USER INTERFACE STORYBOARDS

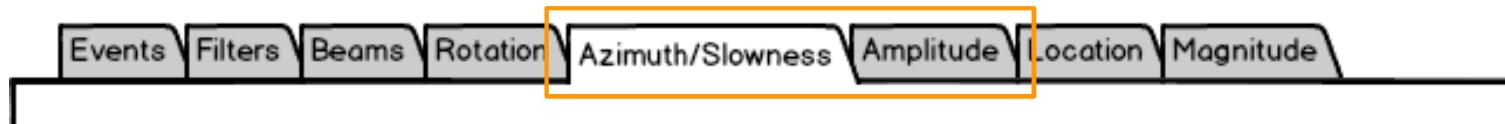

Measures Signal Features

Brief Description

This use case describes how the Analyst measures signal features on waveform data. The Analyst measures the same signal features as are measured in pipeline processing (see ‘System Measures Signal Features’ UC), but the Analyst has the option to select the input parameters rather than the predefined parameters used during pipeline processing.

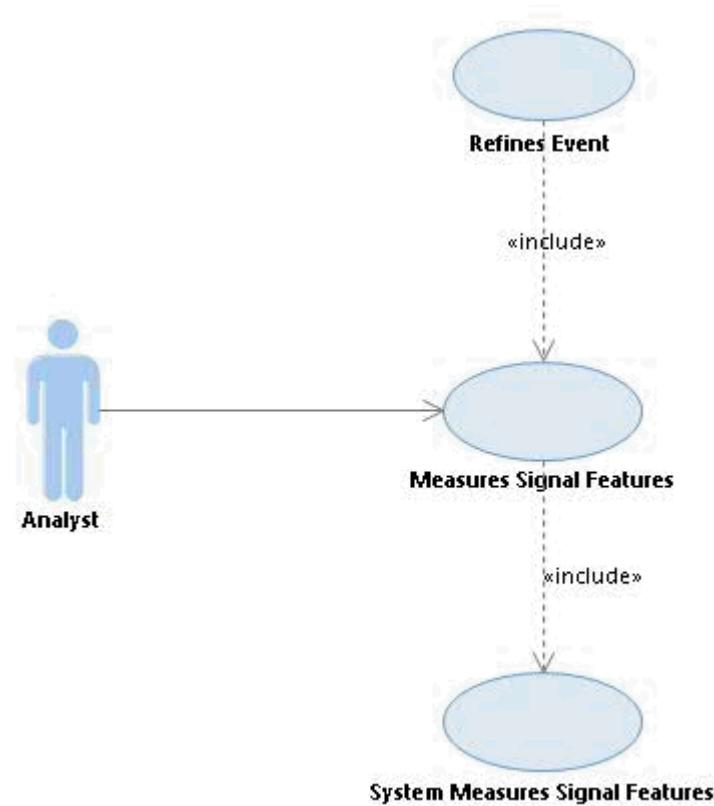

Overview

- The Analyst accesses the displays represented by these storyboards by opening the Analyst workspace (Analyzes Events UC), selecting data for analysis (Selects Data for Analysis UC), and selecting an event to refine (Refines Event UC).
- Alternatively, the Analyst can measure signal features outside the context of a specific event, for example when scanning (see Scans Waveforms and Unassociated Detections UIS).

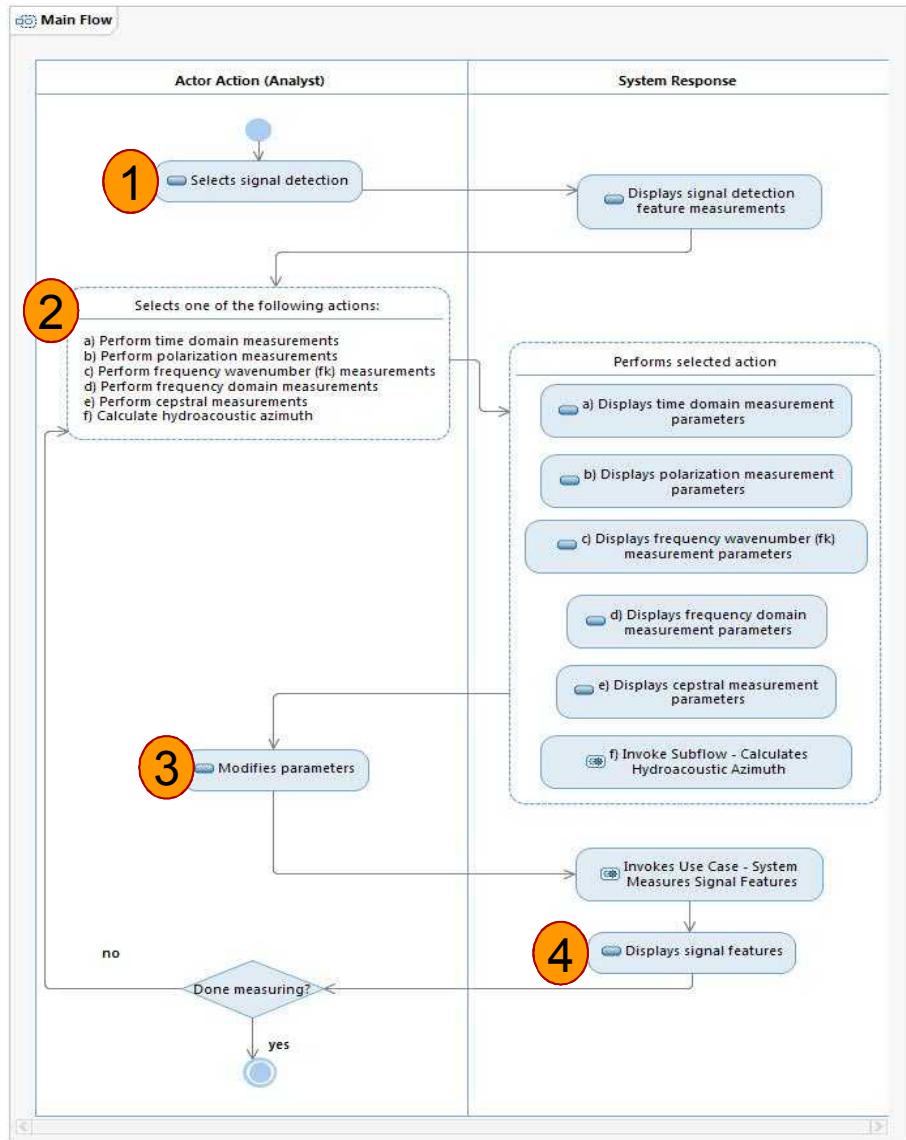

- Azimuth/slowness signal features are measured via the Azimuth/Slowness tab in the Analyst Workspace
- Amplitude signal features are measured via the Amplitude tab

Measures Signal Features: Use Case

Main Flow

- 1) Selects signal detection
- 2) Selects one of the following actions:
 - Perform time domain measurements
 - Perform polarization measurements
 - Perform frequency wavenumber (fk) measurements
 - Perform frequency domain measurements
 - Perform cepstral measurements
 - Calculate hydroacoustic azimuth (subflow)
- 3) Modifies parameters
- 4) Displays signal features

1) Selects signal detection

Select an amplitude cell from the signal detection list in the event magnitude display to populate the Amplitude tab with measurement information for that signal detection and magnitude type.

