NCT cases for the "**fl**" and "**fd**" calculation models are documented in Table 6.9.6-11b. The reference case results based on the uniform dispersal approximation "**cha**" model are highlighted. The corresponding cases for the packaging fraction ("**fl**") and for the dispersed content ("**fd**") calculation models are given in the rows below the reference case. Consider Case **nciabmt11_4_1_5_3** where the quantity of HEU content in the model is calculated based on a discrete number of 1-in. cubes. The HEU in corresponding Cases **nciapbmflt11_1_*n*_4_5** and **nciapbmfdt11_1_*n*_4_5** is not limited to fractional kilogram quantities based on whole cubes as in Case **nciabmt11_4_1_5_3**. Instead, the intended whole kilogram quantities of HEU are evaluated as a function of the packing fraction ("***n***") in the ". . . flt11_1_***n***_ . . ." and ". . . fdt11_1_***n***_ . . ." cases.

An increase of ~0.08 in the k_{eff} + 2σ value is observed as the packing fraction is reduced and more water is homogenized with the fissile material, (i.e., Cases **nciapbmtfl11_1_6_4_5** through **nciapbmtfl11_1_2_4_5**, Table 6.9.6-11b). As the packing fraction is reduced and the volume of the content location increases accordingly, neutron multiplication increases due to increased moderation of the fissile material. A considerable increase of ~0.22 in the k_{eff} + 2σ value is observed when fissile material in the upper can location is homogenized with water in the upper content location and dispersed over that region, (i.e., Case **nciapbmtfl11_1_6_4_5** vs Case **nciapbmtfd11_1_6_4_5**, Table 6.9.6-11b). Nevertheless, the k_{eff} + 2σ values for the packaging fraction "**fl**" and dispersed content calculation "**fd**" models are lower than values for the corresponding uniform dispersal approximation "**cha**" model. The "**cha**" model evaluated without polyethylene bounds results for the more realistic "**fl**" and "**fd**" models evaluated with 500 g polyethylene and the HEU content of the package confined to the specific content locations.

Powder, particulate, or small pieces of HEU potentially present in broken metal are capable of passing between content locations. The quantity of this material, potentially present, represents a small fraction of the total HEU broken metal content. The placement of a limit on content size for criticality control is adopted as a package content loading restriction (Sect. 6.2.4, Item 6). Moreover, the loading limits for broken metal content established based on the "**cha**" model are retained, recognizing that the use of polyethylene is not addressed in "**cha**" model.

Evaluation of arrays of packages with HEU broken metal, turnings, fines, or powder, and no canned spacers. For enrichments 70 to 80 wt % ^{235}U, the maximum amount of ^{235}U permissible in a flooded ES-3100 package is 27,443-g ^{235}U for broken metal or 19,284-g ^{235}U for metal turnings, fines, or powder. As discussed in Sect. 6.4.2, credit for the presence of 277-4 canned spacers for criticality safety cannot be taken when determining the loading limits for metal turnings, fines, and powder. Without 277-4 canned spacers present in the NCT package containing broken metal, turnings, fines, or powder, the potential fissile mass loading limit over the range 70 to 80 wt % ^{235}U and for a CSI = 0 must be 2,967-g ^{235}U (Case **nciabmt11_4_1_5_3**) in order for the k_{eff} + 2σ value (0.921) to be below the USL of 0.925. Suitability of this 2,967-g ^{235}U fissile mass loading limit for a CSI = 0, which is based on an infinite array of NCT packages, is contingent upon an infinite array of damaged packages also being adequately subcritical for HAC (Sect. 6.6.2).

For NCT arrays loaded with the broken metal content, including turnings, fines, or powder with 500 g of polyethylene and with no canned spacers, calculations were performed for various enrichments with a CSI of 0.0, 0.4, 0.8, 2.0, and 3.2. The original broken metal models were used for these calculations. These models were modified by adding 500 g of polyethylene, modifying the format of the input decks to run on SCALE 6.1.3, and adding more particles. The results for the highest broken metal mass are found in Table 6.25, with all cases shown to be below the USL. The results of all of these calculations are found in Table 6.9.6-12a.

Table 6.25. Array, NCT package model, broken metal (including turnings, fines, or powders) mixed with 500 g polyethylene, with no canned spacers

Repetitious use of the evaluation technique. This evaluation technique for determination of mass loading limits for enrichment intervals is repeated over the range of HEU enrichments identified in Tables 6.1c and 6.1d.

6.5.3 HEU Oxide

Like packages with HEU metal or broken metal, the neutron multiplication factor for an NCT array of packages with HEU product oxide decreases as a function of decreasing ^{235}U mass [parametric Cases **nciapdoxt11_1_*n*_24_3**, **nciapdoxt11_1_*n*_20_3**, **nciapdoxt11_1_*n*_15_3**, **nciapdoxt11_1_*n*_12_3**, **nciapdoxt11_1_*n*_11_3**, and **nciapdoxt11_1_1_10_3** through **nciapdoxt11_1_1_6_3** (Table 6.9.6-13b)]. For these NCT cases, the MOIFR is set at 1.0E-04 such that neutronic interaction between packages of an array is maximized. Results for the parametric cases reveal the same consistent increase in the $k_{eff} + 2\sigma$ values with decreasing bulk density as observed in the single package calculation results (Sect. 6.4.3). Results for Cases **nciapdoxt11_1_*n*_11_3** and **nciapdoxt11_1_1_10_3** through **nciapdoxt11_1_1_6_3** demonstrate that over the range of HEU oxide bulk densities from 6.54 to 2.0 g/cm^3, the $k_{eff} + 2\sigma$ values are below the USL of 0.925.

Cases **nciask_1_15** through **nciask_10_15** (Appendix 6.9.6, Table 6.9.6-18) evaluate infinite arrays of packages having the 10 skull oxide compositions described in Sect. 6.4.3. The MOIFR is set at 1.0E-04 such that neutronic interaction between packages is maximized. The $k_{eff} + 2\sigma$ values, ranging from 0.656 to 0.764, are substantially below the below the USL value of 0.925, indicating that canned spacers are not required for criticality control.

The CSI is 0.0 for an infinite array of packages having product oxide content with a bulk density ≥2.0 g/cm^3 and with a maximum of 9,682-g ^{235}U or having skull oxide content with a maximum of 16,399-g ^{235}U and 921 g graphite. The suitability of this determination is contingent upon satisfactory results under the HAC evaluation (Sect. 6.6.3).

Additional calculations are performed for bulk densities from 1.75 g/cm^3 to 0.5 g/cm^3 for NCT, varying the specific gravity outside of the CV (MOIFR) from dry to fully flooded. The uranium oxide is evaluated at bulk densities of 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The results for the highest oxide mass are found in Table 6.26 below, with all cases shown to be below the USL. The results of all of these calculations are found in Table 6.9.6-13d. Note that the 2.0 g/cm^3 cases are found in Appendix 6.9.9.

Table 6.26. Infinite array, NCT package model, uranium oxide mixed with 500 g polyethylene, (USL=0.935)

Case	MOIFR	Density (g/cm^3)	UO_2 Mass (kg)	^{235}U Mass (kg)	k_{eff}	σ	$k_{eff} + 2\sigma$
ncialdoxt11_1_19_1	1.0E-20	1.75	10.75	9.4	0.9320	0.0012	0.9344
ncialdoxt11_2_16_3	1.0E-04	1.50	9.5	8.3	0.9313	0.0013	0.9339
ncialdoxt11_3_12_2	1.0E-05	1.25	8.25	7.2	0.9321	0.0013	0.9347
ncialdoxt11_4_9_1	1.0E-20	1.00	6.75	5.9	0.9290	0.0018	0.9326
ncialdoxt11_5_5_2	1.0E-05	0.75	5.5	4.8	0.9306	0.0013	0.9332
ncialdoxt11_6_1_2	1.0E-05	0.50	4.0	3.5	0.9247	0.0012	0.9271

Additional calculations were performed for uranium oxide mixed with thorium oxide and uranium oxide mixed with thorium metal oxide at the same densities as uranium oxide. Thorium is not fissile and would not increase the reactivity of this system; however, the saturated water that is in the thorium oxide model may provide a more optimum moderation configuration, especially at lower bulk densities. Calculations were also performed for uranium oxide mixed with zirconium oxide. Parametric

studies were performed for various uranium oxide loadings varying the amount of thorium oxide, thorium metal, or zirconium oxide.

In the infinite array calculations, the CV is modeled fully flooded and the NCT package is evaluated at various interstitial moderated cases. As in the CV cases, calculations are performed to exam UO_2 mixed with ThO_2, thorium metal, or ZrO_2 at bulk densities of 2.0, 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The amount of ThO_2, thorium metal, or ZrO_2 that is added is dependent upon the amount of available space within the CV and the total amount of oxide allowed (13.15 kg). At lower densities, the amount of ThO_2, thorium metal, or ZrO_2 that can be added to the CV decreases with decreasing density. Unlike the CV and single package cases, as shown in Tables 6.9.6-13h, 6.9.6-13i, and 6.9.6-13j, for all bulk oxide densities, as ThO_2, thorium metal, or ZrO_2 is added, reactivity increases. The UO_2 oxide limit is not bounding for bulk densities of UO_2 mixed with ThO_2. Thus, for these densities, lower limits are required. The results for the highest oxide mass are found in Table 6.27 for thorium oxide, Table 6.28 for zirconium oxide, and Table 6.29 for thorium metal, with all cases shown to be below the USL.

6.5.4 UNH Crystals

Unlike the HEU metal, broken metal, or oxide content, UNH crystals are soluble in water (Sect. 6.4.4). The most reactive content condition occurs at an optimum solution concentration derived from the UNH crystal loading and the volume of water flooding the CV. Both flooding of the CV and a reduced loading of UNH crystals going into solution is required to achieve the most reactive configuration.

Similar to packages with HEU metal, broken metal, or oxide, the neutron multiplication factor for an array of packages with UNH crystals decreases as a function of increasing MOIFR. Cases **nciaunhct11_8_24_1_1** through **nciaunhct11_8_24_1_15** for content without polyethylene and Cases **nciapunhct11_24_1** and **nciapunhct11_24_15** for content with 500 g polyethylene (Table 6.9.6-15) reveal the effect of isolating the individual array units from each other with the introduction of water above ~0.01 MOIFR. Array reactivity ($k_{eff} + 2\sigma = 0.721$ without polyethylene and 0.729 with polyethylene) approaches the reactivity of the water-saturated, water-reflected single-unit package ($k_{eff} + 2\sigma = 0.702$ without polyethylene and 0.708 with polyethylene).

In a series of NCT calculations (Cases **nciapunhct11_*nn*_3**), the $k_{eff} + 2\sigma$ values are above the USL of 0.925 for mass loadings between 8,000 and 24,000-g UNH crystals. Credit is not taken for water tightness that is demonstrated by the NCT (and HAC) tests. Therefore, mass loading is limited to 7,000-g UNH crystals. The CSI is 0.0 [10 CFR 71.59(a)(1) and 10 CFR 71.59(b)] for ES-3100 packages having a maximum of 3,297-g ^{235}U. The suitability of this determination depends upon satisfactory results under the HAC evaluation of Sect. 6.6.4 [10 CFR 71.59(a)(2) and 10 CFR 71.59(b)].

The $k_{eff} + 2\sigma$ values are expected to range from subcritical to critical for array configurations where UNH crystals are dissolved in the water flooding the CV and the CV well. This requires intrusion of water into the CV, dissolving of UNH crystals in the influent, and leakage of solution out of the CVs in each package of an array (catastrophic failure of all packages in an infinite array). Given that loss of containment is deemed not credible by merit of the 10 CFR 71.71 and 10 CFR 71.73 tests performed on the ES-3100, this accident condition is not credible.

For Cases **ncf1punhct12_*nn*_3**, the $k_{eff} + 2\sigma$ values are below the USL of 0.925. Given that the results for NCT and HAC (Sect. 6.6.4) are adequately subcritical, packages may be shipped under a CSI = 0.4 for packages with a maximum of 24,000-g UNH crystals [10 CFR 71.59(a)(1) and

10 CFR 71.59(b)]. Likewise, the suitability of this determination depends upon satisfactory results under the HAC evaluation of Sect. 6.6.4.

6.6 EVALUATION OF PACKAGE ARRAYS UNDER HYPOTHETICAL ACCIDENT CONDITIONS

Except for UNH crystals, the package content is confined within the CV for the HAC array evaluation of ES-3100 packages, consistent with the result of the tests specified in 10 CFR 71.73 (Hypothetical Accident Conditions). The array sizes examined in this evaluation are infinite, 13×13×6, 9×9×4, 7×7×3, 5×5×2, ETP 16×3, and the degenerate single unit. The "N" and corresponding CSI values for arrays determined to be adequately subcritical are as follows: N = ∞, CSI = 0; N =162, CSI = 0.4; N = 73, CSI = 0.7; N = 25, CSI = 2.0; and N = 24, CSI = 2.1. All arrays, except the infinite array, are reflected with 30 cm (1 ft) of water. These array are nearly cubic in shape for optimum reactivity of the array, thus eliminating the need for placing criticality controls on package arrangements in terms of stack height, width, and depth of an array. The array configurations and the range of water contents (Table 6.4) evaluated bound all possible packaging arrangements and moderation conditions for HAC.

For the single damaged package, and for infinite and finite arrays of damaged packages with HEU metal, HEU oxide, or UNH crystal content, the neutron multiplication factor changes as a function of the ^{235}U mass, MOIFR, or applicable solution concentration in the same manner as in an array of undamaged packages.

6.6.1 Solid HEU Metal of Specified Geometric Shapes

For infinite and finite arrays of damaged packages with HEU metal, the neutron multiplication factor increases as a function of the ^{235}U mass and decreases as a function of MOIFR. For example, consider the ES-3100 package loaded with three convenience cans that contain a 3.24-in.-diam cylinder with 12,000-g ^{235}U for a total of 36,000-g ^{235}U. For package content without 277-4 canned spacers, the $k_{eff} + 2\sigma$ values range from 1.027 to 0.967 with increasing MOIFR in the damaged packages [Cases **hciacyct12_36_1_1** through **hciacyt12_36_1_15** (Appendix 6.9.6, Table 6.9.6-3)]. For package content with 277-4 canned spacers, the $k_{eff} + 2\sigma$ values range from 0.956 to 0.884 with increasing MOIFR in the damaged package [Cases **hciacyt12_36_2_1** through **hciacyt12_36_2_15** (Appendix 6.9.6, Table 6.9.6-3)].

The introduction of water above ~0.01 MOIFR shows the effect of isolating the individual array units from each other. The neutron multiplication factor approaches k_{eff} for the single, water-reflected unit at a full content-water fraction (MOIFR = 1.0). Comparison of these results with the corresponding NCT cases (Sect. 6.5.1) indicates no significant differences. This result is as expected given that the neutron multiplication in an infinite array is independent of pitch between fissile contents but is dependent on changes in mass and moderation in the array. The changes in both the outer dimensions and the compositions of the Kaolite and 277-4 of the ES-3100 package due to HAC result in changes to the neutron multiplication factor on the order of ~0.001 to 0.002.

Repeated for 4.25-in.-diam cylinders (Appendix 6.9.6, Table 6.9.6-7); 2.29-in.-square bars (Table 6.9.6-5); and 1.5-in.-diam × 2-in.-tall slugs (Table 6.9.6-9), this type of analysis for the 3.24-in.-diam cylinders demonstrates that arrays of damaged packages with restricted fissile material (^{235}U) loading remain subcritical over the entire range of water content or MOIFR. HEU metal or alloy content not covered by the specified geometric shapes (cylinder, square bar, or slug contents) will be in the HEU broken metal category, and so limited.

For the two types of annular cylinders, the NCT cases for an infinite array of packages, the CV is modeled fully flooded and the interstitial water moderation is modeled at MOIFR = 1E-04. Each cylinder is modeled at the bottom of the CV. Case **nciacylc11** for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.83219 (k_{eff} = 0.83107, σ = 0.00056), while Case **nciacyld11** for Cylinder D has a calculated $k_{eff} \pm 2\sigma$ value of 0.85387 (k_{eff} = 0.85241, σ = 0.00073). Additional cases were run with the cylinder modeled vertically centered in the CV. Case **nciacylcc11** for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.80889 (k_{eff} = 0.80727, σ = 0.00081), while Case **nciacyldc11** for Cylinder D has a calculated $k_{eff} \pm 2\sigma$ value of 0.82521 (k_{eff} = 0.82393, σ = 0.00064).

For the HAC cases for an infinite array of damaged packages (Appendix 6.9.6, Table 6.9.6-3d), the CV is modeled fully flooded and the interstitial water moderation is modeled at MOIFR = 1E-04. Each cylinder is modeled at the bottom of the CV. Case **hciacylc12** for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.83238 (k_{eff} = 0.83124, σ = 0.00057), while for Case **hciacyld12** for Cylinder D has a calculated $k_{eff} \pm 2\sigma$ value of 0.85459 (k_{eff} = 0.85343, σ = 0.00058). Additional cases were run with the cylinder modeled vertically centered in the CV. Case **hciacylcc**12 for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.80679 (k_{eff} = 0.80557, σ = 0.00061), while Case **hciacyldc12** for Cylinder D has a calculated $k_{eff} \pm 2\sigma$ value of 0.82510 (k_{eff} = 0.82380, σ = 0.00065).

All Cylinder C and D infinite array cases were shown to be below the USL of 0.9352, with the models in which the cylinders are at the bottom of the CV being the most reactive.

Cases **hciatriga_1_1_3** through **hciatriga_1_15_3** (Appendix 6.9.6, Table 6.9.6-20) represent infinite arrays of damaged packages containing the bounding TRIGA fuel content (20 % enrichment with 45 wt % U containing 307-g ^{235}U), without 277-4 canned spacers. For these cases, the $k_{eff} + 2\sigma$ values increase from 0.218 to 0.526 as MOIFR increases. The $k_{eff} + 2\sigma$ = 0.526 for Case **hciatriga_1_15_3** is substantially below the USL of 0.925, indicating that canned spacers are not required for criticality control. Given that the results for NCT (Sect. 6.5.2) and HAC are adequately subcritical, packages with TRIGA fuel content ≤ 921-g ^{235}U may be shipped under a CSI = 0.

As stated in Sect. 6.5.1, calculation results presented in Table 6.9.6-20d for an infinite array of ES-3100 packages (NCT packaging with extremely damaged TRIGA fuel content) is substantially below the USL of 0.925. Similar results are expected for an infinite array of ES-3100 packages (HAC packaging with extremely damaged TRIGA fuel content) given that changes external to the CV due to the HAC do not result in an appreciable change in the neutron multiplication for the an array of packages. Therefore, the 10 CFR 71.55(e)(1) requirement that the package be adequately subcritical under HAC with the package contents in the most reactive credible configuration is satisfied.

The array results for three slug configurations presented in Table 6.9.6-9 (Appendix 6.9.6) are for five or ten slugs touching or spaced apart in a pentagonal ring (Cases **hcia5st12** and **hcia5est12**) and for seven slugs formed by a hexagonal ring of slugs with one slug in the center of the ring **(hcia70st12**). These cases are used to establish the mass loading limitations for damaged packages, which in turn limit the number of slugs in the package to less than the number required to assemble a critical configuration.

Cases **hcia5est12_1_1_8_3** through **hcia5est12_1_1_1_3** and Cases **hcia5st12_1_1_8_3** through **hcia5st12_1_1_1_3** (Appendix 6.9.6, Table 6.9.6-9) represent infinite arrays of damaged packages containing 18,277-g U without 277-4 canned spacers. Infinite array Cases **hcia70st11_2_8_3** through **hcia70st11_2_1_3** represent damaged packages containing 25,588-g U with 277-4 canned spacers, while Cases **hcia5est12_2_2_8_3** through **hcia5est12_2_2_1_3** represent damaged packages containing 36,558-g U also with 277-4 canned spacers. Cases **hcf25est12_2_2_8_3** through **hcf25est12_2_2_1_3** represent a 9 × 9 × 4 array of damaged packages containing 36,558-g U with 277-4 canned spacers. The $k_{eff} + 2\sigma$ values for these cases representing arrays of damaged packages are slightly less than values for the corresponding cases representing undamaged packages. (The changes in both the outer dimensions of

the package and the compositions of the Kaolite and 277-4 due to HAC result in an ~0.001 change in the neutron multiplication factor.) Therefore, the prospective CSI values determined in the NCT evaluation (Sect. 6.5.1) for arrays of undamaged packages with slug content are controlling.

6.6.2 HEU Broken Metal; Solid HEU Metal of Unspecified Geometric Shape and Characterized as Broken Metal; or Turnings, Fines, or Powder

The evaluation of various HAC array configurations for establishing the CSI for packages with broken metal (Table 6.9.6-11) reveals that 277-4 canned spacers are required in packages with enrichments >80%. As discussed in Sect. 6.4.2, credit for the presence of canned spacers required for criticality safety cannot be taken when determining the loading limits for HEU metal turnings, fines, or powder. An evaluation of HEU metal turnings, fines, or powder with enrichments ranging from 80% to 100% is presented in Appendix 6.9.11.

Like arrays of packages with solid HEU metal shapes, the neutron multiplication factor for arrays of packages with HEU broken metal, turnings, fines, or powder decreases as a function of MOIFR and increases as a function of the ^{235}U mass. Consider the ES-3100 package loaded with three convenience cans for a total of 35,142-g ^{235}U with no canned spacers between content locations. The $k_{eff} + 2\sigma$ values range from 1.14 to 0.939 with increasing MOIFR, Cases **hciabmt12_36_1_8_1** through **hciabmt12_36_1_8_15** (Appendix 6.9.6, Table 6.9.6-11). The introduction of water above MOIFR = 0.01 shows the effect of isolating the individual array units from each other. Array reactivity ($k_{eff} + 2\sigma = 0.939$) approaches the reactivity of the water-saturated, water-reflected single package ($k_{eff} + 2\sigma = 0.891$, Case **hcsrbmt12_36_1_15**, Table 6.9.6-11).

Cases **hciabmt12_1_*nn_mm*_3** through **hciabmt12_36_*nn_mm*_3** model the ES-3100 with the reduced-diameter HAC package model where the enrichment of the content is varied from 60 wt % to 100 wt % ^{235}U. These array cases with MOIFR = 1E-04 pertain specifically to HAC packages where the neutron poison of the body weldment liner inner cavity is at 90% moisture content, but the Kaolite is dry (in the as-manufactured condition), and neither recess of the package external to the CV and the interstitial space between the drums of the array contains any residual moisture. As stated before, this HAC case is more reactive than all other HAC cases where more moisture is present in the Kaolite and recesses of the package. Increasing the interspersed water between the CVs in the array will reduce neutronic interaction between the flooded contents to a point where the packages of the array become isolated.

Evaluation of arrays of packages with HEU broken metal and canned spacers present. For enrichments < 95 wt % ^{235}U, the maximum amount of ^{235}U permissible in a flooded ES-3100 package is 25,894-g ^{235}U in the broken metal. With 277-4 canned spacers present in the HAC package, the potential fissile mass loading limit for broken metal >95 to 100 wt % ^{235}U and for a CSI = 0 must be limited to 2,774-g ^{235}U (Case **hciabmt12_3_2_8_3**) in order for the $k_{eff} + 2\sigma$ value (= 0.905) to be below the USL of 0.925. Given that the results for NCT (Sect. 6.5.2) and HAC are adequately subcritical, packages ≤ 2,774-g ^{235}U and enrichment >95 wt % ^{235}U may be shipped under a CSI = 0.

For HAC arrays loaded with the broken metal content, (excluding turnings, fines, or powder) with 500 g of polyethylene and with canned spacers, calculations were performed for various enrichments with a CSI of 0.0, 0.4, 0.8, 2.0, and 3.2. The original broken metal models in this SARP were used for these calculations. These models were modified by adding 500 g of polyethylene, modifying the format of the input decks to run on SCALE 6.1.3, and adding more particles. The results for the highest broken metal mass are found in Table 6.30 below, with all cases shown to be below the USL. The results of all of these calculations are found in Table 6.9.6-11a.

Table 6.30. Infinite array, HAC package model, broken metal mixed with 500 g polyethylene, with canned spacers

Case	Enrichment (%)	U mass (kg)	^{235}U mass (kg)	k_{eff}	σ	$k_{eff} + 2\sigma$	USL

The loading limits for solid HEU metal of unspecified geometric shape or for HEU broken metal are summarized in Table 6.2a based on array calculations performed using the uniform dispersal approximation "**cha**" model (Fig. 6.9.1-5d). The calculation results on which the determination of the loading limits is based are summarized in Table 6.1c.

As discussed in Sect. 6.5.2, criticality calculations with the "**cha**" model for a packing fraction of ~0.59 bound similar cases at the lower packing fractions. The "**cha**" model is characteristic of the situation where the dimensions of the broken metal pieces are sufficiently small to allow for HEU to pass between void space formed between the inner wall of the CV and the exterior wall of each canned spacer.

As shown in Fig. 6.9.3.1-3, HEU broken metal content typically consists of irregular pieces, sufficiently large (0.5 in. to several inches on a side), that will not pass between the 277-4 canned spacer locations. The packing fraction calculation model "**fl**" and the dispersed content calculation model "**fd**" better represent broken metal content which does not pass between the canned spacer locations.

HAC cases are documented in Table 6.9.6-11c. The reference case results based on the uniform dispersal approximation "**cha**" model are highlighted. The corresponding cases for the packaging fraction ("**fl**") and for the dispersed content ("**fd**") calculation models are given in the rows below the reference case.

An increase of ~0.08 in the $k_{eff} + 2\sigma$ value is observed as the packing fraction is reduced and more water is homogenized with the fissile material (i.e., Cases **hciapbmtfl11_1_6_4_5** through **hciapbmtfl11_1_2_4_5**, Table 6.9.6-11c). As the packing fraction is reduced and the volume of the content location is increased, moderation of the fissile material increases. A considerable increase of ~0.22 in the $k_{eff} + 2\sigma$ value is observed when fissile material in the upper can location is homogenized with water in the upper content location and dispersed over that region (i.e., Case **hciapbmtfl11_1_6_4_5** vs Case **hciapbmtfd11_1_6_4_5**, Table 6.9.6-11c). Nevertheless, the $k_{eff} + 2\sigma$ values for the packaging fraction "**fl**" and dispersed content calculation "**fd**" models are lower than values for the corresponding uniform dispersal approximation "**cha**" model. The "**cha**" model evaluated without polyethylene bounds results for the more realistic "**fl**" and "**fd**" models evaluated with 500 g polyethylene and the HEU content of the package confined to the specific content locations.

Powder, particulate, or small pieces of HEU potentially present in broken metal are capable of passing between content locations. The quantity of this material, potentially present, represents a small fraction of the total HEU broken metal content. The placement of a limit on content size for criticality control is adopted as a package content loading restriction (Sect. 6.2.4, Item 6). Moreover, the loading limits for broken metal content established based on the "**cha**" model are retained, recognizing that the use of polyethylene is not addressed in "**cha**" model.

Evaluation of arrays of packages with HEU broken metal, turnings, fines, or powder, and no canned spacers. For enrichments >70 and ≤ 80 wt % ^{235}U, the maximum amount of ^{235}U permissible in a flooded ES-3100 package is 27,443-g ^{235}U for broken metal or 19,284-g ^{235}U for metal turnings, fines, or powder. As discussed in Sect. 6.4.2, credit for the presence of 277-4 canned spacers for criticality safety cannot be taken when determining the loading limits for metal turnings, fines, and powder. Without 277-4 canned spacers present in the HAC package containing broken metal, turnings, fines, or powder, the potential fissile mass loading limit over the range >70 and ≤80 wt % ^{235}U and for a CSI = 0 must be 2,967-g ^{235}U (Case **hciabmt12_4_1_5_3**) in order for the $k_{eff} + 2\sigma$ value (0.925) to be at the USL of 0.925. Given that the results for NCT (Sect. 6.5.2) and HAC are adequately subcritical, packages ≤ 2,967-g ^{235}U and enrichment >70 and ≤ 80 wt % ^{235}U may be shipped under a CSI = 0.

For HAC arrays loaded with the broken metal content, including turnings, fines, or powder with 500 g of polyethylene and with no canned spacers, calculations were performed for various enrichments with a CSI of 0.0, 0.4, 0.8, 2.0, and 3.2. The original broken metal models were used for these calculations. These models were modified by adding 500 g of polyethylene, modifying the format of the input decks to run on SCALE 6.1.3, and adding more particles. The results for the highest broken metal mass are found in Table 6.31, with all cases shown to be below the USL. The results of all of these calculations are found in Table 6.9.6-11a.

Table 6.31. Infinite array, NCT package model, broken metal (including turnings, fines, or powders) mixed with 500 g polyethylene, with no canned spacers

Repetition of the evaluation technique. This evaluation technique for determination of mass loading limits for enrichment intervals is repeated over the range of HEU enrichments identified in Tables 6.1c and 6.1d. At HEU enrichments ≤ 60 wt % ^{235}U, the evaluated package mass loading limit of 35.32-kg uranium is achieved, so further delineation of fissile mass loading limits by g ^{235}U is not required.

