Environmental Considerations for SCC Testing

Charles Bryan and David Enos

*Las Vegas, NV
September 22, 2015*

Used Fuel Disposition

ISFSI locations

Different settings

– Varying salt assemblages

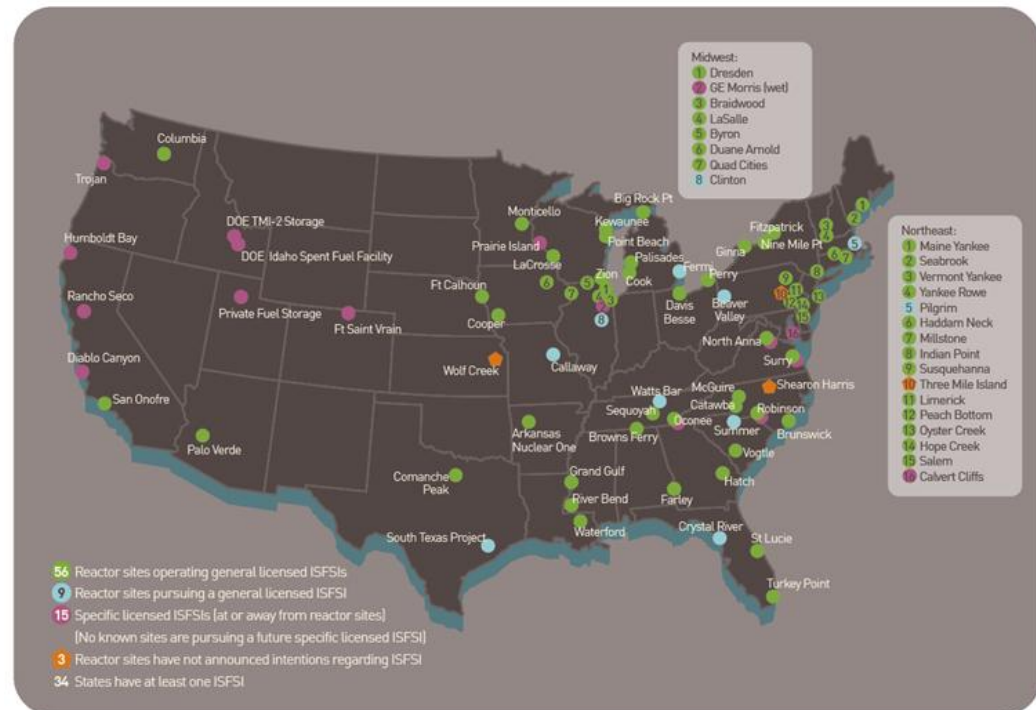

- Coastal (marine salt aerosols)
- Inland (ammonium, sulfate, and nitrate-rich aerosols; possible road salts, cooling tower emissions)
- Salt assemblages control DRH and RH_L