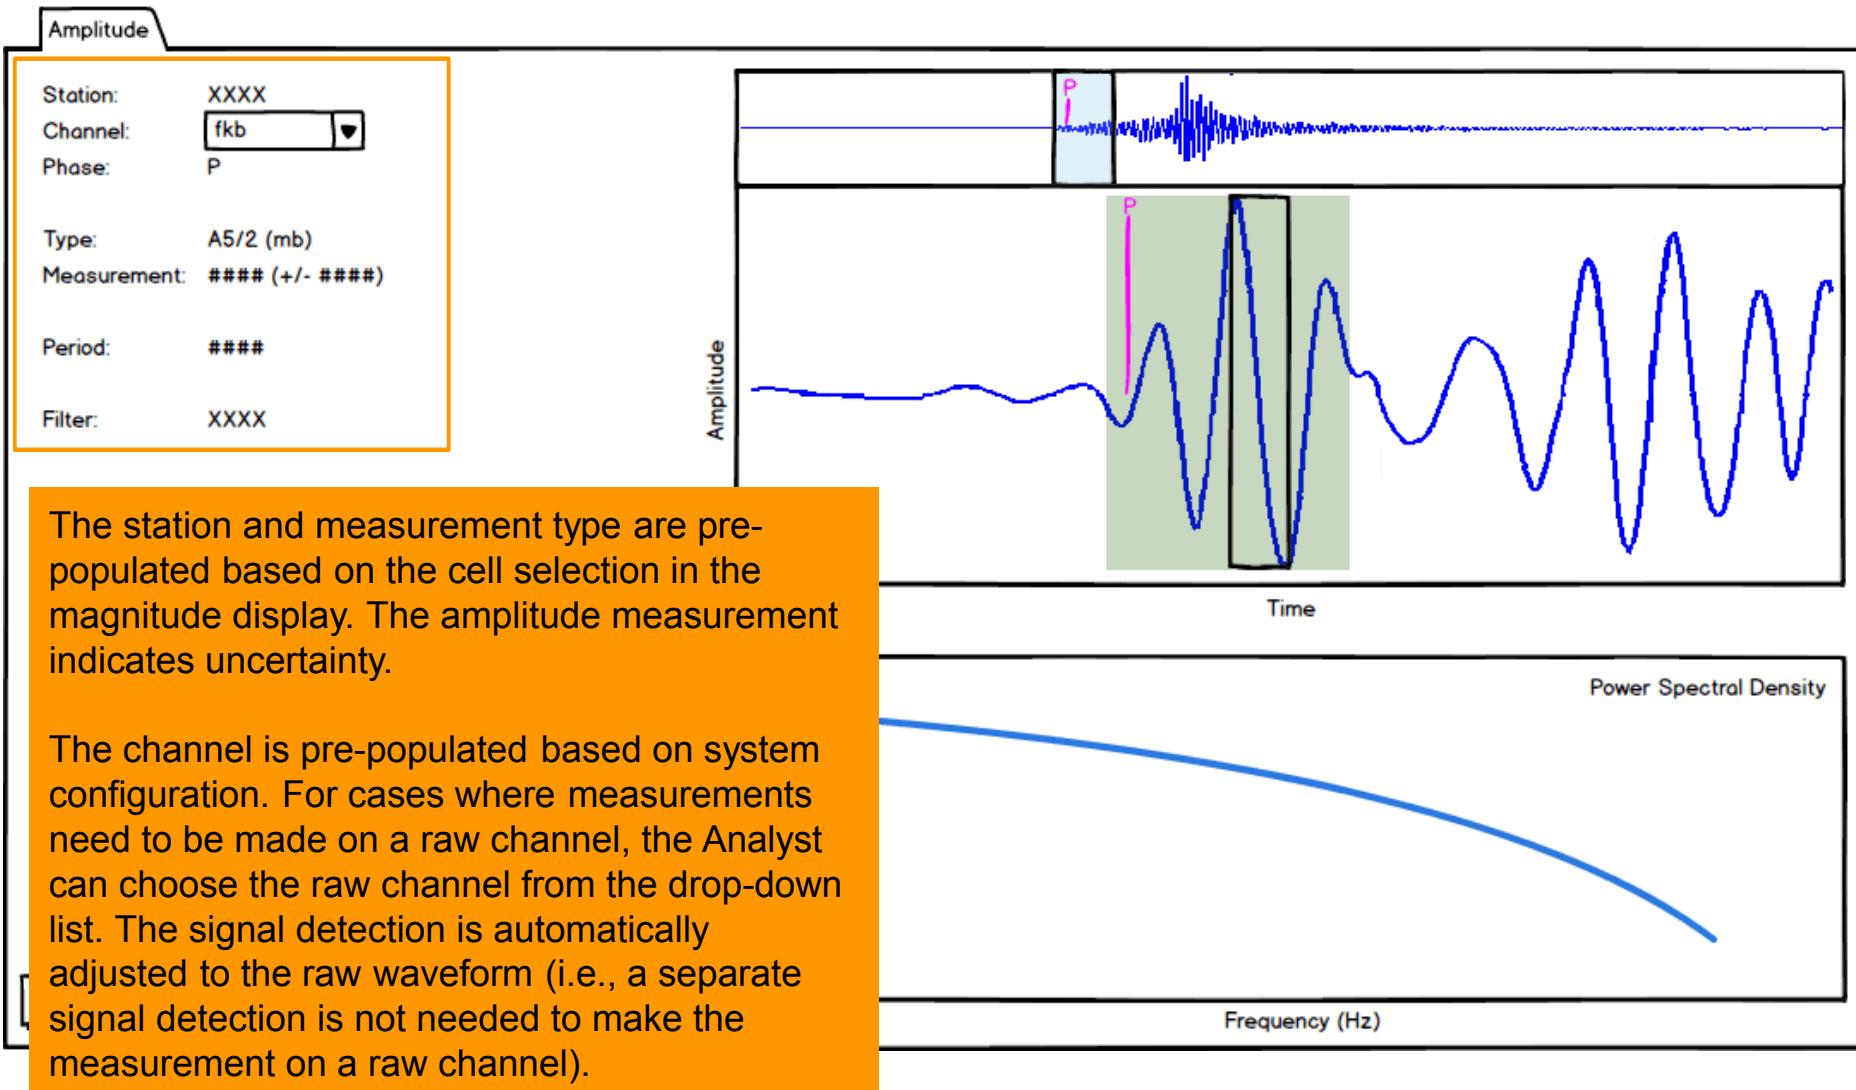

Yellow cells indicate measurements that the Analyst should review; however, the Analyst can also select non-highlighted cells to review those measurements.

See Refines Event Magnitude UIS for more information about the event magnitude display.

2a, d) Time and frequency domain: Amplitude

2a, d) Time and frequency domain: Amplitude

3) Modifies parameters

Amplitude measurements are shown in both the time and frequency domains.

Amplitude

Top - Context waveform. The box represents the time period shown in the zoomed-in waveform below.

Middle - Zoomed-in waveform for making measurements. The green rectangle represents the time window (lead/lag) within which measurements can be made.

Drag the black rectangle to specify the location of peak and trough. Measurements update automatically as the window is adjusted.

Signal detections can be retimed here, depending on the filter type (e.g., cannot retime for acausal filters)

Bottom - Power Spectral Density plot

Channel: fk beam

Fstat:

Azimuth:

Slowness:

Channel participation is shown on this display but cannot be modified here. The Analyst masks waveforms via the main waveform display, which is likely to be open beside this display. If the Analyst masks a channel, then the participation checkboxes shown here are automatically updated.

