- ❖ Computational Challenges

## Surrogate Modeling

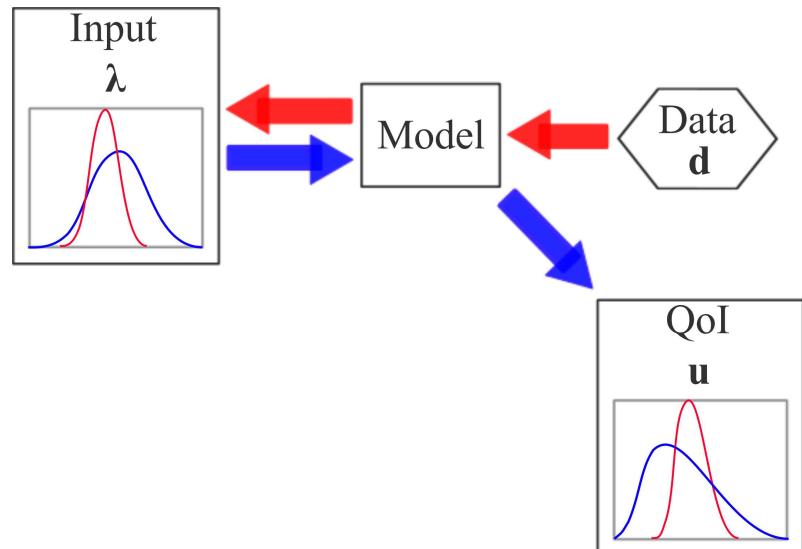

### Polynomial Chaos Expansion

### Application to Reacting Flows

### Hybrid PCE-Padé Approximant surrogates

### Application to Chemical Kinetics

## Conclusion

- UQ in computational models:
  - ◆ Validation of physical models
  - ◆ Statistical inverse problems
  - ◆ Calibration and design optimization
  - ◆ Use of computational predictions for decision-support
  - ◆ Assessment of confidence in computational predictions
- UQ methods:
  - ◆ Local sensitivity analysis and error propagation
  - ◆ Fuzzy logic; Evidence theory
  - ◆ Probabilistic framework; Measure theory
    - Sampling (Monte Carlo)
    - Polynomial Chaos

# Computational Challenges

## Conclusion

---

- Solution of statistical inverse problems and optimization problems can be computationally taxing
  - ◆ Large dimensionality of the input space
  - ◆ Large-scale forward model (arising from PDEs)
  - ◆ Complex (non-linear) behavior is input-output map
- Reducing computational cost:
  - ◆ Reducing dimension of input space
    - Parameter-space reduction
    - Truncated Karhunen-Loève expansions for stochastic processes
  - ◆ Reduction in number of forward simulations
    - Smarter sampling schemes for inverse problems
    - More efficient optimization algorithms
  - ◆ Reducing cost of forward simulations
    - **Surrogate models**
    - Reduced-order models
    - Multigrid/multiscale approaches

# Surrogates for Forward Models

Introduction

Surrogate Modeling

❖ Surrogates for  
Forward Models

Polynomial Chaos  
Expansion

Application to Reacting  
Flows

Hybrid PCE-Padé  
Approximant surrogates

Application to Chemical  
Kinetics

Conclusion

- Classically, surrogate models can be categorized into [Eldred et al., 2004]
  - ◆ Data-fit models
    - Based on interpolation or regression
    - Rely on repeated forward simulations (Black-box)
    - Examples: Gaussian processes, radial basis functions
  - ◆ Reduced-order models
    - Derived using a projection framework
    - Rely on full forward problem simulations, or "snapshots"
    - Examples: Proper orthogonal decomposition, reduced basis methods
  - ◆ Hierarchical surrogate models
    - Based on constructing a series of physics-based models of decreasing accuracy
    - Rely on using high and low accuracy models in tandem
    - Examples: mesh coarsening methods, alternative basis expansions

# Polynomial chaos expansion surrogates

Introduction

Surrogate Modeling

Polynomial Chaos  
Expansion

❖ Polynomial chaos  
expansion surrogates

❖ Polynomial Chaos  
Expansion (PCE)