– Range of weather conditions

- Dewpoints (absolute humidity (AH) values)
- Ambient temperatures

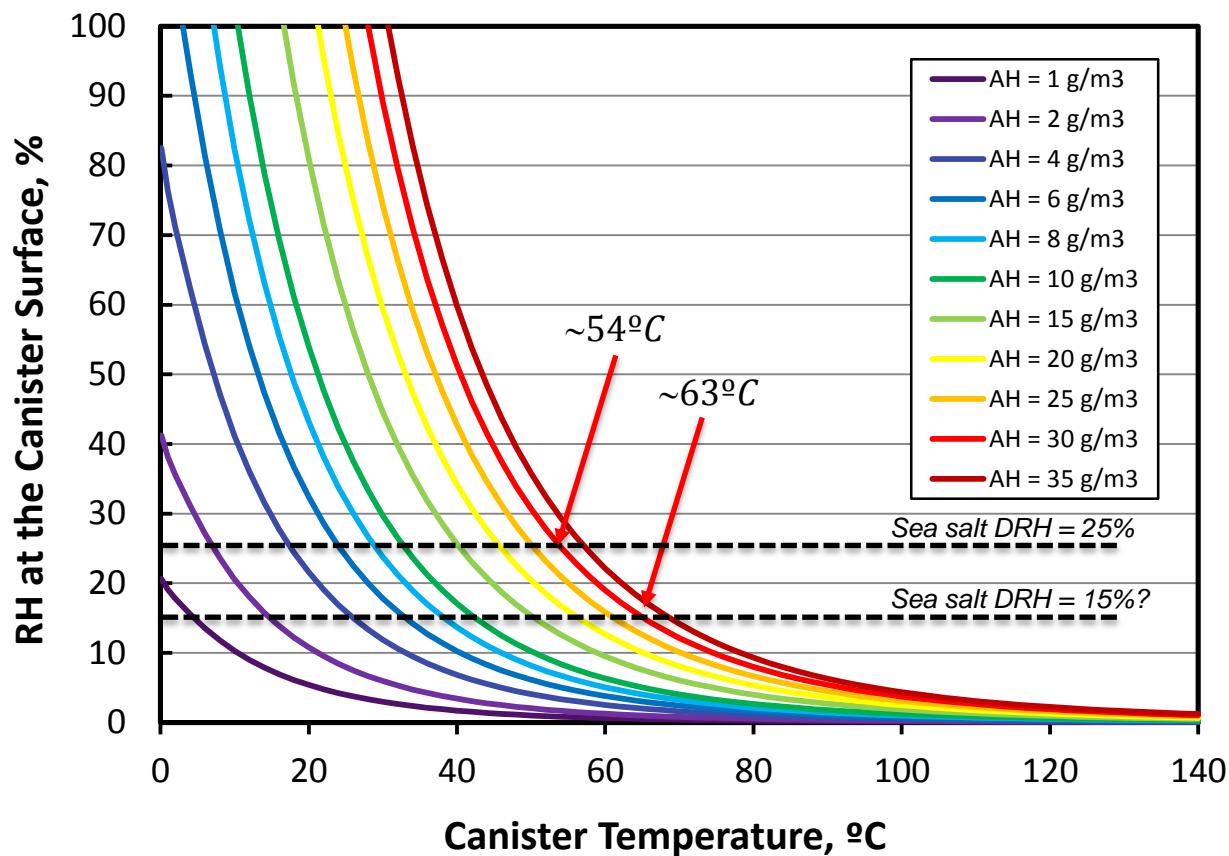

– Temperature range of interest

- Determined by RH_L and AH

Temperature Range of Interest

The temperature range of interest for corrosion experimental work is a function of AH and RH_L.

Used Fuel Disposition

Marine aerosols—observed

Sea salt/spray — generally simulated with synthetic ocean water (ASTM D1141-98)