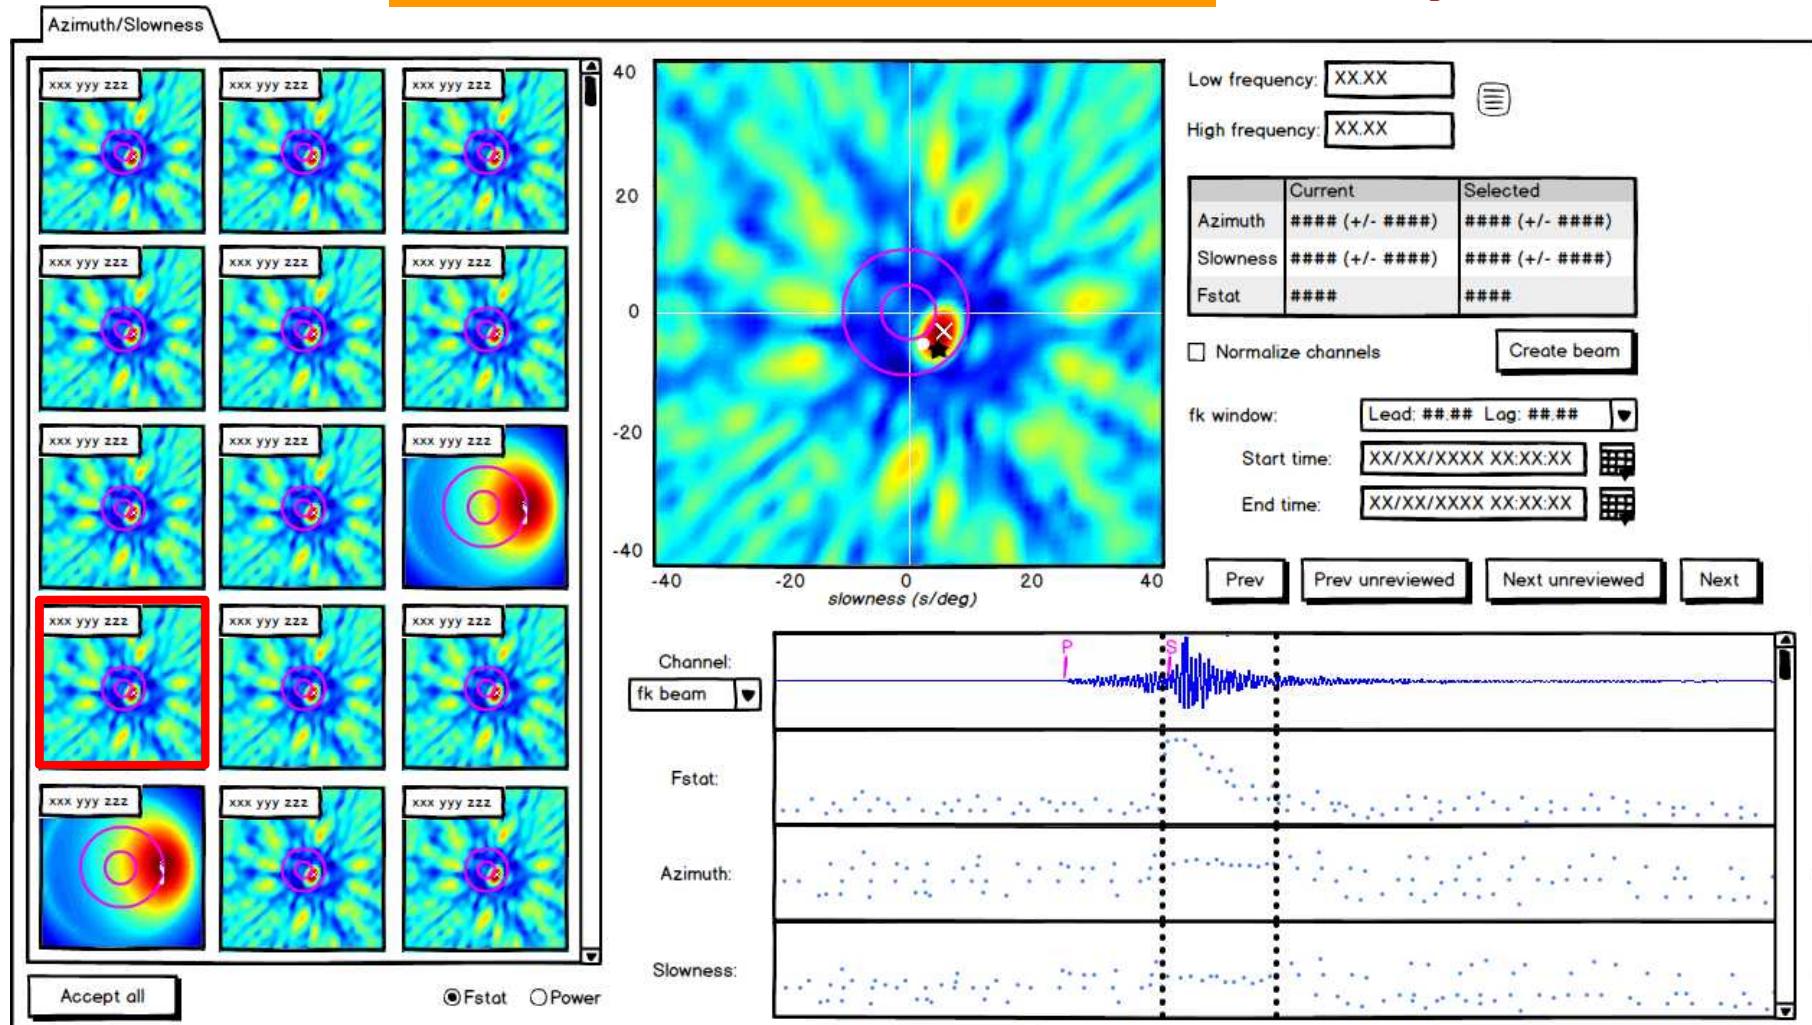

See UIS Determines Waveform Data Quality for more details on masking.