❖ PCE example: a map  
from standard RV to QoI

Application to Reacting  
Flows

Hybrid PCE-Padé  
Approximant surrogates

Application to Chemical  
Kinetics

Conclusion

- Represent model inputs/outputs as random variables
- Construct PCEs for uncertain parameters
- Obtain PCEs for model outputs using *Non-intrusive Spectral Projection*:
  - ◆ *Sampling-based*
  - ◆ Relies on **black-box** utilization of the computational model
  - ◆ Evaluate projection integrals *numerically* using
    - A variety of Monte Carlo methods
      - ◆ Slow convergence;  $\sim$  indep. of dimensionality
    - Quadrature/**Sparse-Quadrature** methods
      - ◆ Fast convergence; depends on dimensionality

# Polynomial Chaos Expansion (PCE)

Introduction

Surrogate Modeling

Polynomial Chaos  
Expansion

❖ Polynomial chaos  
expansion surrogates

❖ Polynomial Chaos  
Expansion (PCE)

❖ PCE example: a map  
from standard RV to QoI

Application to Reacting  
Flows

Hybrid PCE-Padé  
Approximant surrogates

Application to Chemical  
Kinetics

Conclusion

- Model uncertain quantities as random variables (RVs)
- Any RV in  $L^2(\Omega, \mathfrak{S}(\xi), P)$  can be written as a PCE:

$$u(\mathbf{x}, t, \boldsymbol{\xi}) \simeq \sum_{k=0}^N u_k(\mathbf{x}, t) \Psi_k(\boldsymbol{\xi})$$

- $\boldsymbol{\xi} = \{\xi_1, \dots, \xi_n\}$  a set of *i.i.d.* RVs
- $u_k(\mathbf{x}, t)$  are coefficients (deterministic):

$$u_k(\mathbf{x}, t) = \frac{\langle u(\mathbf{x}, t, \boldsymbol{\xi}) \Psi_k(\boldsymbol{\xi}) \rangle}{\langle \Psi_k^2(\boldsymbol{\xi}) \rangle}$$

- $\Psi_k()$  are functions orthogonal w.r.t.  $p(\boldsymbol{\xi})$ 
  - ◆ e.g. Legendre polynomials with Uniform germ
- Advantage: numerous functional analysis methods
  - ◆ Computational efficiency
  - ◆ Sensitivity information

# PCE example: a map from standard RV to QoI

Introduction

Surrogate Modeling

Polynomial Chaos Expansion

❖ Polynomial chaos expansion surrogates

❖ Polynomial Chaos Expansion (PCE)