Sea-salt aggregate on Diablo Canyon ISFSI storage canister

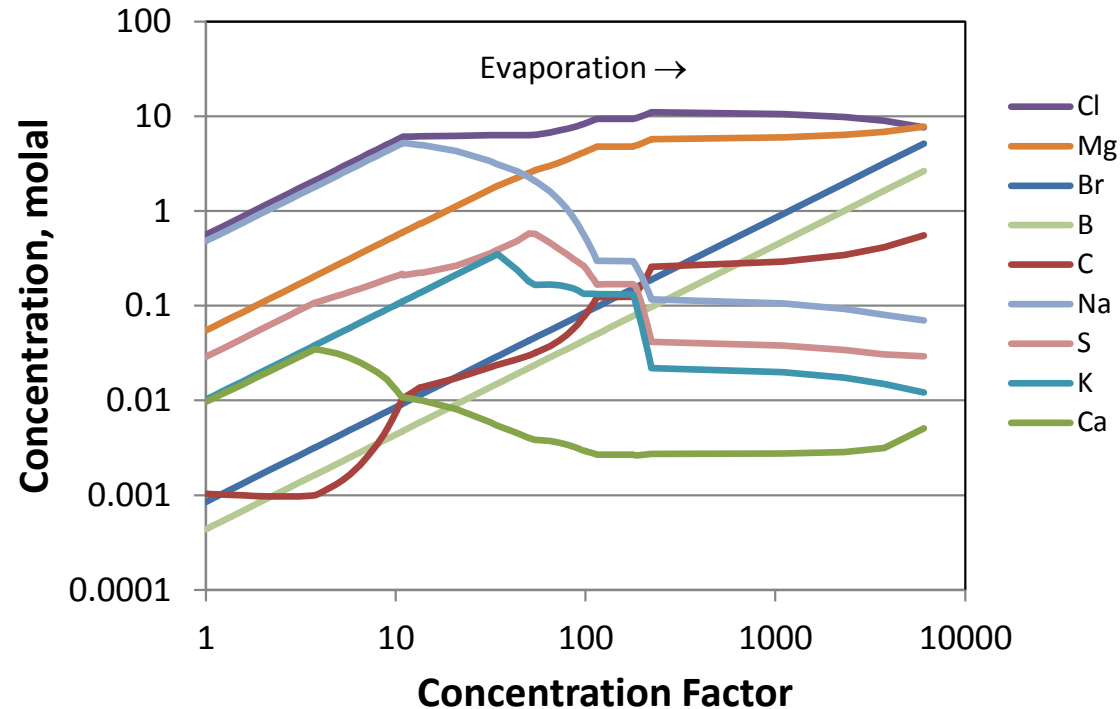

| Species | Conc., mg/L | |
|-------------------------------|---------------|-------------------------|
| | ASTM D1141-98 | McCaffrey et al. (1987) |
| Na ⁺ | 11031 | 11731 |
| K ⁺ | 398 | 436 |
| Mg ²⁺ | 1328 | 1323 |
| Ca ²⁺ | 419 | 405 |
| Cl ⁻ | 19835 | 21176 |
| Br ⁻ | 68 | 74 |
| F ⁻ | 1 | — |
| SO ₄ ²⁻ | 2766 | 2942 |
| BO ₃ ³⁻ | 26 | — |
| HCO ₃ ⁻ | 146 | — |
| pH | 8.2 | 8.2 |

Seawater evaporation

Brine composition:

- Upon evaporation, salts precipitate and redissolve. Removed salts dictate the composition of remaining brine
- Seawater evolves towards concentrated Mg-Cl brine as NaCl precipitates
- Br and B conserved (but YMP Pitzer database is not qualified for B, and may not be accurate)
- Ca, K, S are mostly removed by minerals, and are very low in the remaining brine.