fk measurements: Hydro fk selected

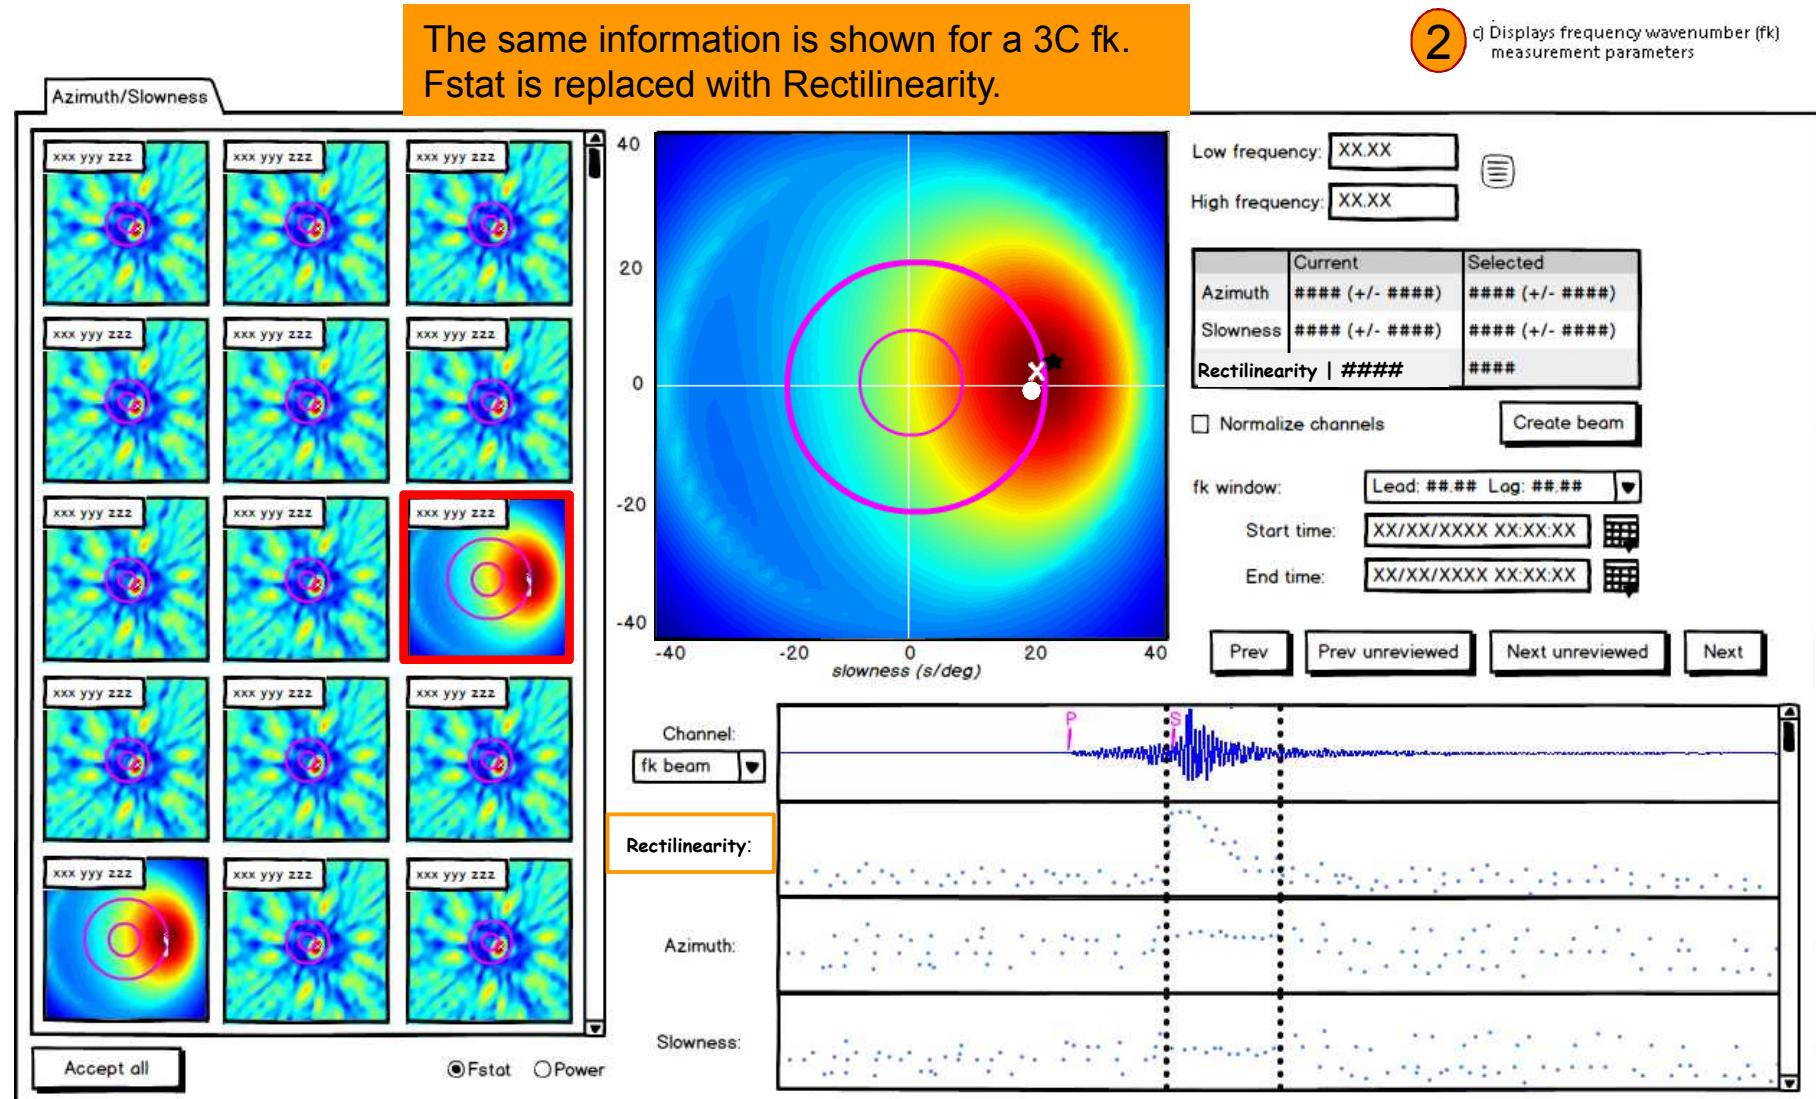

The same information is shown for a Hydro fk

2

c) Displays frequency wavenumber (fk) measurement parameters

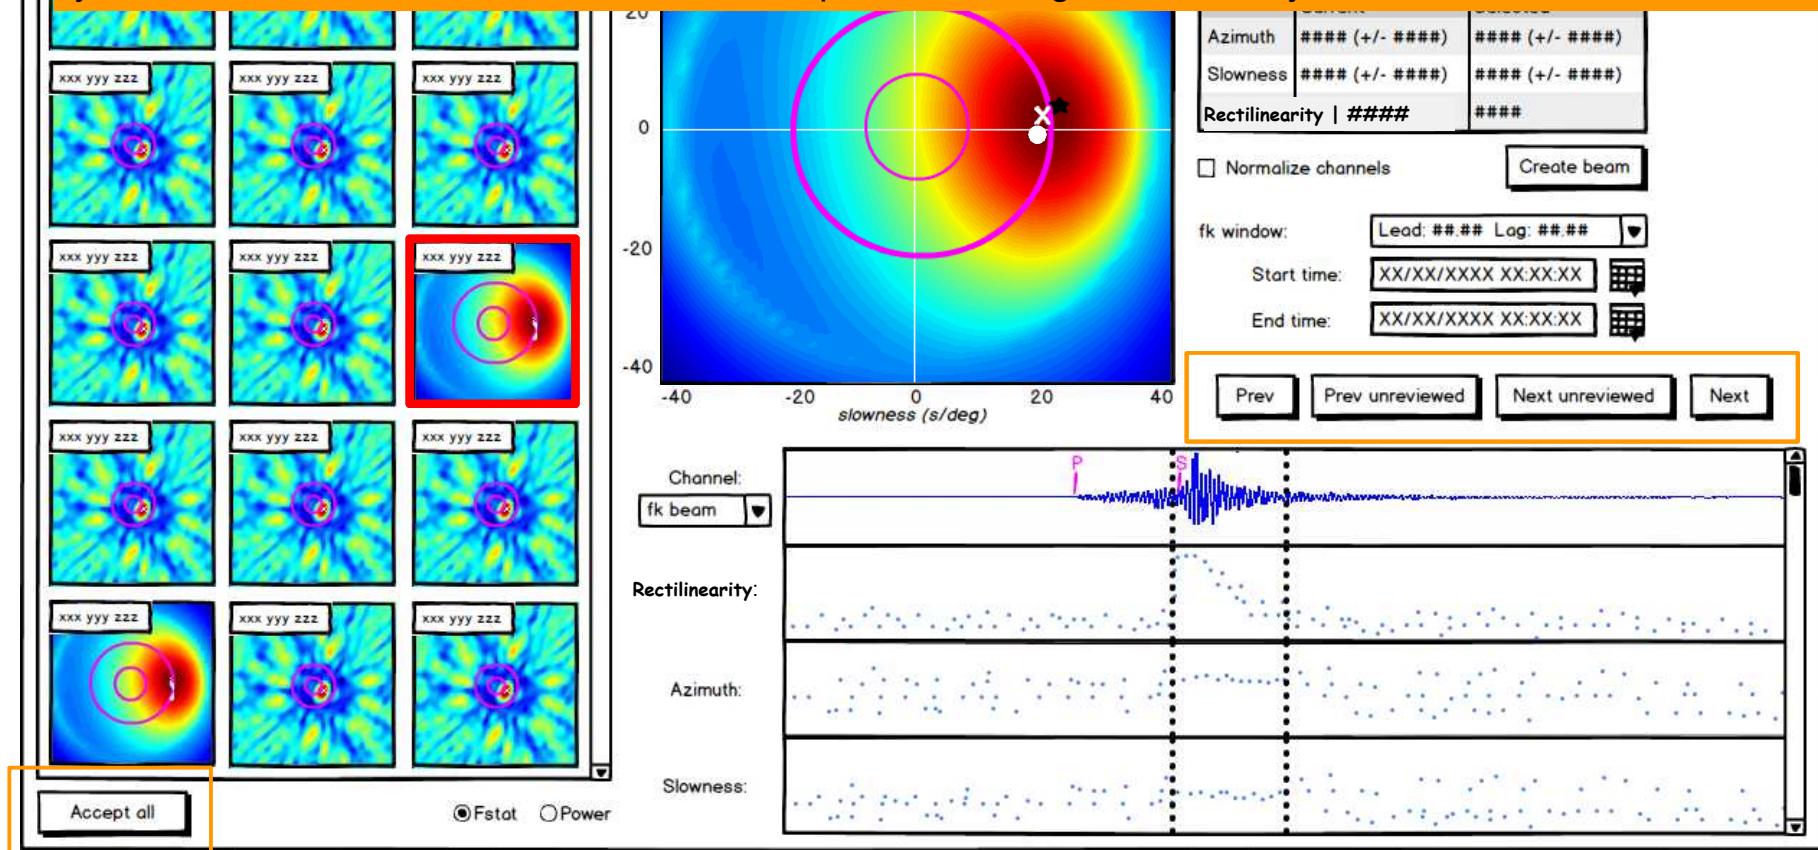

fk measurements: 3C fk selected

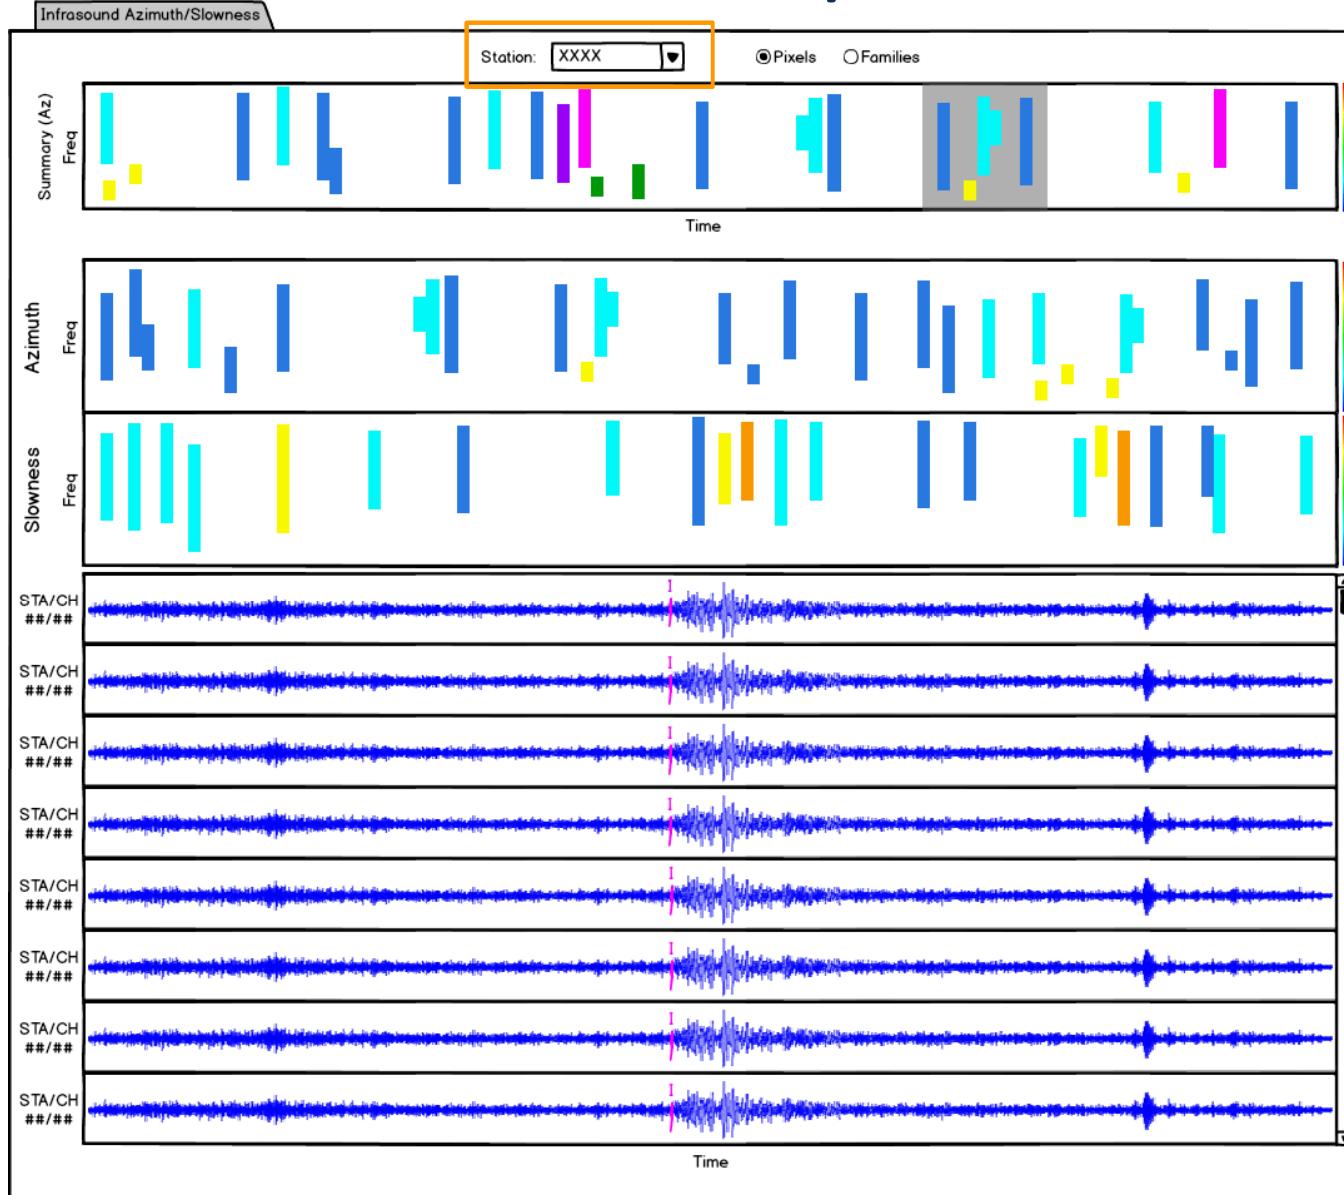

4) Displays updated signal features

Press 'Next' to accept the changes to this measurement and move on to the next signal detection in the list. Press 'Next unreviewed' to skip forward to the next signal detection that is highlighted for review. Use the 'previous' buttons to move backward in the list. Alternatively, press "Accept all" to accept all of the measurements in the list. The Azimuth and Slowness columns in the event location display change from yellow to white as each measurement is accepted, indicating that the Analyst has reviewed them.

