Real-time Social Internet Data to Guide Forecasting Models

Sara Del Valle, PhD

Team: Geoffrey Fairchild, Nick Generous, Kyle Hickmann, Dave Osthus, Reid Priedhorsky

Operated by Los Alamos National Security, LLC for the U.S. Department of Energy's NNSA

Our goal

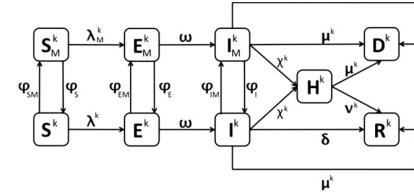

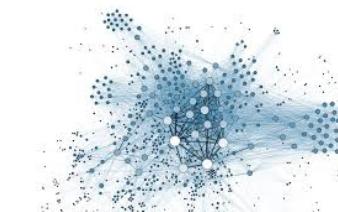

Improve decision support by monitoring and forecasting events using social media, mathematical models, and quantifying model uncertainty.

Our approach

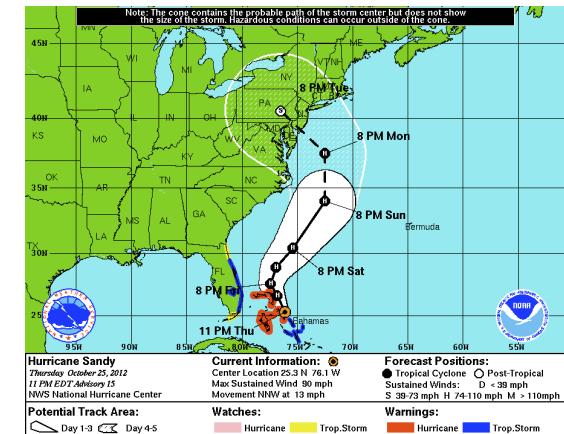

Real-time, data-driven forecasts with quantified uncertainty:
Not just for weather anymore.