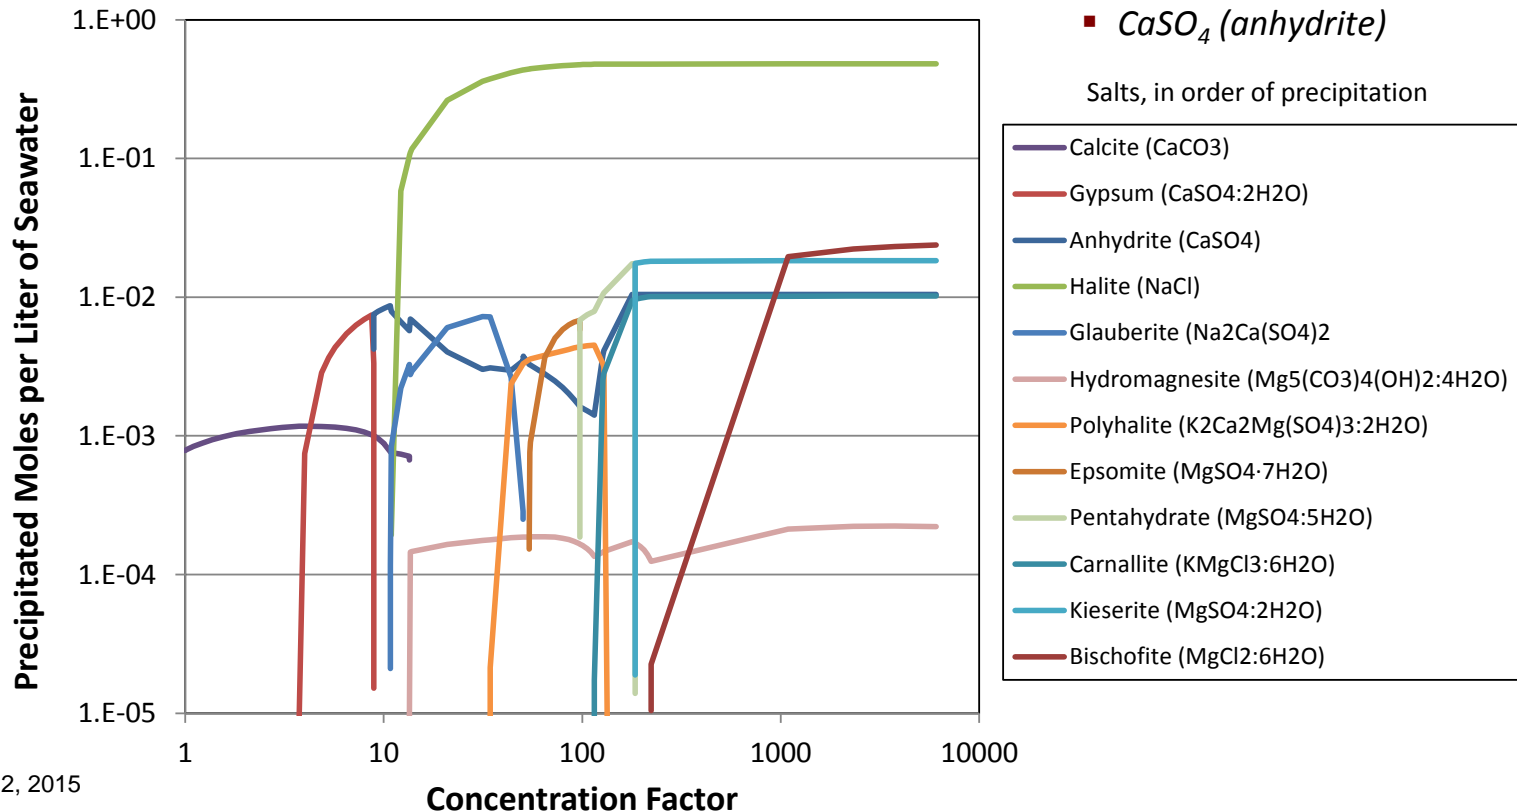

Seawater evaporation

Precipitated salts:

Upon evaporation, several salts precipitate and re-dissolve (order given below)

Final assemblage determines deliquescence RH (DRH)

- NaCl (halite)
- $MgCl_2 \cdot 6H_2O$ (bischofite)
- $MgSO_4 \cdot 2H_2O$ (kieserite)
- $KMgCl_3 \cdot 6H_2O$ (carnallite)
- $CaSO_4$ (anhydrite)

Deliquescence RH Values for Sea Salts

Deliquescence points:

- Ca-SO_4 (gypsum or anhydrite):
DRH >99%
- Mg-SO_4 (four different hydrates):
DRH = 93-84%
- NaCl:
DRH = ~77% at all temperatures
- $\text{KMgCl}_3 \cdot 6\text{H}_2\text{O}$ (\pm sylvite):
DRH = 55-49%
- $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$:
DRH = 36-29%
- $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ plus any or all other salts:
DRH = ~Same as $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$

Used Fuel Disposition

NRC/CNWRA Sea-Salt Deliquescence Experiments

Salts evaluated:

- CaCl_2
- $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$
- NaCl
- Na_2SO_4
- Synthetic sea-salts