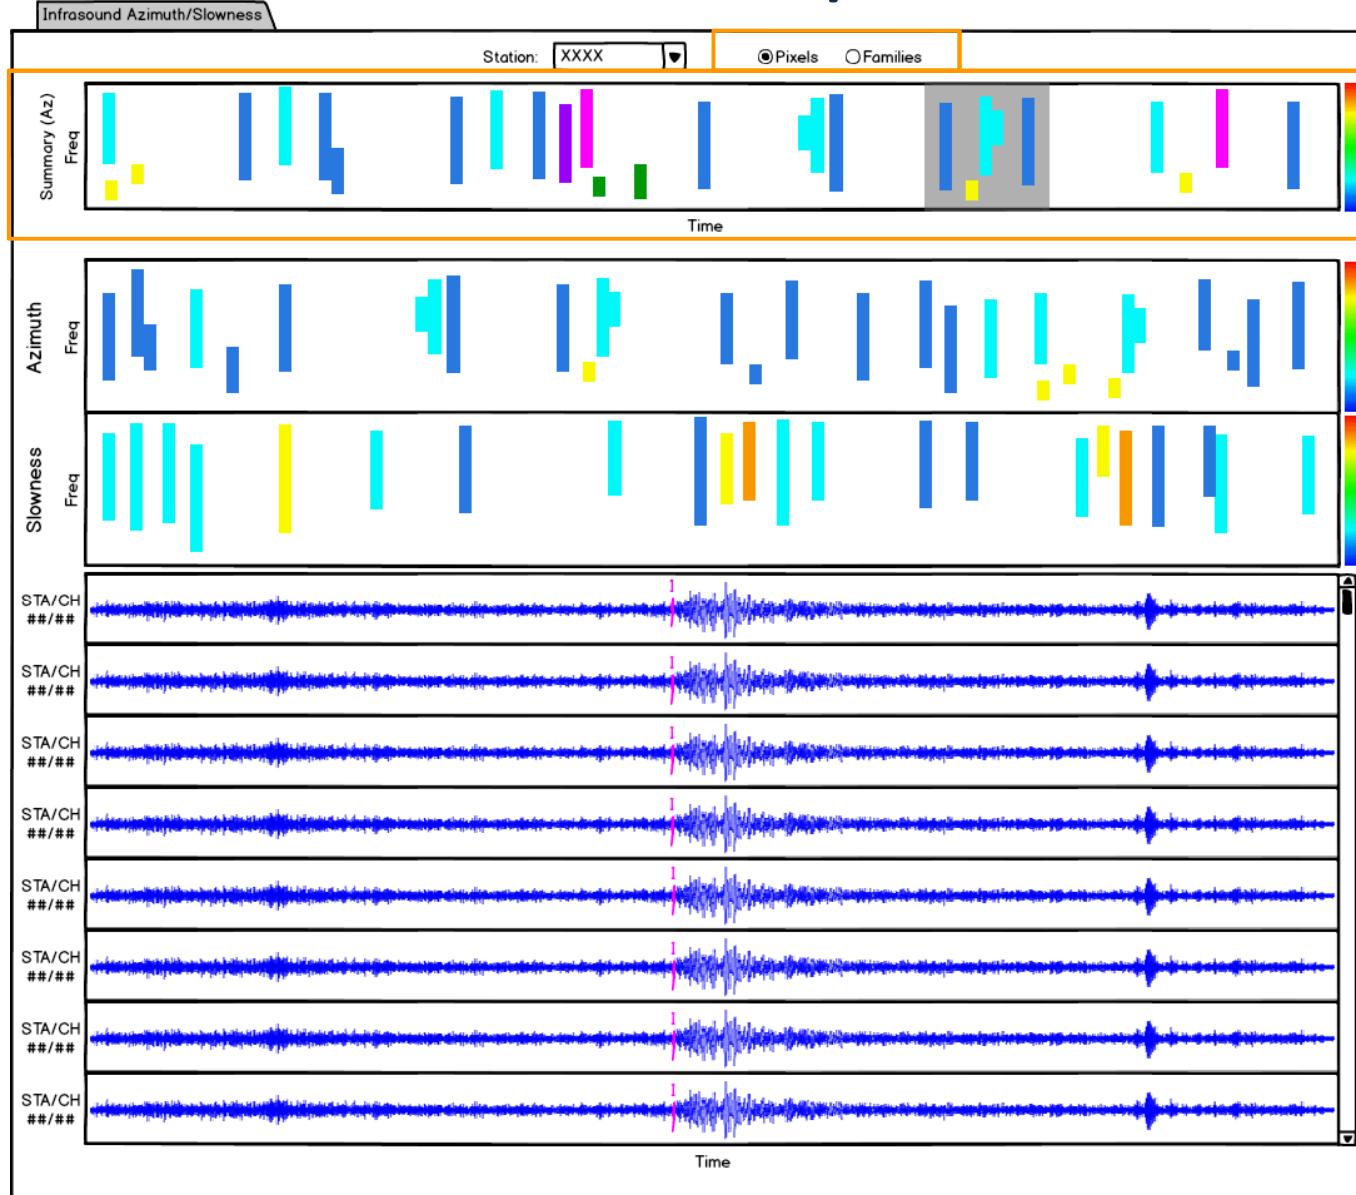

Infrasound azimuth/slowness

Additional infrasound azimuth/slowness information (i.e. PMCC) can be viewed on a separate display for a single selected station.

The Analyst can select an infrasound station from the drop down list here or via the main waveform display.

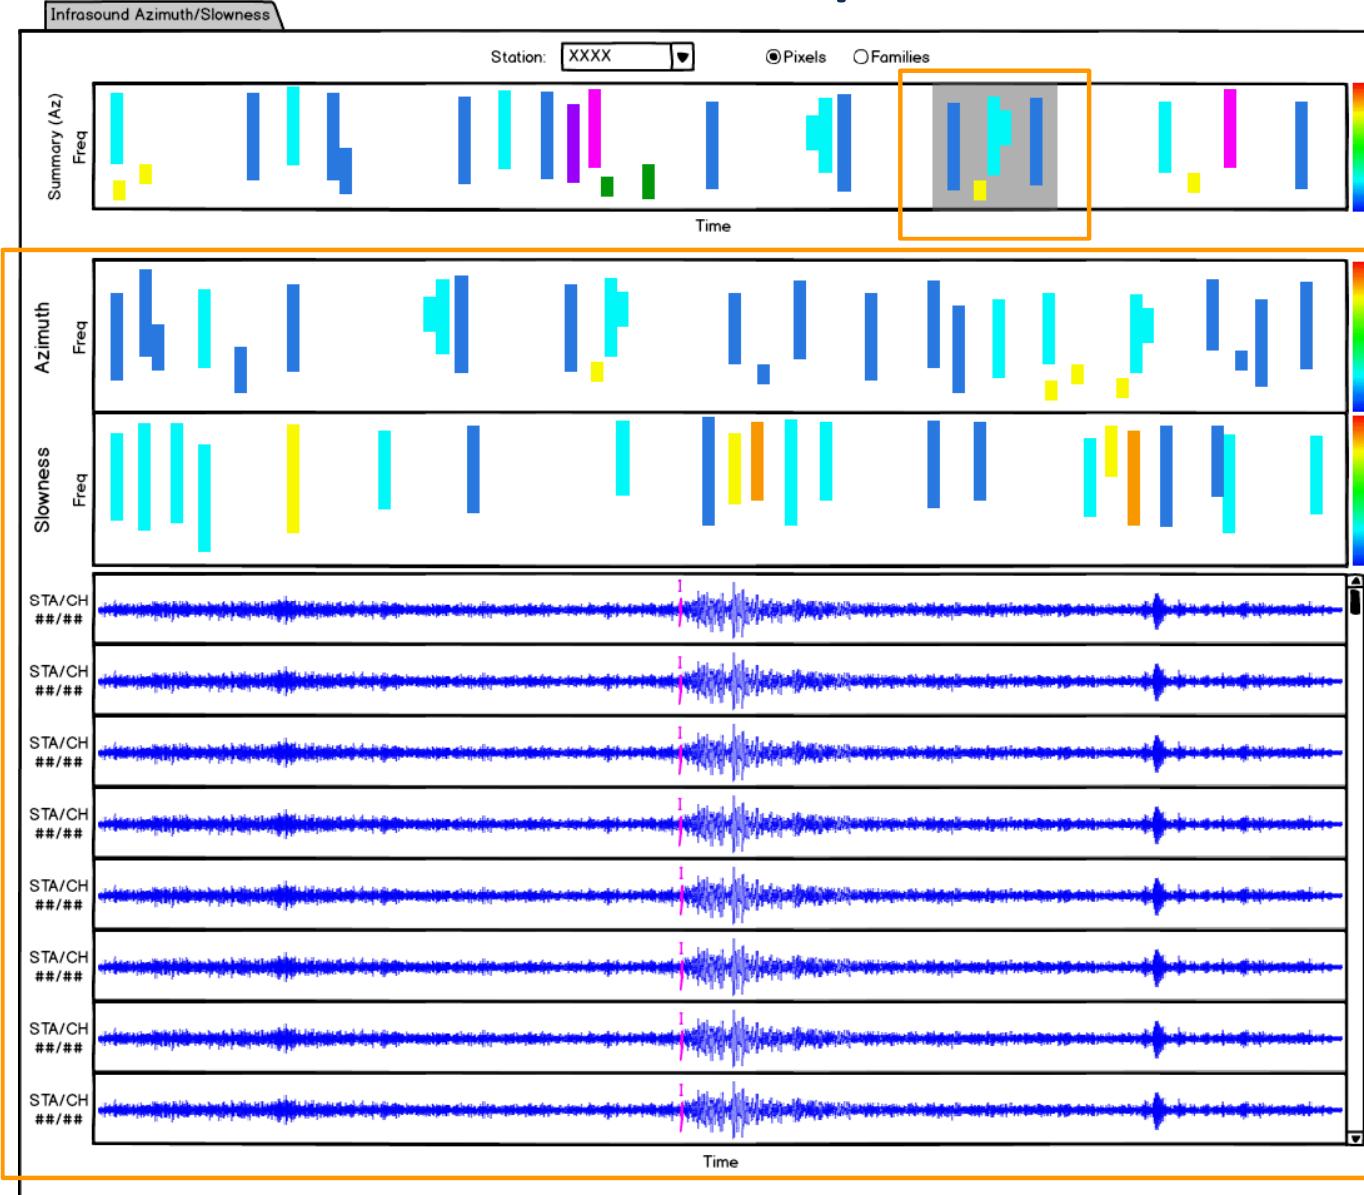

Infrasound azimuth/slowness

A summary plot at the top of the display shows azimuth information over time. The Analyst can zoom in/out to adjust the time range.

The display can be configured to show individual pixels or pixel families.