+

=

Real-time, voluminous,
extremely noisy data

Mathematical models

Forecasts with
quantified uncertainty

1

+

1

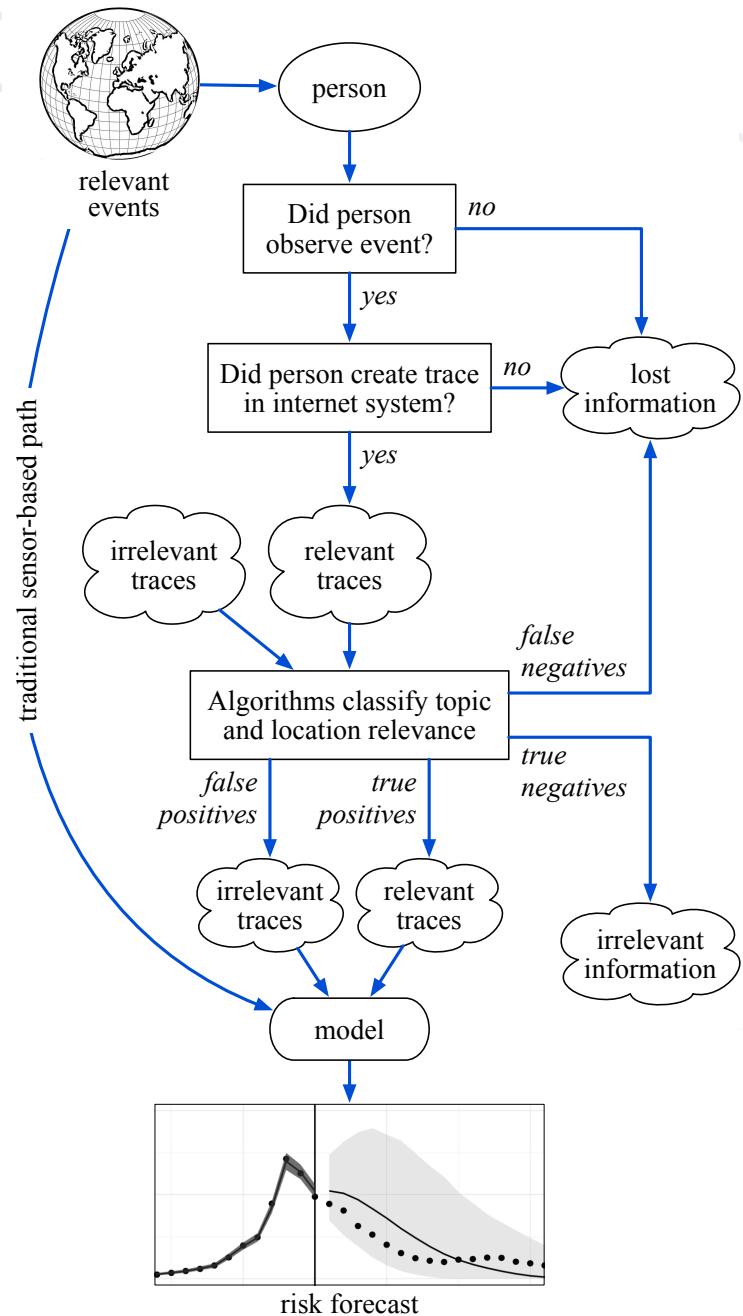

=

3

The whole is greater than the sum of its parts! – Aristotle

Our approach

Information flow from human observations of events through an Internet system and classification algorithms to produce quantitatively uncertain forecast.

What do we want?