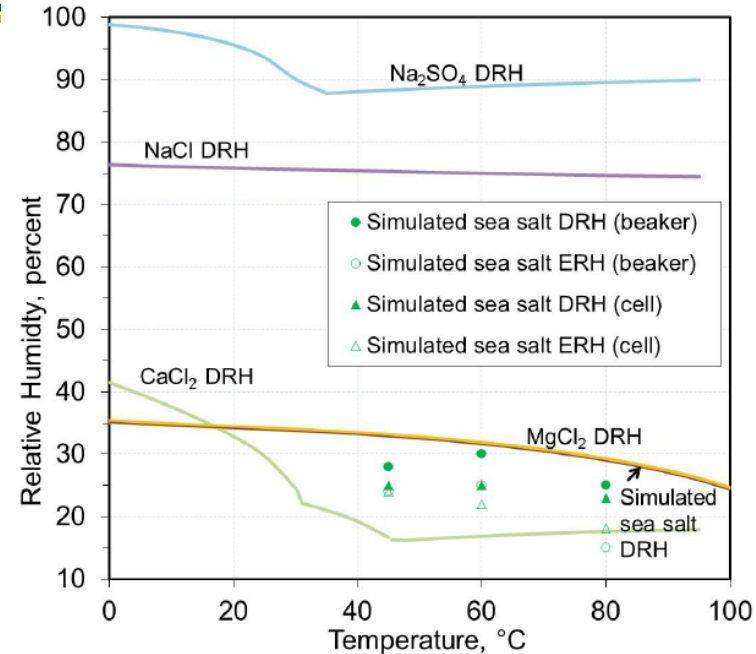

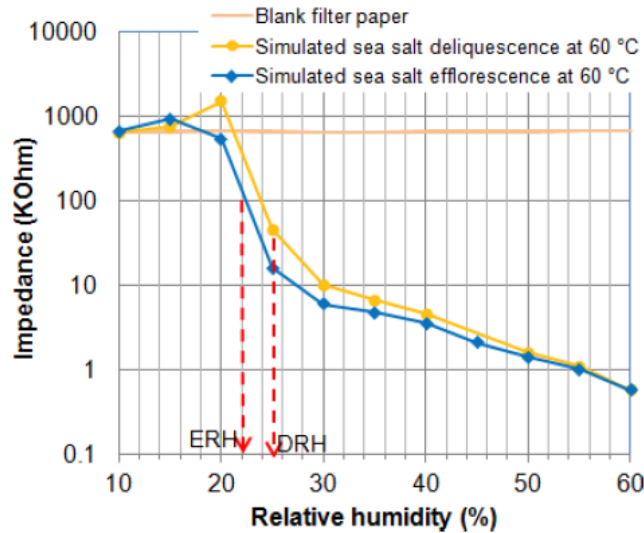

Table 2-1. Chemical Composition of Simulated Sea Salt (Wt%)*

| NaCl | $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ | Na_2SO_4 | CaCl_2 | KCl | NaHCO_3 | KBr | H_3BO_3 | $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$ | NaF |
|--------|---|--------------------------|-----------------|-------|------------------|-------|-------------------------|---|-------|
| 58.490 | 26.460 | 9.750 | 2.765 | 1.645 | 0.477 | 0.238 | 0.071 | 0.095 | 0.007 |

*Simulated sea salt purchased from Lake Products Company LLC, Florissant, Missouri.

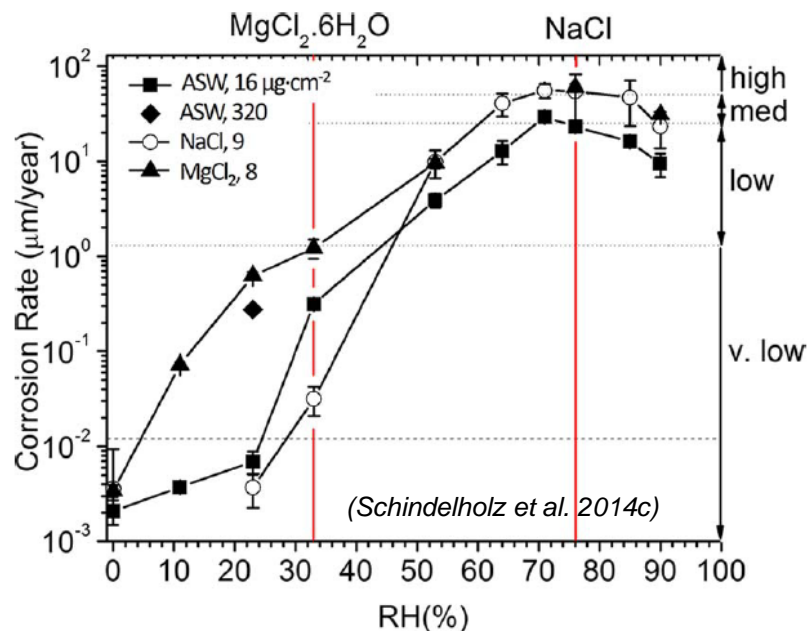

NRC (2014)

NRC Conclusion: Sea-salt deliquescence is controlled by MgCl_2 and CaCl_2 , and a deliquescent brine could form at RH conditions between those two. **This assumption seems incorrect. Ca is present as Ca-SO_4 in dried sea-salts, and is not present as $\text{CaCl}_2 \cdot \text{XH}_2\text{O}$.**

- If CaCl_2 were present, then the deliquescence point would have to be equal to or lower than that of CaCl_2 , as a brine mixture must deliquesce at a lower RH than any component salt
- Would the correct salt assemblage have the same deliquescence behavior?