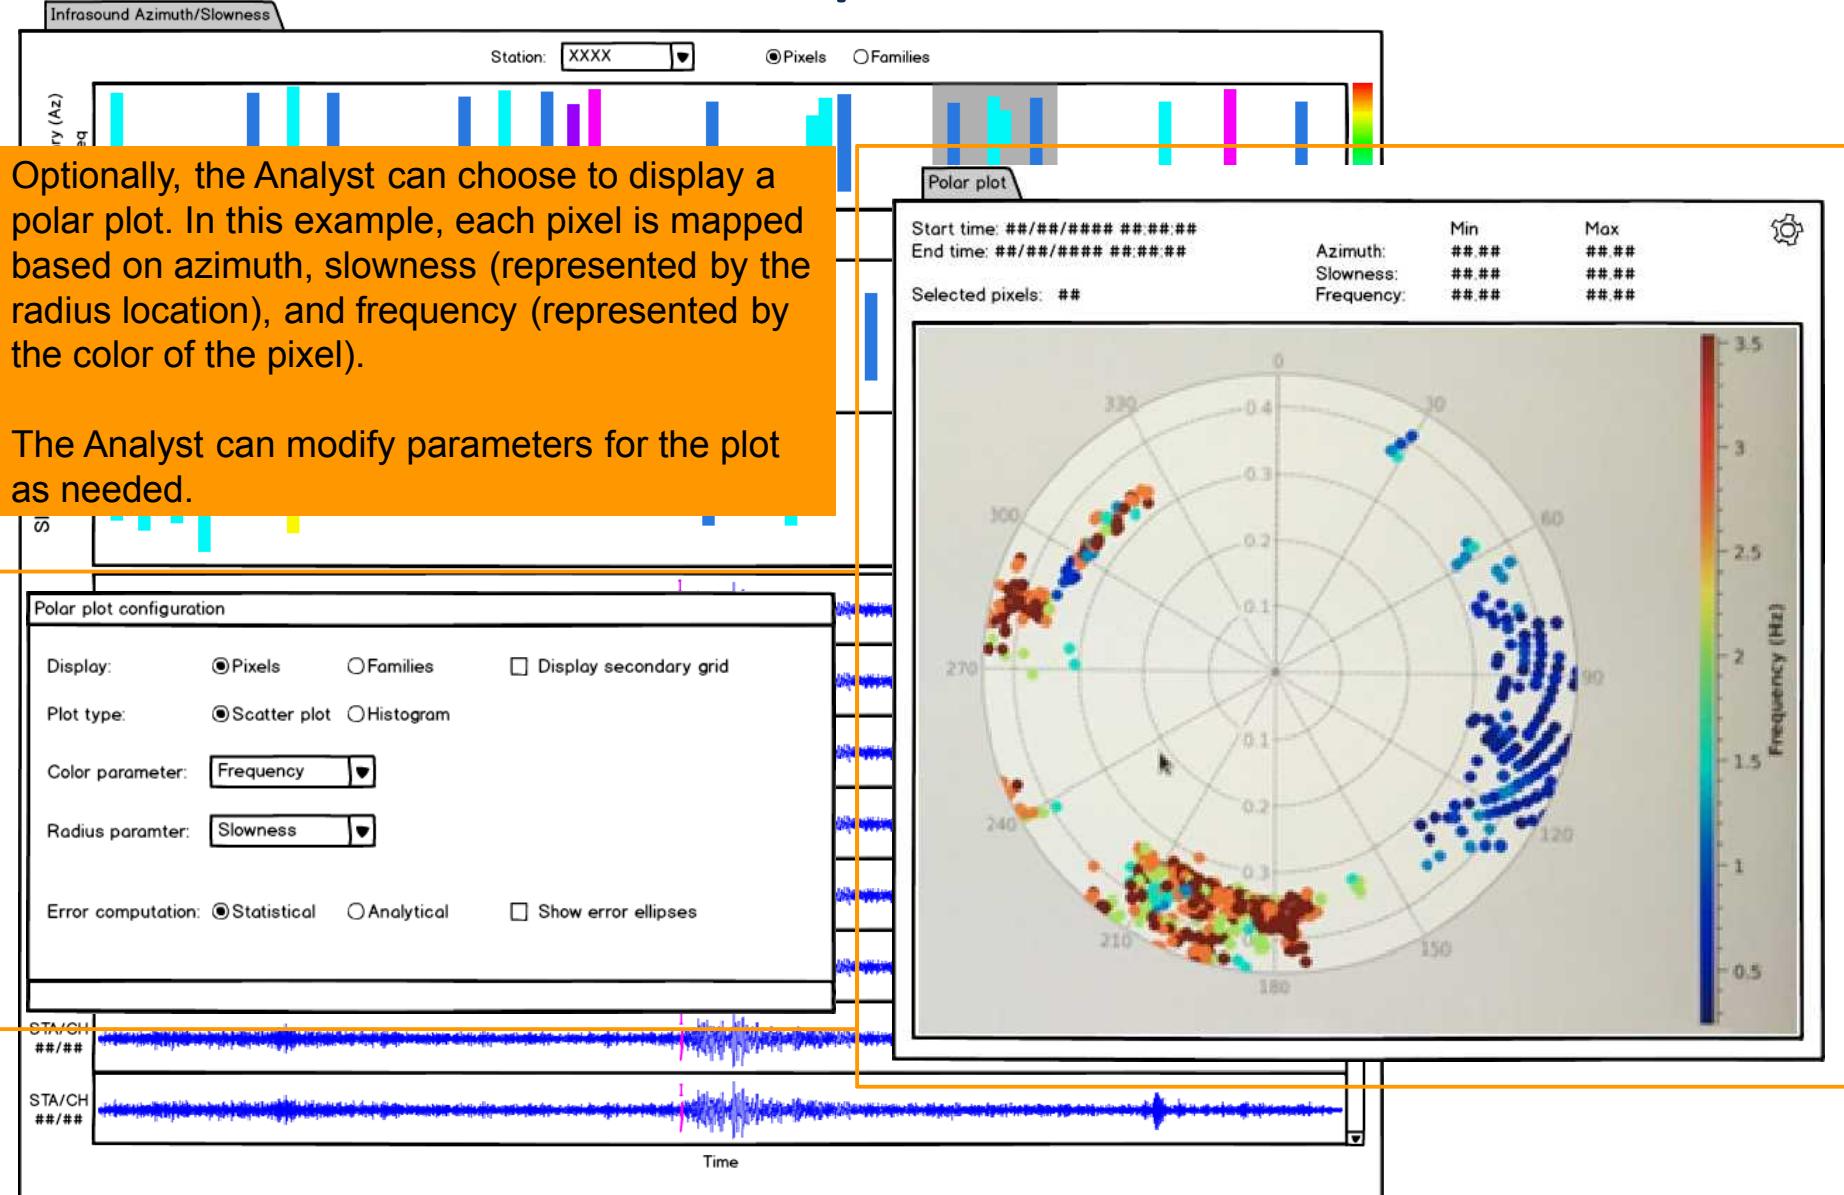

Infrasound azimuth/slowness

The Analyst selects a smaller time window in the summary plot to see additional detail in the remaining plots. Azimuth, slowness, and the individual channel waveforms are stacked vertically over the same “zoomed in” time range.