■ **Holy grail**

- Predict events before they occur/start

■ **Realistic alternative**

- Accurate, quantitatively uncertain **forecast**

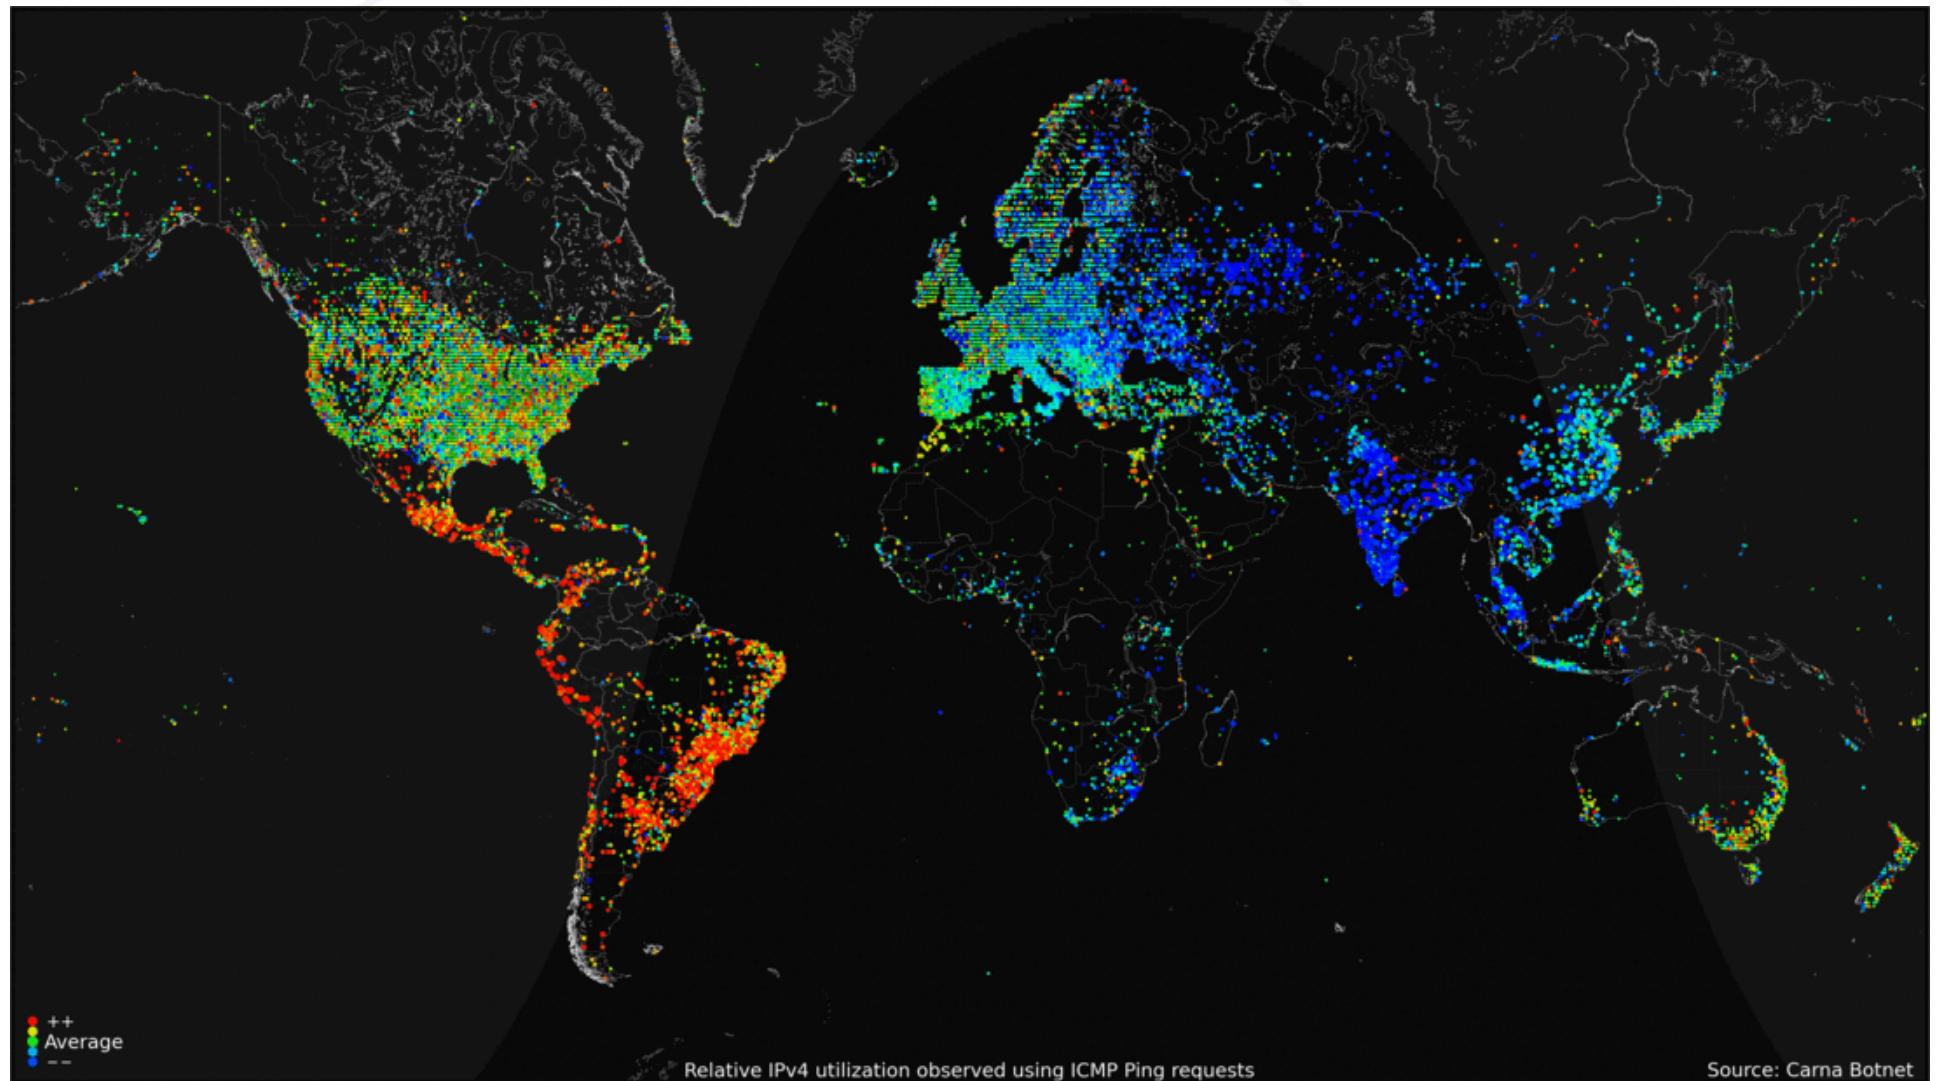

■ **Our proposal**

- Social Internet data can help

Global internet penetration

Internet data sources

- Information sharing
- Information seeking

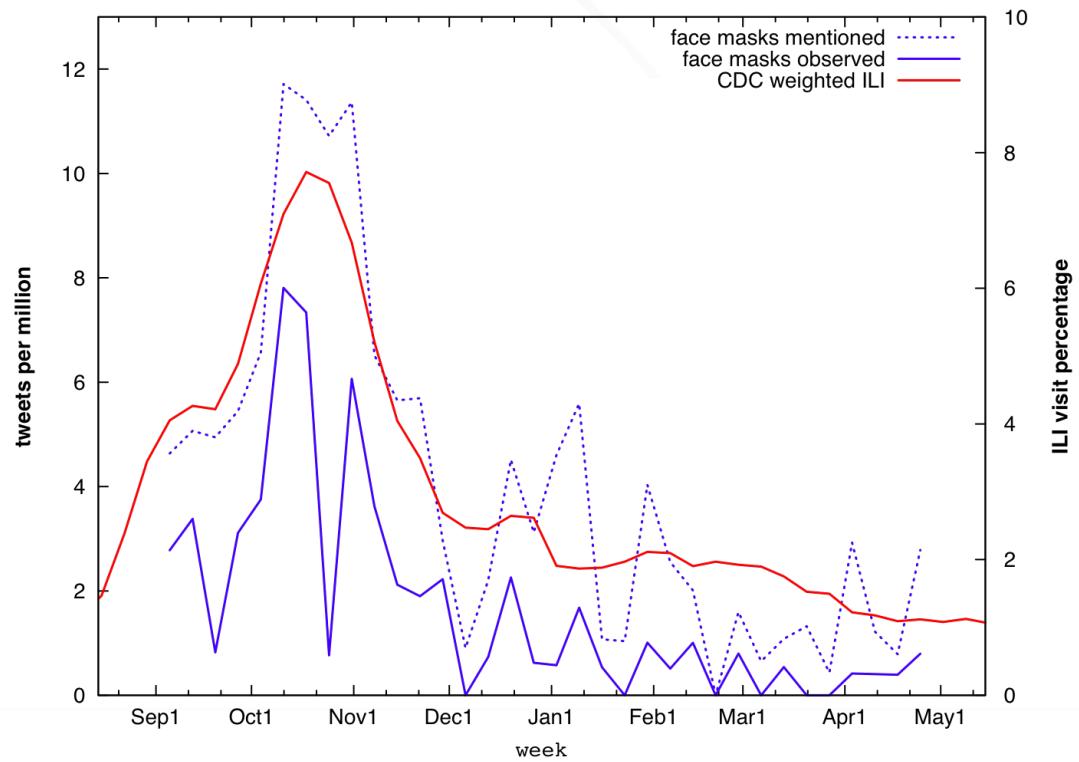

WIKIPEDIA
The Free Encyclopedia

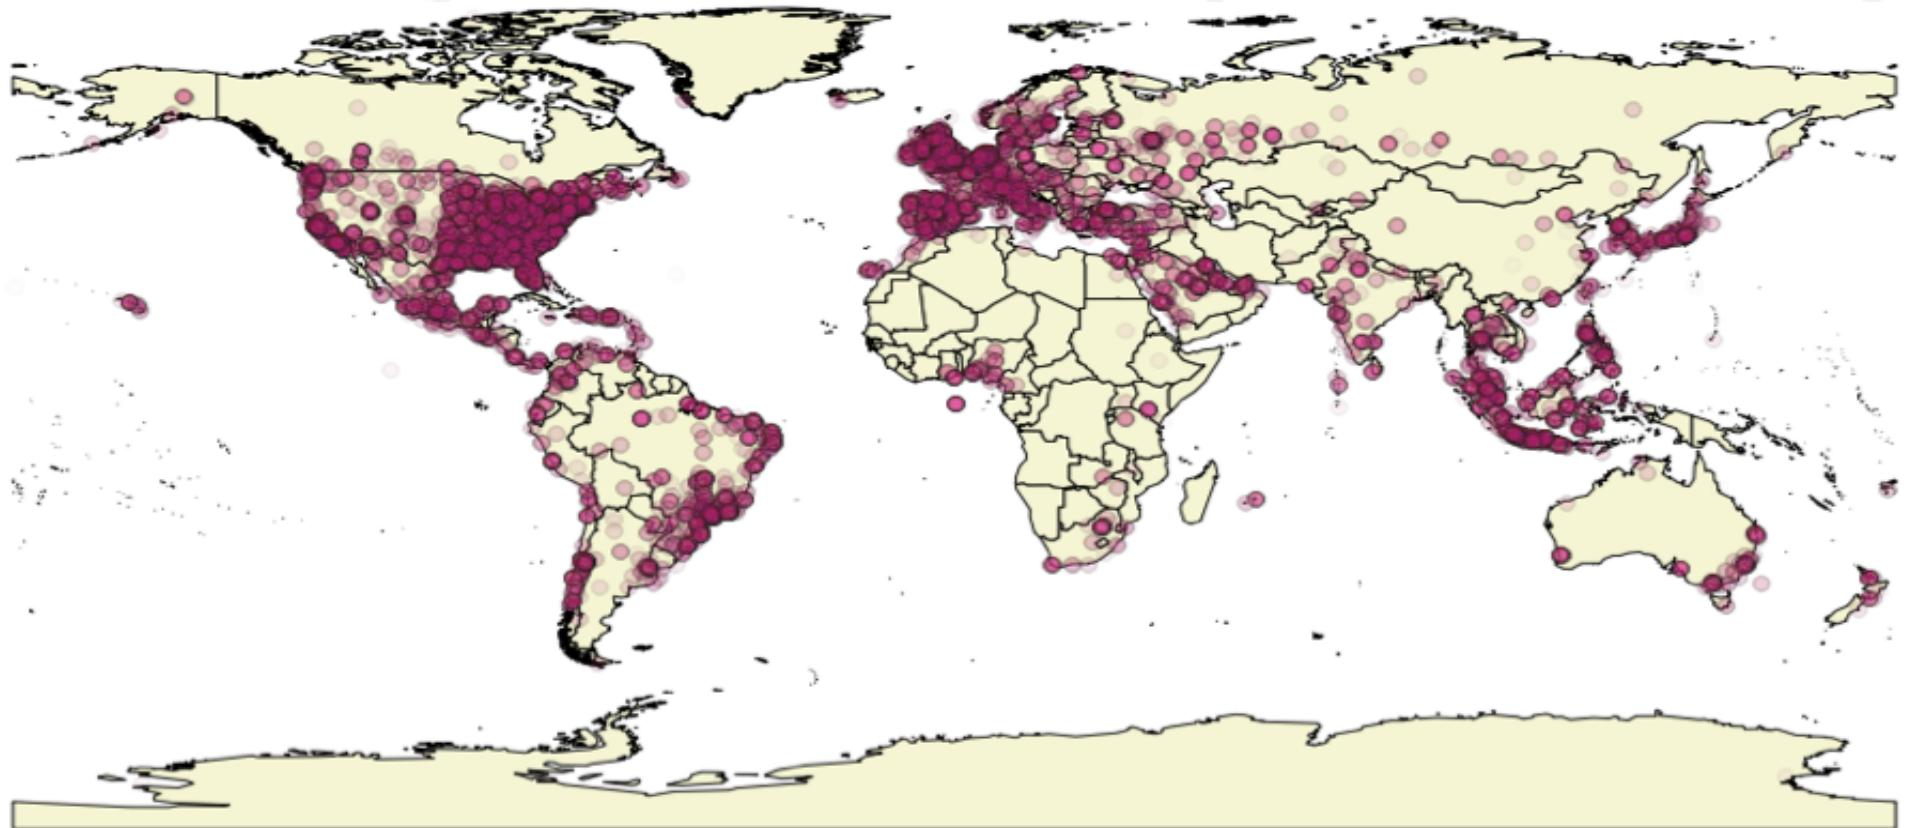

Using Twitter to Extract Behavior

- 10,000 Tweets/hour about “swine flu” in 2009
- Extract emergent behaviors such as facemask usage
- Use information to inform models and quantify impact

Where are people tweeting from?

- Challenges
 - Only 1-2% of tweets carry a geotag
 - Behavior is not demographically and **geographically** uniform