Corrosion Below the Deliquescence RH

- **NaCl (DRH 77%)**
 - Schindelholz et al. (2014b) summarizes several studies--corrosion of mild steel at RH values of 50-58% RH. Their own study showed corrosion as low as 33% RH.
 - Once corrosion starts, it can persist to lower RH (at least 27% RH) due to highly deliquescent iron chloride salts.
- **MgCl₂ (DRH ~33%) (Schindelholz et al. 2014c)**
 - observed corrosion (mild steel) as low as 11% RH (21°C), at a loading of 8 μg/cm².
- **Sea-salts (Schindelholz et al. 2014c)**
 - Corrosion (mild steel) observed as low as 33% RH (21°C), at a loading of 16 μg/cm².
 - Corrosion observed as low as 23% RH (21°C), at a loading of 160 mg/m².
 - Inferred that at higher sea-salts loadings, results would match MgCl₂
- **Sea-salts (NRC)**
 - SCC (304SS) observed as between 20% and 30% RH (variable temperatures).
- **Sea-salts (Mayuzumi et al. 2008)**
 - SCC (304SS) observed at 15% RH and 80°C.

Why Corrosion Below the Deliquescence RH?

■ Salt surfaces have adsorbed water films well below the deliquescence

- NaCl has adsorbed water films on all surfaces down to 35% RH. Water adsorbs at surface steps (high energy sites) to even lower RH values. (Dai et al., 1997, “Adsorption of Water on NaCl (100) Surfaces: Role of Atomic Steps”)
- SNL experiments with ammonium salts. Salts absorb increasing amounts of water with increasing RH prior to deliquescence.

■ Metastable salt phases?

- Schindelholz et al. (2014a) observed $MgCl_2 \cdot xH_2O$ deliquescence at ~15% RH in 3 replicate experiments (complete dissolution did not occur until 33%). Attributed to possible presence of metastable hydrate phase?

What is a reasonable value for RH_L ?

Note hysteresis in deliquescence/efflorescence. Schindelholz et al. suggest that Mg-Cl containing salt assemblages, once deliquesced, may never dry out. Time-of-wetness for periodic wetting/drying may be much greater than current models calculate.

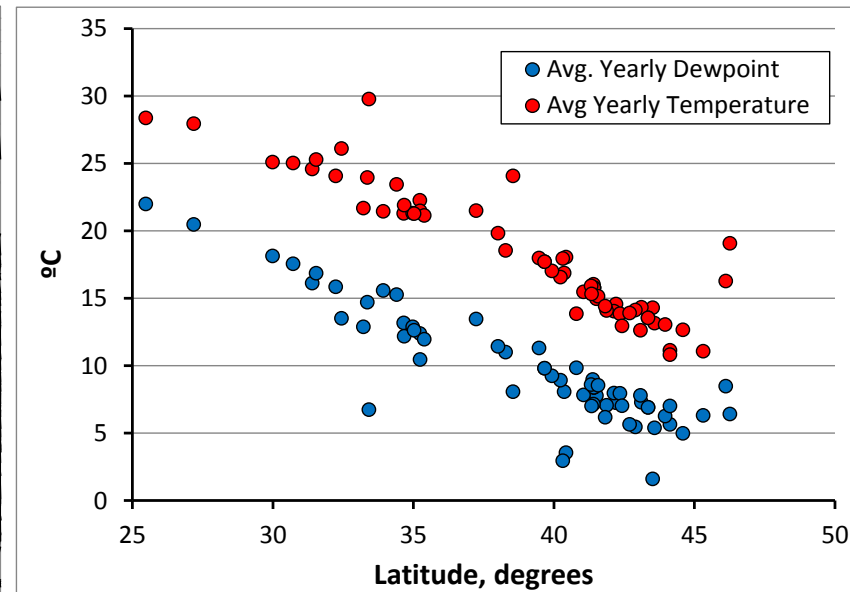

Possible Range of AH at ISFSI Sites

NRC/CNWRA (2014) suggested 30 g/m³ was an upper limit for AH, "based on meteorological monitoring data"

Weather data from 65 ISFSI sites, collected for the probabilistic SCC model, confirm this is true.

Average yearly dewpoint may be a better indicator of time of wetness. Dominant control on average AH? Latitude.

Inland salt compositions

Inland salts—ammonium, calcium, sulfate, and nitrate are the most abundant species. Chloride is present, but minor.

Inland site—continental salt aerosols. For example, data from an Iowa NADP site.

Data from 5 selected IMPROVE Monitoring sites, showing relative abundances of nitrate, chloride, and sulfate (NRC 2014 NUREG/CR-7170).

| Species | Rain Conc., µeq/L |

Negative values in the database were excluded.