❖ PCE example: a map from standard RV to QoI

Application to Reacting Flows

Hybrid PCE-Padé Approximant surrogates

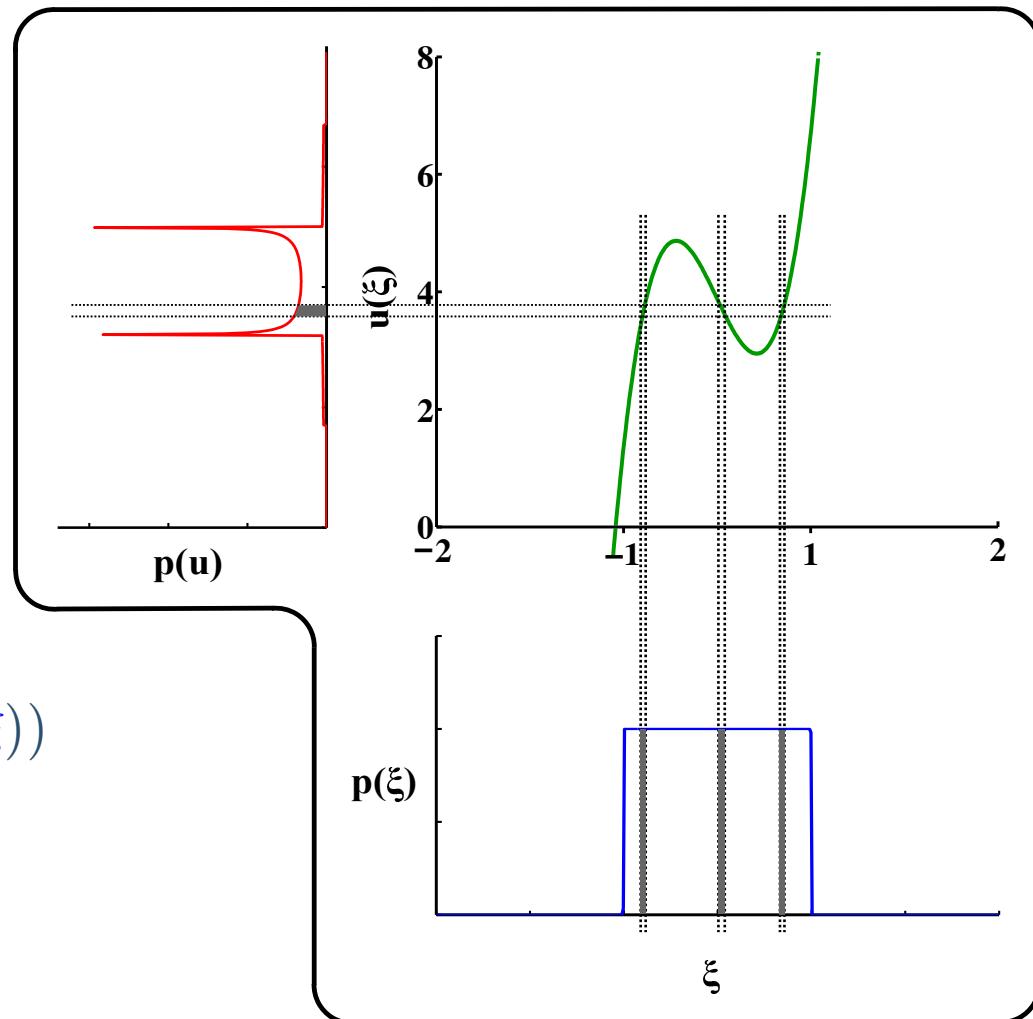

Application to Chemical Kinetics

Conclusion

$$u = \sum_{k=0}^P u_k \psi_k(\xi)$$

- $u$ : random variable
- $u_k$ : PC coefficients
- $\psi_k$ : 1D Legendre polynomial of order  $k$
- $\xi$ : Uniform RV

$$u = 4 + 2.25 \left( \frac{1}{2} (5\xi^3 - 3\xi) \right)$$

# Application: Turbulent bluff-body non-premixed flame

Introduction

Surrogate Modeling

Polynomial Chaos  
Expansion

Application to Reacting  
Flows

❖ Application: Turbulent  
bluff-body non-premixed  
flame

❖ Application: Numerics  
❖ Response Surfaces  
❖ Global Sensitivity  
Analysis

Hybrid PCE-Padé  
Approximant surrogates

Application to Chemical  
Kinetics

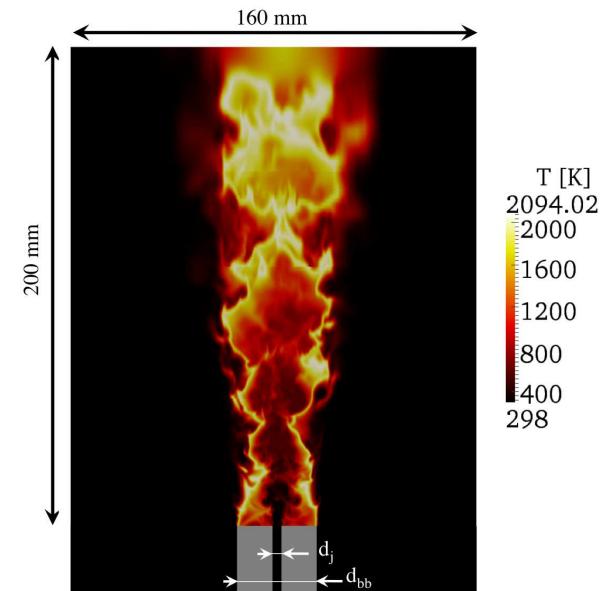

Conclusion

## Collaborators:

- Guilhem Lacaze, Joe Oefelein, and Habib Najm (Sandia)