6.6.3 HEU Oxide

Like packages with HEU metal or broken metal, the neutron multiplication factor for an array of HAC packages with HEU product oxide decreases as a function of decreasing ^{235}U mass [parametric Cases **hciapdoxt11_1_*n*_24_3**, **hciapdoxt11_1_*n*_20_3**, **hciapdoxt11_1_*n*_15_3**, **hciapdoxt11_1_*n*_12_3**, **hciapdoxt11_1_*n*_11_3**, and **hciapdoxt11_1_1_10_3** through **hciapdoxt11_1_1_6_3** (Table 6.9.6-13b)]. For these HAC cases, the MOIFR is set at 1.0E-04 such that neutronic interaction between packages of an array is maximized. Results for the parametric cases reveal the same consistent increase in the $k_{eff} + 2\sigma$ values with decreasing bulk density as observed in the single package calculation results (Sect. 6.4.3). Results for Cases **hciapdoxt11_1_*n*_11_3** and **hciapdoxt11_1_1_10_3** through **hciapdoxt11_1_1_6_3** demonstrate that over the range of HEU oxide bulk densities from 6.54 to 2.0 g/cm^3, the $k_{eff} + 2\sigma$ values are below the USL of 0.925. Given that the results for NCT (Sect. 6.5.3) and HAC are adequately subcritical, packages may be shipped under a CSI = 0.0 for an infinite array of packages having product oxide with a maximum of 9,682-g ^{235}U.

Cases **hciask_1_15** through **hciask_10_15** (Appendix 6.9.6, Table 6.9.6-18b) evaluate infinite arrays of damaged packages having the 10 skull oxide compositions described in Sect. 6.4.3. The differences between the HAC case results and the NCT case results are not statistically significant. The $k_{eff} + 2\sigma$ values, ranging from 0.658 to 0.767, are substantially below the USL value of 0.925. Given that the results for NCT (Sect. 6.5.3) and HAC are adequately subcritical, packages may be shipped under a CSI = 0.0 for an infinite array of packages having skull oxide content with a maximum of 16,399-g ^{235}U and 921 g graphite.

Additional calculations are performed for bulk densities ranging from 1.75 g/cm^3 to 0.5 g/cm^3 for HAC and varying the specific gravity outside of the CV (MOIFR) from dry to fully flooded. The uranium oxide is evaluated at bulk densities of 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The results for the highest oxide mass are found in Table 6.32, with all cases shown to be below the USL.

Table 6.32. Infinite array, HAC package model, uranium oxide mixed with 500 g polyethylene, (USL=0.935)

Case	MOIFR	Density (g/cm^3)	UO_2 mass (kg)	^{235}U mass (kg)	k_{eff}	σ	$k_{eff} + 2\sigma$
hcialdoxt12_1_19_2	1.0E-05	1.75	10.75	9.4	0.9324	0.0013	0.9350

The HAC cases are about as reactive as the NCT cases except at a bulk density of 1.25 g/cm^3. At this bulk density, the HAC cases are slightly more reactive at 8.25 kg oxide (7.2 kg ^{235}U) than the NCT cases and are above the USL. Additional calculations at 8.00 kg oxide (7.0 kg ^{235}U) for HAC are shown to be below the USL.

Additional calculations were performed for uranium oxide mixed with thorium oxide and uranium oxide mixed with thorium metal oxide at the same densities as uranium oxide. Thorium is not

fissile and would not increase the reactivity of this system; however, the saturated water that is in the thorium oxide model may provide a more optimum moderation configuration, especially at lower bulk densities. Calculations were also performed for uranium oxide mixed with zirconium oxide. Parametric studies were performed for various uranium oxide loadings varying the amount of thorium oxide, thorium metal, or zirconium oxide.

In the infinite array calculations, the CV is modeled fully flooded and the HAC package is evaluated at various interstitial moderated cases. As in the CV cases, calculations are performed to exam UO_2 mixed with ThO_2, thorium metal, or ZrO_2 at bulk densities of 2.0, 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The amount of ThO_2, thorium metal, or ZrO_2 that is added is dependent upon the amount of available space within the CV and the total amount of oxide allowed (13.15 kg). At lower densities, the amount of ThO_2, thorium metal, or ZrO_2 that can be added to the CV decreases with decreasing density. Unlike the CV and single package cases, as shown in Tables 6.9.6-13h, 6.9.6-13i, and 6.9.6-13j, for all bulk oxide densities, as ThO_2, thorium metal, or ZrO_2 is added, reactivity increases. The UO_2 oxide limit is not bounding for bulk densities of UO_2 mixed with ThO_2. Thus, for these densities, lower limits are required. The results for the highest oxide mass are found in Table 6.33 for thorium oxide, Table 6.34 for zirconium oxide, and Table 6.35 for thorium metal, with all cases shown to be below the USL.

3_7_2b	1.0E-04	0.50	3.75	1.05	3.301	0.93407	0.00078	0.93563	0.93680

The HAC cases are about as reactive as the NCT cases, with all cases, both NCT and HAC, were shown to be below the USL.

6.6.4 UNH Crystals

Unlike the HEU metal, broken metal, or oxide content, UNH crystals are soluble in water (Sect. 6.4.4). The most reactive content condition occurs at an optimum solution concentration derived from the UNH crystal loading and the volume of water flooding the CV. Both flooding of the CV and a reduced loading of UNH crystals going into solution is required to achieve the most reactive configuration.

Similar to packages with HEU metal, broken metal, or oxide, the neutron multiplication factor for an array of damaged packages with UNH crystals decreases as a function of increasing MOIFR. Cases **hciaunhct12_8_24_1_1** through **hciaunhct12_8_24_1_15** for content without polyethylene and Cases **hciapunhct12_24_1** and **hciapunhct12_24_15** for content with 500 g polyethylene (Table 6.9.6-15) reveal the effect of isolating the individual array units from each other with the introduction of water above ~0.01 MOIFR. Array reactivity ($k_{eff} + 2\sigma = 0.729$ without polyethylene

and 0.733 with polyethylene) approaches the reactivity of the water-saturated, water-reflected unit single package ($k_{eff} + 2\sigma = 0.704$ without polyethylene and 0.711 with polyethylene).

In a series of HAC calculations (Cases **hciapunhct11_*nn*_3**), the calculated $k_{eff} + 2\sigma$ values are below the USL of 0.925 for loading with <8,000-g UNH crystals. Given that the results for NCT (Sect. 6.5.4) and HAC are adequately subcritical, the CSI is 0.0 [10 CFR 71.59(a)(2) and 10 CFR 71.59(b)] for packages having a maximum of 3,297-g ^{235}U.

The $k_{eff} + 2\sigma$ values are expected to range from subcritical to critical for array configurations where UNH crystals are dissolved in the water flooding the CV and the CV well. This requires intrusion of water into the CV, dissolving of UNH crystals in the influent, and leakage of solution out of the CVs in each package of an array. The leakage out of the CV of content moderated "to such an extent as to cause maximum reactivity consistent with the physical and chemical form of material" is not considered credible HAC based on results for tests specified in 10 CFR 71.73.

In a series of HAC calculations (Cases **hcf2punhct12_*nn*_3**), the calculated $k_{eff} + 2\sigma$ values are below the USL of 0.925. Given that the results for NCT (Sect. 6.5.4) and HAC are adequately subcritical, packages may be shipped under a CSI = 0.4 for packages with a maximum of 24,000-g UNH crystals.

6.7 FISSILE MATERIAL PACKAGES FOR AIR TRANSPORT

A series of calculations is performed for determining the most reactive configuration of the content and surrounding packaging material in an ES-3100 package that undergoes catastrophic destruction. Fissile content mass loadings that remain under the USL for these catastrophic events are identified. Subcriticality is demonstrated after due consideration of such aspects as the efficiency of moderator, loss of neutron absorbers, rearrangement of packaging components and contents, geometry changes and temperature effects. The six calculation models used in this evaluation are described in Sect. 6.3.1.4. Key model dimensions and parameters are tabulated in Tables 6.9.6-21 through 6.9.6-23, Appendix 6.9.6.

6.7.1 Results for HEU Metal (Excluding TRIGA Fuel Elements)

In this section, "HEU metal" refers to HEU metal content of specified geometric shape (cylinder, bar, or slug), of an unspecified geometric shape (characterized as broken metal), or broken metal. The uranium is homogenized with hydrogenous packaging material and evaluated as a distinct lump ("fissile core") that is not mixed with other packing or packaging materials.

Cases **atdmr_10_8** through **atdmr_7_1** (Table 6.9.6-21, Appendix 6.9.6) pertain to Model 1 (Fig. 6.11, Sect. 6.3.1.4). HEU metal of three convenience cans is homogenized with 500 g of polyethylene, representing the potential use of hydrogenous packing materials in the ES-3100. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. As shown in Fig. 6.20 and Table 6.9.6-21, the $k_{eff} + 2\sigma$ values decrease as a function of both enrichment and ^{235}U mass. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.925. The $k_{eff} + 2\sigma$ value for 7 kg of HEU at 100 % enrichment is 0.791.

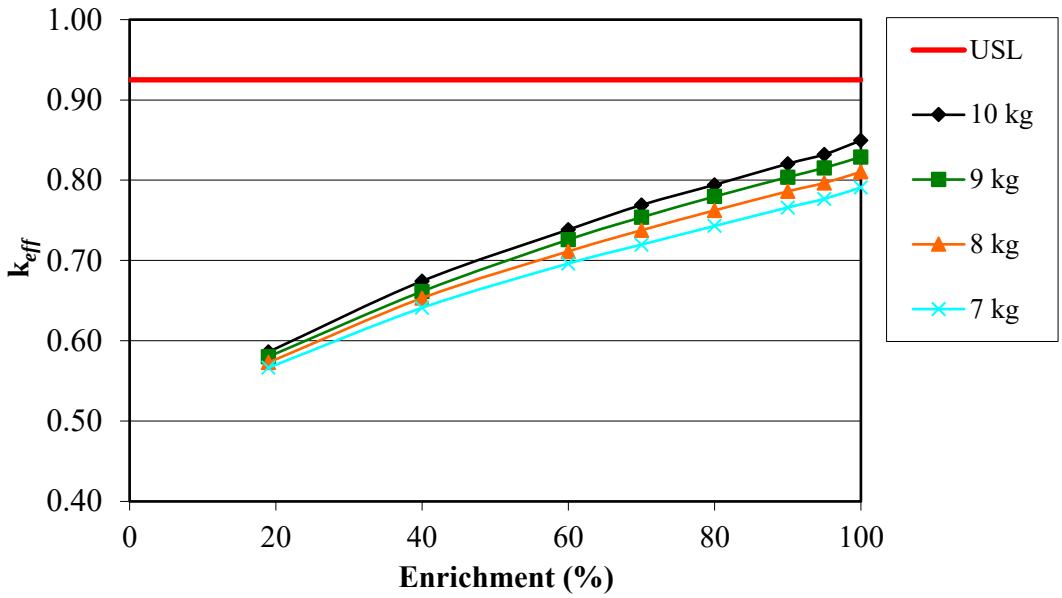

Fig. 6.20. k_{eff} vs enrichment (wt % ^{235}U) for HEU ranging from 7 to 10 kg.

Cases **atdmsr_7_8_11** through **atdmsr_7_1_1** (Table 6.9.6-21, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell and an exterior 20 cm water reflector. As shown in Fig. 6.21 and Table 6.9.6-21, the maximum $k_{eff} + 2\sigma$ values occur at zero stainless steel thickness. The $k_{eff} + 2\sigma$ value for 7 kg of HEU at 100% enrichment and zero stainless steel thickness is 0.791. The $k_{eff} + 2\sigma$ values decrease to minimum values for steel thicknesses of 2.49 cm over the range of 100% enrichment to 19% enrichment, while the NLF decreases from ~ 0.07 to 0.05. The NLF further decreases to a value of 0.03 as stainless steel is added up to the 66,133 g amount of the CV, and the liner and drum assembly. At maximum stainless steel thickness, the $k_{eff} + 2\sigma$ values increase to within 0.02 of the values for zero stainless steel thickness. The stainless steel of the ES-3100 packaging is not as effective a reflector as the 20 cm water surrounding the core. The overall effect of adding the stainless steel of the ES-3100 packaging to the configuration is the reduction in the neutron multiplication factor for the system. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.925.

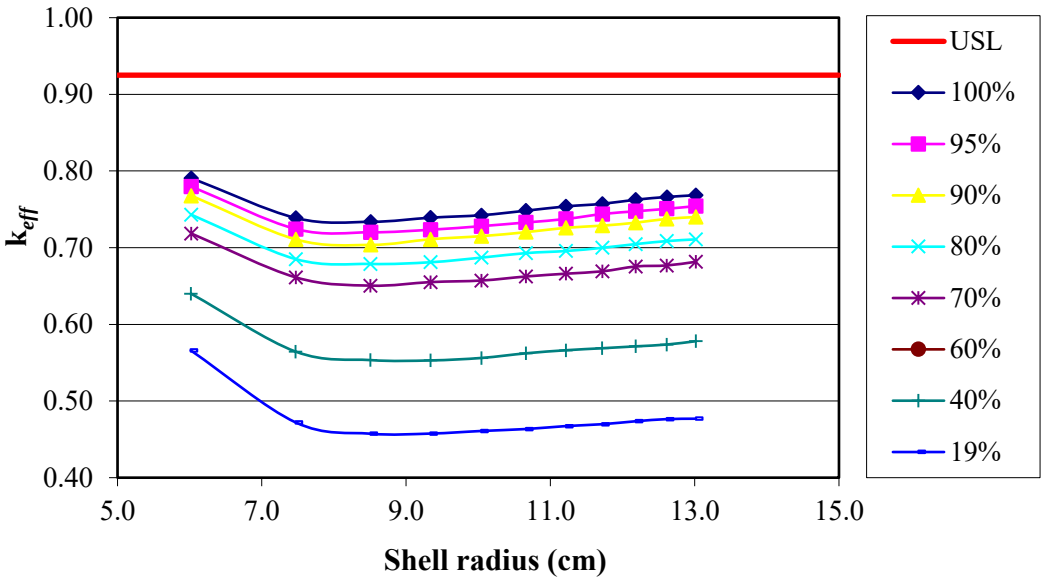

Fig. 6.21. k_{eff} vs stainless steel shell radius (cm) for 7 kg HEU with enrichments ranging from 19 to 100 wt % ^{235}U.

Cases **atdm15kr_7_8_6** through **atdm15kr_7_1_1** (Table 6.9.6-21, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell and an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Fig. 6.22 and Table 6.9.6-21, the maximum $k_{eff} + 2\sigma$ values at various enrichments occur at zero shell-thickness for the wet Kaolite. Consider the curve for 7 kg of HEU at 100 % enrichment where $k_{eff} + 2\sigma = 0.790$. At a shell radius of ~ 23 cm (24,089.2 g wet Kaolite with a shell thickness of ~ 17 cm), $k_{eff} + 2\sigma$ becomes quasi-asymptotic and the decrease in the NLF from ~ 0.07 to 0.05 is slight. With the addition of ~8.1 cm of wet Kaolite to the shell, the NLF decreases further from 0.05 to 0.04. The $k_{eff} + 2\sigma$ value decreases to a minimum value at a shell radius of 31.08 cm (60,223 g wet Kaolite with a steel thickness of 25.06 cm). In the range of 17 to 25 cm shell thickness, the quasi-asymptotic values for $k_{eff} + 2\sigma$ are ~ 0.04 below maximum $k_{eff} + 2\sigma$ values occurring at zero Kaolite thickness. To summarize, a significant drop in the neutron multiplication factor is observed for the addition of the initial 17 cm of wet-Kaolite shell to the fissile core, but an asymptotic value is not reached. With increasing build-up in the shell thickness, neutron multiplication decreases rather than increases, and the decrease in neutron leakage from the system is small. This behavior occurs because water at saturation levels, which is required for the Kaolite to act as a modest reflector, is not present in the wet Kaolite.

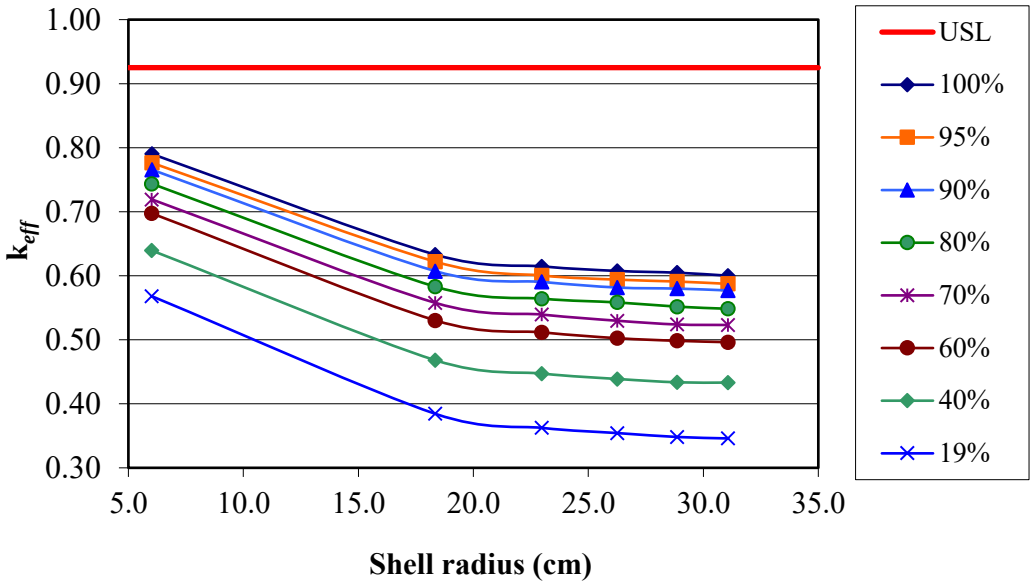

Fig. 6.22. k_{eff} vs wet Kaolite shell radius (cm) for 7 kg HEU with enrichments ranging from 19 to 100 wt % ^{235}U.

Cases **atdmdkr_7_8_6** through **atdmdkr_7_8_1** (Table 6.9.6-21, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4), where dry Kaolite is being evaluated consistent with test results of 10 CFR 71.55(d). As explained in Sect. 6.3.1.4, 53,419.1 g of dry Kaolite contained inside the body weldment outer liner and the drum top plug is NCT Kaolite (51,214.9 g vermiculite-cement and 2,204.7 g bound water). Only 7 kg of HEU at 100% enrichment is evaluated in the "atdmdkr" cases. As shown in Fig. 6.23 and Table 6.9.6-21, the behavior in $k_{eff} + 2\sigma$ for dry Kaolite where the value decreases to a minimum at a shell radius of 31.08 cm (shell thickness of 25.06 cm) is the same as for wet Kaolite. The $k_{eff} + 2\sigma$ values for the system with dry or wet Kaolite are substantially below the USL of 0.925. The decrease in NLF from ~ 0.07 to 0.05 for dry Kaolite is slightly less than from ~ 0.07 to 0.04 for wet Kaolite. The overall effect of adding dry or wet Kaolite to the system is the reduction of the neutron multiplication in the system. NCT Kaolite of the ES-3100 packaging or wet Kaolite is not as effective a reflector as the 20 cm water surrounding the core. The absence of water in the Kaolite minimizes its effect.

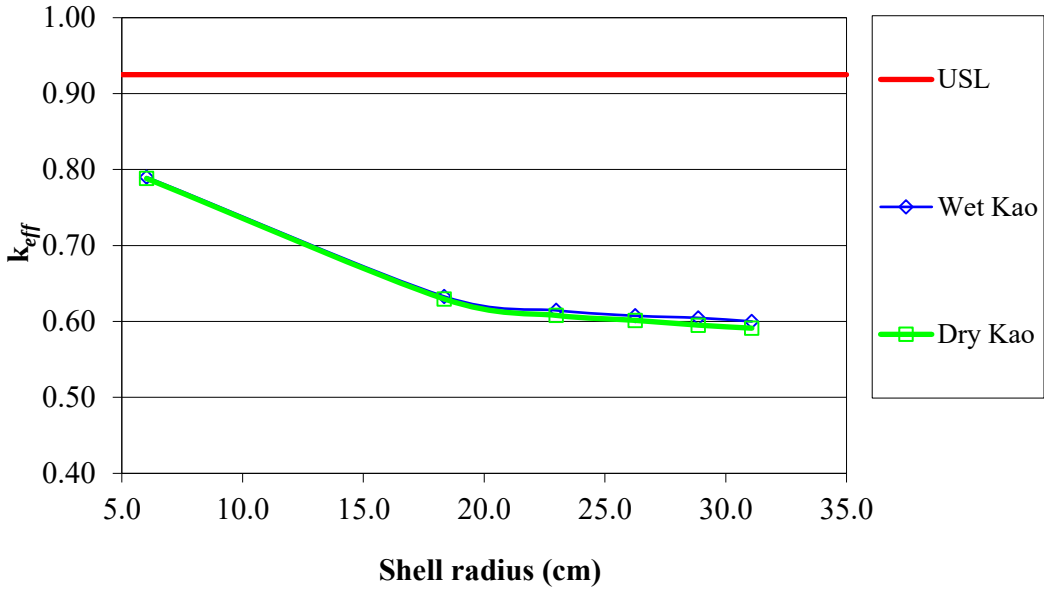

Fig. 6.23. k_{eff} vs shell radius for wet and dry Kaolite for 7 kg HEU at 100% enrichment.

A uranium alloy is conservatively assessed when scattering media (aluminum or molybdenum) is treated as multiplying media (^{235}U) in the calculation models. Thus, limits established for HEU metal apply to the alloy.

6.7.2 Results for TRIGA Fuel Elements, Three Pieces per Convenience Can

Case **atdzr** pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which 10.4 kg of $UZrH_x$ (921-g ^{235}U) of three TRIGA fuel elements is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The $k_{eff} + 2\sigma$ value of 0.679 (Table 6.9.6-22a, Appendix 6.9.6) is substantially below the USL of 0.925. Similarly, Case **atdzr_70** pertains to Model 1, in which 6.85 kg of $UZrH_x$ (408-g ^{235}U) of three TRIGA fuel elements is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The $k_{eff} + 2\sigma$ value is 0.682 (Table 6.9.6-22b, Appendix 6.9.6). The statistical difference between the $k_{eff} + 2\sigma$ values for Cases **atdzr** and **atdzr_70** is not significant.

Cases **atdzsr_11** through **atdzsr_1** pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Fig. 6.24 and Table 6.9.6-22a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 10.4 kg of $UZrH_x$ and zero stainless steel thickness is 0.678. The $k_{eff} + 2\sigma$ value decreases to minimum value for a stainless steel thickness of 1.87 cm, while the NLF decreases from ~ 0.06 to 0.04. The NLF decreases to 0.03 as stainless steel is added up to the 66,133 g amount of the CV and the liner and drum assembly. At maximum stainless steel thickness, the $k_{eff} + 2\sigma$ values increase to within 0.058 of the values for zero stainless steel thickness. The overall effect of adding stainless steel to the system is the reduction of the neutron multiplication in the system. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.925.

Cases **atdzsr70_11** through **atdzsr70_1** for 6,847 g of $UZrH_x$ at 70% enrichment having 408-g ^{235}U also pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4). Case results (Table 6.9.6-22b, Appendix 6.9.6) manifest the same behavior as results for corresponding Cases **atdzsr_11** through **atdzsr_1** for 10.4 kg of $UZrH_x$ at 20% enrichment having 921-g ^{235}U.

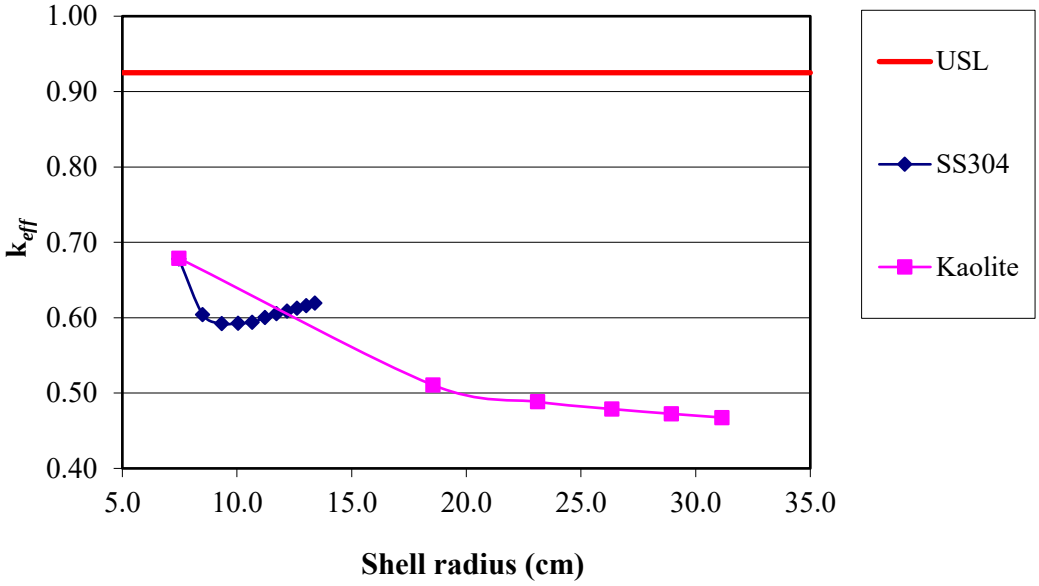

Fig. 6.24. k_{eff} vs shell radius (cm) for 10.4 kg core of $UZrH_x$ with stainless steel or wet Kaolite shell.

Cases **atdz15kr_6** through **atdz15kr_1** pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Fig. 6.24 and Table 6.9.6-22a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.679$ for 10.4 kg of $UZrH_x$. At a shell radius of ~23 cm (24,089.2 g wet Kaolite with a shell thickness of ~ 17 cm), $k_{eff} + 2\sigma$ becomes quasi-asymptotic and the decrease in the NLF from ~ 0.06 to 0.05 is slight. With the addition of ~8.1 cm of wet Kaolite to the shell, the NLF decreases further from 0.05 to 0.04. The $k_{eff} + 2\sigma$ value decreases to a minimum value at a shell radius of 31.08 cm (60,223 g wet Kaolite with a steel thickness of 25.06 cm). The quasi-asymptotic values for $k_{eff} + 2\sigma$ are ~ 0.21 below the maximum $k_{eff} + 2\sigma$ value occurring at zero Kaolite thickness. To summarize, a significant drop in the neutron multiplication factor is observed for the addition of the initial 17 cm of wet-Kaolite shell to the fissile core, but an asymptotic value is not reached. With increasing build-up in the shell thickness, neutron multiplication decreases rather than increases, and the decrease in neutron leakage from the system is small. This behavior occurs because water at saturation levels, which is required for the Kaolite to act as a modest reflector, is not present in the wet Kaolite.

Dry Kaolite is consistent with test results of 10 CFR 71.55(d). As explained in Sect. 6.3.1.4, 53,419.1 g of dry Kaolite contained inside the body weldment outer liner and the drum top plug is NCT Kaolite (51,214.9 g vermiculite-cement and 2,204.7 g bound water). Demonstrated for HEU metal in Sect. 6.7.1, the behavior in $k_{eff} + 2\sigma$ where the value decreases to a minimum at a shell radius of 31.08 cm (shell thickness of 25.06 cm) is the same in dry Kaolite as for wet Kaolite. The overall effect of adding

dry or wet Kaolite to the system is the reduction of the neutron multiplication in the system. NCT Kaolite of the ES-3100 packaging or wet Kaolite is not as effective a reflector as the 20 cm water surrounding the core. The absence of water in the Kaolite minimizes its effect. The $k_{eff} + 2\sigma$ values for Model 3 with dry or wet Kaolite are substantially below the USL of 0.925.

Cases **atdz15kr70_6** through **atdz15kr70_1** for 6,847 g of $UZrH_x$ at 70% enrichment having 408-g ^{235}U also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). Case results (Table 6.9.6-22b, Appendix 6.9.6) manifest the same behavior as results for corresponding Cases **atdz15kr_6** through **atdz15kr_1** for 10.4 kg of $UZrH_x$ at 20% enrichment having 921-g ^{235}U.

Cases **athzp15kr_5** through **athzp15kr_1** pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 10.4 kg of $UZrH_x$ at 19.7% enrichment having 921-g ^{235}U, 500 g of polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-22a, Appendix 6.9.6]. For Model 4, the overall radius at 31.1484 cm is constant for several reasons. First, the 500 g of polyethylene has a fixed volume. Second, the Kaolite is a porous material and its volume does not change appreciably as the material is dried out or absorbs water.

Cases **athzp15kr70_6** through **athzp15kr70_1** for 6,847 g of $UZrH_x$ at 70% enrichment having 408-g ^{235}U also pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). While the $k_{eff} + 2\sigma$ values are lower, the results for these cases (Table 6.9.6-22b, Appendix 6.9.6) manifest the same behavior as corresponding Cases **athzp15kr_6** through **athzp15kr_1** for 10.4 kg of $UZrH_x$ at 20% enrichment having 921-g ^{235}U.

As shown in Fig. 6.25 and Tables 6.9.6-22a and 6.9.6-22b, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2ó = 0.4675$ in Case **atdz15kr_6** to $k_{eff} + 2ó = 0.3577$ in Case **athzp15kr_5**), and
- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2ó = 0.3100$ in Case **athpz15kr_1** to $k_{eff} + 2ó = 0.3577$ in Case **athzp15kr_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athzpw15kr_5** through **athzpw15kr_1** pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 10.4 kg of $UZrH_x$ at 19.7% enrichment having 921-g ^{235}U, 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-22a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 7.4677 to 12.6903 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material and its volume does not change appreciably as the material loses or gains water. Consequently, the overall radius of the system increases from 31.1484 to 31.6977 cm.