Evaluating inland salts— ammonium mineral stability

- Ammonium salts decompose in the solid state to release NH_3 and acid gas:

SNL 2008, Figure 6.1-2

Deposition of soluble salts using an airbrush

- Aqueous solutions—for individual salts (0.1M)
- Deposited mass monitored using a QCM
- 25-50 multiscan passes = $100 \pm 2 \mu\text{g}/\text{cm}^2$ ($1 \text{ g}/\text{m}^2$)
- Each pass is $\sim 20 \text{ mg}/\text{m}^2$ ($2 \mu\text{g}/\text{cm}^2$)
- Lower surface loads, down to perhaps a few mg/m^2 , can be achieved using a more dilute starting solution

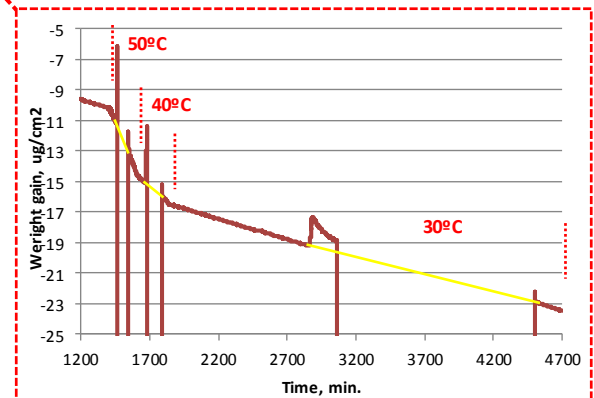

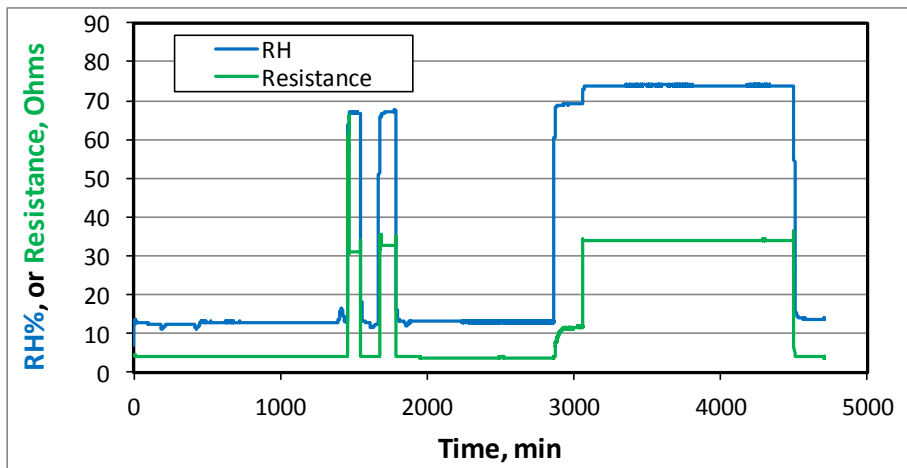

Quartz Crystal Microbalance (QCM)

Tiny mass changes are measured by a change in the vibrational frequency of the piezoelectrically stimulated quartz wafer. The active area is the area of overlap between the two electrodes (38 mm^2). Mass sensitivity is on the order of 1/10 of a monolayer of salt...