Locating a tweet

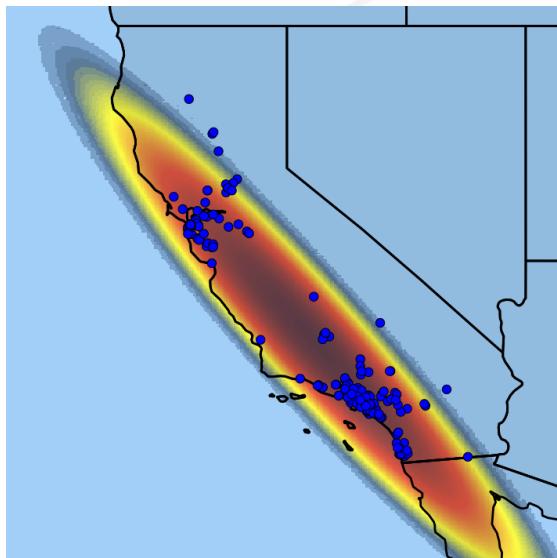

- Scalable, content-based approach – Gaussian mixture model
- Experiments on 13M global, multi-lingual tweets
- Only requires 30,000 tweets to train model

Fields: user location, user time zone, tweet text, user description, user language

The screenshot shows the Wikipedia article for 'Influenza'. The page title is 'Influenza' and it is described as 'From Wikipedia, the free encyclopedia'. The article text discusses the common name 'the flu', its status as an infectious disease of birds and mammals caused by RNA viruses, and its symptoms. It compares influenza to the common cold and gastroenteritis. A sidebar on the right contains a transmission electron micrograph (TEM) of influenza virions, their classification, and external