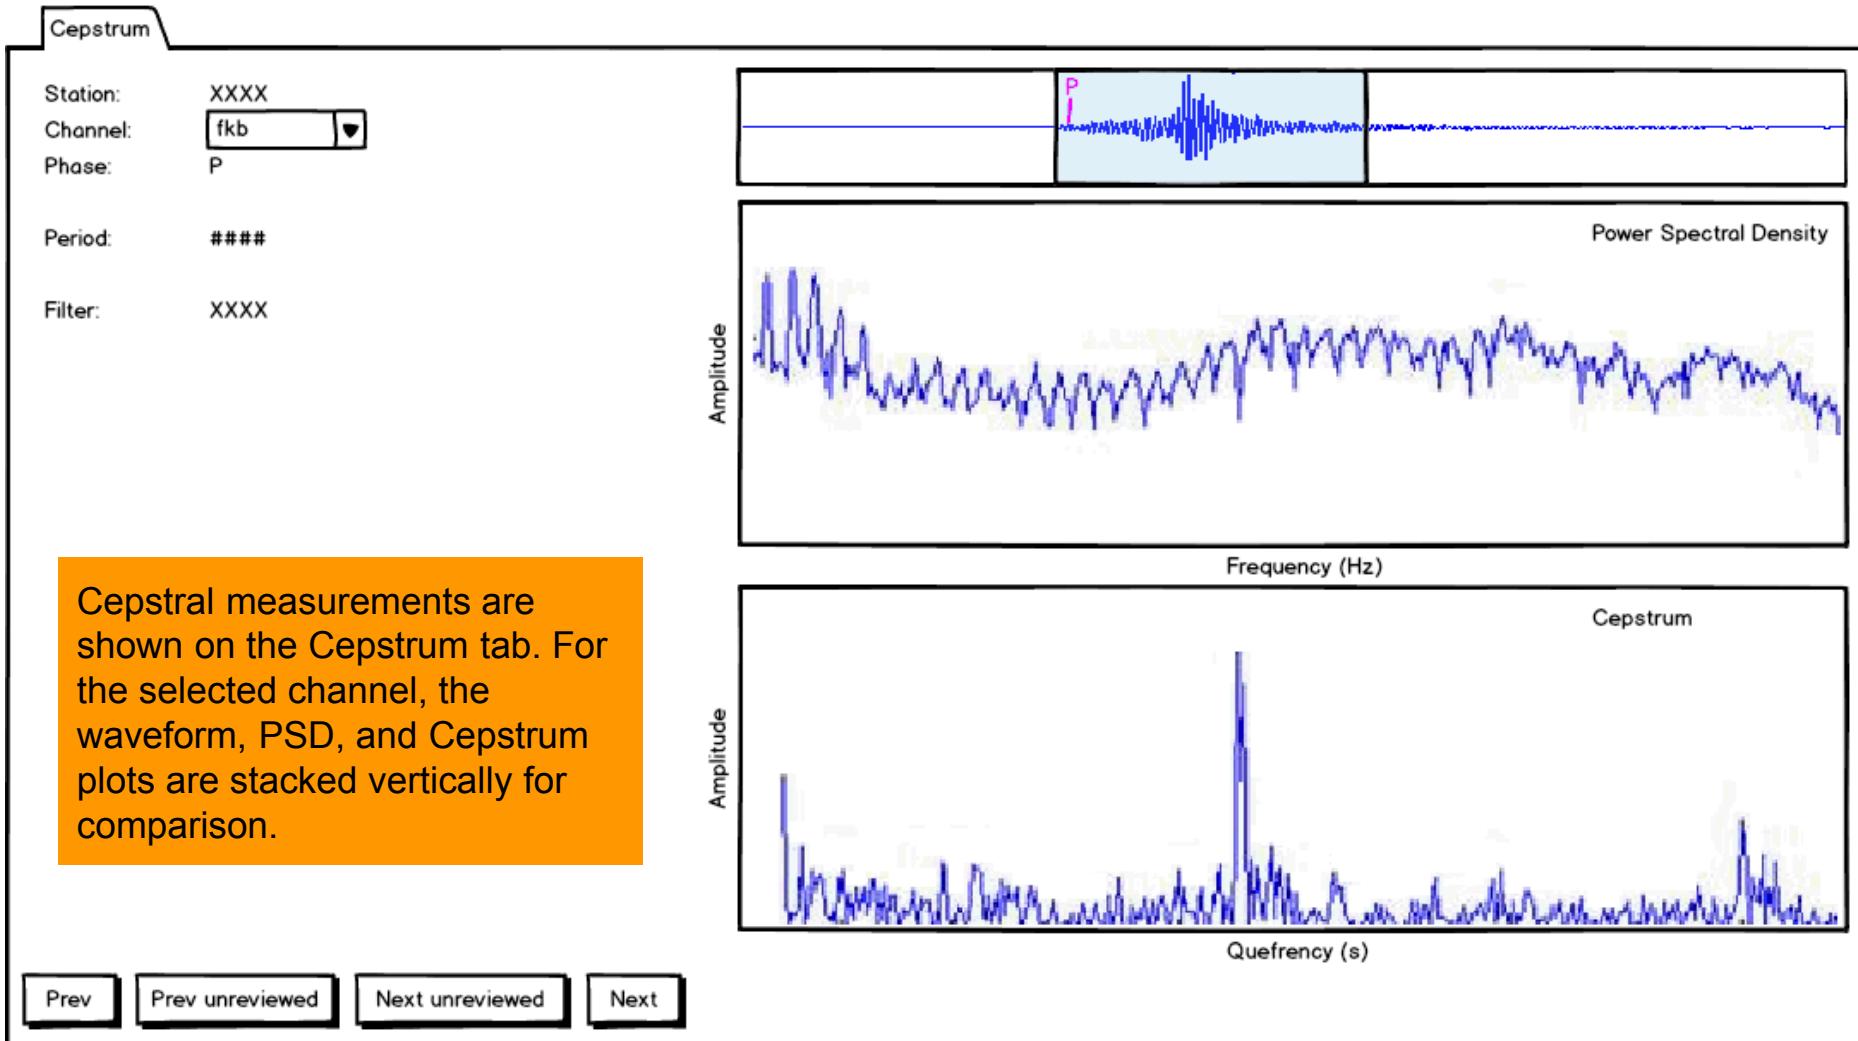

The Analyst can add new detections or modify existing ones (e.g., retime, associate/unassociate) via these channel waveforms or via the main waveform display. Changes are automatically synchronized between the two displays.

Infrasound azimuth/slowness

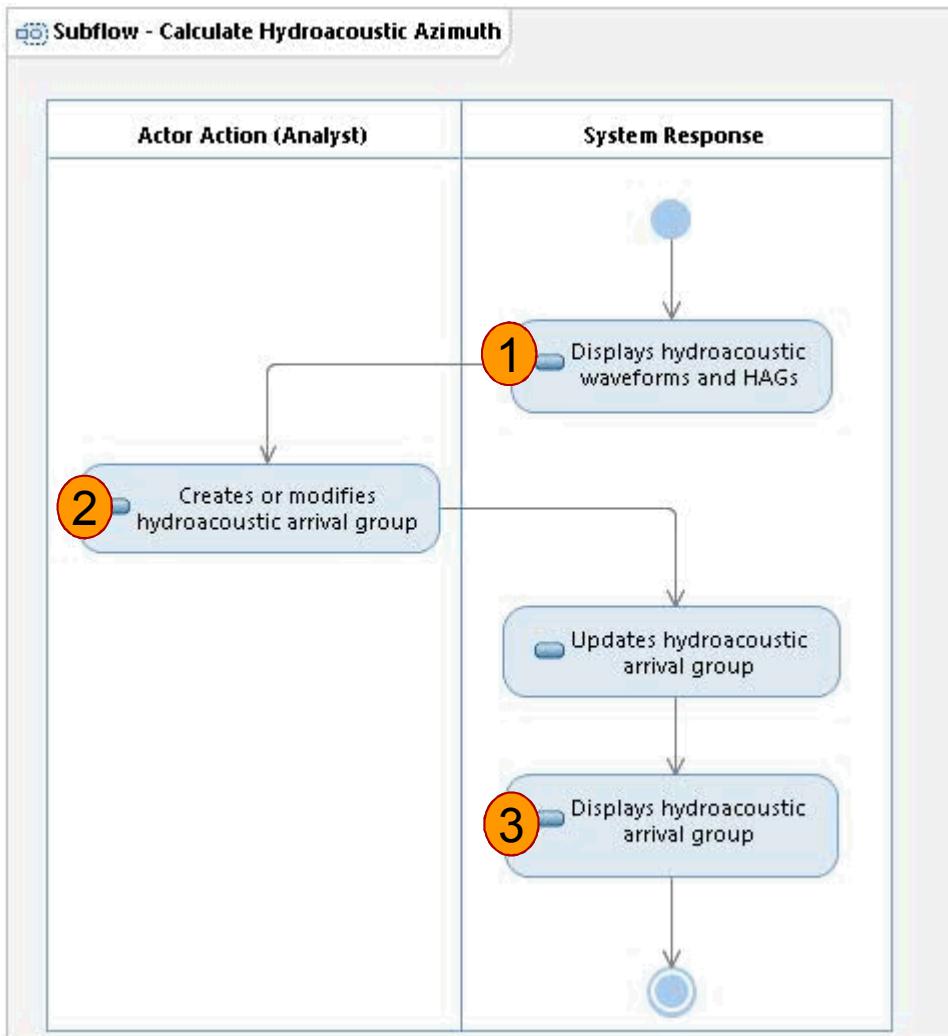

PERFORM CEPSTRAL MEASUREMENTS

2e) Perform cepstral measurements

HYDROACOUSTIC AZIMUTH

2f) Subflow: Calculate Hydroacoustic Azimuth

- 1) Displays hydroacoustic waveforms and HAGs
- 2) Creates or modifies hydroacoustic arrival group
- 3) Displays updated hydroacoustic arrival group

Hydroacoustic azimuth

- See open issue, this is TBD

Notes

- Timing uncertainties for signal detections are viewed/modified via the main waveform display. See UIS Detects Signals.

Open Issues

- Need to finalize infrasound/PMCC details. What did we get right in slides 27-30, what is missing? (CR1993)
- Need to address hydroacoustic arrival groups (CR1994)
 - We would like to see how HAGs are created/modified/viewed today. What is needed in the modernized system?
 - How would a HAG display differ from the hydro fk shown on Slide 24? Are both useful?
- We would like to see how cepstral measurements are currently being used by analysts. What measurement is being made? Can the Analyst accept/modify the measurement?