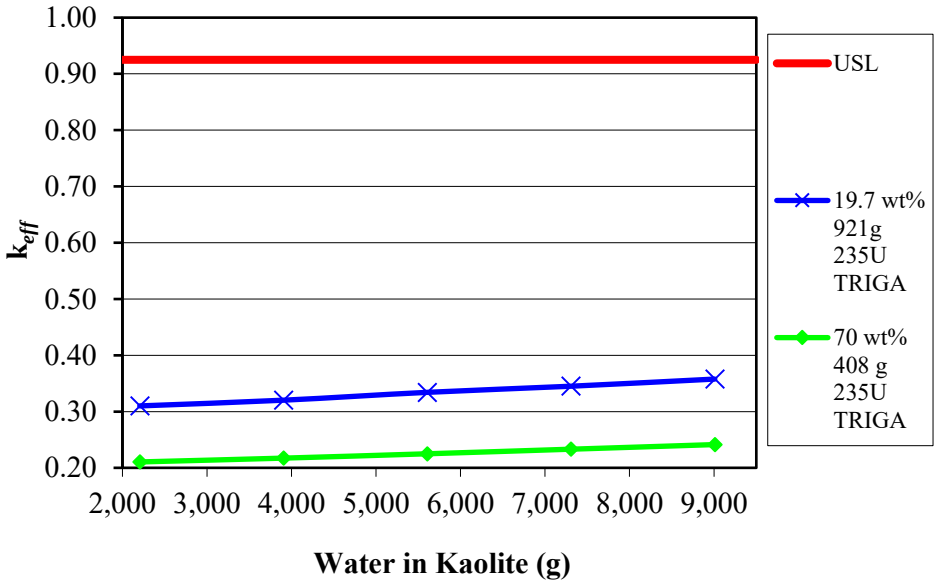

Fig. 6.25. k_{eff} vs water content (g) for homogenized core of $UZrH_x$, 500 g polyethylene and Kaolite where the Kaolite water content ranges from the dry to the wet condition.

Cases **athzpw15kr70_6** through **athzpw15kr70_1** for 6,847 g of $UZrH_x$ at 70% enrichment having 408-g ^{235}U also pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). While the $k_{eff} + 2\sigma$ values are lower, the results for these cases (Table 6.9.6-22b, Appendix 6.9.6) manifest the same behavior as corresponding Cases **athzpw15kr_6** through **athzpw15kr_1** for 10.4 kg of $UZrH_x$ at 20% enrichment having 921-g ^{235}U.

As shown in Fig. 6.26 and Tables 6.9.6-22a and 6.9.6-22b (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximums of 0.8078 and 0.7215 with the addition of the entire 6,803.9 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.925. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 15 lb (6,803.9 g).

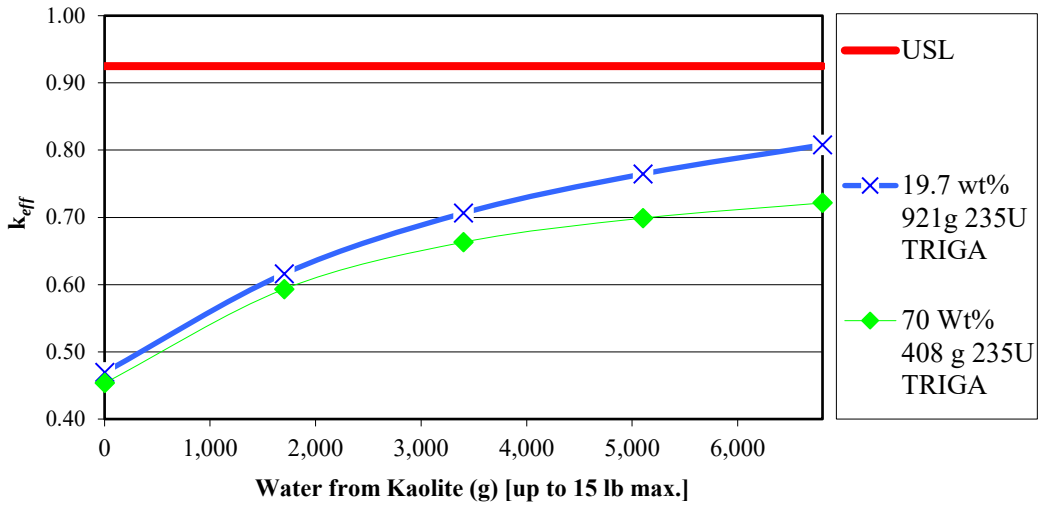

Fig. 6.26. k_{eff} vs excess water (g) from wet Kaolite for fissile core blanketed with a variable thickness Kaolite shell.

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the TRIGA fuel content following the air transport accident cannot be established.

Case results are presented in Table 6.9.6-22c (Cases **athopw15kr20_1** through **athopw15kr20_5**, Cases **athopw15kr70_1** through **athopw15kr70_5**, and Cases **athopw15kr93_1** through **athopw15kr93_5**) for U_3O_8-Al at the TRIGA content limits of 921-g ^{235}U for 20% enrichment and 408-g ^{235}U for 70% and 93.2% enrichments, respectively. As shown in Fig. 6.27 and Table 6.9.6-22c (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values for U_3O_8-Al are exceeded by values for TRIGA content; therefore, the TRIGA loading limits are bounding for the research reactor related contents of U_3O_8 and U_3O_8-Al oxide.

Case results are presented in Table 6.9.6-22d (Cases **athupw15kr09_1** through **athupw15kr09_5**, Cases **athupw15kr20_1** through **athupw15kr20_5**, and Cases **athupw15kr93_1** through **athupw15kr93_5**) for UO_2-Mg in Al cladding at content limits of 921-g ^{235}U for 9.89% and 20% and 408-g ^{235}U for 93.2% enrichment, respectively. Cases **athbpw15kr93_1** through **athbpwskr93_5** for UO_2 are at content limits of 408-g ^{235}U for 93.2% enrichment. As shown in Fig. 6.28 and Table 6.9.6-22d (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values for research reactor contents of UO_2-Mg or UO_2 exceed values for TRIGA content. These values are well below the USL; therefore, the TRIGA loading limits may be applied to the research reactor related contents of UO_2 and UO_2-Mg oxide.

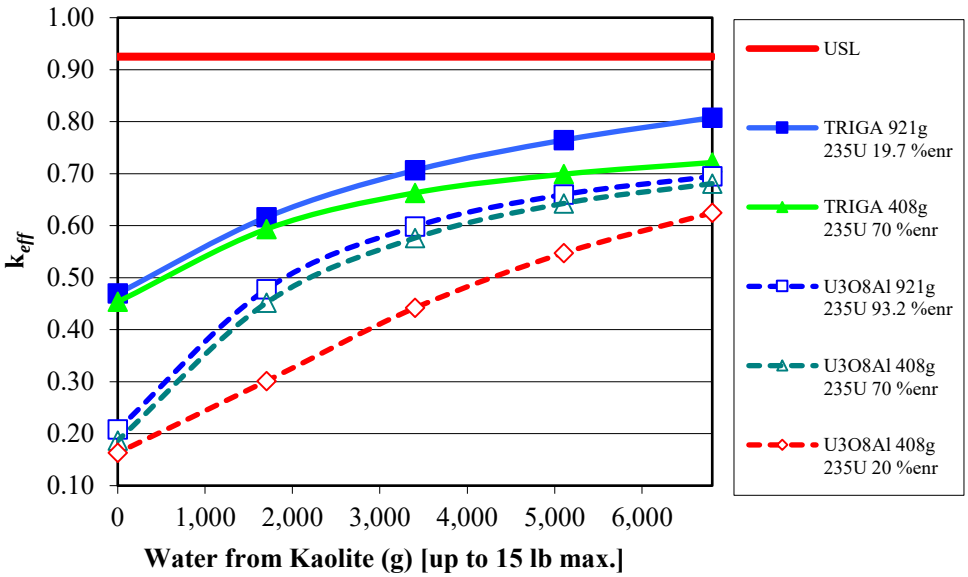

Fig. 6.27. k_{eff} vs excess water (g) from wet Kaolite for fissile material core blanketed with a variable thickness Kaolite shell.

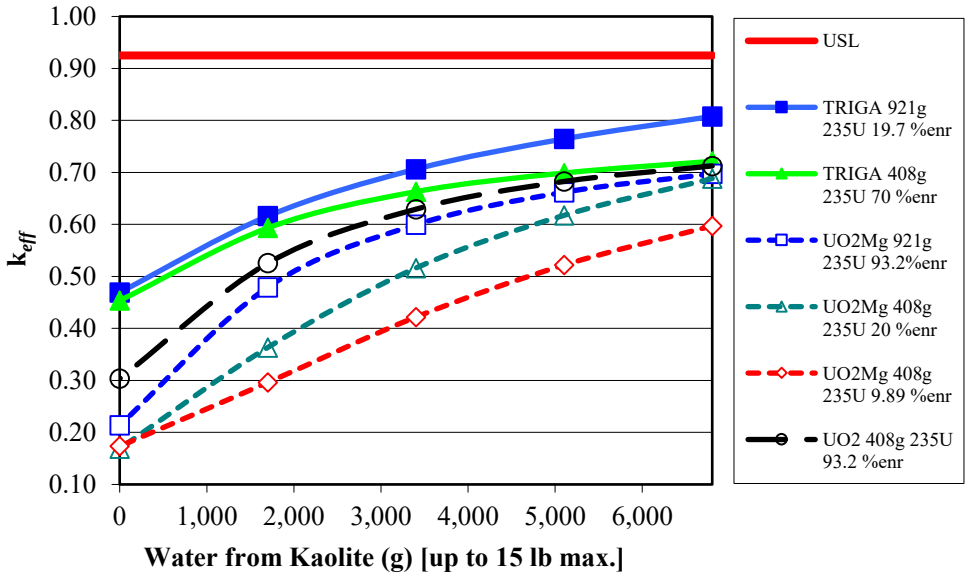

Fig. 6.28. k_{eff} vs excess water (g) from wet Kaolite for fissile material core blanketed with a variable thickness Kaolite shell.

Model 6 (Fig. 6.16, Sect. 6.3.1.4) pertains to the case where fissile material from the homogenized core of Model 4 forms a shell external to the core. Given that the total amount of fissile material is limited to 921-g ^{235}U, the quantity is not sufficient to form a critical configuration. As shown

in Section 6.7.3, this is apparent even if kilogram quantities of additional fissile material were located in the shell adjacent to the core.

6.7.3 Results for HEU Broken Metal, Turnings, Fines, or Powder

The results for Models 1–3 presented in Sect. 6.7.1 address HEU metal evaluated as a fissile core uranium metal and hydrogenous packing material surrounded by but not mixed with other materials. Results for Models 4–6 presented in this section address HEU metal evaluated as a fissile core but where the integrity of the fissile core is lost. Preferential mixing of the fissile core with packing material (non-hydrogenous) and packaging material (stainless steel, Kaolite) is evaluated. Also, reconfiguration of the fissile core is evaluated. This evaluation addresses broken metal, metal turnings, fines, and powder. HEU oxide content for air transport is addressed in Appendix 6.9.10.

Cases **athmp15kr_12_8_5** through **athmp15kr_12_8_1** and Cases **athmp15kr_12_1_5** through **athmp15kr_12_1_1** (Table 6.9.6-23, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). In the former set of cases, the homogenized core consists of 7 kg of HEU metal at 100% enrichment, 500 g of polyethylene, and Kaolite. In the latter set of cases, the homogenized core consists of 35 kg of HEU metal at 20% enrichment having 7 kg ^{235}U, 500 g of polyethylene, and Kaolite. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-23, Appendix 6.9.6]. For Model 4, the overall radius is 31.0803 cm for homogenized core with 100% enrichment and is 31.2009 cm for homogenized core with 20% enrichment. The core radius is constant with changing moisture conditions for the following reasons. First, the 500 g of polyethylene has a fixed volume. Second, the Kaolite is a porous material and its volume does not change appreciably as the material is dried out or absorbs water.

As shown in Fig. 6.29 and Table 6.9.6-23, a gradual increase in the $k_{eff} + 2\sigma$ value occurs from the dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a slight decrease in neutron multiplication (from $k_{eff} + 2ó = 0.6001$ in Case **atdm15kr_7_8_6** to $k_{eff} + 2ó = 0.5909$ in Case **athmp15kr_12_8_5**) and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2ó = 0.5024$ in Case **athmp15kr_1** to $k_{eff} + 2ó = 0.5909$ in Case **athmp15kr_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athmpw15kr_12_8_5** through **athmpw15kr12_8_1**, Cases **athmpw13kr_12_8_5** through **athmpw13kr12_8_1**, and Cases **athzpw12kr70_5** through **athzpw12kr70_1** pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. In each set of cases, the homogenized core consists of HEU metal loading of 7 kg ^{235}U for uranium at 100% enrichment, 500 g of polyethylene, and excess water from the wet Kaolite. In the three sets of cases "**athmpw15kr**," "**athmpw13kr**," and "**athmpw12kr**," the corresponding amounts of free water for the wet condition are 15 lb (6,803.9 g), 13 lb (5,896.7 g), and 12 lb (5,443.1 g), respectively. For all of these sets of parametric cases, the water content of the Kaolite shell ranges from the wet condition (9,008.5 g water or 8,101.4 g or 7,647.8 g) to the dry condition (2,204.7 g water) [Table 6.9.6-23, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the radius for either fuel type expands accordingly but the

volume of the Kaolite shell remains constant. Consequently, the overall radius of the system increases. As stated previously, the 500 g of polyethylene has a fixed volume. Also, Kaolite is a porous material and its volume does not change appreciably as the material looses or gains water.

As shown in Fig. 6.30 and Table 6.9.6-23 (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximums of 0.9062, 0.9272, and 0.9596 with the addition to the fissile core of the entire 12 lb, 13 lb, and 15 lb amounts of free water from wet Kaolite. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. However, $k_{eff} + 2\sigma$ exceeds the USL of 0.925 for those cases where the total free water is greater than 12 lb (5,443.1 g). This signifies the fissile mass loading limit for HEU is 7 kg ^{235}U and the range of excess water cannot exceed 12 lb from the Kaolite and the CV well in order for the content to be shipped by air transport. Therefore, the evaluation of Model 6 is focused on this limit.

Cases **athmp15kmr_13_1_8_5** through **athmp15kmr_1_13_8_1** (Table 6.9.6-23, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of HEU at 100% enrichment, 500 g polyethylene, and Kaolite. In a series of cases, the amount of HEU in the shell is varied from 500 g to 6,500-g ^{235}U in 500 g increments and the remainder of the 7 kg ^{235}U is contained in the homogenized core. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). As shown in Fig. 6.31, all $k_{eff} + 2\sigma$ values are adequately below the USL of 0.925.

As stated previously, uranium alloy is conservatively assessed when alloy constituents, such as aluminum, molybdenum, zirconium, stainless steel, titanium, tungsten, niobium, silicon, or vanadium, are modeled as ^{235}U. Thus, limits established for HEU metal apply to the uranium alloys where the content mass of ^{235}U includes the mass of the non-uranium alloy constituents.

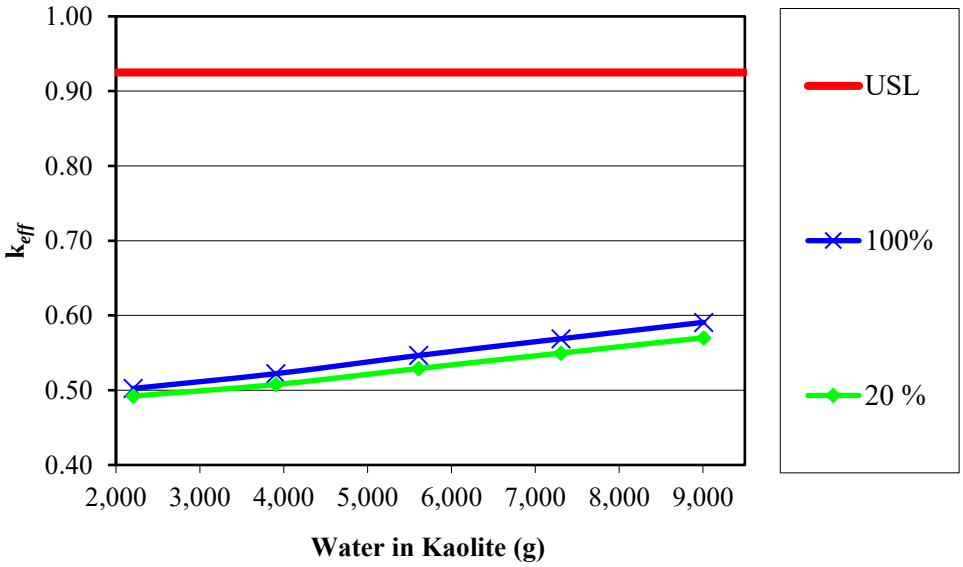

Fig. 6.29. k_{eff} vs water content (g) for homogenized core of HEU with 7 kg ^{235}U, 500 g polyethylene, and Kaolite where the Kaolite water content ranges from the dry to the wet condition.

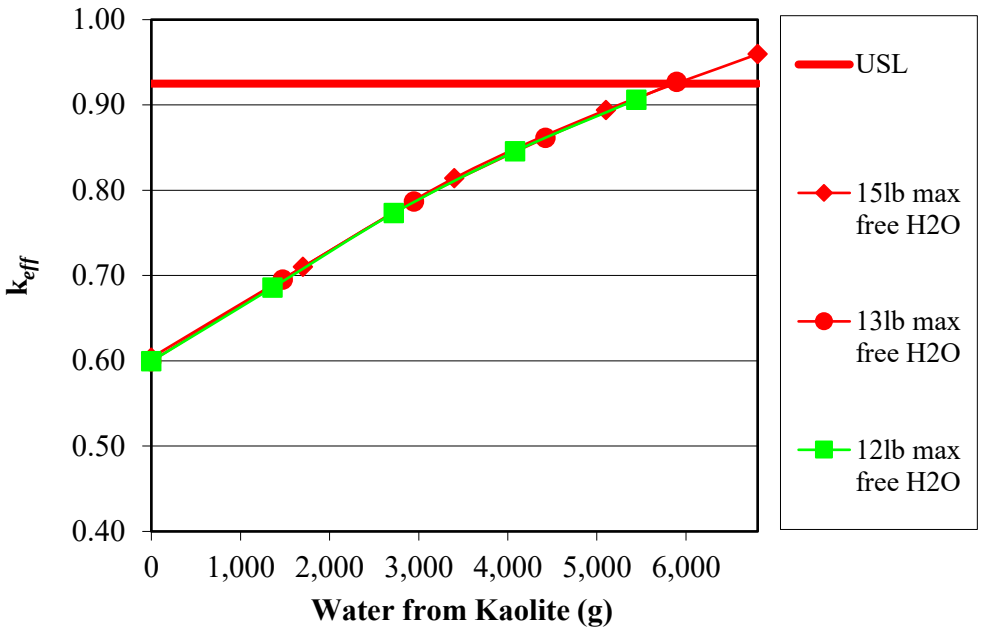

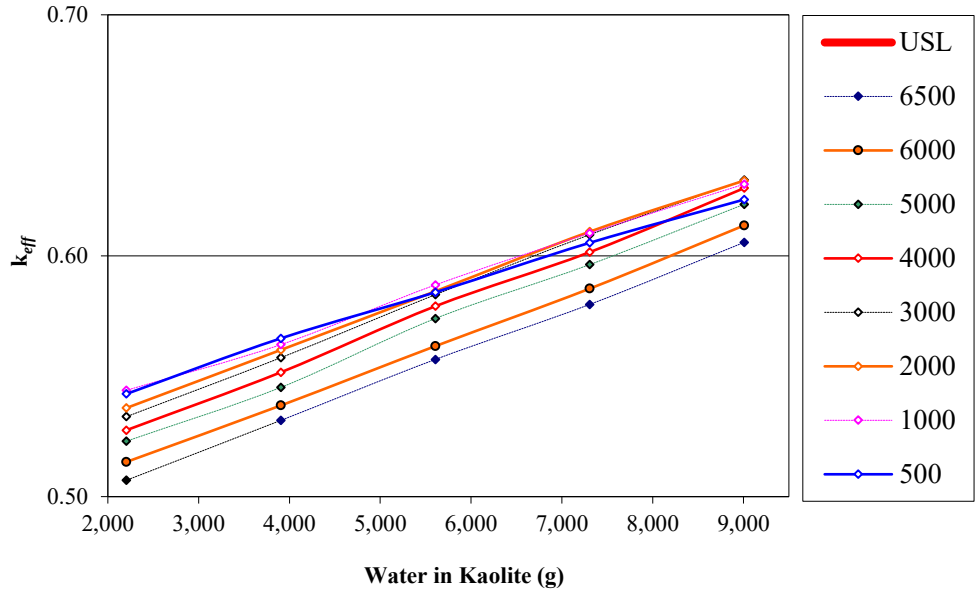

Fig. 6.30. k_{eff} vs excess water (g) from wet Kaolite for fissile core blanketed with a variable thickness Kaolite shell.

Note: Total quantity of HEU is 7-kg ^{235}U where the shell ranges from 500-g to 6,500-g ^{235}U and the remainder of the HEU is contained in the homogenized core.

Fig. 6.31. k_{eff} vs water (g) in Kaolite for homogenized core of HEU at 100% enrichment, 500-g polyethylene, and wet Kaolite encompassed by shell of ^{235}U.

6.7.4 Results for UF_4 Compounds

Case **atduf4r_1** through **atduf4r_10** (Table 6.9.6-24a, Appendix 6.9.6) pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which varying amounts of UF_4 is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The UF_4 mass is evaluated up to 24 kg (which is the maximum allowed for ground transport), and the highest $k_{eff} + 2\sigma$ value of 0.807 (Table 6.9.6-24a, Appendix 6.9.6) is well below the USL of 0.93520.

Cases **atduf4sr_1** through **atduf4sr_11** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4), in which 24 kg of UF_4 is homogenized with 500 g polyethylene. The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 24 kg of UF_4 and zero stainless steel thickness is 0.805. Reactivity decreases, then increases as stainless steel is added to a maximum of 66,133 g, which is the highest amount of the CV and the liner and drum assembly. At maximum stainless steel thickness, the $k_{eff} + 2\sigma$ values increase but are well below the maximum reactivity at zero stainless steel thickness. The overall effect of adding stainless steel to the system is the reduction of the neutron multiplication in the system. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atduf4dkr_1** through **atduf4dkr_6** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness dry-Kaolite shell with an exterior 20 cm water reflector. Dry Kaolite consists of 51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the dry Kaolite. The $k_{eff} + 2\sigma = 0.679$ for 24 kg of UF_4. As the amount of dry Kaolite is added to the shell surrounding the UF_4, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the dry-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atduf415kr_1** through **atduf415kr_6** (Table 6.9.6-24a, Appendix 6.9.6) also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.806$ for 24 kg of UF_4. As the amount of wet Kaolite is added to the shell surrounding the UF_4, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the wet-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Note that in these calculations the water comes from three sources: bound water in the Kaolite, free water in the Kaolite, and saturated water inside the compound. The amount of bounded water in the Kaolite is 2,205 g. The amount of free water is calculated at 12 and 15 pounds, which is 5,445 g of free water and 6,804 g, respectively. The remaining water is the saturated water that is originally in the compound.

Cases **athuf4p15kr_1** through **athuf4p15kr_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 24 kg of UF_4, 500 g of polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-24a, Appendix 6.9.6]. For Model 4, the overall radius at 31.34526 cm is constant for several reasons. First, the 500 g of

polyethylene has a fixed volume. Second, the Kaolite is a porous material and the volume does not change appreciably as the material is dried out or absorbs water.

As shown in Table 6.9.6-24a, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2\sigma = 0.806$ in Case **atduf415kr_1** to $k_{eff} + 2\sigma = 0.603$ in Case **atduf415kr_6**), and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2\sigma = 0.568$ in Case **athuf4p15kr_1** to $k_{eff} + 2\sigma = 0.661$ in Case **athuf4p15kr_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athuf4pw12kr_1_7** through **athuf4pw12kr_5_7** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 24 kg of UF_4, 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-24a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 9.9770 to 13.18986 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material and the volume does not change appreciably as the material loses or gains water.

As shown in Table 6.9.6-24a (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximum of 0.908 with the addition of the entire 6,803.9 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 12 lb (5,443 g).

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the content following the air transport accident cannot be established.

Cases **athuf4p15kor_1_1_1** through **athuf4p15kor_5_5_5** (Table 6.9.6-24b, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of 24 kg of UF_4, 500 g polyethylene, and Kaolite. In a series of cases, the amount of UF_4 in the shell is varied from 2,000 g to 22,000-g UF_4 in 4,000 g increments and the remainder of the 24 kg UF_4 is contained in the homogenized core [Table 6.9.6-24b, Appendix 6.9.6]. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). All $k_{eff} + 2\sigma$ values are adequately below the USL of 0.93680.

6.7.5 Results for UO_2F_2 Compounds

Case **atduo2f2r_1 through atduo2f2r_3** (Table 6.9.6-24a, Appendix 6.9.6) pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which varying amounts of UO_2F_4 is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The UO_2F_2 mass is evaluated up to 3 kg (which is the maximum allowed for ground transport), with the highest $k_{eff} + 2\sigma$ value of 0.678 (Table 6.9.6-24a, Appendix 6.9.6) is well below the USL of 0.93520.

Cases **atduo2f2sr_1** through **atduo2f2sr_11** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4), in which 3 kg of UO_2F_4 is homogenized with 500 g polyethylene. The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 3 kg of UO_2F_2 and zero stainless steel thickness is 0.678. Reactivity decreases, then increases as stainless steel is added to a maximum of 66,133 g, which is the highest amount of the CV and the liner and drum assembly. At maximum stainless steel thickness, the $k_{eff} + 2\sigma$ values increase but are well below the maximum reactivity at zero stainless steel thickness. The overall effect of adding stainless steel to the system is the reduction of the neutron multiplication in the system. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atduo2f2dkr_1** through **atduo2f2dkr_6** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness dry-Kaolite shell with an exterior 20 cm water reflector. Dry Kaolite consists of 51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the dry Kaolite. The $k_{eff} + 2\sigma = 0.679$ for 3 kg of UO_2F_2. As the amount of dry Kaolite is added to the shell surrounding the UO_2F_4, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the dry-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atduo2f215kr_1** through **atduo2f215kr_6** (Table 6.9.6-24a, Appendix 6.9.6) also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.678$ for 3 kg of UO_2F_4. As the amount of wet Kaolite is added to the shell surrounding the UO_2F_2, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the wet-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Note that in these calculations the water comes from three sources: bound water in the Kaolite, free water in the Kaolite, and saturated water inside the compound. The amount of bounded water in the Kaolite is 2,205 g. The amount of free water is calculated at 12 and 15 pounds, which is 5,445 g of free water and 6,804 g respectively. The remaining water is the saturated water that is originally in the compound.

Cases **athuo2f2p15kr_1** through **athuo2f2p15kr_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 3 kg of UO_2F_2, 500 g of polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-24a, Appendix 6.9.6]. For Model 4, the overall radius at 31.10196 cm is constant for several

reasons. First, the 500 g of polyethylene has a fixed volume. Second, the Kaolite is a porous material and the volume does not change appreciably as the material is dried out or absorbs water.

As shown in Table 6.9.6-24a, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2\sigma = 0.679$ in Case **atduo2f215kr_1** to $k_{eff} + 2\sigma = 0.433$ in Case **atduo2f215kr_6**), and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2\sigma = 0.405$ in Case **athuo2f2p15kr_1** to $k_{eff} + 2\sigma = 0.478$ in Case **athuo2f2p15kr_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athuo2f2pw12kr_1_3** through **athuo2f2pw12kr_5_3** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 3 kg of UO_2F_2, 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-22a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 6.55398 to 11.40090 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material, and the volume does not change appreciably as the material loses or gains water.

As shown in Table 6.9.6-24a (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximum of 0.864 with the addition of the entire 5,445 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93680. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 12 lb (5,443 g).

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the content following the air transport accident cannot be established.

Cases **athuo2f2p15kor_1_1_1** through **athuo2f2p15kor_5_5_5** (Table 6.9.6-24b, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of 3 kg of UO_2F_4, 500 g polyethylene, and Kaolite. In a series of cases, the amount of UO_2F_2 in the shell is varied from 500 g to 2,500-g UO_2F_2 in 500 g increments and the remainder of the 3 kg UO_2F_2 is contained in the homogenized core. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). All $k_{eff} + 2\sigma$ values are adequately below the USL of 0.93680.

6.7.6 Results for UC Compounds

Case **atducr_1 through atducr_4** (Table 6.9.6-24a, Appendix 6.9.6) pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which varying amounts of UC is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The UC mass is evaluated up to 2 kg (which is the maximum allowed for ground transport), with the highest $k_{eff} + 2\sigma$ value of 0.756 (Table 6.9.6-24a, Appendix 6.9.6) is well below the USL of 0.93680.