## Flame specifications:

- Sydney Bluff-body burner
- Fuel: 50/50 mixture of methane and hydrogen injected at 108 m/s with coflow at 35 m/s at the combustor section

## Large-Eddy simulation theoretical framework [Oefelein 2006]:

- Fully-coupled, compressible conservation equations
- Transport of mass, momentum, energy and mixture fraction
- Combustion closure: Flamelet (tabulation of heat-release) with presumed-pdf
- Dynamic SGS modeling turned off

# Application: Numerics

Introduction

Surrogate Modeling

Polynomial Chaos  
Expansion

Application to Reacting  
Flows

❖ Application: Turbulent  
bluff-body non-premixed  
flame

❖ Application: Numerics

❖ Response Surfaces

❖ Global Sensitivity  
Analysis

Hybrid PCE-Padé  
Approximant surrogates

Application to Chemical  
Kinetics

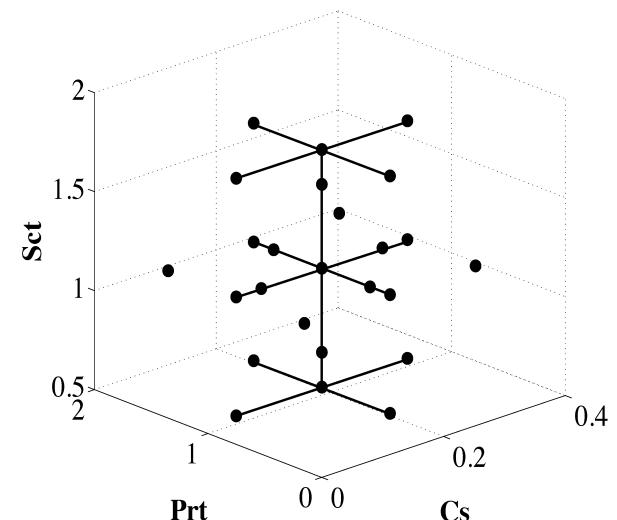

Conclusion

Current UQ investigation focuses on

- $0.065 < C_s < 0.346$  [Piomelli 1989]
- $0.5 < Pr_t < 1.7$  [Erlebacher 1992]
- $0.5 < Sct < 1.7$  [Reynolds 1976]

Computational aspects:

- 25 LESs: explore the parametric space and build surrogate
- 18 LESs: test surrogate accuracy
- Mesh: 12 million hexahedral cells
- Simulation is run for 400 ms to attain steady state and the subsequent 30 ms used to gather statistics
- One forward simulation  $\sim 62$  hours on 1024 processors
- Total CPU consumption  $\sim 2.7 \times 10^6$  cpu hours
- NERSC's newest supercomputer Edison (Cray XC30)