NH₄Cl experiment

Used Fuel Disposition

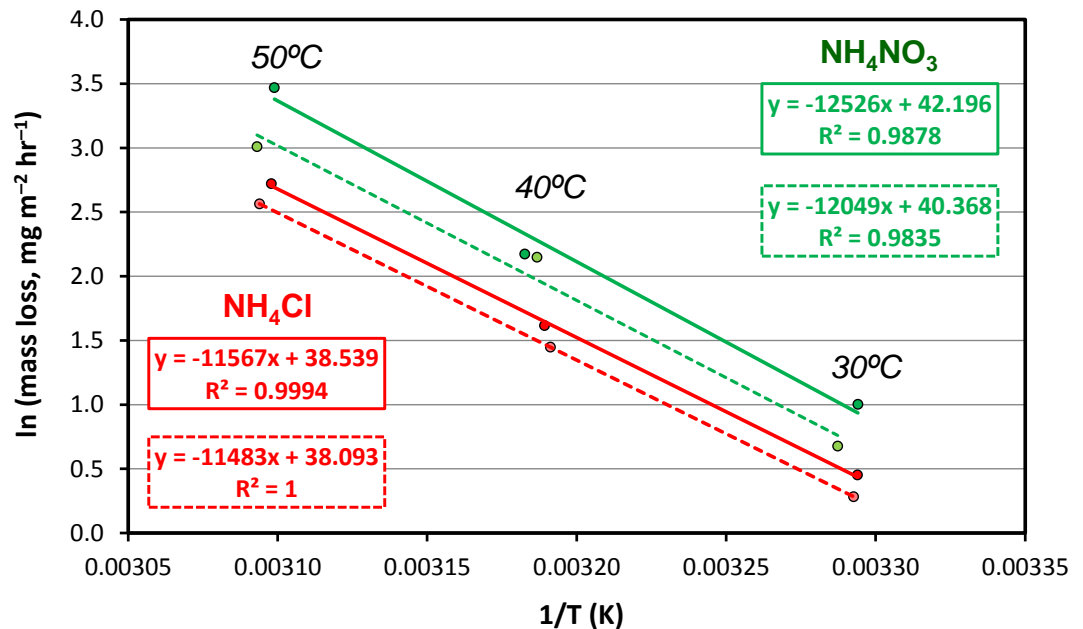

NH₄NO₃ and NH₄Cl degassing rates

NH₄Cl

| T, °C | RH | Rate, mg/m ⁻² hr ⁻¹ | Days to degas 1 g/m ⁻² |
|--------------------|------|---|-----------------------------------|
| Dry | | | |
| 49.8 | 12.6 | -15.20 | 2.7 |
| 40.6 | 12.5 | -5.03 | 8.3 |
| 30.6 | 13.0 | -1.57 | 26.5 |
| Deliquesced | | | |
| 50.2 | 63.9 | -12.98 | 3.2 |
| 40.4 | 62.1 | -4.26 | 9.8 |
| 30.7 | 72.9 | -1.33 | 31.4 |

NH₄NO₃

| T, °C | RH | Rate, mg/m ⁻² hr ⁻¹ | Days to degas 1 g/m ⁻² |
|--------------------|------|---|-----------------------------------|
| Dry | | | |
| 49.7 | 13.2 | -32.10 | 1.3 |
| 41.2 | 13.2 | -8.78 | 4.7 |
| 30.6 | 13.0 | -2.72 | 15.3 |
| Deliquesced | | | |
| 50.3 | 41.2 | -20.28 | 2.1 |
| 40.8 | 41.0 | -8.56 | 4.9 |
| 31.2 | 50.3 | -1.97 | 21.2 |

| Salt | E _a , kJ/mol |
|---|-------------------------|
| NH ₄ NO ₃ , dry | 104.1 |
| NH ₄ NO ₃ , deliquesced | 100.2 |
| NH ₄ Cl, dry | 96.2 |
| NH ₄ Cl, deliquesced | 95.5 |

Degassing is faster here than in the YMP experiments because particles sizes are smaller (higher surface area). Real dust aerosols much smaller, and will degas even more rapidly.

Relevant Inland Salt Assemblages

- Dry salts of NH_4NO_3 or NH_4Cl cannot persist on the canister surface at even low temperatures.
- Dry $(\text{NH}_4)_2\text{SO}_4$ can persist on the canister surface for long periods.
- Deliquesced brines containing NH_4 and either NO_3^- or Cl^- cannot exist on the canister at above ambient temperatures.
- Incidentally deposited chloride salts (e.g. road salts or cooling tower salts) will only form persistent chloride-rich brines *if the chloride deposition rate is greater than the ammonium deposition rate.*
- **Relevant chloride-rich inland assemblages? NaCl + sulfates \pm nitrates?**

Does this mean that SCC is unlikely at inland sites? Maybe, but each site would have to be evaluated independently. For instance....

Used Fuel Disposition

Palo Verde

- *Far from ocean; desert location with low AH (based on weather data from Buckeye).*
- *But there are cooling towers, using 40,000-50,000 gallons of water per minute.*
- *Towers use 20 billion gallons of recycled grey water from Phoenix each year.*

Environmental conditions for corrosion testing

- Maximum AH 30 g/m³
- RH_L? For sea-salts, may be a function of salt load (minimum brine volume required). MgCl₂ data suggest it may be as low as 10-15%, if sufficient sea-salt present.
- Maximum temperature to consider? At least 65°C (RH_L =15%)?
- Salt compositions:
 - Sea-salts
 - Inland salts. Uncertain, but no NH₄Cl, NH₄NO₃, or combinations that would produce brines containing (NH₄⁺ + Cl⁻), or (NH₄⁺ + NO₃⁻)