Cases **atducsr_1** through **atducsr_11** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4), in which 2 kg of UC is homogenized with 500 g polyethylene. The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 2 kg of UC and zero stainless steel thickness is 0.757. Reactivity decreases, then increases as stainless steel is added to a maximum of 66,133 g, which is the highest amount of the CV and the liner and drum assembly. At maximum stainless steel thickness, the $k_{eff} + 2\sigma$ values increase but are well below the maximum reactivity at zero stainless steel thickness. The overall effect of adding stainless steel to the system is initially a reduction of the neutron multiplication in the system, but as the maximum amount of steel is added there is an increase of the neutron multiplication in the system. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atducdkr_1** through **atducdkr_6** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness dry-Kaolite shell with an exterior 20 cm water reflector. Dry Kaolite consists of 51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the dry Kaolite. The $k_{eff} + 2\sigma = 0.756$ for 2 kg of UC. As the amount of dry Kaolite is added to the shell surrounding the UC, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the dry-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atduc15kr_1** through **atduc15kr_6** (Table 6.9.6-24a, Appendix 6.9.6) also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.757$ for 2 kg of UC. As the amount of wet Kaolite is added to the shell surrounding the UC, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the wet-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Note that in these calculations the water comes from three sources: bound water in the Kaolite, free water in the Kaolite, and saturated water inside the compound. The amount of bounded water in the Kaolite is 2,205 g. The amount of free water is calculated at 12 and 15 pounds, which is 5,445 g of free water and 6,804 g respectively. The remaining water is the saturated water that is originally in the compound.

Cases **athucp15kr_1** through **athucp15kr_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 2 kg of UC, 500 g of polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-24a, Appendix 6.9.6]. For Model 4,

the overall radius at 31.13189 cm is constant for several reasons. First, the 500 g of polyethylene has a fixed volume. Second, the Kaolite is a porous material, and the volume does not change appreciably as the material is dried out or absorbs water.

As shown in Table 6.9.6-24a, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2\sigma = 0.757$ in Case **atduc15kr_1** to $k_{eff} + 2\sigma = 0.531$ in Case **atduc15kr_6**), and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2\sigma = 0.401$ in Case **athucp15kr_1** to $k_{eff} + 2\sigma = 0.473$ in Case **athucp15kr_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athucpw12kr_1_5** through **athucpw12kr_4_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 2 kg of UC, 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-24a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 7.16920 to 11.86429 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material and the volume does not change appreciably as the material loses or gains water.

As shown in Table 6.9.6-24a (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximum of 0.882 with the addition of the entire 5,445 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 12 lb (5,443 g).

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the content following the air transport accident cannot be established.

Cases **athucp15kor_1_1_1** through **athucp15kor_5_3_3** (Table 6.9.6-24b, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of 2 kg of UC, 500 g polyethylene, and Kaolite. In a series of cases, the amount of UC in the shell is varied from 500 g to 1,500-g UC in 500 g increments and the remainder of the 2 kg UC is contained in the homogenized core. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). All $k_{eff} + 2\sigma$ values are adequately below the USL of 0.93680.

6.7.7 Results for UN Compounds

Case **atdunr_1** through **atdunr_4** (Table 6.9.6-24a, Appendix 6.9.6) pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which varying amounts of UN is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The UC mass is evaluated up to 2 kg (which is the maximum allowed for ground transport), with the highest $k_{eff} + 2\sigma$ value of 0.755 (Table 6.9.6-24a, Appendix 6.9.6) is well below the USL of 0.93680.

Cases **atdunsr_1** through **atducnr_11** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4), in which 2 kg of UN is homogenized with 500 g polyethylene. The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 2 kg of UN and zero stainless steel thickness is 0.756. Reactivity decreases, then increases as stainless steel is added to a maximum of 66,133 g, which is the highest amount of the CV and the liner and drum assembly. At maximum stainless steel thickness, the $k_{eff} + 2\sigma$ values increase but are well below the maximum reactivity at zero stainless steel thickness. The overall effect of adding stainless steel to the system is the reduction of the neutron multiplication in the system. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atdundkr_1** through **atdundkr_6** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness dry-Kaolite shell with an exterior 20 cm water reflector. Dry Kaolite consists of 51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the dry Kaolite. The $k_{eff} + 2\sigma = 0.756$ for 2 kg of UN. As the amount of dry Kaolite is added to the shell surrounding the UN, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the dry-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atdun15kr_1** through **atdun15kr_6** (Table 6.9.6-24a, Appendix 6.9.6) also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.756$ for 2 kg of UN. As the amount of wet Kaolite is added to the shell surrounding the UN, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the wet-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Note that in these calculations the water comes from three sources: bound water in the Kaolite, free water in the Kaolite, and saturated water inside the compound. The amount of bounded water in the Kaolite is 2,205 g. The amount of free water is calculated at 12 and 15 pounds, which is 5,445 g of free water and 6,804 g respectively. The remaining water is the saturated water that is originally in the compound.

Cases **athunp15kr_1** through **athunp15kr_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 2 kg of UN, 500 g of polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-24a, Appendix 6.9.6]. For Model 4, the overall radius at 31.13189 cm is constant for several reasons. First, the 500 g of polyethylene has a

fixed volume. Second, the Kaolite is a porous material and the volume does not change appreciably as the material is dried out or absorbs water.

As shown in Table 6.9.6-24a, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2\sigma = 0.756$ in Case **atdun15kr_1** to $k_{eff} + 2\sigma = 0.531$ in Case **atdun15kr_6**), and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2\sigma = 0.399$ in Case **athunp15kr_1** to $k_{eff} + 2\sigma = 0.470$ in Case **athunp15kr_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athunpw12kr_1_5** through **athunpw12kr_4_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 2 kg of UN, 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-24a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 7.16920 to 11.86429 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material and the volume does not change appreciably as the material loses or gains water.

As shown in Table 6.9.6-24a (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximum of 0.882 with the addition of the entire 5,445 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 12 lb (5,443 g).

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the content following the air transport accident cannot be established.

Cases **athunp15kor_1_1_1** through **athunp15kor_5_3_3** (Table 6.9.6-24b, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of 2 kg of UC, 500 g polyethylene, and Kaolite. In a series of cases, the amount of UN in the shell is varied from 500 g to 1,500-g UN in 500 g increments and the remainder of the 2 kg UN is contained in the homogenized core. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). All $k_{eff} + 2\sigma$ values are adequately below the USL of 0.93680.

6.7.8 Results for U_3Si_2 Compounds at 40% Enriched

Case **atdu3si2r40_1** through **atdu3si2r40_8** (Table 6.9.6-24a, Appendix 6.9.6) pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which varying amounts of U_3Si_2 is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The U_3Si_2 mass is evaluated up to 11 kg (which is less than what is allowed for ground transport), with the highest $k_{eff} + 2\sigma$ value of 0.938 (Table 6.9.6-24a, Appendix 6.9.6) is above the USL of 0.93520. A lower U_3Si_2 mass is evaluated, 10.5 kg, with the $k_{eff} + 2\sigma$ value of 0.930 (Table 6.9.6-22a, Appendix 6.9.6) is below the USL of 0.93520

Cases **atdu3si2sr40_1** through **atdu3si2sr40_11** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4), in which 10.5 kg of U_3Si_2 is homogenized with 500 g polyethylene. The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 10.5 kg of U_3Si_2 and zero stainless steel thickness is 0.930. The $k_{eff} + 2\sigma$ value decreases to minimum value for a stainless steel thickness. Reactivity decreases, then increases as stainless steel is added to a maximum of 66,133 g, which is the highest amount of the CV and the liner and drum assembly. At maximum stainless steel thickness, the $k_{eff} + 2\sigma$ values increase but are well below the maximum reactivity at zero stainless steel thickness. The overall effect of adding stainless steel to the system is the reduction of the neutron multiplication in the system. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atdu3si2dkr40_1** through **atdu3si2dkr40_6** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness dry-Kaolite shell with an exterior 20 cm water reflector. Dry Kaolite consists of 51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the dry Kaolite. The $k_{eff} + 2\sigma = 0.930$ for 11 kg of U_3Si_2. As the amount of dry Kaolite is added to the shell surrounding the U_3Si_2, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the dry-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93520.

Cases **atdu3si215kr40_1** through **atdu3si215kr40_6** (Table 6.9.6-24a, Appendix 6.9.6) also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.930$ for 10.5 kg of U_3Si_2. As the amount of wet Kaolite is added to the shell surrounding the U_3Si_2, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the wet-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93520.

Note that in these calculations the water comes from three sources: bound water in the Kaolite, free water in the Kaolite, and saturated water inside the compound. The amount of bounded water in the Kaolite is 2,205 g. The amount of free water is calculated at 12 and 15 pounds, which is 5,445 g of free water and 6,804 g respectively. The remaining water is the saturated water that is originally in the compound.

Cases **athu3si2p15kr40_1** through **athu3si2p15kr40_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 10.5 kg of U_3Si_2, 500 g of

polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-24a, Appendix 6.9.6]. For Model 4, the overall radius at 31.47701 cm is constant for several reasons. First, the 500 g of polyethylene has a fixed volume. Second, the Kaolite is a porous material and the volume does not change appreciably as the material is dried out or absorbs water.

As shown in Table 6.9.6-24a, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2\sigma = 0.930$ in Case **atdu3si215kr40_1** to $k_{eff} + 2\sigma = 0.769$ in Case **atdu3si215kr40_6**), and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2\sigma = 0.500$ in Case **athu3si2p15kr40_1** to $k_{eff} + 2\sigma = 0.582$ in Case **athu3si2p15kr40_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athu3si2pw12kr40_1_5** through **athu3si2pw12kr40_7_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 8.5 kg of U_3Si_2 (note this mass is less than 10.5 kg evaluated in Models 1 through 4), 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-24a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 10.45974 to 13.47350 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material and the volume does not change appreciably as the material loses or gains water.

As shown in Table 6.9.6-24a, the $k_{eff} + 2\sigma$ values increase to maximum of 0.924 with the addition of the entire 5,445 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93680. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 12 lb (5,443 g).

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the content following the air transport accident cannot be established.

Cases **athu3si2p15kor40_1_1_1** through **athu3si2p15kor40_5_6_6** (Table 6.9.6-24b, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of 8.5 kg of U_3Si_2, 500 g polyethylene, and Kaolite. In a series of cases, the amount of U_3Si_2 in the shell is varied from 1,000 g to 7,500-g U_3Si_2 in various increments and the remainder of the 8.5 kg U_3Si_2 is contained in the homogenized core. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). All $k_{eff} + 2\sigma$ values are adequately below the USL of 0.93680.

6.7.9 Results for U_3Si_2 Compounds at 60% Enriched

Case **atdu3si2r60_1** through **atdu3si2r60_4** (Table 6.9.6-24a, Appendix 6.9.6) pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which varying amounts of U_3Si_2 is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The U_3Si_2 mass is evaluated up to 7 kg (which is the maximum allowed for ground transport), with the highest $k_{eff} + 2\sigma$ value of 0.888 (Table 6.9.6-24a, Appendix 6.9.6) is below the USL of 0.93520.

Cases **atdu3si2sr60_1** through **atdu3si2sr60_11** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4), in which 7 kg of U_3Si_2 is homogenized with 500 g polyethylene. The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 7 kg of U_3Si_2 and zero stainless steel thickness is 0.888. Reactivity decreases, then increases as stainless steel is added to a maximum of 66,133 g, which is the highest amount of the CV and the liner and drum assembly. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atdu3si2dkr60_1** through **atdu3si2dkr60_6** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness dry-Kaolite shell with an exterior 20 cm water reflector. Dry Kaolite consists of 51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the dry Kaolite. The $k_{eff} + 2\sigma = 0.887$ for 7 kg of U_3Si_2. As the amount of dry Kaolite is added to the shell surrounding the U_3Si_2, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the dry-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93520.

Cases **atdu3si215kr60_1** through **atdu3si215kr60_6** (Table 6.9.6-24a, Appendix 6.9.6) also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.887$ for 7 kg of U_3Si_2. As the amount of wet Kaolite is added to the shell surrounding the U_3Si_2, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the wet-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93520.

Note that in these calculations the water comes from three sources: bound water in the Kaolite, free water in the Kaolite, and saturated water inside the compound. The amount of bounded water in the Kaolite is 2,205 g. The amount of free water is calculated at 12 and 15 pounds, which is 5,445 g of free water and 6,804 g respectively. The remaining water is the saturated water that is originally in the compound.

Cases **athu3si2p15kr60_1** through **athu3si2p15kr60_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 7 kg of U_3Si_2, 500 g of polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-24a, Appendix 6.9.6]. For Model 4, the overall radius at 31.33582 cm is constant for several reasons. First, the 500 g of polyethylene has a fixed volume. Second, the Kaolite is a porous material and the volume does not change appreciably as the material is dried out or absorbs water.

As shown in Table 6.9.6-24a, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2\sigma = 0.887$ in Case **atdu3si215kr60_1** to $k_{eff} + 2\sigma = 0.708$ in Case **atdu3si215kr60_6**), and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2\sigma = 0.487$ in Case **athu3si2p15kr60_1** to $k_{eff} + 2\sigma = 0.569$ in Case **athu3si2p15kr60_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athu3si2pw12kr60_1_5** through **athu3si2pw12kr60_6_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 6.5 kg of U_3Si_2 (note this mass is less than 7 kg evaluated in Models 1 through 4), 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-24a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 9.67497 to 13.02005 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material and the volume does not change appreciably as the material loses or gains water.

As shown in Table 6.9.6-24a (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximum of 0.934 with the addition of the entire 5,445 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93680. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 12 lb (5,443 g).

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the content following the air transport accident cannot be established.

Cases **athu3si2p15kor60_1_1_1** through **athu3si2p15kor60_5_6_6** (Table 6.9.6-24b, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of 6.5 kg of U_3Si_2, 500 g polyethylene, and Kaolite. In a series of cases, the amount of U_3Si_2 in the shell is varied from 1,000 g to 5,500-g U_3Si_2 in various increments and the remainder of the 6.5 kg U_3Si_2 is contained in the homogenized core. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). All $k_{eff} + 2\sigma$ values are adequately below the USL of 0.93680.

6.7.10 Results for U_3Si Compounds at 40% Enriched

Case **atdu3sir40_1** through **atdu3sir40_7** (Table 6.9.6-24a, Appendix 6.9.6) pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which varying amounts of U_3Si_2 is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The U_3Si_2 mass is evaluated up to 10.5 kg (which is less than what is allowed for ground transport), with the highest $k_{eff} + 2\sigma$ value of 0.936 (Table 6.9.6-24a, Appendix 6.9.6) is above the USL of 0.93520. A lower U_3Si mass is evaluated, 10 kg, with the $k_{eff} + 2\sigma$ value of 0.926 (Table 6.9.6-24a, Appendix 6.9.6) is below the USL of 0.93520

Cases **atdu3sisr40_1** through **atdu3sisr40_11** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4), in which 10 kg of U_3Si is homogenized with 500 g polyethylene. The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 10 kg of U_3Si and zero stainless steel thickness is 0.926. The $k_{eff} + 2\sigma$ value decreases to minimum value for a stainless steel thickness. Reactivity decreases, then increases as stainless steel is added to a maximum of 66,133 g, which is the highest amount of the CV and the liner and drum assembly. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atdu3sidkr40_1** through **atdu3sidkr40_6** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness dry-Kaolite shell with an exterior 20 cm water reflector. Dry Kaolite consists of 51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the dry Kaolite. The $k_{eff} + 2\sigma = 0.926$ for 10 kg of U_3Si. As the amount of dry Kaolite is added to the shell surrounding the U_3Si_2, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the dry-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93520.

Cases **atdu3si15kr40_1** through **atdu3si15kr40_6** (Table 6.9.6-24a, Appendix 6.9.6) also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.926$ for 10 kg of U_3Si. As the amount of wet Kaolite is added to the shell surrounding the U_3Si, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the wet-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93520.

Note that in these calculations the water comes from three sources: bound water in the Kaolite, free water in the Kaolite, and saturated water inside the compound. The amount of bounded water in the Kaolite is 2,205 g. The amount of free water is calculated at 12 and 15 pounds, which is 5,445 g of free water and 6,804 g respectively. The remaining water is the saturated water that is originally in the compound.

Cases **athu3sip15kr40_1** through **athu3sip15kr40_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 10 kg of U_3Si, 500 g of polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-24a, Appendix 6.9.6]. For Model 4, the overall radius at 31.45691 cm is constant for several reasons. First, the 500 g of

polyethylene has a fixed volume. Second, the Kaolite is a porous material and the volume does not change appreciably as the material is dried out or absorbs water.

As shown in Table 6.9.6-24a, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2\sigma = 0.926$ in Case **atdu3si15kr40_1** to $k_{eff} + 2\sigma = 0.764$ in Case **atdu3si15kr40_6**), and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2\sigma = 0.500$ in Case **athu3sip15kr40_1** to $k_{eff} + 2\sigma = 0.582$ in Case **athu3sip15kr40_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athu3sipw12kr40_1_5** through **athu3sipw12kr40_7_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 8.5 kg of U_3Si (note this mass is less than 10 kg evaluated in Models 1 through 4), 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-24a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 10.45974 to 13.47350 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material and the volume does not change appreciably as the material loses or gains water.

As shown in Table 6.9.6-24a (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximum of 0.931 with the addition of the entire 5,445 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93680. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 12 lb (5,443 g).

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the content following the air transport accident cannot be established.

Cases **athu3sip15kor40_1_1_1** through **athu3sip15kor40_5_6_6** (Table 6.9.6-24b, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of 8.5 kg of U_3Si, 500 g polyethylene, and Kaolite. In a series of cases, the amount of U_3Si in the shell is varied from 1,000 g to 7,500-g U_3Si_2 in various increments and the remainder of the 8.5 kg U_3Si is contained in the homogenized core. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). All $k_{eff} + 2\sigma$ values are adequately below the USL of 0.93680.

6.7.11 Results for U_3Si Compounds at 60% Enriched

Case **atdu3sir60_1** through **atdu3sir60_5** (Table 6.9.6-24a, Appendix 6.9.6) pertains to Model 1 (Fig. 6.11, Sect. 6.3.1.4), in which varying amounts of U_3Si is homogenized with 500 g polyethylene. The fissile core is configured into a spherical shape with an exterior 20 cm water reflector. The U_3Si mass is evaluated up to 8.5 kg, with the highest $k_{eff} + 2\sigma$ value of 0.924 (Table 6.9.6-24a, Appendix 6.9.6) is below the USL of 0.93520.

Cases **atdu3sisr60_1** through **atdu3sisr60_11** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 2 (Fig. 6.12, Sect. 6.3.1.4), in which 8.5 kg of U_3Si is homogenized with 500 g polyethylene. The fissile core of Model 1 is blanketed with a variable thickness stainless steel shell with an exterior 20 cm water reflector. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero steel thickness. The $k_{eff} + 2\sigma$ value for 8.5 kg of U_3Si and zero stainless steel thickness is 0.923. Reactivity decreases, then increases as stainless steel is added to a maximum of 66,133 g, which is the highest amount of the CV and the liner and drum assembly. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.93520.

Cases **atdu3sidkr60_1** through **atdu3sidkr60_6** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness dry-Kaolite shell with an exterior 20 cm water reflector. Dry Kaolite consists of 51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the dry Kaolite. The $k_{eff} + 2\sigma = 0.927$ for 8.5 kg of U_3Si. As the amount of dry Kaolite is added to the shell surrounding the U_3Si, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the dry-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93520.

Cases **atdu3si15kr60_1** through **atdu3si15kr60_6** (Table 6.9.6-24a, Appendix 6.9.6) also pertain to Model 3 (Fig. 6.13, Sect. 6.3.1.4). The fissile core of Model 1 is blanketed with a variable thickness wet-Kaolite shell with an exterior 20 cm water reflector. As explained in Sect. 6.3.1.4, wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite [51,214.9 g vermiculite-cement and 2,204.7 g bound water from inside the body weldment outer liner and the drum top plug] and up to 6,803.8 g free water—moisture which dampens the Kaolite and may also be present in the CV well. As shown in Table 6.9.6-24a (Appendix 6.9.6), the maximum $k_{eff} + 2\sigma$ value occurs at zero shell-thickness for the wet Kaolite. The $k_{eff} + 2\sigma = 0.927$ for 8.5 kg of U_3Si. As the amount of wet Kaolite is added to the shell surrounding the U_3Si, reactivity decreases. A significant drop in the neutron multiplication factor is observed for the addition of the wet-Kaolite shell to the fissile core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93520.

Note that in these calculations the water comes from three sources: bound water in the Kaolite, free water in the Kaolite, and saturated water inside the compound. The amount of bounded water in the Kaolite is 2,205 g. The amount of free water is calculated at 12 and 15 pounds, which is 5,445 g of free water and 6,804 g respectively. The remaining water is the saturated water that is originally in the compound.

Cases **athu3sip15kr60_1** through **athu3sip15kr60_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 4 (Fig. 6.14, Sect. 6.3.1.4). The homogenized core consists of 8 kg of U_3Si, 500 g of polyethylene, and Kaolite. For this set of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water) [Table 6.9.6-24a, Appendix 6.9.6]. For Model 4, the overall radius at 31.39648 cm is constant for several reasons. First, the 500 g of polyethylene has a fixed volume. Second, the Kaolite is a porous material and the volume does not change appreciably as the material is dried out or absorbs water.

As shown in Table 6.9.6-24a, a gradual increase in $k_{eff} + 2\sigma$ occurs from dry condition to the wet condition. The homogenization of the Kaolite shell and the fissile material core from Model 3 produces two competing effects in Model 4:

- homogenization expands the fissile material core resulting in a decrease in neutron multiplication (from $k_{eff} + 2\sigma = 0.927$ in Case **atdu3si15kr60_1** to $k_{eff} + 2\sigma = 0.758$ in Case **atdu3si15kr60_6**), and

- the increase in the free water content of the Kaolite (and CV well) increases neutron multiplication in the core (from $k_{eff} + 2\sigma = 0.513$ in Case **athu3sip15kr60_1** to $k_{eff} + 2\sigma = 0.600$ in Case **athu3sip15kr60_5**).

Consequently, the scenario of water penetration of fissile material core under Model 5 requires evaluation.

Cases **athu3sipw12kr60_1_5** through **athu3sipw12kr60_6_5** (Table 6.9.6-24a, Appendix 6.9.6) pertain to Model 5 (Fig. 6.15, Sect. 6.3.1.4). Model 5 is a variation of Model 3, which represents a fissile material core blanketed with wet Kaolite and reflected by 20 cm of water. In Model 5, excess water from the wet Kaolite shell is assumed to migrate into the homogenized core. The homogenized core consists of 6.5 kg of U_3Si (note this mass is less than 8 kg evaluated in Models 1 through 4), 500 g of polyethylene, and excess water from the wet Kaolite. The water content of the Kaolite shell ranges from the wet condition (7,648 g water, free and bounded) to the dry condition (2,205 g bounded water) [Table 6.9.6-24a, Appendix 6.9.6]. As excess water migrates from the wet Kaolite shell into the homogenized core, the core radius expands from 9.67497 to 13.02005 cm. However, the volume of the Kaolite shell remains constant because the Kaolite is a porous material and the volume does not change appreciably as the material loses or gains water.

As shown in Table 6.9.6-24a (Appendix 6.9.6), the $k_{eff} + 2\sigma$ values increase to maximum of 0.936 with the addition of the entire 5,445 g of water from wet Kaolite into the fissile material core. The $k_{eff} + 2\sigma$ values are below the USL of 0.93680. The homogenized core is under moderated because sufficient water is not present in the wet Kaolite and CV well to reach the point of optimum moderation. The total free water is conservatively evaluated up to 12 lb (5,443 g).

In the absence of 10 CFR 71.55(f) test data or dynamic impact simulations per Type-C test criteria, the assumption of water penetration of the fissile material core is valid under the severe air transport evaluation criteria. Model 5 is applicable to air transport of the ES-3100 package given that the geometric form of the content following the air transport accident cannot be established.

Cases **athu3sip15kor60_1_1_1** through **athu3sip15kor60_5_6_6** (Table 6.9.6-24b, Appendix 6.9.6) pertain to Model 6 (Fig. 6.16, Sect. 6.3.1.4), where fissile material from the homogenized core of Model 4 forms a shell external to the core. The homogenized core consists of 6.5 kg of U_3Si, 500 g polyethylene, and Kaolite. In a series of cases, the amount of U_3Si in the shell is varied from 1,000 g to 5,500-g U_3Si_2 in various increments and the remainder of the 6.5 kg U_3Si_2 is contained in the homogenized core. For these sets of parametric cases, the Kaolite water content ranges from the wet condition (9,008.5 g water) to the dry condition (2,204.7 g water). All $k_{eff} + 2\sigma$ values are adequately below the USL of 0.93680.

6.7.12 Conclusions

Given that the results for catastrophic damage are adequately subcritical, ES-3100 packages may be shipped via air transport with:

- up to 7-kg ^{235}U HEU metal in the form of solid shapes (cylinders, bars, billets, buttons, or slugs), broken metal, metal turnings, fines, powder, or as an unspecified geometric shape (characterized as broken metal) unless a lesser amount is determined by ground transport consideration (Table 6.2a);
- up to 7-kg ^{235}U with enrichment up to 100%;
- three fuel sections ("meats") of $UZrH_x$ per loaded convenience can and up to three loaded cans per package where the ^{235}U does not exceed 921 g at 20% enrichment or 408-g ^{235}U at 70%;
- ~15-in.-long clad fuel rods, each rod derived from a single TRIGA fuel element, and where per package ^{235}U does not exceed 921 g at 20% enrichment or 408-g ^{235}U at 70%; or
- research reactor related contents of U_3O_8-Al, UO_2, and UO_2-Mg where the per package ^{235}U content does not exceed 921 g at enrichments less than or equal to 20% or 408-g ^{235}U at enrichments greater than 20%.
- up to 24 kg UF_4 (18.13-kg ^{235}U) with enrichments up to 100% unless a lesser amount is determined by ground transport consideration;
- up to 3 kg UO_2F_2 (2.067-kg ^{235}U) with enrichments up to 100%;
- up to 2 kg UC (1.815-kg ^{235}U) with enrichments up to 100%;
- up to 2 kg UN (1.888 kg ^{235}U) with enrichments up to 100%;
- up to 8.5 kg U_3Si_2 (3.150-kg ^{235}U) with enrichments up to 40%;
- up to 6.5 kg U_3Si_2 (3.613-kg ^{235}U) with enrichments up to 60%;
- up to 8.5 kg U_3Si (3.270-kg ^{235}U) with enrichments up to 40%;
- up to 6.5 kg U_3Si (3.751-kg ^{235}U) with enrichments up to 60%;

6.8 BENCHMARK EXPERIMENTS

6.8.1 Applicability of Benchmark Experiments

The criticality validation is specific to uranium, plutonium, and uranium-233 systems encompassing a substantial subset of the database used to prepare the Organization for Economic Cooperation and Development (OECD) Handbook, Volumes I–VI. The benchmark specifications are intended for use by criticality safety engineers to validate the application of criticality calculation techniques such as SCALE 4.4a. Example calculations presented in the handbook do not constitute a validation of the codes or cross-section data sets by themselves, but the Handbook information can be and has been used to validate SCALE 4.4a by competent nuclear criticality safety persons.

The data from the benchmark experiments involving uranium represent a sufficiently wide range of enrichments and physical and chemical forms to cover many existing or presently planned activities for Y-12. These include enriched uranium with ^{235}U only and natural and depleted uranium, as well as highly enriched uranium, intermediate enriched uranium, and low enriched uranium. Data analyzed from critical experiments in this validation include systems having fast, intermediate, and thermal neutron energy spectra, and they include materials in various physical and chemical forms such as uranium metals, solutions, and oxide compounds. With the benchmark experiments that are directly applicable to uranium systems, there is a high level of confidence that the calculated results presented in this evaluation are sufficiently accurate to establish the safety of the package under both NCT and HAC. This conclusion is based on the validation of the code and cross-section library described in Sect. 6.3.3.

6.8.2 Details of Benchmark Calculations

The validation of CSAS25 control module of SCALE 4.4a with the 238-group ENDF/B-V cross-section library is documented in Y/DD-896/R1 and Y/DD-972R1. Y/DD-896/R1 addresses the establishment of bias, bias trends, and uncertainty associated with the use of SCALE 4.4a for performance of criticality calculations. This evaluation is directed at uranium systems consisting of fissile and fissionable material in metallic, solution, and other physical forms, as well as plutonium and ^{233}U systems, as described in the OECD Handbook [NEA/NSC/DOC(95)03]. The focus is on comparison of k_{eff} with the associated experimental results for establishment of bias, bias trends, and uncertainty as a final step. Compiled data for 1217 critical experiments are used as the basis for the calculation models. The calculated results from SCALE 4.4a using the 238-group ENDF/B-V cross-section library have been compared with reported results for the benchmark experiments. Comparison of results demonstrates that SCALE 4.4a run on the SAE HP J-5600 unclassified workstation (CMODB) produces the same results within the statistical uncertainty of the Monte Carlo calculations as reported by the OECD for the experiments.

Y/DD-972R1 addresses determining USL and for incorporating uncertainty and margin into this USL. Y/DD-972R1 establishes subcritical limits determined through an evaluation of statistical parameters of calculation results for critical experiments. The correlating parameters (i.e., mass, enrichment, geometry, absorption, moderation, reflection) and values for applying additional margin to the subcritical limits are application dependent. The determination of correlating parameters and additional margin is an integral part of the process analysis for a particular application. For the critical experiment results, no correlation between calculation results and neutron energy causing fission was found. As such, this document does not specify "final" USL values as has been done in the past.

The criticality validation for SCALE 6.1.1 is based on benchmark experiments documented in the Organization for Economic Cooperation and Development (OECD) Handbook [NEA/NSC/DOC(95)03, *International Handbook of Evaluated Criticality Safety Benchmark Experiments*]. The upper subcritical limit (USL) without any safety margin for running SCALE 6.1.1 on this workstation is 0.985 (which covers all HEU systems with enrichments > 60%) as documented in RP YAREA-F-0455. NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Using this safety margin, the USL for the calculations performed would be 0.935.