# Response Surfaces

Introduction

Surrogate Modeling

Polynomial Chaos  
Expansion

Application to Reacting  
Flows

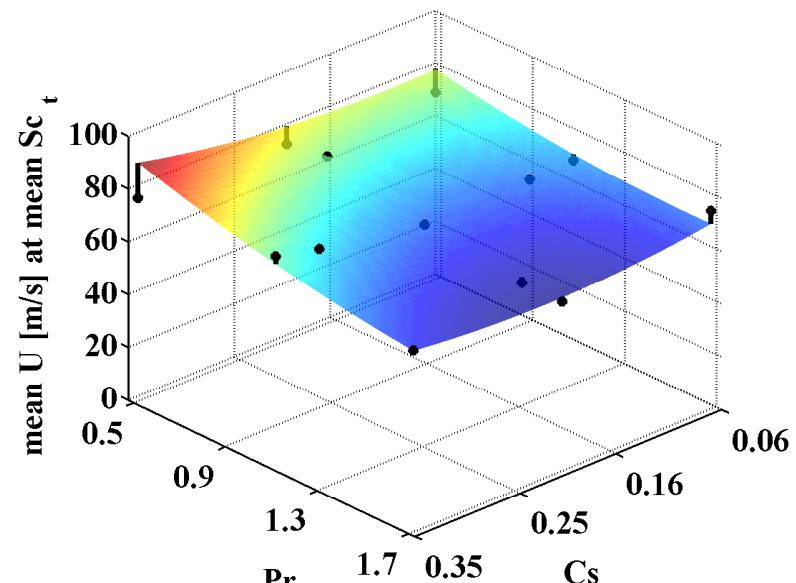

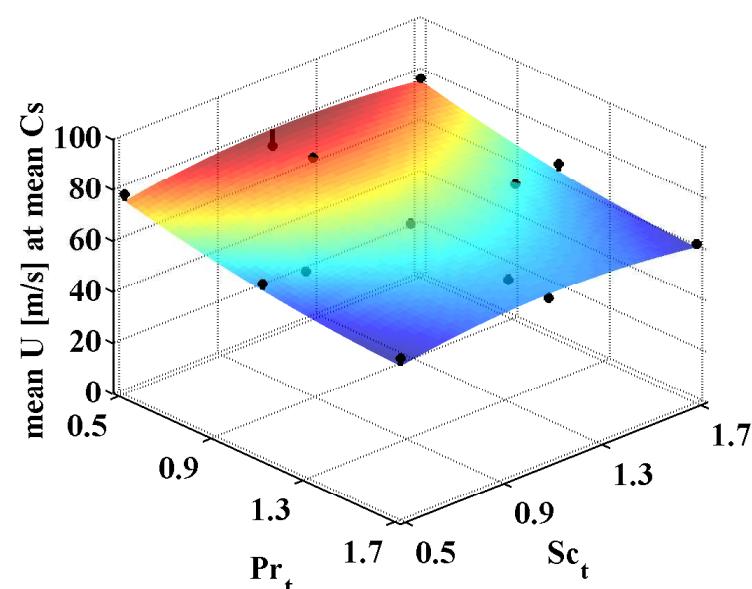

- ❖ Application: Turbulent bluff-body non-premixed flame
- ❖ Application: Numerics
- ❖ Response Surfaces
- ❖ Global Sensitivity Analysis

Hybrid PCE-Padé  
Approximant surrogates

Application to Chemical  
Kinetics

Conclusion

- From the 25 simulations at quadrature points, the following selected second order PC surrogate models are obtained:

NRMS error estimated from 18 additional LESs to be 4.4%

# Global Sensitivity Analysis

[Introduction](#)

[Surrogate Modeling](#)

[Polynomial Chaos  
Expansion](#)

[Application to Reacting  
Flows](#)

