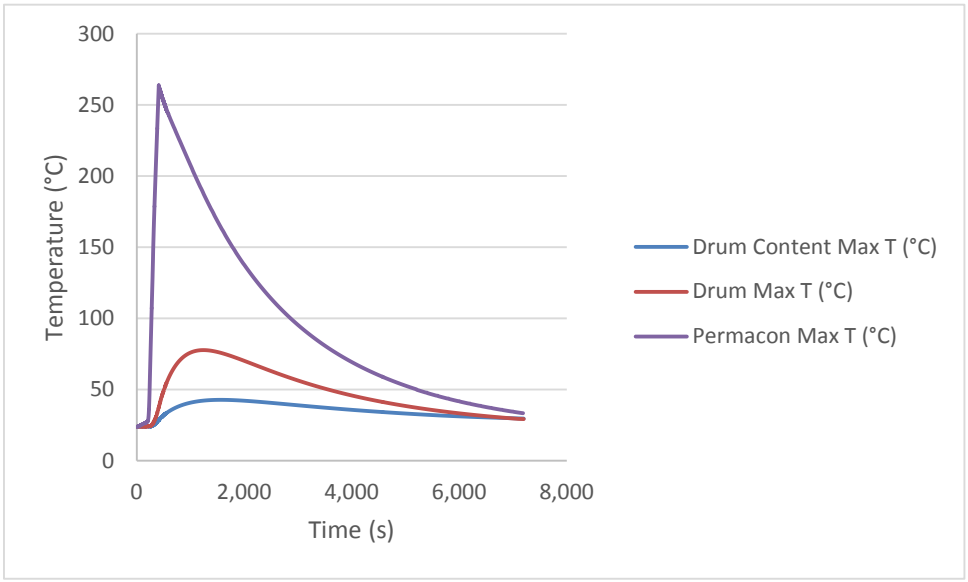

Figure 10: Maximum temperature results for the refined wildland fire radiation inputs (Reference 4), cable fire inputs (Reference 10) without the SWB present

Since the drum content temperature was over the allowable value of 40 °C, an SWB was added to the axisymmetric model. The dimensions of the SWB are shown in Figure 1. With the SWB present the maximum temperature of the drum contents over time was found to be 35 °C. Figure 11 shows the transient results for the case with the cable fire heat flux with SWB present.

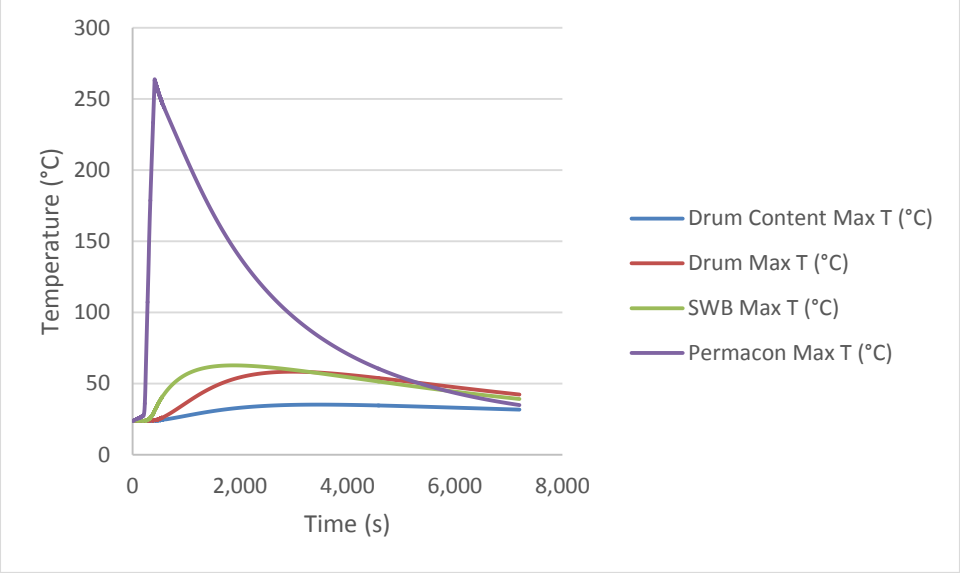

Figure 11: Figure 6: Maximum temperature results for the refined wildland fire radiation inputs (Reference 4), cable fire inputs (Reference 10) with the SWB present

TABLE 17
Model (L4) > Transient Thermal (L5) > Loads

Object Name	*Temperature*	*Radiation 2*	*Radiation 3*	*Radiation 4*	*Radiation 5*	*Radiation 6*	*Radiation 7*	*Convection*	*Heat Flux*	*Radiation*
State	Fully Defined									
Scope										
Scoping Method	Geometry Selection									
Geometry	1 Edge	2 Edges	1 Edge	4 Edges	1 Edge	2 Edges	1 Edge	5 Edges		
Definition										
Type	Temperature	Radiation						Convection	Heat Flux	Radiation
Magnitude	22.25 °C (step applied)								Tabular Data	
Suppressed	No									
Correlation		Surface to Surface								To Ambient
Emissivity		0.9 (step applied)	0.393 (step applied)	0.9 (step applied)	0.393 (step applied)	0.9 (step applied)	0.93 (step applied)			1. (step applied)
Enclosure		1.								
Enclosure Type		Perfect								
Film Coefficient								Tabular Data		
Ambient Temperature								Tabular Data		16.85 °C (step applied)
Convection Matrix								Program Controlled		
Edit Data For								Film Coefficient		
Tabular Data										
Independent Variable								Time