The criticality validation for SCALE 6.1.3 is based on benchmark experiments documented in the Organization for Economic Cooperation and Development (OECD) Handbook [NEA/NSC/DOC(95)03, *International Handbook of Evaluated Criticality Safety Benchmark Experiments*]. The USL without any safety margin—derived for the validation of CSAS5 control module of SCALE 6.1.3 with the multi-group V7-238-gr cross-section library run on ENGHPC workstation—is 0.9852 for intermediate energy HEU systems as documented in RP YAREA-F-0524. NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Using this safety margin, the USL for the calculations performed in this document would be 0.9368 for thermal energy systems, 0.9352 for intermediate energy systems, and 0.9386 for fast energy systems.

6.8.3 Bias Determination

The USL is based on the non-parametric statistics-based lower tolerance limit (LTL) for greater than 0.99/99% where there is a probability of greater than 0.99 that 99% of the population is greater than a specified result, reduced by additional margin. From Table 1 of Y/DD-972R1, the LTL combining bias and bias uncertainty is 0.975 for uranium systems, including HEU metal. Tables 4.2, 4.3, and 4.4 of Y/DD-896/R1 list the maximum (positive) and minimum (negative) biases for HEU (metal, compound, solution), IEU (metal, compound) and LEU (compound, solution) systems. Since the positive bias is

conservatively treated as a “zero” bias in the validation analysis, the negative bias is applied to determine the USL for the systems. The minimum bias for the HEU, IEU, and LEU systems is given as −0.14356, −0.0055 and −0.0247, respectively.

The minimum result for the HEU systems is from one of four k-infinite models, which are somewhat different than the actual benchmark experiments. As discussed in Sect 5.3 of Y/DD-896/R1, four outlier results are for benchmark experiments that were modeled infinite in extent. The models required additional interpretation and adjustment form the actual finite experiment configuration to create an infinite benchmark model. After eliminating the outlier models from the bias determination, the minimum bias determined from data in Table 4.2 (Y/DD-896/R1) is −0.0203 for HEU systems.

The global minimum bias for these uranium systems [−0.0247 (conservatively rounded to −0.025)] is applied to all uranium enrichments. Ordinarily, the USL would be 0.955 where an additional margin of subcriticality of 0.02 is subtracted from the LTL of 0.975. However, NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Thus, the USL is equal to 0.95 plus the minimum bias (−0.025), giving a value of 0.925.

Fissile Content and Packaging Models

Calculation model for solid HEU metal, 3.24-in.-diam cylinders. Figure 6.9.1-1 depicts the wire-mesh view of the 3.24-in.-diam highly enriched uranium (HEU) cylindrical content configuration inside the containment vessel (CV). The interstitial water has been removed for illustration purposes. As can be seen from Fig. 6.9.1-1, the cylindrical content model contains one cylinder per convenience can and 1.4-in.-thick 277-4 canned spacers between the can locations. Cylinders are at the maximum diameter that will fit through the opening of a press-fit lid type convenience can. The cylindrical content shown is at the maximum mass loading; the height of the cylinders may change depending upon the mass loading. Figure 6.9.1-1b depicts a section view of the CV with 3.24-in.-diam cylinders at 4.826 and 0.254 cm separation.

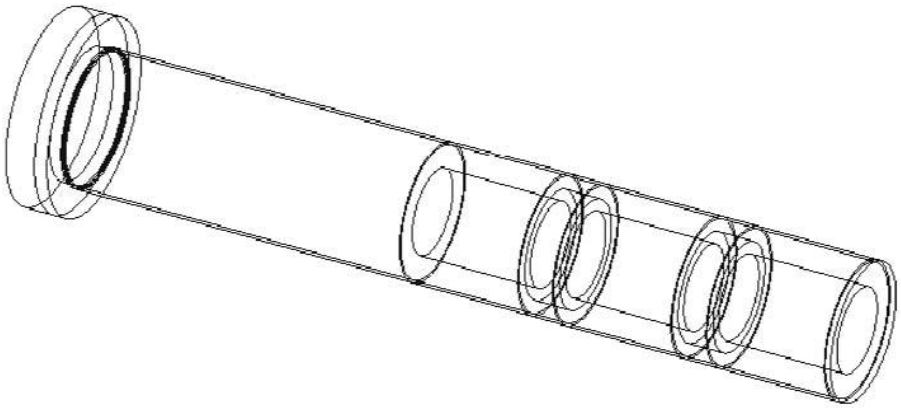

Fig. 6.9.1-1. Containment vessel containing 3.24-in.-diam cylinders and 1.4-in.-thick 277-4 canned spacers.

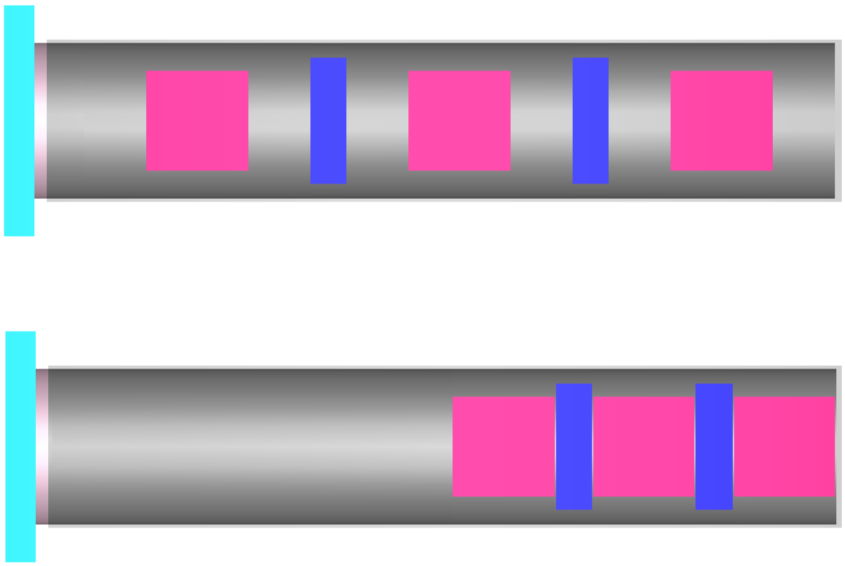

Fig. 6.9.1-1b. Section view of the containment vessel depicting 4.826 and 0.254 cm separation distances for 3.24-in.-diam cylinders (pink) with 1.4-in.-thick canned spacers (blue).

Calculation model for solid HEU metal, 4.25-in.-diam cylinders. Figure 6.9.1-2 depicts the wire-mesh view of the 4.25-in.-diam HEU cylindrical content configuration inside the CV. The interstitial water has been removed for illustration purposes. As can be seen from Fig. 6.9.1-2, the cylindrical content model contains one cylinder per convenience can and 1.4-in.-thick 277-4 canned spacers between the can locations. Cylinders are at the maximum diameter that will fit through the opening of a crimp-seal lid type convenience can. The cylindrical content shown is at the maximum mass loading; the height of the cylinders may change depending upon the mass loading.

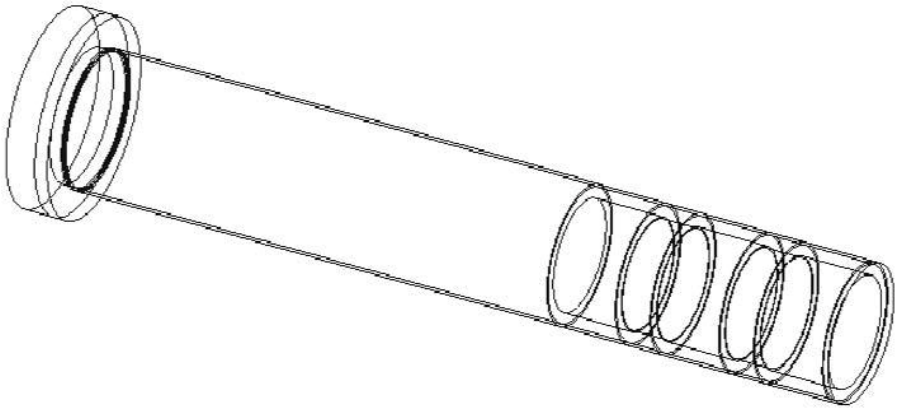

Fig. 6.9.1-2. Containment vessel containing 4.25-in.-diam cylinders and 1.4-in.-thick 277-4 canned spacers.

Calculation model for solid HEU metal, bars. Figure 6.9.1-3 depicts the wire-mesh view of the 2.29-in.-square HEU bar content configuration inside the CV. The interstitial water inside the CV has been removed for illustration purposes. The square bar content model contains one bar per convenience can and 1.4-in.-thick 277-4 canned spacers between the can locations. The 2.29-in.-square bar is the largest size that will fit through the 3.24-in.-diam opening of a press-fit lid type convenience can. Similar to the cylindrical model, the height of the square bar is dependent upon the HEU mass.

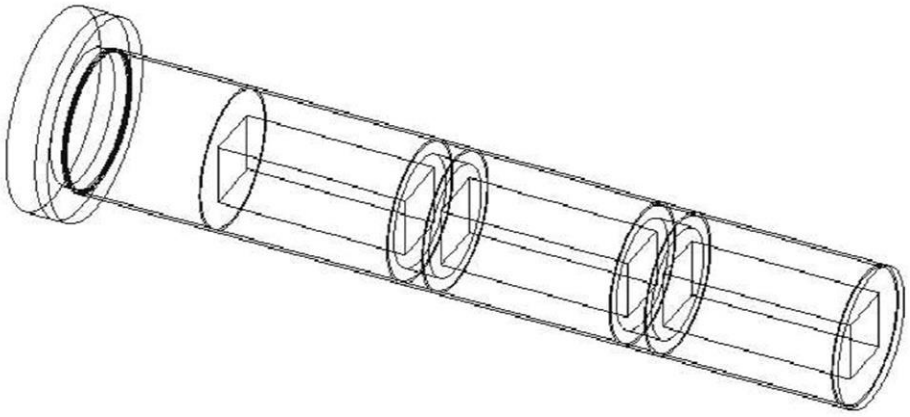

Fig. 6.9.1-3. Containment vessel containing 2.29-in.-square bars and 1.4-in.-thick 277-4 canned spacers.

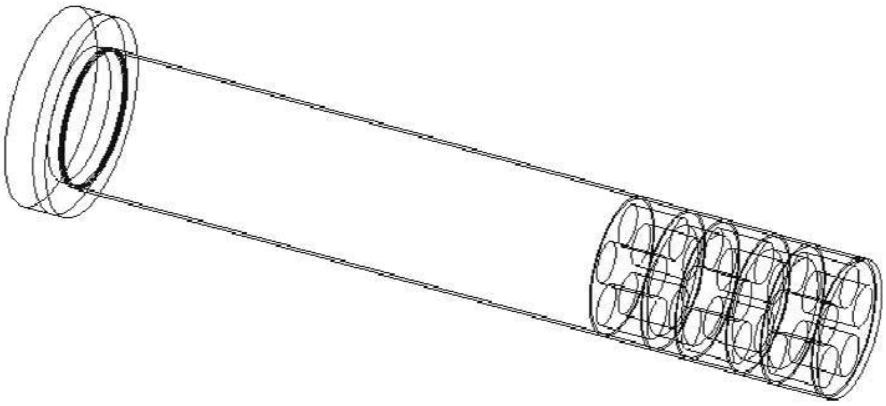
Calculation model for solid HEU metal, slugs. Figure 6.9.1-4 depicts the wire-mesh view of a pentagonal ring configuration of the 1.5-in.-diam × 2.0-in.-tall slugs inside the CV. The axial centerline of each slug is located 1.27598 in. from the origin of the pentagon such that a tight fitting configuration of slugs is modeled (i.e., there are no gaps between adjacent slugs). The slug content model contains two rings of the 1.5-in.-diam × 2.0-in.-tall slugs per convenience can and the 277-4 canned spacers between the convenience cans locations. The interstitial water inside the CV has been removed for illustration purposes. Figure 6.9.1-4b depicts typical slug configurations that were evaluated.



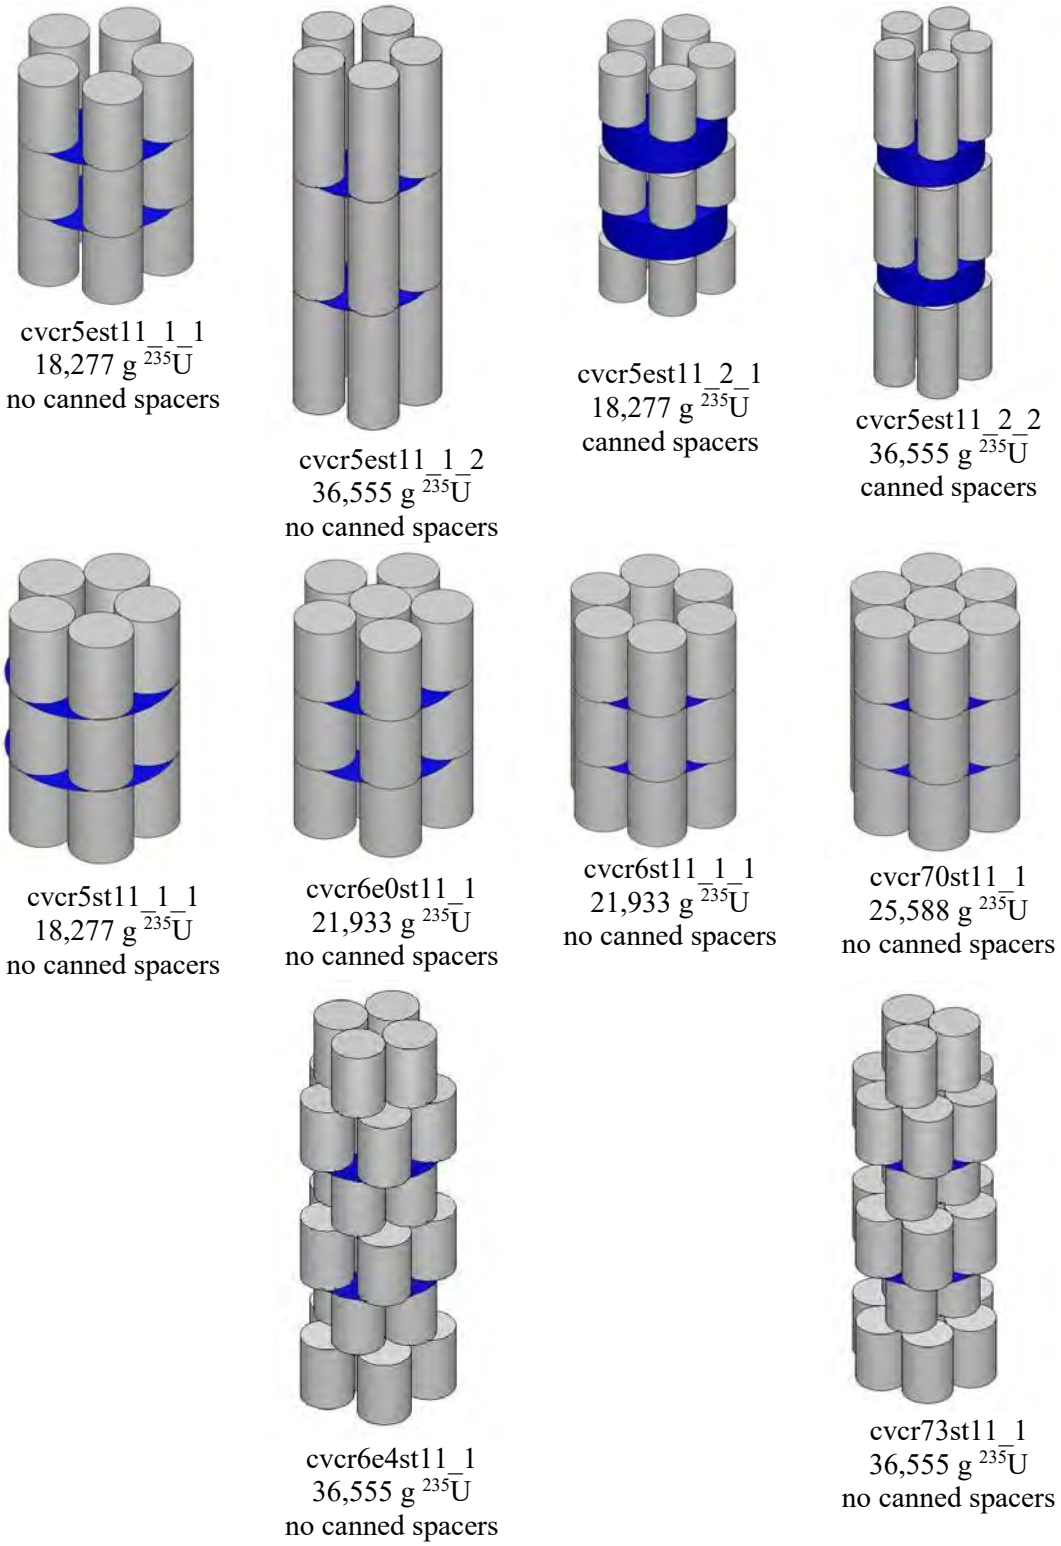


Fig. 6.9.1-4. Containment vessel containing the 1.5-in.-diam × 2.0-in.–tall slugs in a pentagonal ring configuration with 0.0-cm spacing between slugs and 1.4-in.-thick 277-4 canned spacers.

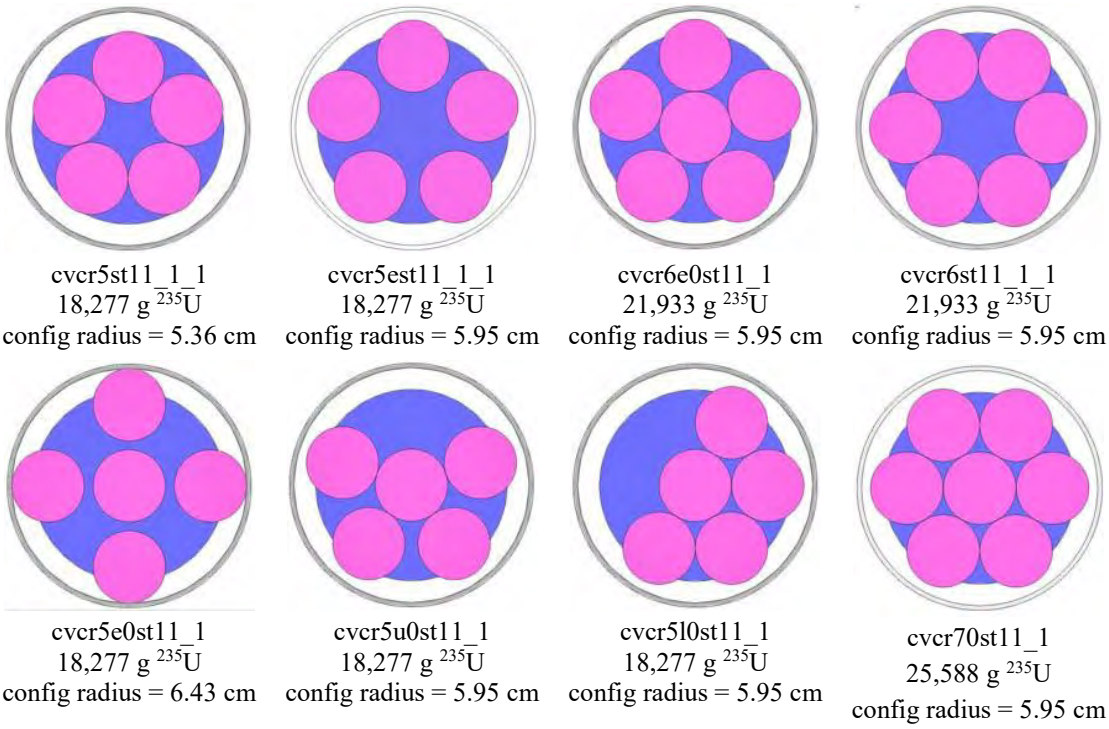
A 1.5-in.–diam × 2.0-in.–tall slug was modeled with a maximum tolerance of 1/16 in. applied to both the radius and height. The resulting dimensions are 1.984375 cm in radius and 5.23875 cm in height; the calculated volume of a single slug is 64.80746 cm^3. For 100% enriched uranium (density = 18.81109 g/cm^3), the calculated mass of 15 slugs is 18,286.5 g. Subsequently, the radius of each slug was reduced by 0.0005 cm thus eliminating a geometry intersection error in KENO V.a which occurs when the hole option is used to place slugs into an encompassing piece of the geometry unit. In the case of a pentagonal ring with spaced-apart slugs (Case **cvcr5est11_1_1**, Fig. 6.9.1-4b), the calculated volume reported for 15 slugs in KENO V.a is 971.622 cm^3 and the corresponding mass is 18277.3 g or 1,218.5 g per slug. This reduction in mass of 0.6333 g per slug is insignificant when considering the mass of a slug is nominally 1,089 g.

The maximum tolerance slug was also used in other slug geometry configurations, such as, “cvcr5s”, “cvcr6e0s”, “cvcr6s”, “cvcr70s”, “cvcr6e4s”, and “cvcr73s” orientations shown in Fig. 6.9.1-4b. For the pentagonal geometry configuration with slugs stacked two high in a ring (Case **cvcr5est11_1_2** or **cvcr5st11_1_2**), the model volume and mass of the slugs are twice the values of the single ring (Case **cvcr5est11_1_1** or **cvcr5st11_1_1**). For a pentagonal geometry configuration with a central slug (“cvcr6e0s”) and the hexagonal geometry configuration (“cvcr6"), the calculated volume reported in KENO V.a is 1,165.95 cm^3 and the corresponding mass is 21,932.7 g. For a hexagonal geometry configuration with a central slug (“cvcr70s”), the calculated volume reported in KENO V.a is 1,360.27 cm^3 and the corresponding mass is 25,588.2 g. For the compact ten-slug-per-can configurations (“cvcr5est”, “cvcr5est”, “cvcr6e4s”, and “cvcr73s”), the calculated volume reported in KENO V.a is 1,943.24 cm^3, and the corresponding mass is 36,554.6 g.

Note: Blue marker depicted for configurations without 1.4-in.-thick 277-4 canned spacers.

Fig. 6.9.1-4b. Isometric views for typical slug configurations.



Several slug arrangements were evaluated for demonstrating that the most conservative arrangement of slugs has been analyzed. Figure 6.9.1-4c depicts radial section views of the CV showing the slugs (pink) in relation to the footprint (blue) for a 4.25-in.–diam (5.3975-cm) convenience can. Cases **cvcr5st11_1_1**, **cvcr5est11_1_1**, **cvcr5e0st11_1**, **cvcr5u0st11_1**, and **cvcr5l0st11_1** depict different arrangements with five slugs per convenience can, three cans per package. Cases **cvcr6e0st11_1_1** and **cvcr6st11_1_1** depict arrangements with six slugs per convenience can, and Case **cvcr70st11_1** depicts seven slugs per convenience can. (Considerable deformation of a 4.25-in.–diam convenience can wall is required to achieve all but the simple pentagonal-ring arrangement of slugs.) The 277-4 canned spacers are not present in these calculation models.

Calculation models for solid HEU metal of unspecified geometric shapes characterized as broken metal. The intended use of the "broken metal" category is for shipment of solid HEU metal of unspecified geometric shape characterized as broken metal, packed in 4.25-in.-diam convenience cans where the packing fraction would not exceed 0.59. The packing fraction is a parameter which characterizes the volume that broken metal occupies. A typical broken metal content is depicted in Fig. 6.9.3.1-3 where the packing fraction for content in a convenience can ranges from 0.2 to ~0.6.

In the criticality evaluation of broken metal, convenience cans are not credited for containing the content nor for maintaining spacing between the 277-4 canned spacers. Consequently, the shape and size of the broken metal pieces establishes the separation between canned spacers which in turn determines the size of the HEU content locations inside the CV. Given the irregular shape of broken metal, the packing fraction is the parameter which quantifies the volume of space that the broken metal occupies. The use of a large packing fraction (~0.6) results in minimum separation between canned spacers which minimizes the size of the lower and middle content locations and maximizes the size of the upper content location. Reactivity of the CV is driven by the oversized upper content location. Conversely, the use of a small packing fraction (~0.2) results in greater separation between the canned spacers which increases the size of the lower and middle content locations, while reducing the size of the upper content location. Reactivity of the CV decreases accordingly.

The "**sqa**", "**lha**", and "**cha**" calculation models are devised for evaluating broken metal in the idealized forms described in the following paragraphs. The heights of the lower can locations and separation between the first and second 277-4 canned spacers inside the CV are conservatively established on the basis that broken metal is confined within a rectangular lattice formed by the unit cells of fissile material having a packing fraction of ~0.59.

In the "sqa" model for HEU broken metal, a uniform-size metal cube is contained inside a unit cell of content. The unit cells are configured into arrays with one array for each can location inside the CV. HEU metal cubes ranging in size from 1.0 to 0.25 in. are correspondingly arranged into 3 × 3, 6 × 6, or 12 × 12 configurations with ***N*** layers stacked vertically. A rectangular lattice of unit cells is defined by a square prism circumscribed by the wall of the CV with an inner diameter of 5.06 in. (12.8524 cm). The width and depth of the square base is 3.57796 in. (9.08802 cm). The height of the lattice is determined by both the size of a cube and the number of layers of cubes required for a given HEU mass loading.

Note: Blue marker depicts 4.25-in.–diam wall of the convenience can.

Fig. 6.9.1-4c. Plan view of slug configurations in the confines of the containment vessel.

Figure 6.9.1-5 depicts a wire mesh view of the CV and lid with three 12 × 12 × 18 arrays of HEU content separated by 277-4 canned spacers. Figure 6.9.1-5b depicts an isometric view of this same content with the **evaluation** water surrounding the HEU removed for illustration. The corner unit cells touch the inside wall of the CV. The HEU cubes are centered within the individual unit cells and uniform spacing between cubes is modeled. The 277-4 canned spacers are modeled as cylindrical disks with dimensions of 4.13-in. diam × 1.37-in. height.

Uranium mass is reduced in the calculation model by removing one or more cubes from the array and filling these vacancies with water. The location of the 277-4 canned spacers between the arrays of cubes decreases as complete layers of cubes are removed from each array. The volume of the CV above the top layer of the top array of cubes is filled with full-density water.

In the "lha" model of HEU broken metal, the metal cubes of the "sqa" model are homogeneously mixed with **evaluation** water within the square prism of the "sqa" model. Figure 6.9.1-5c depicts an isometric view of the "lha" model. The boundaries of each square prism shown in the figure are defined by the 12 × 12 × 18 array of unit cells of the explicit "sqa" model. Each prism contains the same mass of HEU and **evaluation** water that the respective explicit cube model contains. The volume outside the prisms and the canned spacers is filled with full density water.

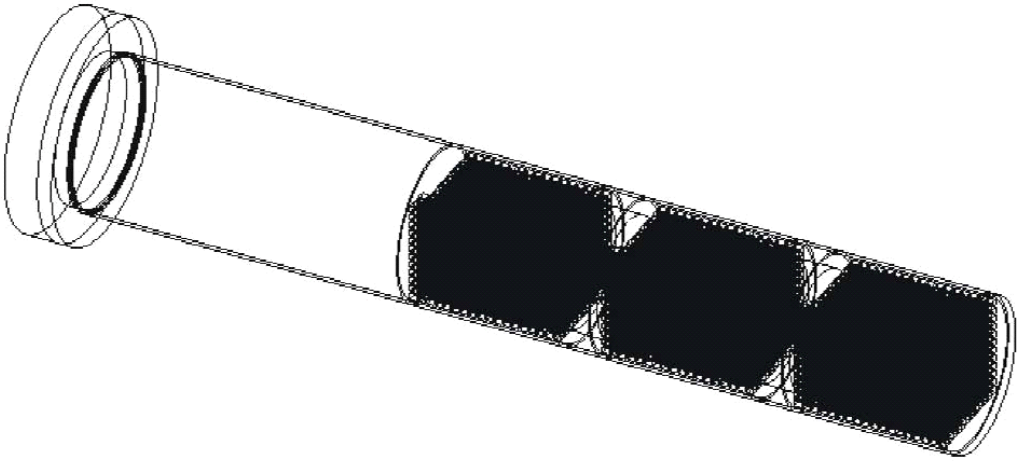


Fig. 6.9.1-5. Wire mesh view of the "sqa" model with three 12 × 12 × 18 lattices of HEU broken metal as 1-in. cubes separated by 1.4-in. 277-4 canned spacers.

In the "cha" model of HEU broken metal, the metal cubes of the "sqa" model are homogeneously mixed with the **evaluation** water within the free volume of the CV. Figure 6.9.1-5d depicts an isometric view of the "cha" model. The 277-4 canned spacers are positioned for similarity with the "sqa" and "lha" models using the height of the prism, defined in this case by the 12 × 12 × 18 array of unit cells of the explicit "sqa" model. The mass of HEU and **evaluation** water of the explicit "sqa" model is preserved.

Once the locations of the canned spacers in the CV are established based on the height of the square prism, the HEU broken metal and evaluation water inside the CV are homogenized over the internal volume of the 12.8524-cm-diam CV not being occupied by the canned spacers. The homogenization of fissile material with moderator to represent discrete solid HEU metal of unspecified geometric shape characterized as broken metal is unquestionably bounding only when the overall volume (and shape) containing HEU and interstitial moderator between the pieces of HEU is preserved in the approximation model.