resources. The sidebar also lists medical codes (ICD-10, ICD-9, DiseasesDB), databases (MedlinePlus, eMedicine), and MeSH terms.

Influenza

From Wikipedia, the free encyclopedia

"Flu" redirects here. For other uses, see *Flu (disambiguation)*.
"Grippe" redirects here. For other uses, see *Grippe (disambiguation)*.

Influenza, commonly known as "the flu", is an infectious disease of birds and mammals caused by RNA viruses of the family Orthomyxoviridae, the influenza viruses. The most common symptoms are chills, fever, runny nose, sore throat, muscle pains, headache (often severe), coughing, weakness/fatigue and general discomfort. Although it is often confused with other influenza-like illnesses, especially the common cold, influenza is a more severe disease caused by a different type of virus.^[1] Influenza may produce nausea and vomiting, particularly in children,^[2] but these symptoms are more common in the unrelated gastroenteritis, which is sometimes inaccurately referred to as "stomach flu" or "24-hour flu".^[3]

Typically, influenza is transmitted through the air by coughs or sneezes, creating aerosols containing the virus. Influenza can also be transmitted by direct contact with bird droppings or nasal secretions, or through contact with contaminated surfaces. Airborne aerosols have been thought to cause most infections, although which means of transmission is most important is not absolutely clear.^[4] Influenza viruses can be inactivated by sunlight, disinfectants and detergents.^{[5][6]} As the virus can be inactivated by soap, frequent hand washing