❖ Application: Turbulent  
bluff-body non-premixed  
flame

❖ Application: Numerics

❖ Response Surfaces

❖ Global Sensitivity  
Analysis

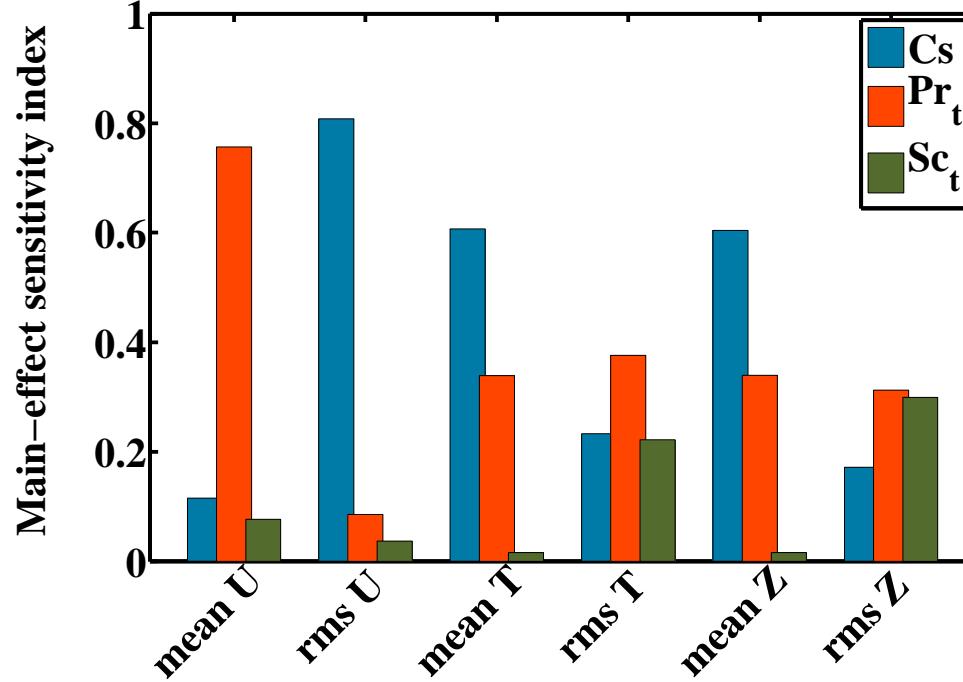

[Hybrid PCE-Padé  
Approximant surrogates](#)

[Application to Chemical  
Kinetics](#)

[Conclusion](#)

- The PC surrogate models allow us to perform global sensitivity analysis **analytically** in order to quantify the uncertainty in the QoIs due to each uncertain parameter:

mean	70.9	38.6	479	90.3	0.809	0.098
sd	5.27	3.70	54.8	12.2	0.062	0.011
cov (%)	7.4	9.6	11	14	7.7	11

# A hybrid approach to surrogate modeling

Introduction

Surrogate Modeling

Polynomial Chaos  
Expansion

Application to Reacting  
Flows

Hybrid PCE-Padé  
Approximant surrogates

❖ A hybrid approach to  
surrogate modeling

Application to Chemical  
Kinetics

Conclusion

- Constructing an accurate PCE surrogate over the entire parameter space may be prohibitive due to strong nonlinearities in the quantities of interest
- Two approaches to increase the accuracy of PCE surrogates
  - ◆ Domain decomposition
    - Split the parameter space into non-overlapping subdomains
    - For each subdomain, construct a low-order local PCE surrogate
  - ◆ Hybrid construction using Padé Approximants
    - Expand output using PCE along  $N - 1$  dimensions
    - Use Padé Approximant representation along  $N$ th dimension exhibiting strong nonlinearity
    - Padé Approximant is formulated as a ratio of PCEs

$$\begin{aligned}
 u(\boldsymbol{x}, t, \boldsymbol{\xi}) = u(\boldsymbol{\theta}) &\simeq \sum_{n=0}^N u_n(\theta_i) \Psi_n(\boldsymbol{\theta}_{(\sim i)}) \\
 &= \sum_{n=0}^N \frac{\sum_{m=0}^M p_{m,k} \Phi_m(\theta_i)}{\sum_{l=0}^L q_{l,k} \Phi_l(\theta_i)} \Psi_n(\boldsymbol{\theta}_{(\sim i)})
 \end{aligned}$$

[Conclusion](#)

❖ Conclusion

- Polynomial chaos expansion surrogates for large-scale systems via efficient sparse-quadrature
  - ◆ Forward UQ in LES of a turbulent non-premixed hydrocarbon flame
- Hybrid surrogate model formulation using Padé approximants and polynomial chaos expansion for strong nonlinear behavior
  - ◆ Application: Inference of the Arrhenius parameters for the rate coefficient of the H<sub>2</sub>/O<sub>2</sub> mechanism branching reaction  
 $H + O_2 \rightarrow OH + O$
- Methodology can be extended to combine PCE with other techniques
  - ◆ Radial basis functions
  - ◆ Neural networks