In the "cha" model, the uniform dispersal of the homogenized HEU and evaluation water over the residual internal volume of the CV has the effect of relocating ^{235}U from the two lower can locations into the upper can location. When the 277-4 canned spacers are present, the neutronic coupling of can locations is weak and the reactivity of the packaged content is determined by the reactivity of the largest can location. This model may not be conservative when canned spacers are absent because nothing would prevent settling of content inside the CV into a single mass given that the convenience cans are not credited for containing the content nor for maintaining spacing between the contents of each can.

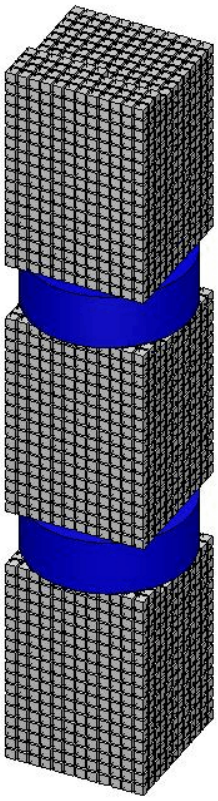

Fig. 6.9.1-5b. Detailed isometric view of the explicit "sqa" model for HEU broken metal. Three 12 × 12 × 18 lattices of 1-in. cubes separated by 1.4-in. 277-4 spacers are shown.

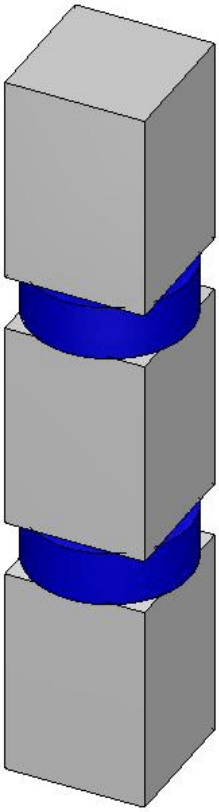

Fig. 6.9.1-5c. Isometric view of the homogeneous "lha" model with HEU homogeneously mixed with evaluation water within the rectangular lattices formed by the units cells.

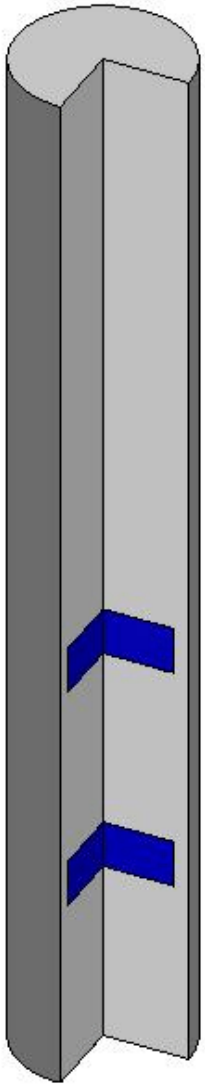

Fig. 6.9.1-5d. Isometric view of the homogeneous "cha" model with HEU homogeneously mixed with evaluation water within the interior of the containment vessel.

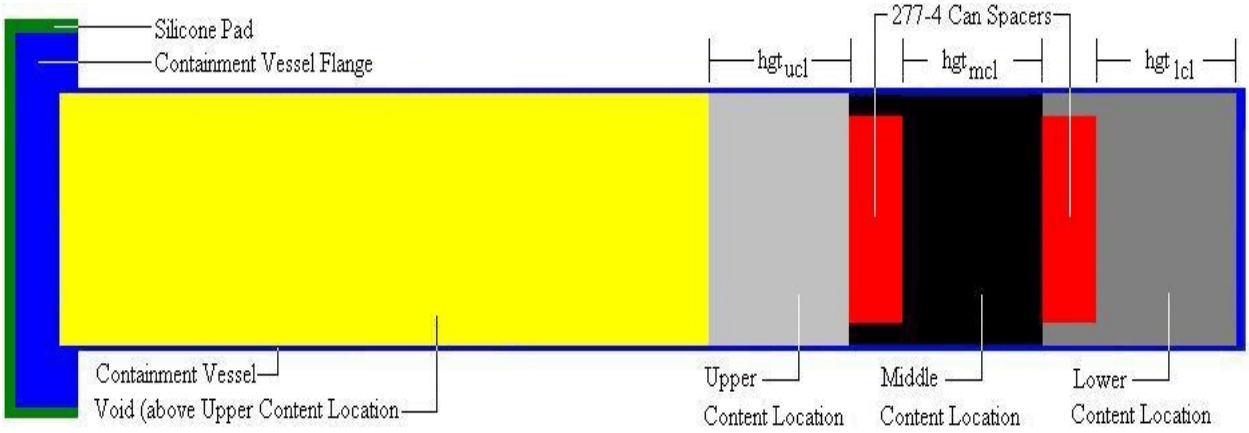


As stated in Sect. 6.9.3.1, the "cha" model is used to represent broken metal in single packages and the array of packages under NCT and HAC. For addressing the issue that the uniform dispersal approximation model ("cha") may not be conservative, especially when the 277-4 canned spacers are absent, the settling of content may be evaluated by establishing the material geometry and composition based on a maximum packing fraction. The packing fraction calculation model is described for this purpose.

In the packing fraction model, the material within a variable height can location is evaluated over the range of packing fractions from loosely packed material (PF ~0.2) to densely packed material (PF ~0.6). The height of can locations is determined based on the packing fraction instead of the fictitious cube stacking algorithm which was used in the "cha" uniform dispersal approximation model. The height of can locations used in the packing fraction calculation model is given by the following formula:

$$hgt = [(HEU_{vol} / PF) + Poly_{vol}] / CV_{area}$$

(500 g of polyethylene is included in the calculation model to represent the potential use of packing material.)

Fig. 6.9.1-5e depicts a section view of the CV for the packing fraction calculation model. The height of the lower, middle, and upper can locations are equal. Only in the upper location does the can location coincide with the content location. The "**fl**" is used in the case name to designate calculations are based on the packing fraction model.

Note: The height (hgt) of the upper, middle, and lower can locations are determined by the HEU packing fraction.

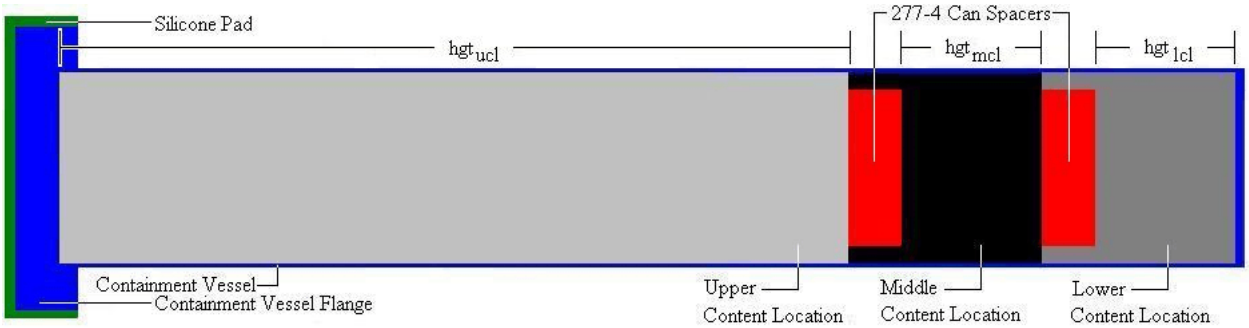
Fig. 6.9.1-5e. Section view of the containment vessel for the packaging fraction calculation model depicting the content locations for broken metal.

The volume fractions for material constituents in the middle and lower content locations are calculated as follows:

$$VF_{HEU} = HEU_{vol} / (hgt \times CV_{area} + Spacer_{void})$$

where HEU_{vol} is the volume of HEU at theoretical density and $Spacer_{void}$ is the volume of the void region between the CV wall an the can spacer assumed filled with evaluation water.

$$VF_{H2O} = [(HEU_{vol} / PF) - HEU_{vol} + Spacer_{void}] / (hgt \times CV_{area} + Spacer_{void})$$
$$VF_{Poly} = Poly_{vol} / (hgt \times CV_{area} + Spacer_{void})$$



The volume fractions for material constituents in the upper content location are calculated as follows:

$$VF_{HEU} = HEU_{vol} / (hgt \times CV_{area})$$
$$VF_{H2O} = [(HEU_{vol} / PF) - HEU_{vol}] / (hgt \times CV_{area})$$
$$VF_{Poly} = Poly_{vol} / (hgt \times CV_{area})$$

The void region above the upper content location (Vol_{above}) is filled with full density water.

In addressing the issue that the uniform dispersal approximation "cha" model may not be conservative because homogenization of HEU is performed over a much larger volume and shape than the HEU content conceivably occupies, the effect of dispersing content within a can location may be evaluated using a variation of the packing fraction calculation model. The dispersed content calculation model is described for this purpose.

In the dispersed content calculation model, the HEU, the polyethylene, and the evaluation water of the upper content location is homogenized over the entire volume of this location. Figure 6.9.1-5f depicts a section view of the CV for the dispersed content calculation model. The height of the lower and middle content locations are equal, while the height of the upper content location extends to the top of the CV cavity. The "**fd**" designation in the case name is used to identify the dispersed content calculation model.

Note: The height (hgt) of the middle and lower content locations are determined by the HEU packing fraction. The height of the upper content location extends to the top of the containment vessel cavity.

Fig. 6.9.1-5f. Section view of the containment vessel in the dispersed content calculation model depicting the content locations for broken metal.

The volume fractions for material constituents in the middle and lower content locations are specified the same as in the "**fl**" model. However, the volume fractions for material constituents dispersed into the upper content location are calculated as follows:

$$VF_{HEU} = HEU_{vol} / (hgt \times CV_{area} + Vol_{above})$$

where Vol_{above} is the void region above the upper can location into which the content is dispersed.

$$VF_{H2O} = [(HEU_{vol} / PF) - HEU_{vol} + Vol_{above}] / (hgt \times CV_{area} + Vol_{above})$$
$$VF_{H2O} = Poly_{vol} / (hgt \times CV_{area} + Vol_{above})$$

For example, consider reference Case **hciabmt12_4_1_5_3** (Table 6.9.6-11) which defines the loading limit for broken metal in the 70% < enr. ≤ 80% range where canned spacers are not used in the CV. In revised Case **hciapbmflt12_1_6_4_5**, HEU broken metal with a packing fraction of 0.6, the 500 g of polyethylene and evaluation water in each can location is homogenized over the content location. Case **hciapbmflt12_1_2_4_5** is the same as Case **hciapbmflt12_1_6_4_5**, except the packing fraction is 0.2. In Case **hciapbmfdt12_1_6_4_5**, HEU broken metal with a packing fraction of 0.6, the 500 g of polyethylene and evaluation water in each content location is homogenized over the content location. Case **hciapbmfdt12_1_2_4_5** is the same as Case **hciapbmfdt12_1_6_4_5,** except the packing fraction is 0.2. Table 6.9.1.0 provides details for the packing fraction and dispersed content calculation models.

Powder, particulate, or small pieces of HEU potentially present in broken metal are capable of passing between content locations. The quantity of this material represents a small fraction of the total broken metal content. The placement of a limit on content size for criticality control is adopted as a package content loading restriction (Sect. 6.2.4, Item 6).

Calculation model for solid HEU of unspecified geometric shape, HEU oxides. Figure 6.9.1-6 depicts the wire-mesh view of the HEU oxide content inside the CV. The interstitial water inside the CV has been removed for illustration purposes. The HEU oxide mixture at bulk density is located at the bottom of the CV and fills the space to the wall of the CV. The height of the HEU oxide mixture is dependant upon the mass loading.

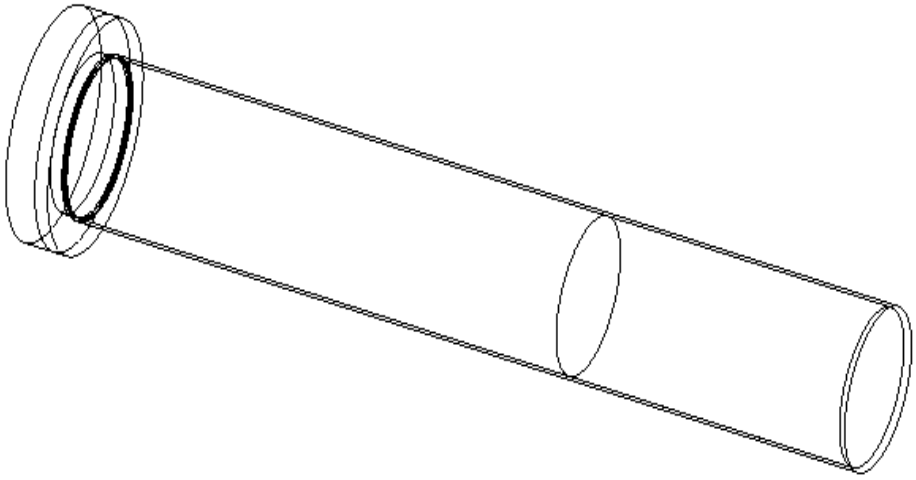

Fig. 6.9.1-6. Wire-mesh view of the containment vessel containing the HEU oxide mixture.

HEU product oxide is assumed to be saturated with water in the criticality calculation models. Maximum saturation in the oxide material occurs in a volume defined as the difference between the specific volume of bulk oxide and the minimum specific volume of the product oxide. Product oxide has a bulk density of 6.54 g/cm^3 or a specific volume of 0.152905 cm^3/g (Sect. 6.9.3.1). UO_2 has a theoretical density of 10.96 g/cm^3 or a minimum specific volume of 0.091241 cm^3/g. Therefore, the maximum volume per gram of UO_2 available for saturation by water is 0.061664 cm^3/g. Additionally, an assumed maximum of 500 g of polyethylene is homogenized with the water-saturated product oxide. The homogenized oxide containing polyethylene (density = 0.92 g/cm^3) occupies an additional 543.47826 cm^3.

The height of polyethylene homogenized with water-saturated product oxide inside the CV is calculated by dividing the volume of the homogenized oxide by the internal area of the base of the CV. The area of the base is 129.73536 cm^2 for the CV with an inner diameter of 5.06 in. (12.8524 cm). The height of the void space above the homogenized oxide is calculated by subtracting the homogenized oxide height from the 78.84-cm (31.0-in.) inside height of the CV.

As an example, consider Case **cvcrpoxt11_1_21_15** where 21,000 g of UO_2 (18,484.3 g ^{235}U) is saturated with 1,292.62 g water (Table 6.9.6-12). The calculated H/X ratio for the water saturated product oxide is 1.83. The water-saturated product oxide homogenized with 500 g of polyethylene rises to a height of ~28.93955 cm inside the CV. The 6,460.87 cm^3 of void space is flooded with 6449.2 g of evaluation water, such that the calculated H/X ratio inside the CV is 11.84. The 500 g of polyethylene adds 0.90 to the calculated H/X ratio of water-saturated product oxide. The calculated H/X ratio for the water-saturated product oxide homogenized with 500 g of polyethylene in a dry CV is 1.83 + 0.90 = 2.73 (Case **cvcrpoxt11_1_21_1**). In all cases, the H/X ratio is a computed value rather than an evaluation parameter.

The same modeling technique is applied to product oxides of U_3O_8 and UO_3. U_3O_8 has a theoretical density of 8.30 g/cm^3 or a minimum specific volume of 0.120482 cm^3/g. UO_3 has a theoretical

density of 7.29 g/cm^3 or a minimum specific volume of 0.137174 cm^3/g. The maximum volumes per gram of U_3O_8 and UO_3 available for saturation by water are 0.032423 cm^3/g and 0.015731 cm^3/g, respectively.

The eight skull oxide content compositions described in Table 6.9.3.1-3b for evaluating skull oxide are derived from 292 samples of canned skull oxide. Two additional compositions are listed in the table for addressing skull oxides with an enrichment of 93.2 wt %. The skull oxide content is assumed to be U_3O_8 plus polyethylene, graphite, and unidentified material. A maximum of 513 g of polyethylene is assumed to be present in the skull oxide content. The volume of skull oxide content in the CV (**vsoc**) is calculated as the grams of skull oxide content (**gsoc**) divided by the bulk density of the skull oxide content (**densoc**). The height of skull oxide content inside the CV is calculated by dividing the volume of skull oxide content (**vsoc**) by the internal area of the base of the CV (129.73536 cm^3).

Calculation model for solid HEU of unspecified geometric shape, UNH crystals. Figure 6.9.1-7 depicts the wire-mesh view of the UNH crystal content inside the CV. A solution of UNH crystals dissolved in water fills the entire volume of the CV.

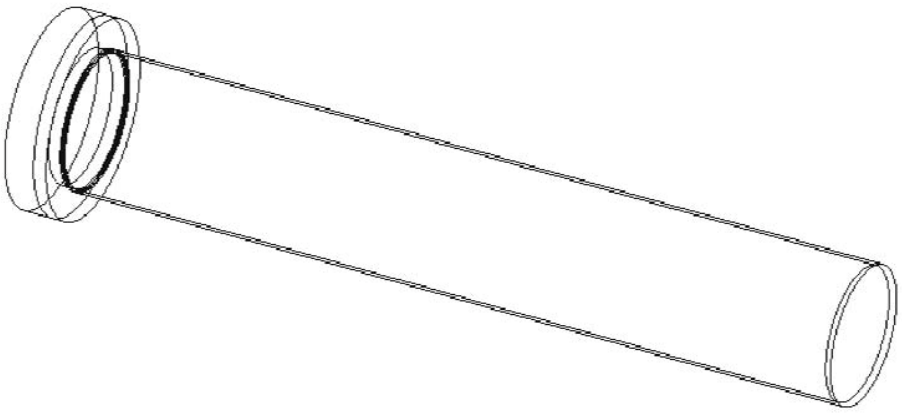

Fig. 6.9.1-7. Wire mesh view of the containment vessel containing the UNH crystal mixture.

Table 6.9.1.1 provides details of the calculation models used to establish the mass loading limits identified in Table 6.2a for surface-only modes of transportation. The table provides exact dimensions of the fissile material used in the analyses; the mass of fissile material, enrichment, and density of the fissile material used in the analysis; moderating properties of materials inside the CV (water, hydrogenous packing material, represented by polyethylene, etc.), moderator density and h/x ratios; and arrangement of the fissile material including amount of spacing (if any) between the fissile material and/or 277-4 canned spacers. In the creation of a generalized geometry model for treatment of 277-4 canned spacers, the use of a non-zero thickness spacer was required by KENO V.a. An insignificant thickness of 0.0001 cm was used for representing this imaginary region.

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
Cylinders (d ≤ 3.24 in.)			
nciacyt11_18_1_3	r = 4.1148 cm h = 5.99639 cm	100	18.81109
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked cylindrical contents. The contents have an overall stack height of 17.99171 cm (7.08335 in.). No polyethylene was used in this model. Each cylindrical content is separated by a 0.0001 cm 277-4 canned spacer and 0.0012 cm of moderating material. The bottom cylinder has a 0.0005 cm gap between it and the bottom of the CV. The contents sit in the exact center on the bottom of the CV. Therefore, the cylinder content has 2.3114 cm of moderating material around each side and 60.74779 cm of moderating material above. The modeled material masses are: 18 kg ^{235}U, 9.2418 kg H_2O, resulting in an h/x ratio of ~13.40.			
nciacyt11_30_2_3	r = 4.11480 cm h = 9.99399 cm	100	18.81109
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked cylindrical contents separated by 277-4 canned spacers between each cylindrical content. The contents (uranium and spacers) have an overall stack height of 37.09657 cm (14.60495 in.). No polyethylene was used in this model. Each cylindrical content is separated by a 3.5561 cm spacer and 0.0012 cm of moderating material. The bottom cylinder has a 0.0005 cm gap between it and the bottom of the CV. The contents sit in the exact center on the bottom of the CV. Therefore, the cylinder content has 2.3114 cm of moderating material around each side and 41.64293 cm of moderating material above. The modeled material masses are: 30 kg ^{235}U, 7.9915 kg H_2O, resulting in an h/x ratio of ~6.95.			
Cylinders (3.24 in. < d ≤ 4.25 in.)			
nciacyct11_15_1_3	r = 5.39750 cm h = 2.90416 cm	100	18.81109
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked cylindrical contents separated by 277-4 canned spacers. The contents have an overall stack height of 8.71508 cm (3.43133 in.). No polyethylene was used in this model. Each cylindrical content is separated by a 0.0001 cm spacer and 0.0012 cm of moderating material. The bottom cylinder has a 0.0005 cm gap between it and the bottom of the CV. The contents sit in the exact center on the bottom of the CV. Therefore, the cylinder content has 1.0287 cm of moderating material around each side and 70.02442 cm of moderating material above. The modeled material masses are: 15 kg ^{235}U, 9.4010 kg H_2O, resulting in an h/x ratio of ~16.36.			
nciacyct11_25_2_3	r = 5.39750 cm h = 4.84031 cm	100	18.81109
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked cylindrical contents separated by 277-4 canned spacers. The contents have an overall stack height of 21.63433 cm (8.517453 in.). No polyethylene was used in this model. Each cylindrical content is separated by a 3.5561 cm spacer and 0.0012 cm of moderating material. The bottom cylinder has a 0.0005 cm gap between it and the bottom of the CV. The contents sit in the exact center on the bottom of the CV. Therefore, the cylinder content has 1.0287 cm of moderating material around each side and 57.10417 cm of moderating material above. The modeled material masses are: 25 kg ^{235}U, 8.2568 kg H_2O, resulting in an h/x ratio of ~8.62.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
Bars			
hciasqt12_30_1_3	x = 5.81920 cm y = 5.81920 cm z = 15.69855 cm	100	18.81109
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked square or cuboid contents separated by 277-4 canned spacers. The contents have an overall stack height of 47.09825 cm (18.54262 in.). No polyethylene was used in this model. Each cuboid content is separated by a 0.0001 cm spacer and 0.0012 cm of moderating material. The bottom cuboid has a 0.0005 cm gap between it and the bottom of the CV. The contents sit in the exact center on the bottom of the CV. Therefore, the cuboid content is surrounded by moderating material ranging from 3.6166 to 2.4144 cm (center to outer edge) and 31.64125 cm of moderating material above. The modeled material masses are: 30 kg ^{235}U, 8.6050 kg H_2O, resulting in an h/x ratio of ~7.49.			
nciasqt11_36_2_3	x = 5.81920 cm y = 5.81920 cm z = 18.83826 cm	100	18.81109
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked square or cuboid contents separated by 277-4 canned spacers. The contents have an overall stack height of 63.62938 cm (25.05094 in.). No polyethylene was used in this model. Each cuboid content is separated by a 3.5561 cm spacer and 0.0012 cm of moderating material. The bottom cuboid has a 0.0005 cm gap between it and the bottom of the CV. Therefore, the cuboid content is surrounded by moderating material ranging from 3.6166 to 2.4144 cm (center to outer edge) and 15.11012 cm of moderating material above. The modeled material masses are: 36 kg ^{235}U, 7.6731 kg H_2O, resulting in an h/x ratio of ~5.56.			
Slugs (enr. ≤ 95%–no can spacers)			
ncia5st11_1_1_7_3	r = 1.983875 cm h = 5.23875 cm	95	18.82298
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked pentagonal rings of slug content separated by 277-4 canned spacers. (Slugs are inserted into the cylindrical geometry segment of the CV using the hole option.) The contents have an overall stack height of 15.71885 cm (6.18852 in.). No polyethylene is used in this model. Each ring is separated by a 0.0001 cm spacer and 0.0012 cm of moderating material. The bottom ring of slugs has a 0.0005 cm gap between it and the bottom of the CV. Above the stack of slugs is 63.02065 cm of moderating material. The modeled material masses are: 18.288 kg U (17.374 kg ^{235}U), 9.2269 kg H_2O, resulting in an h/x ratio of ~13.86. The loading arrangement of slugs is depicted in Fig. 6.9.1-4b for the Case **cvcr5st11_1_1**.			
Slugs (80% < enr. ≤ 95%–with can spacers)			
hcia70st12_2_7_3	r = 1.983875 cm h = 5.23875 cm	95	18.82298
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked rings of slugs, each ring with a central slug surrounded by slugs in a hexagonal pattern. (Slugs are inserted into the cylindrical geometry segment of the CV using the hole option.) Each ring is separated by a 277-4 canned spacer. The contents (uranium and spacers) have an overall stack height of 22.83085 cm (8.98852 in.). No polyethylene was used in this model. Each ring is separated by a 3.5561 cm spacer and 0.0012 cm of moderating material. The bottom ring has a 0.0005 cm gap between it and the bottom of the CV. The stack of slugs has 55.90865 cm of moderating material above. The modeled material masses are: 25.604 kg U (24.324 kg ^{235}U), 8.2253 kg H_2O, resulting in an h/x ratio of ~8.83. The loading arrangement of slugs is similar to that depicted in Fig. 6.9.1-4b for the Case **cvcr70st11_1** except that the canned spacers are present.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
ncf15est11_2_2_7_3	r = 1.983875 cm h = 5.23875 cm	95	18.82298
The moderator is full density water (0.9982 g/cm^3) surrounding three rings of double stacked slugs, each ring separated by a 277-4 canned spacer. (Slugs are inserted into the cylindrical geometry segment of the CV using the hole option.) The contents (uranium and spacers) have an overall stack height of 22.83085 cm (8.98852 in.). No polyethylene was used in this model. Each ring is separated by a 3.5561 cm spacer and 0.0012 cm of moderating material. The bottom ring has a 0.0005 cm gap between it and the bottom of the CV. The stack of slugs has 55.90865 cm of moderating material above. The modeled material masses are: 36.578 kg U (34.749 kg ^{235}U), 7.6434 kg H_2O, resulting in an h/x ratio of ~5.74. The loading arrangement of slugs is depicted in Fig. 6.9.1-4b for the Case **cvcr5est11_2_2**.			
Slugs (enr. ≤ 80%–with can spacers)			
hcia5est12_2_2_5_3	r = 1.983875 cm h = 5.23875 cm	80	18.85873
The moderator is full density water (0.9982 g/cm^3) surrounding three rings of double stacked slugs, each ring separated by a 277-4 canned spacer. (Slugs are inserted into the cylindrical geometry segment of the CV using the hole option.) The contents (uranium and spacers) have an overall stack height of 22.83085 cm (8.98852 in.). No polyethylene was used in this model. Each ring is separated by a 3.5561 cm spacer and 0.0012 cm of moderating material. The bottom ring has a 0.0005 cm gap between it and the bottom of the CV. The stack of slugs has 55.90865 cm of moderating material above. The modeled material masses are: 36.647 kg U (29.318 kg ^{235}U), 7.6434 kg H_2O, resulting in an h/x ratio of ~6.80. The loading arrangement of slugs is depicted in Fig. 6.9.1-4b for the Case **cvcr5est11_2_2**.			
ncf15est11_2_2_5_3	r = 1.983875 cm h = 5.23875 cm	80	18.85873
The moderator is full density water (0.9982 g/cm^3) surrounding three rings of double stacked slugs, each ring separated by a 277-4 canned spacer. (Slugs are inserted into the cylindrical geometry segment of the CV using the hole option.) The contents (uranium and spacers) have an overall stack height of 22.83085 cm (8.98852 in.). No polyethylene was used in this model. Each ring is separated by a 3.5561 cm spacer and 0.0012 cm of moderating material. The bottom ring has a 0.0005 cm gap between it and the bottom of the CV. The stack of slugs has 55.90865 cm of moderating material above. The modeled material masses are: 36.647 kg U (29.318 kg ^{235}U), 7.6434 kg H_2O, resulting in an h/x ratio of ~6.80. The loading arrangement of slugs is depicted in Fig. 6.9.1-4b for the Case **cvcr5est11_2_2**.			
Broken Metal for CSI=0.0			
hciabmt12_4_1_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 3.7085 kg U (2.9668 kg ^{235}U), 10.0007 kg H_2O, resulting in an h/x ratio of ~87.98.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
hciabmt12_5_1_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 4.6415 kg U (3.2490 kg ^{235}U), 9.9516 kg H_2O, resulting in an h/x ratio of ~79.95.			
nciabmt11_6_1_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 5.5768 kg U (3.3461 kg ^{235}U), 9.9025 kg H_2O, resulting in an h/x ratio of ~77.24.			
hciabmt12_3_2_8_3	r = 6.52620 cm h = 78.74000 cm	100	18.81109
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 2.7743 kg ^{235}U, 9.4362 kg H_2O, resulting in an h/x ratio of ~88.78.			
hciabmt12_4_2_7_3	r = 6.52620 cm h = 78.74000 cm	95	18.82298
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 3.7014 kg U (3.5164 kg ^{235}U), 9.3871 kg H_2O, resulting in an h/x ratio of ~69.68.			
hciabmt12_4_2_6_3	r = 6.52620 cm h = 78.74000 cm	90	18.83488
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 3.7038 kg U (3.3334 kg ^{235}U), 9.3871 kg H_2O, resulting in an h/x ratio of ~73.50.			
hciabmt12_6_2_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 5.5627 kg U (4.4502 kg ^{235}U), 9.2890 kg H_2O, resulting in an h/x ratio of ~54.48.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
nciabmt11_8_2_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 7.4263 kg U (5.1984 kg ^{235}U), 9.1908 kg H_2O, resulting in an h/x ratio of ~46.15.			
hciabmt12_12_2_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 11.1537 kg U (6.6922 kg ^{235}U), 8.9945 kg H_2O, resulting in an h/x ratio of ~35.08.			
Broken Metal for CSI=0.4			
ncf1bmt11_7_1_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 6.4898 kg U (5.1919 kg ^{235}U), 9.8535 kg H_2O, resulting in an h/x ratio of ~49.54.			
ncf1bmt11_9_1_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 8.3546 kg U (5.8482 kg ^{235}U), 9.7553 kg H_2O, resulting in an h/x ratio of ~43.54.			
ncf1bmt11_15_1_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 14.8715 kg U (8.9229 kg ^{235}U), 9.4118 kg H_2O, resulting in an h/x ratio of ~27.53.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
ncf1bmt11_6_2_8_3	r = 6.52620 cm h = 78.74000 cm	100	18.81109
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 5.5487 kg ^{235}U, 9.2890 kg H_2O, resulting in an h/x ratio of ~43.70.			
ncf1bmt11_7_2_7_3	r = 6.52620 cm h = 78.74000 cm	95	18.82298
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 6.4775 kg U (6.1536 kg ^{235}U), 9.2399 kg H_2O, resulting in an h/x ratio of ~39.19.			
ncf1bmt11_9_2_6_3	r = 6.52620 cm h = 78.74000 cm	90	18.83488
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 8.3335 kg U (7.5002 kg ^{235}U), 9.1417 kg H_2O, resulting in an h/x ratio of ~31.81.			
ncf1bmt11_12_2_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 11.1254 kg U (8.9003 kg ^{235}U), 8.9945 kg H_2O, resulting in an h/x ratio of ~26.38.			
ncf1bmt11_19_2_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 18.5659 kg U (12.9961 kg ^{235}U), 8.6019 kg H_2O, resulting in an h/x ratio of ~17.28.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
ncf1bmt11_29_2_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 28.8136 kg U (17.2882 kg ^{235}U), 8.0621 kg H_2O, resulting in an h/x ratio of ~12.17.			
Broken metal for CSI=0.8			
ncf2bmt11_12_1_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 11.1254 kg U (8.9003 kg ^{235}U), 9.6081 kg H_2O, resulting in an h/x ratio of ~28.18.			
ncf2bmt11_20_1_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 19.4942 kg U (13.6459 kg ^{235}U), 9.1664 kg H_2O, resulting in an h/x ratio of ~17.53.			
ncf2bmt11_29_1_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 28.8136 kg U (17.2882 kg ^{235}U), 8.6757 kg H_2O, resulting in an h/x ratio of ~13.10.			
ncf2bmt11_10_2_8_3	r = 6.52620 cm h = 78.74000 cm	100	18.81109
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 9.2478 kg ^{235}U, 9.0927 kg H_2O, resulting in an h/x ratio of ~25.66.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
ncf2bmt11_12_2_7_3	r = 6.52620 cm h = 78.74000 cm	95	18.82298
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 11.1043 kg U (10.5491 kg ^{235}U), 8.9945 kg H_2O, resulting in an h/x ratio of ~22.25.			
ncf2bmt11_14_2_6_3	r = 6.52620 cm h = 78.74000 cm	90	18.83488
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 13.8892 kg U (12.5003 kg ^{235}U), 8.8473 kg H_2O, resulting in an h/x ratio of ~31.81.			
ncf2bmt11_21_2_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 20.3966 kg U (16.3173 kg ^{235}U), 8.5038 kg H_2O, resulting in an h/x ratio of ~13.60.			
ncf2bmt11_30_2_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 29.7054 kg U (20.7938 kg ^{235}U), 8.0131 kg H_2O, resulting in an h/x ratio of ~10.06.			
ncf2bmt11_36_2_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 35.3199 kg U (21.1920 kg ^{235}U), 7.7186 kg H_2O, resulting in an h/x ratio of ~9.51.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
Broken metal for CSI=2.0			
ncf3bmt11_22_1_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 21.3237 kg U (17.0590 kg ^{235}U), 9.0683 kg H_2O, resulting in an h/x ratio of ~13.87.			
ncf3bmt11_31_1_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 30.6337 kg U (21.4436 kg ^{235}U), 8.5776 kg H_2O, resulting in an h/x ratio of ~10.44.			
ncf3bmt11_36_1_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 35.3199 kg U (21.1920 kg ^{235}U), 8.3322 kg H_2O, resulting in an h/x ratio of ~10.26.			
ncf3bmt11_14_2_8_3	r = 6.52620 cm h = 78.74000 cm	100	18.81109
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 13.8716 kg ^{235}U, 8.8473 kg H_2O, resulting in an h/x ratio of ~16.65.			
ncf3bmt11_20_2_7_3	r = 6.52620 cm h = 78.74000 cm	95	18.82298
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 19.4326 kg U (18.4609 kg ^{235}U), 8.5529 kg H_2O, resulting in an h/x ratio of ~12.09.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
ncf3bmt11_23_2_6_3	r = 6.52620 cm h = 78.74000 cm	90	18.83488
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 22.2227 kg U (20.0004 kg ^{235}U), 8.4057 kg H_2O, resulting in an h/x ratio of ~10.97.			
ncf3bmt11_32_2_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 31.5220 kg U (25.2176 kg ^{235}U), 7.9149 kg H_2O, resulting in an h/x ratio of ~8.19.			
ncf3bmt11_36_2_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 35.2751 kg U (24.6926 kg ^{235}U), 7.7186 kg H_2O, resulting in an h/x ratio of ~8.16.			
ncf3bmt11_36_2_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Broken metal for CSI=3.2			
ncf5bmt11_35_1_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 34.3034 kg U (27.4427 kg ^{235}U), 8.3813 kg H_2O, resulting in an h/x ratio of ~7.97.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
ncf5bmt11_36_1_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 35.2751 kg U (24.6926 kg ^{235}U), 8.3322 kg H_2O, resulting in an h/x ratio of ~8.81.			
ncf5bmt11_36_1_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. No 277-4 canned spacers are used in this calculation. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls. The modeled material masses are: 35.3199 kg U (21.1920 kg ^{235}U), 8.3322 kg H_2O, resulting in an h/x ratio of ~10.26.			
ncf5bmt11_25_2_8_3	r = 6.52620 cm h = 78.74000 cm	100	18.81109
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 24.9689 kg ^{235}U, 8.2584 kg H_2O, resulting in an h/x ratio of ~8.63.			
ncf5bmt11_28_2_7_3	r = 6.52620 cm h = 78.74000 cm	95	18.82298
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 27.7608 kg U (26.3728 kg ^{235}U), 8.1112 kg H_2O, resulting in an h/x ratio of ~8.03.			
ncf5bmt11_35_2_6_3	r = 6.52620 cm h = 78.74000 cm	90	18.83488
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 34.2600 kg U (30.8340 kg ^{235}U), 7.7677 kg H_2O, resulting in an h/x ratio of ~6.58.			
ncf5bmt11_36_2_5_3	r = 6.52620 cm h = 78.74000 cm	80	18.85873
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 35.2305 kg U (28.1844 kg ^{235}U), 7.7186 kg H_2O, resulting in an h/x ratio of ~7.15.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
ncf5bmt11_36_2_4_3	r = 6.52620 cm h = 78.74000 cm	70	18.88264
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 35.2751 kg U (24.6926 kg ^{235}U), 7.7186 kg H_2O, resulting in an h/x ratio of ~8.16.			
ncf5bmt11_36_2_3_3	r = 6.52620 cm h = 78.74000 cm	60	18.90661
The uranium "broken metal" content is homogenized with a moderator of water with a specific gravity of 1.0×10^{-4} over the interior volume of the CV. The 277-4 canned spacers with a thickness of 3.5561 cm (1.4000 in.) are used and are modeled at 3.02984 cm and 9.61638 cm above the bottom of the CV. No polyethylene was used in this calculation. Since the contents are homogenized over the internal volume of the CV, there is no moderating material between the content and the CV walls or the spacers. The modeled material masses are: 35.3199 kg U (21.1920 kg ^{235}U), 7.7186 kg H_2O, resulting in an h/x ratio of ~9.51.			
Product oxide			
hciapdoxt12_1_1_11_3	r = 6.42620 cm h = 46.58351 cm	100	2.00000
Water-saturated HEU product oxide with 500 g polyethylene (0.9200 g/cm^3) is dispersed within the CV to a height determined by the mass of the product oxide, polyethylene, and saturation moisture. The product oxide is saturated with 4.488 kg H_2O of full density water (0.9982 g/cm^3). Since the product oxide content is assumed to be dispersed within the CV, there are no gaps between the content and the CV wall or bottom. There are 32.15649 cm of moderator above the product oxide content. No 277-4 canned spacers are used in this analysis. The modeled material masses are: 11.00 kg UO_2 (9.682 kg ^{235}U), 8,652.6 kg H_2O, and 500 g polyethylene resulting in an h/x ratio of ~25.06.			
Skull oxide			
nciask_9_15	r = 6.42620 cm h = 28.18623 cm	100	6.54000
The skull oxide is dispersed within the CV to a height determined by the mass of the skull oxide. The skull oxide is saturated with a moderator of full density water (0.9982 g/cm^3). No polyethylene is used in this analysis. Since the skull oxide content is assumed to be dispersed within the CV, there are no gaps between the content and the CV wall or bottom. There are 50.55377 cm of moderator above the skull oxide content. No 277-4 canned spacers are used in this analysis. The modeled material masses are: 21.3000 kg skull oxide, 19.8653 kg U_3O_8, 15.6728 kg ^{235}U, 3.8014 kg H_2O, resulting in an h/x ratio of ~7.43.			
UNX crystals			
nciapunhct11_7_3	r = 6.42620 cm h = 78.74000 cm	100	2.79329
The UNX crystals are homogenized with 1515.7 g full density water (0.9982 g/cm^3) and 500 g polyethylene (0.9200 g/cm^3) dispersed over the entire inner volume of the CV. There is no gap between the homogenized UNX content and the CV bottom or sides. Since the content is homogenized over the inner volume of the CV, no moderating material is above the content. No 277-4 canned spacers are used in this model. The modeled material masses are 7.0 kg UNX crystals (3.2968 kg ^{235}U), 8.6886 kg H_2O, and 500 g polyethylene resulting in an h/x ratio of ~73.73.			