Health and Human Services Regions

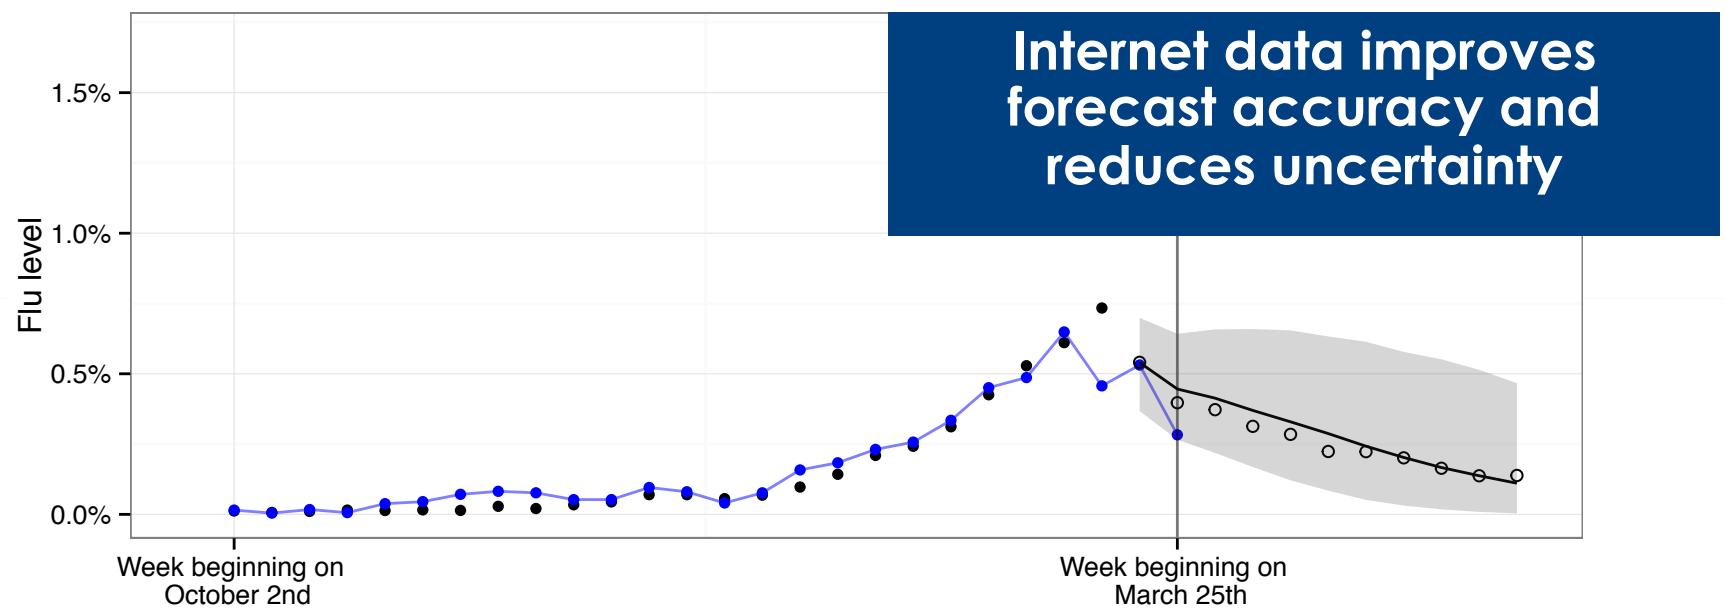

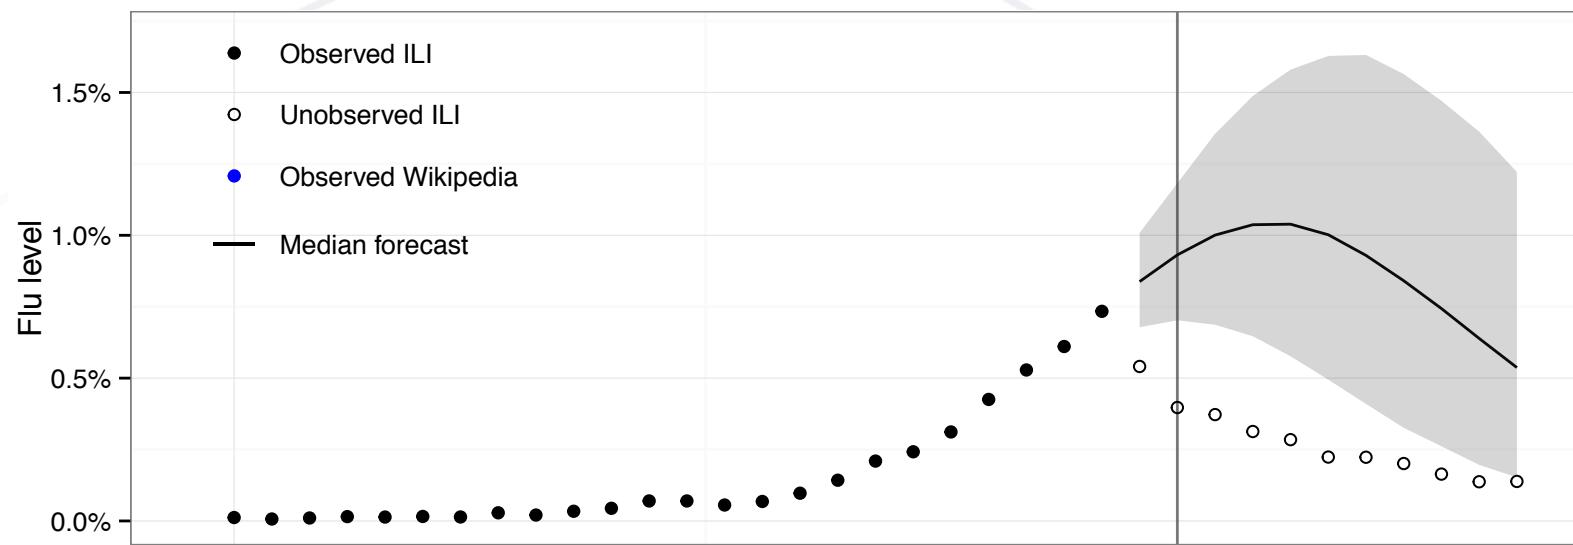

Model description: Our model produces probabilistic forecasts of the flu season, similar to how weather, presidential elections, and sporting event outcomes are forecasted. This means our model produces information such as, “there is an 80% chance the flu will peak after January” rather than “the flu will peak after January”. This approach explicitly acknowledges uncertainty in the data and the model. Forecasts are created at national and regional levels (see map). Our model combines three components: historical flu information, a mathematical representation of how flu spreads through a population, and data for the current flu season provided by the Centers for Disease Control and Prevention. When new data become available, the forecasts are updated. As a result, the model’s uncertainty about what may happen for the remainder of the flu season usually decreases with subsequent updates. Our forecasts will be updated every two weeks for the 2015–2016 flu season.

Previous forecasts can be accessed at
<http://bsvgateway.org/flu/forecast-archives/>

Special thanks to Geoffrey Fairchild, Jim Gattiker, Nicholas Generous, and Kyle Hickmann

The Value of Internet Data – 2014-2015

Quantitative Analysis of Chatter (CUAC)

- Software for acquiring, processing, and analyzing social Internet content.
 - Collects data from Twitter streaming API & Wikipedia access logs & content dumps
 - Estimates origin of locations of tweets with no geotag
 - Turns diverse kinds of Internet data into hourly (daily) time series of event counts
 - Facilitates parallel access to the dataset & reasonable performance

<https://github.com/reidpr/quac>

Summary

- Develop new tools to extract useful information from Internet data streams
- Develop new approaches to assimilate real-time information into predictive models
- Validate approaches by forecasting events
- Our ultimate goal: develop an event forecasting system using mathematical approaches and heterogeneous data streams