Table 6.9.1.1. Details of calculation models used to establish mass loading limits for surface-only modes of transportation identified in Table 6.2a

Case	Dimensions (cm)	Enrichment (wt % ^{235}U)	Density (g/cm^3)
ncf1punhct11_24_3	r = 6.42620 cm h = 78.74000 cm	100	2.79329
The UNX crystals are homogenized with 5,196.7 g full density water (0.9982 g/cm^3) and 500 g polyethylene (0.9200 g/cm^3) dispersed over the entire inner volume of the CV. There is no gap between the homogenized UNX crystals and the CV bottom or sides. Since the content is homogenized over the inner volume of the CV, no moderating material is above the content. No 277-4 canned spacers are used in this model. The modeled material masses are 24.0 kg UNX crystals (11.3031 kg ^{235}U), 6.2746 kg H_2O, and 500 g polyethylene, resulting in an h/x ratio of ~15.97.			
TRIGA fuel			
nciatriga_1_15_3	r = 1.8288 cm h = 12.7000 cm	20	8.65974
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked "bundles" of three TRIGA fuel elements separated by 277-4 canned spacers. The content has an overall height of 38.10310 cm (15.00122 in.). No polyethylene was used in this model. Each content is separated by a 0.0001 cm spacer and 0.0012 cm of moderating material. The bottom content has a 0.0005 cm gap between it and the bottom of the CV. The contents sit in the exact center on the bottom of the CV. The modeled material masses are 10.4 kg $UZrH_x$, 0.9210 kg ^{235}U, and 8.9982 kg H_2O, resulting in an h/x ratio of ~255.01.			
nciatriga70_1_15_3	r = 1.8288 cm h = 12.7000 cm	70	5.70132
The moderator is full density water (0.9982 g/cm^3) surrounding three stacked "bundles" of three TRIGA fuel elements separated by 277-4 canned spacers. The content has an overall height of 38.10310 cm (15.00122 in.). No polyethylene was used in this model. Each content is separated by a 0.0001 cm spacer and 0.0012 cm of moderating material. The bottom content has a 0.0005 cm gap between it and the bottom of the CV. The contents sit in the exact center on the bottom of the CV. The modeled material masses are 6.8471 kg $UZrH_x$, 0.4080 kg ^{235}U, and 8.9982 kg H_2O, resulting in an h/x ratio of ~575.64.

Appendix 6.9.2
HAC Package Model

6.9.2.1 Prediction of HAC Damage in the ES-3100 Package

Finite element analysis of an ES-3100 package under Hypothetical Accident Conditions (HAC) is used to predict the deformed outer diameters of the drum at node points along the vertical axis of an upright package. Selected node points are designated in a downward direction from the top of the drum as "UR," "MUR," "MR," "MLR," and "LR." Table 6.9.2.1-1 lists diameters at the five node points measured along the 90–270° and 0–180° axes. These dimensions represent major and minor axes at each deformation point on the assumption that the drum cross section is ellipsoidal. A corresponding equivalent circular diameter is also listed for each node point in Table 6.9.2.1-1.

A set of KENO V.a calculation models based on reduced package diameters at the "MR," "MLR," and "LR" deformation points are derived from the Normal Conditions of Transport (NCT) geometry model. These geometry models are evaluated for the purpose of establishing a bounding geometry model for representing the ES-3100 package under HAC. The primary changes made to the KENO V.a geometry input statements in the NCT model are reductions in the drum's radii. The change to the drum's inner radius also affects the outer radius of both the angle iron and the Kaolite located inside the CV outer liner. The volume fractions for these materials are adjusted in the KENO V.a calculation models so that material masses of the affected package components are conserved. Table 6.9.2.1-2 provides data for transforming the KENO V.a calculation model from an NCT model into an HAC model.

6.9.2.2 Criticality Calculations

Sets of criticality calculations are performed for the "MR," "MLR," and "LR" models at five different package water contents over the range of HAC. The five package water contents of the void spaces external to the containment vessel (CV) and the interstitial space between drums are as follows: 1e-20 spg water, 1E-04 spg water, 0.1 spg water, 0.3 spg water, and 1.0 spg water. The water content in the Kaolite corresponds to the dry condition (VF= 0.0287) where neutronic interaction between the packages of an array is maximized.

An infinite array of packages is evaluated in order to eliminate any biases arising from spectral leakage effects in the reflector of the finite array. The k_{eff} values for each KENO V.a case are based on 500,000 neutron histories produced by running for 215 generations with 2,500 neutrons per generation and truncating the first 15 generations of data. Each package modeled has 36 kg of 100% enriched uranium in the form of broken metal content.

Each case is rerun using a different starting random number in order to produce sets of computed k_{eff} values that are statistically independent. The random starting number, the mean value (k_{eff}), and the corresponding standard error (s_i) computed for ten individual runs are shown in Tables 6.9.2.2-1, -2, and -3. The same statistical method (described in DAC-FS-900000-A014) used in the evaluation of Kaolite models (Appendix 6.9.3, Sect. 6.9.3.4) is also used here for determining whether or not differences in neutronic performance between the package models are statistically significant.

Table 6.9.2.1-1. Deformation of the ES-3100 drum at five node points, projected by finite element analysis "Case 3100 RUN1HL Lower Bound Kaolite May 2004"

Deformation point	FEA node	Diameter at 90° (in.)	Diameter at 180° (in.)	Equivalent circular diameter	
				(in.)	(cm)

6.9.2.3 Statistical Evaluation

An evaluation of KENO V.a calculation results is made to determine if there is a statistically significant difference between the mean k_{eff} for the "MR" and "MLR" models, for the "MLR" and "LR" models, and for the "MR" and "LR" models. Cases are classified into five groups based on the amount of water assumed to be present in the shipping package. The symbol "I" is used to specify the case. The mean difference and standard deviation for each of the five sets of pair-wise differences are defined as follows:

(a) $d_i = (k_{effBi} - k_{effAi})/n$ and

(b) $s_{di} = \sqrt{[\, n\Sigma d_i^{\,2} - (\Sigma d_i)^2 \,] / n(n-1)}$ (conservatively defined for the t-test appropriate for small sample sizes),

where A_i and B_i denote the model types, and n denotes the sample size of ten. It is reasonable to assume that the paired differences have been randomly selected from a normally distributed population of paired differences with mean (μ_d) and standard deviation (σ_d), then the sampling distribution of

$$(d - \mu_d) / (s_d/\sqrt{n})$$

is a *t* distribution having n-1 degrees of freedom.

The evaluation of the mean differences (d_i) for the 10 sets of cases is accomplished through hypothesis testing, a statistical tool used to provide evidence that a difference exists or does not exist. The t_i values are given in Table 6.9.2.3-1. A value of 3.25 is obtained from the standard table for critical values for the t distribution from which the decision to accept or reject the null hypothesis H_0 is made with a Type I error probability (α) of 0.01.

For $|t| < 3.25$, the H_o hypothesis is not rejected. Acceptance of the null hypothesis is the result of insufficient evidence to reject it. Thus, it can be concluded that the mean estimates of the difference in k_{eff} between the "MR" and "MLR" calculation models, between the "MLR" and "LR" calculation models, and between the "MR" and "LR" calculation models are not statistically significant for the dry condition where neutronic interaction between packages is significant. Also, the mean estimate of the difference in k_{eff} between the "MR" and "MLR" calculation models is not statistically significant for wet or flooded conditions where the packages of the array become isolated.

Table 6.9.2.3-1. T-test values for establishing the statistical significance of the differences in calculated k_{eff} values for the ES-3100 package models at the "MR," "MLR," and "LR" node points

[a] critical value = 3.25 for 10 cases.

For $|t| > 3.25$, the H_o hypothesis is rejected. Therefore, it can be concluded that the mean estimate of the difference in k_{eff} between the "MLR" and "LR" calculation models, and between the "MR" and "LR" calculation models, is statistically significant for wet or flooded conditions where the packages of the array become isolated. The negative t-values indicate that the calculated k_{eff} value for the "LR" model is slightly higher than for the "MR" and "MLR" models. This result is consistent with an expected increase in k_{eff} due to "tighter or closer" water reflector surrounding the package content.

Although flattening of the side of the package represents a reduction in the diameter of the drum, the points at which minimum flattening occurs provide an indication of the reduction of lattice spacing between packages of an array under HAC. The composite of the minimum deformation points at perpendicular axes (90–270° and 0–180°) represents the modified lattice spacing in an array of ES-3100 packages. As illustrated in Table 6.9.2.3-2, the equivalent diameter of the package for "composite" lattice spacing is not significantly different from the 18.37-in. diam of the pre-test package. Even though significant crushing of the drum midsection and bottom occurs, the effective center-to-center spacing of the contents actually increases under HAC. Selective rearrangement of alternating packages would be required to achieve a more compact array; however, this event is not credible.

As described in Sect. 6.3.1.2, a close-pack (triangular-pitch) array of packages would be represented by a reduced package in a rectangular-pitch configuration. For HAC, the 17.26-in. reduced diameter for the "composite close-pack" package is slightly larger than the 17.20-in. diam of the "MLR" calculation model used in the HAC calculations of Sect. 6.6. Therefore, packages evaluated with the "MLR" calculation model of packages in a rectangular-pitch configuration are deemed adequate for the HAC criticality evaluation. Considering both the irregular shape of the deformed drums and that array spacing is determined by overall (maximum) dimensions rather than by mean or minimum dimensions of a damaged package, the use of the "MLR" model for representing the ES-3100 package under HAC is conservative and bounding.

Table 6.9.2.3-2. Deformation of the ES-3100 drum projected by finite element analysis "Case 3100 RUN1HL Lower Bound Kaolite May 2004"

	FEA node	Diameter at 90° (in.)	Diameter at 180° (in.)	Equivalent circular diameter (in.)

Package Material Compositions

Table 6.4 (Sect. 6.3.2) provides basic information for deriving the compositions for the ES-3100 package (Figs. 6.1 and 6.2). The atomic densities presented in Table 6.4 can be verified using additional information provided in Appendix 6.9.5. The following sections provide the rationale, the justification, or both for the material compositions used in the criticality calculations.

6.9.3.1 HEU, Unirradiated TRIGA, and Research Reactor Related Contents

HEU considered for shipment in the ES-3100 is categorized into the following material forms: highly enriched uranium (HEU) solid or broken metal; HEU oxide; uranyl nitrate hexahydrate (UNH) crystals. In the interest of adding conservatism, uranium is modeled as ^{235}U and ^{238}U, while the ^{234}U and ^{236}U isotopes are excluded. Any positive change in neutron multiplication represented by the presence of the ^{234}U is covered by the higher than actual ^{235}U content (Rothe). The theoretical density of 100 wt % ^{235}U HEU is 18.8111 g/cm^3. This value is determined by adjusting the density of natural uranium included in the SCALE Standard Composition Library with 100 wt % weight factors. The theoretical density of HEU oxide types are 10.96 g/cm^3 for UO_2, 8.30 g/cm^3 for U_3O_8, and 7.29 g/cm^3 for UO_3. The theoretical density of UNH crystals is 2.79 g/cm^3. Table 6.9.3.1-1 provides details of the calculated weight percentages input to KENO V.a calculated on the basis of the stoichiometric formula of $UO_2(NO_3)_2+6H_2O$ and crystalline density. The maximum enrichment considered in the analysis is 100 wt % ^{235}U, although actual material enrichments are lower. The unirradiated solid form TRIGA fuel is uranium zirconium hydride ($UZrH_x$) where "x" is ≤ 2, having a density of 8.65 g/cm^3. Research reactor related contents are fuel elements or fuel components, broken metal, U-Al alloy, or oxides. These contents are described at the end of this subsection.

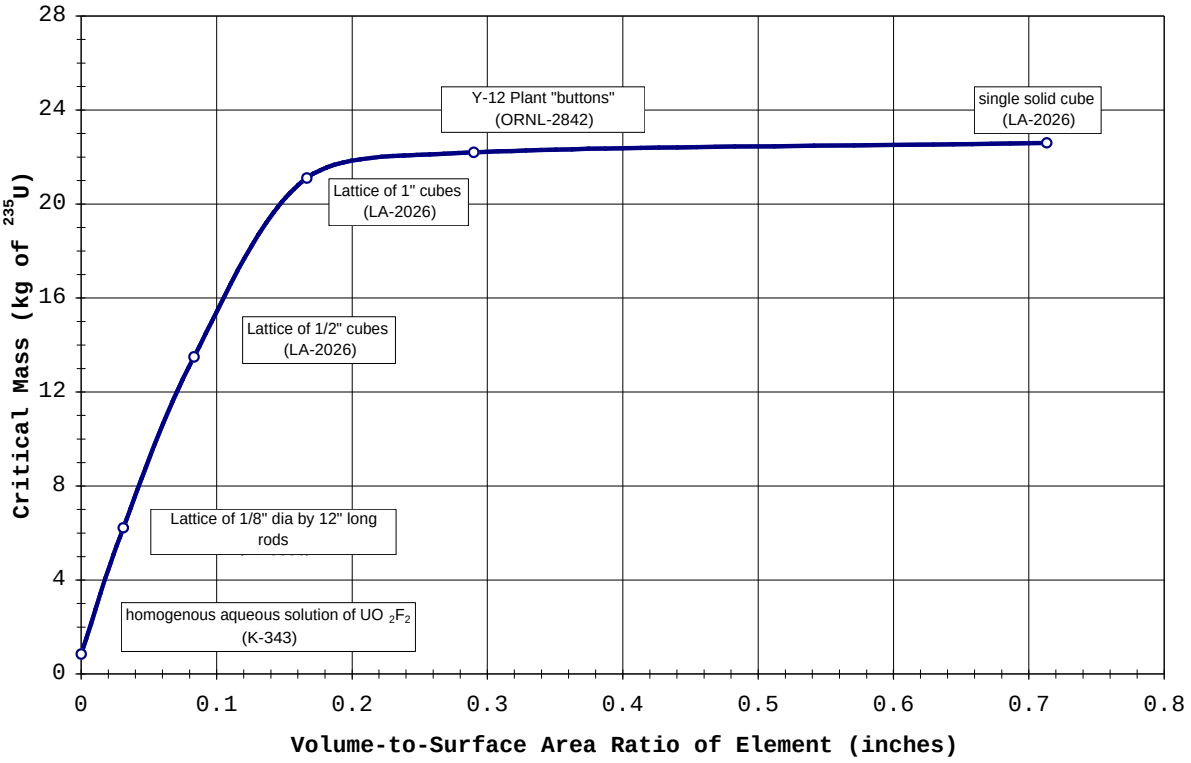

Table 6.9.3.1-1. Calculation of constituent weight-percentage values for uranyl nitrate hexahydrate crystals used in KENO V.a calculation models

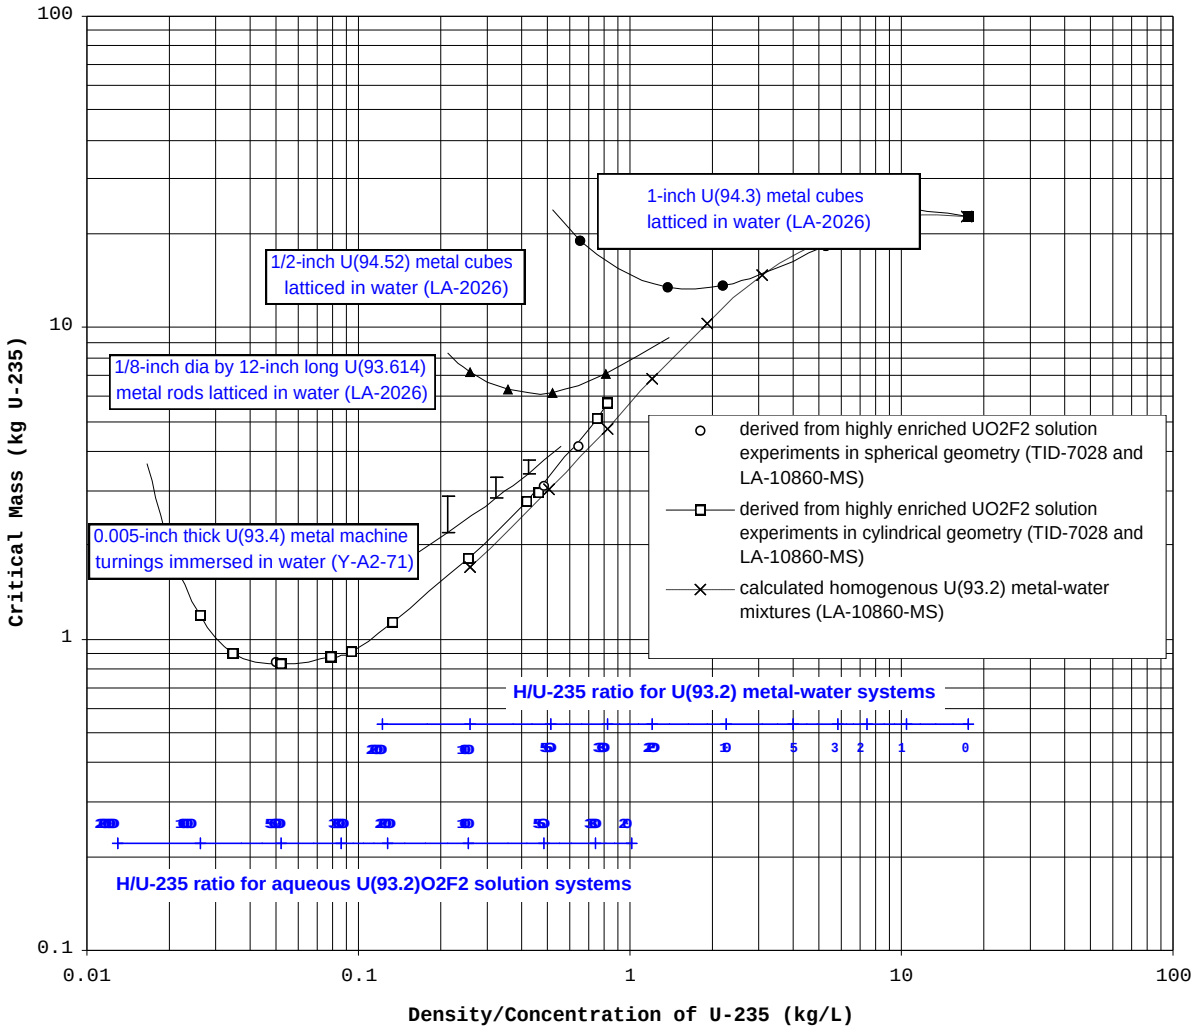
HEU broken metal. The critical mass of fissile material is dependent on factors such as the form and shape of the material, bulk density if the material is broken into pieces, and the enrichment. Broken metal can be compared to the minimum critical mass of submerged metal lattices of regular-shaped fissile material. Using experimental data, the approximation of a heterogeneous mixture of fissile material and moderator to a homogeneous mixture is justified as follows.

Figure 6.9.3.1-1 depicts the experimentally determined minimum critical mass of U (~ 94) lattices immersed in water as a function of the volume-to-surface area ratio of the fissile element (TID-7028). The critical mass is shown to increase from 850 g to 21 kg over the range of volume-to-surface ratios from 0 to 0.18 in. The critical mass is nearly constant in the range of volume-to-surface ratios from 0.18 to 0.8 in. For pieces greater than 1-in. cubes, the minimum critical mass will not be less than 21 kg. For smaller pieces, the minimum critical mass is a nearly linear function of the volume-to-surface-area ratio of the fissile element.



Source: H. C. Paxton et al., *Critical Dimensions of Systems Containing 235U,* TID-7028, Los Alamos Scientific Lab. and Oak Ridge Natl. Lab., June 1964, Fig. 19. Y-12 data have been added.

Fig. 6.9.3.1-1. Experimentally determined minimum critical mass U(~94) metal lattices immersed in water as a function of volume-to-surface area ratio of fissile material.

Figure 6.9.3.1-2 depicts the experimentally determined minimum critical mass of U (~ 94) metal water and solution systems as a function of the concentration of ^{235}U. The figure with added data reveals that: (1) a minimum critical mass exists for each metal lattice system plotted, and (2) as the bulk density of uranium or the uranium concentration increases, the curves for the critical mass of metal lattice systems converge with the curve for highly enriched solution experiments or the curve for calculated homogeneous metal water mixtures. Conversely stated, the critical mass is greater for a heterogenous system than for a homogeneous system, and this difference increases as the H/X ratio increases.

Therefore, the practice of approximating a heterogeneous mixture of fissile material and moderator as a homogeneous mixture is justifiable and also conservative at the higher H/X ratios.

Fig. 6.9.3.1-2. Experimentally determined minimum critical mass of U(~94) metal water and solution systems as a function of the concentration of ^{235}U.

Approximating broken metal as a homogeneous mixture of uranium and water requires a defined space within which masses of the components are conserved. This space is generally characterized by a lattice constructed of unit cells and defined by the dimensions of the fissile material being approximated.

The broken HEU metal consists of large, irregular pieces ranging from 0.5 in. to several inches on a side as shown in Fig. 6.9.3.1-3. A lattice of cubes is chosen to represent broken metal inside the ES-3100 CV. Due to the constraints of KENO V.a, an idealized configuration is defined by a square lattice circumscribed by the inner wall of the CV. Water fills the truncated cylindrical regions between the inner wall of the CV and the vertical faces of the lattice. Two additional models are developed to evaluate conservatism at various stages of model approximations for broken metal.

Fig. 6.9.3.1-3. Pan of HEU broken metal.

Together, these models include an explicit arrangement of HEU metal cubes forming a compact rectangular lattice inside the CV, HEU metal homogeneously mixed with water within the rectangular lattice formed by the unit cells, and HEU metal homogeneously mixed with water within the volume of the CV.

Parameters varied in each of these three models include (1) the cube size in the explicit model from 1.0 in. to 0.25 in. on a side, (2) water moderation inside the CV from dry to the fully flooded condition, (3) enrichment from 100.0 wt % ^{235}U to 20.0 wt % ^{235}U, (4) thickness of the 277-4 canned spacers located between each convenience can, and (5) the mass of the uranium metal at each content location. One-quarter inch, 0.5-in., and 1.0-in. cubes are selected to evaluate "approach-to-homogeneity" of broken metal in this idealized form. The corresponding array configurations for 0.25-in., 0.5-in., and 1.0-in. cubes are 12 × 12 × N, 6 × 6 × N, and 3 × 3 × N. The N-th layer of unit cells for a given mass loading may not all contain HEU metal; the empty cells are filled with water. Nevertheless, a slight variation still arises in the total mass of HEU metal between these array configurations given whole cubes are contained in the calculation models.

The results for the calculation models representing the various configurations of broken uranium metal are shown in the Table 6.9.3.1-2. As the explicitly modeled cubes become smaller in size, the calculated k_{eff} values for the explicit "sqa" models approach values for the "lha" models where HEU metal cubes are homogenized with water within the rectangular lattice formed by the unit cells of the array. A representative or converged k_{eff} value is 0.87 for increasing by smaller cubes based on calculation results for the "lha" models. The "lha" results indicate a slight difference between the k_{eff} values for the three array sizes; these differences are attributed to the difference in the HEU for the arrays of whole cubes.

Calculation results reveal that the explicit ("sqa") model of HEU broken metal in a water moderated lattice is bounded by the homogeneous mixture ("lha") model of HEU metal and water. Calculation results for the "cha" models, where arrays of cubes are fully homogenized with the water

Table 6.9.3.1-2. Summary for evaluation of HEU broken metal models (95 wt % ^{235}U) in a flooded containment vessel, 1.4-in. canned spacers and full water reflection of containment vessel

Array type	U (g)	^{235}U (g)	H_2O (g)	h/x	k_{eff}	σ	$k_{eff} + 2\sigma$
Discrete array of cubes ("sqa" cases)							
$3 \times 3 \times n$	35,164	33,406	7,719	6.03	0.8352	0.0012	0.84
$6 \times 6 \times n$	35,973	34,175	7,676	5.86	0.8559	0.0011	0.86
$12 \times 12 \times n$	35,988	34,188	7,765	5.86	0.8603	0.0012	0.86
Cubes homogenized within footprint of lattice ("lha" cases)							
$3 \times 3 \times n$	35,164	33,406	7,719	6.03	0.8586	0.0011	0.86
$6 \times 6 \times n$	35,973	34,175	7,675	5.86	0.8650	0.0012	0.87
$12 \times 12 \times n$	35,988	34,188	7,675	5.86	0.8677	0.0010	0.87
Cubes homogenized within containment vessel ("cha" cases)							
$3 \times 3 \times n$	35,164	33,406	7,719	6.03	0.9427	0.0013	0.95
$6 \times 6 \times n$	35,973	34,175	7,676	5.86	0.9495	0.0015	0.95
$12 \times 12 \times n$	35,988	34,188	7,675	5.86	0.9517	0.0016	0.95

for the flooded CV, indicate the highest k_{eff} values. The neutron multiplication factor jumps from 0.87 to 0.95. The "cha" model is deemed to be overly conservative when applied to broken metal for the following reasons:

- HEU metal does not dissolve in water.
- HEU metal is not in an oxide or powder form that will absorb moisture or readily mix and become homogenized with the water inside the flooded CV.
- Because HEU metal is much denser than water, it will not float and become distributed throughout a flooded CV; instead it will gravitate toward the bottom of the CV.

However, the "cha" model is deemed an appropriate content model for the criticality evaluation when applied to HEU metal powder where fissile uranium as particulate is more fully homogenized with water than large pieces of broken metal and where fissile uranium could be in suspension. For simplicity, the "cha" model is chosen to represent HEU broken metal or metal powder inside a flooded CV under full water reflection and as content in a single package or in arrays of packages under NCT and HAC. Details regarding the "sqa," "lha," and "cha" calculation models are presented in Appendix 6.9.1.

HEU Oxide. Theoretical (crystalline) densities for HEU oxide are 10.96 g/cm^3, 8.30 g/cm^3, and 7.29 g/cm^3 for UO_2, U_3O_8, and UO_3, respectively. While bulk densities of product oxides with enrichments ranging from 19 to 100 wt % ^{235}U are typically on the order of 6.54 g/cm^3, the bulk density of HEU oxides considered for shipment in the ES-3100 ranges from 2.0 to 6.54 g/cm^3. Therefore, only less-than-theoretical mass loadings would actually be achieved. Skull oxides are a mixture of graphite and U_3O_8 with densities on the order of 2.44 g/cm^3 for poured material and 2.78 g/cm^3 for tapped material. The combined water saturation and crystallization of the HEU oxide are not expected in the HAC, given that UO_2 and UO_3 are non-hygroscopic, while U_3O_8 is only mildly hygroscopic. Table 6.9.3.1-3 provides summary data for 292 samples of canned skull oxide.

Table 6.9.3.1-3. Summary data for 292 samples of skull oxide

Statistic	wt % U	wt % ^{235}U	µg C/g U	µg C /g ^{235}U	Net wt (g)	U wt (g)	^{235}U wt (g)
Maximum	84.52	93.19	171,000	252,861	**7,072**	5,938	4,165
Minimum	12.93	20.28	13	17	442	312	221
Median	81.66	37.62	5,590	13,910	4,448	3,541	1,414
Mean	79.64	45.02	16,968	41,333	4,419	3,532	1,563
Std. dev.	6.87	16.40	24,304	59,027	745	698	606

Values of wt % U, wt % ^{235}U, µg C/g U, etc. for a given statistic (maximum, minimum, medium, or mean) do not occur simultaneously in a specific sample. Inspection of sample data reveals the following characteristics:

(1) the fissile material content is ≤ 221 g ^{235}U in samples with concentrations up to 252,861 µg C/g^{235}U,
(2) the enrichment is 93.2 wt % ^{235}U for samples with concentrations in the range of 12,600 to 18,600 µg C/gU,
(3) the enrichment ranges from 60 to 70.2 wt % ^{235}U for samples with concentrations in the range of 3,231 to 87,720 µg C/gU, and
(4) the enrichment ranges from 37 to 38 wt % ^{235}U for samples with concentrations in the range of 400 to 233,366 µg C/gU.

Eight skull oxide compositions representative of 292 samples of canned skull oxide were selected for establishing the bounding content calculation models. The skull oxide content is assumed to be U_3O_8 plus graphite, polyethylene, and unidentified material. Two additional compositions were derived for addressing skull oxides with an enrichment of 93.2 wt % ^{235}U where unidentified material is treated as ^{235}U and the carbon content is either maximized or minimized. Treatment of the unidentified material as fissile material in the criticality analysis assures that its presence in skull oxide does not increase reactivity beyond what is considered in the bounding analysis.

The composition of the skull oxide content is given in terms of the following parameters: the grams skull oxide content in a content can (**gramskul**), the content bulk density (**densoc**), the wt % uranium in skull oxide content (**wtpuskul**), the wt % ^{235}U in uranium (**wtpu25u**), and the grams of graphite in the content can (**gramg**). Values for the content specification parameters are provided in Table 6.9.3.1-3b.

Table 6.9.3.1-3b. Content specification parameters for skull oxide content

Content	gramskul (g)	densoc (g/cm^3)	wtpuskul (wt %)	wtpu25u (wt %)	gramg (g)
sk_01	3863	1.899	58.92	69.78	139
sk_02	4978	2.447	66.15	69.42	168
sk_03	4607	1.981	72.77	69.88	124
sk_04	5082	2.186	82.77	70.07	20
sk_05	7072	3.042	83.97	69.91	9
sk_06	5037	2.476	72.53	37.61	307
sk_07	4385	2.156	75.15	37.55	203
sk_08	4550	2.237	72.57	37.73	87
sk_09	7100	3.054	78.95	93.20	307
sk_10	7100	3.054	82.61	93.20	1.0E-05

The information in Table 6.9.3.1-3c is derived from the content specification parameters of Table 1-3b on the assumption that 513 g of polyethylene is present in the skull oxide content in three content locations inside the CV.

The amount of skull oxide content (Column 2, Table 6.9.3.1-3c) is **gsoc** = 3.0 × **gramskul**.

The amount of uranium in the skull oxide content (Column 6, Table 6.9.3.1-3c) is **gusoc** = **gsoc** × **wtpuskul** / 100.0.

The amount of ^{235}U (Column 7, Table 6.9.3.1-3c) is **gr235** = **gusoc** × **wtpu25u** / 100.0.

The amount of graphite in the skull oxide content (Column 8, Table 6.9.3.1-3c) is **ggsoc** = 3.0 × **gramg**.

The micrograms graphite per gram uranium in skull oxide content (Column 9, Table 6.9.3.1-3c) is **mggraphgu** = **ggsoc** × 1.0e6 / **gusoc**.

The amount of U_3O_8 in the skull oxide content (**guox**) [Column 3, Table 6.9.3.1-3c] is **guox** = **gusoc** / **wtpuuox**,

where **gusoc** (Column 6, Table 6.9.3.1-3c),
wtpuuox is the weight percent uranium in uranium oxide, and
wtpuuox = **mwu** / (**mwu** + **mwo**),

where **mwu** = (3){(235.0441 × wtpu25u) + [238.0510 × (100 − wtpu25u)]} /100.0 and
mwo = (8)(15.9949).

The amount of unidentified material in skull oxide content (**gramunid**) [Column 12, Table 6.9.3.1-3c] is **gramunid** = (**gsoc** − **guox** − **ggsoc** − **grampoly**)

Skull oxide content is assumed to be saturated with water. The amount of saturation moisture (**gmsatm**) [Column 4, Table 6.9.3.1-3c] is **gmsatm** = 0.9982 × **volsatm**,

where **volsatm** is the volume of saturation moisture in the skull oxide content and
volsatm = **vsox** − **volminsox**

The volume of skull oxide (**vsox**) in the CV is **vsox** = (**gsoc** / **densoc**) − (**grampoly** / **denpoly**),

where **gsoc** (Column 2, Table 6.9.3.1-3c),
densoc is the bulk density of skull oxide content,
grampoly is the 513 g of polyethylene, and
denpoly is the density of polyethylene, 0.92 g/cm^3.

The minimum volume of skull oxide (**volminsox**) in the CV is **volminsox** = (**gsoc** − **grampoly** − **gramunid**) / **dnsoxtheo**,

where **gsoc** (Column 2, Table 6.9.3.1-3c),
grampoly (513 g),
gramunid (Column 12, Table 6.9.3.1-3c), and
dnsoxtheo is the theoretical density of skull oxide.

Table 6.9.3.1-3c. Canned skull oxide (SO) content for ES-3100 calculation models, assuming 513 g polyethylene present and can spacers absent.

Content	SO (g)	UO_x (g)	Sat. H_2O (g)	SO h/x	U (g)	^{235}U (g)	C (g)	µg C/ g ^{235}U	CV H_2O (g)	CV h/x	Unident. (g)

[a] Positive value specifies grams of miscellaneous neutron-absorber elements in content, modeled as water.
[b] Negative value specifies grams of excess polyethylene included in the content model.

The theoretical density of skull oxide (**dnsoxtheo**) is **dnsoxtheo** = (**ggsoc** + **guox**) / [(**ggsoc** / **dnctheo**) + (**guox** / **dnuoxtheo**)],

where **ggsoc** (Column 8, Table 6.9.3.1-3c),
guox (Column 3, Table 6.9.3.1-3c),
dnuoxtheo is the theoretical density of U_3O_8, 8.3 g/cm^3, and
dnctheo is the theoretical density of graphite, 4.2 g/cm^3.

The hydrogen to fissile uranium ratio of canned skull (Column 5, Table 6.9.3.1-3c) is **sochtox** = {[(**gmsatm** × **wtphwat**) + (**grampoly** × **wtphpoly**)] × **atwu25**} / (**gr235** × **atwth** × 100.0),

where **gmsatm** (Column 4, Table 6.9.3.1-3c),
wtphwat is the weight percent hydrogen in water, 11.1913%,
grampoly (513 g),
wtphpoly is the weight percent hydrogen in polyethylene, 14.3811%,
atwu25 is the atomic weight of ^{235}U, 235.0441,
gr235 (Column 7, Table 6.9.3.1-3c), and
atwth is the atomic weight of hydrogen, 1.0078.

The amount of water in the voided region of the CV (Column 10, Table 6.9.3.1-3c) is **gwatcv** = 0.9982 × **volvcv**,

where **volvcv** is the void volume of the CV and
volvcv = (**cvarea** × **cvih**) − (**gsoc** / **densoc**),

where **cvarea** is the internal area (129.73536 cm^2) of the CV,
cvih is the internal height (78.74 cm),
gsoc (Column 2, Table 6.9.3.1-3c), and
densoc (Table 6.9.3.1-3b).

The hydrogen to fissile uranium ratio inside the CV (Column 11, Table 6.9.3.1-3c) is
htox = ⟨{[(**gmsatm** + **gwatcv**) × **wtphwat**] + [**grampoly** × **wtphpoly**]}
× **atwu25**⟩ / (**gr235** × **atwth** × 100.0),

where **gmsatm** (Column 4, Table 6.9.3.1-3c),
gwatcv is the amount of water in the voided region of CV,
wtphwat is the weight percent hydrogen in water, 11.1913%,
grampoly (513 g),
wtphpoly is the weight percent hydrogen in polyethylene, 14.3811%,
atwu25 is the atomic weight of ^{235}U, 235.0441,
gr235 (Column 7, Table 6.9.3.1-3c), and
atwth is the atomic weight of hydrogen, 1.0078.

Unirradiated TRIGA reactor fuel. TRIGA fuel is uranium zirconium hydride ($UZrH_x$), an alloy of uranium metal homogeneously dispersed as fine particles in a zirconium hydride matrix. The fuel is stable because uranium hydride does not form to any considerable extent. Moreover, uranium hydride has never been detected in the photomicrographic evaluations of TRIGA fuel.

The General Atomics catalog of stock items lists ~40 TRIGA fuel elements classified into four basic types: standard element, instrumented element, fuel-follower control rod, or cluster assembly. The TRIGA element active fuel region consists of three 5-in long sections "fuel meats" of $UZrH_x$. The H/Z atom ratio "x" in $UZrH_x$ equals 1.6 in all cases except for two stock items. For these cases, x = equals 1.0 and the fissile content is < 40 g ^{235}U. The unirradiated solid form TRIGA fuel is identified as either 20 % enriched or 70 % enriched, and has dimensions and material properties specific to its design function.

The fuel diameter for the 20 % enriched TRIGA elements is either 1.44 in., 1.41 in., 1.40 in., 1.37 in., 1.34 in., or 1.31 in. The uranium composition of the fuel is 45 wt %, 30 wt %, 20 wt %, 12 wt %, and 8.5 wt %. As illustrated in Table 6.9.3.1.4-a, the TRIGA element with a maximum fissile content of 307 g ^{235}U in 1,560 g U, 45 wt % U in $UZrH_x$, and a H/Zr atom ratio of 1.6 has a computed fuel density of ~8.66 g/cm^3. The calculated number density (N_i) for each element or isotope is also given. The TRIGA fuel element with a fuel diameter of 1.44 in. contains 3,466.7 g $UZrH_x$. Further evaluation of the manufacturers data reveals that fuel density is proportional to the uranium weight fraction. Calculated density values are: 8.6597 g/cm^3 for 45 wt % U in $UZrH_x$, 6.8995 g/cm^3 for 30 wt % U in $UZrH_x$, 6.2825 g/cm^3 for 20 wt % U in $UZrH_x$, 5.9328 g/cm^3 for 12 wt % U in $UZrH_x$, and 5.7895 g/cm^3 for 8.5 wt % U in $UZrH_x$.

The active fuel diameter for 70 % enriched TRIGA fuel is 1.44 in. in both the standard element and instrumented element, and 1.31 in. in the fuel follower control rod. The uranium composition of the fuel is 8.5 wt %. The standard element and instrumented elements contain ~136 g ^{235}U in 194 g U, while the fuel follower control rod contains ~113 g ^{235}U in 162 g U. As the calculation in Table 6.9.3.1.4-b illustrates, the 70 wt % enriched TRIGA fuel has a computed density of ~5.70 g/cm^3. The TRIGA fuel element with a fuel diameter of 1.44 in. contains 2,282.4 g $UZrH_x$, while the element with a fuel diameter of 1.31 in. contains 1,888.9 g $UZrH_x$.

The clad thickness is ~0.02 in. for a TRIGA fuel element with stainless steel cladding and ~0.03 in. for an element with aluminum cladding. In preparation for shipment in the ES-3100, a TRIGA fuel element is disassembled, the fuel meats are removed from the thin cladding and packed into convenience cans.

The TRIGA fuel may also be configured as clad fuel rods. Each clad fuel rod will be derived from a single TRIGA fuel element by removal of the stainless steel or aluminum clad extending beyond the plenum adjacent to the axial ends of the active fuel section. Each ~15-in.-long rod consists of the 3 fuel pellets and an

exterior sheath of stainless steel or aluminum clad, where the protruding clad at each end has been crimped in. The fuel rods will be packed into stainless steel or tin-plated carbon steel convenience cans, with a maximum of three fuel rods per loaded convenience can. This shipping configuration requires a minimum of two convenience cans; where only one convenience can is loaded with clad fuel rods. The loaded can is 17.5-in. tall, while the empty one is 8.75-in. tall. Although can spacers are not required for criticality control, can spacers or stainless steel pads may be used to take up free volume over the 31 in. internal height of the CV. The maximum quantity of fissile material per package is 408 g ^{235}U.

The clad fuel rod with 1.44-in.-diam fuel pellets contains 2,282.4-g $UZrH_x$, while rod with the 1.31-in.-diam fuel pellets contains 1,888.9-g $UZrH_x$. The 0.02-in.-thick sheath of stainless steel clad adds ~179 g to the mass of the active fuel for the 1.48-in.-diam standard element or instrumented element, and ~163 g to active fuel mass for the 1.35-in.-diam fuel follower control rod. Allowance for ½ in. of residual stainless steel crimped on each end of the clad fuel rod adds ~11–12-g stainless steel to these amounts. Likewise, the 0.03 in thick sheath of aluminum clad adds ~90 g to the mass of the active fuel for the 1.47-in.-diam standard element or instrumented element. Allowance for ½ in. of residual aluminum crimped on each end of the clad fuel rod adds ~6-g aluminum.

Research reactor fuel elements or fuel components are composed of U-Al, U_3O_8-Al, or UO_2-Mg. These items contain small quantities of fissile uranium typically ranging from 4.2–152-g ^{235}U. The maximum enrichment is ~93%. Components are of various solid shapes (rods, square bars, plates, or tubes) where diameters typically range from 0.18 to 4.0 in. and cross-sections typically range from 0.05 × 1.28 in. for an individual piece and 3.14 × 3.0 in. for an assembly of pieces. The active length for the various solid shapes ranges from 19.7 to 24 in.

U_3O_8-Al fuel elements are evaluated for demonstrating that research reactor related oxide contents are bounded by limits specified for TRIGA content. An aluminum-clad THAR plate (0.224 × 7.23 × 60.96 cm) contains ~101.52212 g of uranium and the enrichment is 20% ^{235}U. Table 6.9.3.1-4c presents the calculation of density values at enrichments of 20%, 70%, and 93.2% ^{235}U using plate dimensions, uranium mass, and theoretical density values of 8.3 g/cm^3 for U_3O_8 and 2.702 g/cm^3 for aluminum.

Table 6.9.3.1-4c. Calculation of constituent weight-percentage and content density values for 20 wt %, 70 wt %, and 93.2 wt % enriched uranium oxide-aluminum content in KENO V.a calculation models [a]

[a] Actual material at 20% enrichment, hypothetical materials at 70% and 93.2% enrichments.

A UO_2-Mg fuel element is evaluated for demonstrating that this form of research reactor related content is also bounded by limits specified for TRIGA content. An aluminum-clad EK-10 fuel rod (2.54 cm diameter and 139.7 cm length) contains ~92.35 g of uranium dioxide, 13.03 g of magnesium and 65.7 g of aluminum as cladding. The ^{235}U content is 8.05 g with a corresponding enrichment of 9.89%. Table 6.9.3.1-4d presents the calculation of density values at enrichments of 9.89%, 20%, and 93.2% ^{235}U using rod dimensions, material masses and theoretical density values of 10.96 g/cm^3 for UO_2 and 2.702 g/cm^3 for aluminum. For UO_2 content at 93.2% ^{235}U, an oxide density of 6.54 g/cm^3 is assumed consistent with bulk densities observed for product oxides with enrichments ranging from 19–100 wt % ^{235}U.

Table 6.9.3.1-4d. Calculation of constituent weight-percentage and content density values used in KENO V.a calculation models for 9.89 wt %, 20 wt %, and 93.2 wt % enriched uranium dioxide-magnesium, aluminum clad content, and for 93.2 wt % enriched uranium dioxide content [a]

6.9.3.2 Type 304 Stainless Steel

The metallic components of the ES-3100 package are composed of Type 304 stainless steel. These include the CV, the convenience cans, the drum liner, and the drum. Type 304 stainless steel with a density of 7.9400 g/cm^3 is included as a material in the SCALE Standard Composition Library.

6.9.3.3 277-4 Neutron Absorber

Catalog No. 277-0 dry mix is a proprietary mixture for producing a heat-resistant shielding material which combines the most effective shielding components into a single homogeneous composite. The shielding composite material is designed to maximize the hydrogen content necessary for thermalizing fast neutrons for capture in the boron constituent. Widely used in nuclear power plant

applications, the heat-resistant shielding material is capable of retaining a significant portion of its shielding properties up to 230°C (450°F). The recommended operating limit is 350°F, which is well above HAC temperatures expected inside the body weldment liner inner cavity and canned spacers.

The 277-4 neutron-absorber material used in the ES-3100 is a formulation of Cat 277-0 dry mix, a boron carbide additive, and water. 277-4 is produced through a quality-controlled batch process of dry blending, wet mixing, vibration casting, and timed cure (Equipment Specification JS-YMN3-801580-A005, Appendix 1.3.5). "Loss on drying" (LOD) tests are used to measure the amount of water in the as-manufactured 277-4 casting. The as-manufactured 277-4 at 100 lb/ft^3 and 31.8 % LOD has a hydrogen concentration of 3.56 wt % and a natural boron concentration of 4.359 wt % (DAC-PKG-801624-A001, Table 5).

The ability of 277-4 to perform its function depends upon the masses of hydrogen and ^{10}B locked inside the high alumina borated cement cast into the body weldment liner inner cavity and the spacer cans. A calculated amount of boron carbide is added to Cat 277-0 dry mix for producing as-manufactured 277-4 material with a volumetric isotopic concentration >7.621×10^{20} at/cm^3 of ^{10}B. The additive is boron carbide (B_4C) with small amount of a frit-like compound and trace amounts of unaccounted elements (0.17 wt %). Boron carbide has a theoretical density from 2.45 to 2.52 g/cm^3. 277-4 contains a large amount of hydrated alumina, also known as aluminum trihydrate [$Al(OH)_3$]. It is a nonabrasive powder with a specific gravity of 2.42. Given that both materials are of like density and similar particle size, separation and in homogeneity of 277-4 material is not expected during the controlled vibration casting process.

Table 6.9.3.3-1 provides detailed elemental composition data derived for as-manufactured neutron-absorber material at 100 lb/ft^3 and 31.8% LOD. This material description allows for clear specification of reduced boron and water contents required in the evaluation of NCT and HAC. As shown in Table 6.9.3.3-1, both the water and boron components are extracted from the material specification for the neutron absorber, and the constituent weight percents are recalculated accordingly (green box). 277-4 is specified in KENO V.a as three arbitrary materials: **arbmnpmx** with a density of 1.02276 g/cm^3, **arbmnph2o** with a density of 0.509253 g/cm^3, and **arbmboron** with a density of 6.98257E-02 g/cm^3. Model densities for 277-4 inside the body weldment liner inner cavity are reduced by a factor of 0.966893 to account for a material gap at the top of the liner. This material description allows for clear specification of reduced boron and water contents required in the evaluation of NCT and HAC.

The testing of 277-4 reveals that the material will dehydrate at elevated temperatures. Test specimens were dried at 250°F for 168 hours to reach the NCT state, and weight measurements were taken. These specimens where subsequently heated to 320°F for 4 hours to reach the HAC state, and weight measurements were again taken. The compositions of 277-4 at NCT and HAC states were derived by adjustment of the formulation specification for measured losses taking into account the statistical variations in the data. Conservation of mass for nonvolatile materials was observed in the derivation of material specifications based upon testing. Given that hydrogen must be present for the neutron absorber to be effective, conservative material specifications were derived for minimum hydrogen content and minimum material density.

Tables 6.9.3.3-2 and 6.9.3.3-3 respectively provide NCT and HAC composition data for as-manufactured 277-4 material at minimum density and hydrogen content. Respectively, Tables 6.9.3.3-4 and 6.9.3.3-5 provide NCT and HAC composition data or as-manufactured neutron-absorber material at minimum density and boron content. Because the amount of ^{10}B present in the neutron-absorber material is near saturation, a change in the hydrogen concentration has a major effect on the neutron multiplication factor, while a change in the amount of boron has a minor effect.

The neutron-absorbing material used in the ES-3100 Shipping Package will perform as analyzed. The analysis of 277-4 with criticality calculations is adequate in lieu of neutron transmission testing for the demonstration of acceptable performance by experimental means. Criticality calculations show boron content is adequate and k_{eff} is not dependent on absolute (microscopic) homogeneity. Geometry characteristics of the ES-3100 system preclude the need for uniformity in boron areal density as a prerequisite for criticality safety control. The neutron-absorbing material will be fabricated under strict quality control and accepted for use under an NQA-1 compliant quality assurance (QA) program. A QA-approved mixing process provides a method for creating an exact mix for the neutron absorber during ES-3100 fabrication. An important part of this QA-approved process is a 277-4 material verification and acceptance testing program. The following discussion elaborates on these key points:

The analysis of 277-4 with criticality calculations is adequate in lieu of neutron transmission testing for the demonstration of acceptable performance. Early on in the licensing process, BoroBond 4 ™ was selected as the neutron-absorber material for use in the ES-3100 package. The decision to use BoroBond 4 ™ in the ES-3100 was made because of favorable experience with its use in the Highly Enriched Uranium Materials Facility Rackable Can Storage Box (RCSB). From an economic standpoint, however, BoroBond 4 ™ proved not to be a viable option for the small quantities needed for the ES-3100 project. 277-4 neutron-absorber material, which has very similar nuclear material properties to BoroBond 4 ™, was then selected as an alternative.

Both the RCSB and the ES-3100 are fast systems in the normal condition when the HEU fissile material is essentially unmoderated. A key factor for an effective neutron absorber is that hydrogen should be present for moderation, and it should be interspersed with ^{10}B, thus promoting neutron capture. The potential for neutron streaming through an absorber is significant when a hydrogenous moderator is absent, as in the case of an aluminum boron-carbide matrix (a Boral alloy).

BoroBond 4 is a ceramicrete material with slightly greater than 4 wt % boron carbide (B_4C). The boron carbide powder is micro encapsulated by the crystalline matrix of the ceramic; therefore, leaching out the boron is not feasible. In BoroBond 4, 100 wt % of the B_4C has a particle size <500 μm; 90 wt % of the other constituents range from <164 μm to <36 μm. Given the differences in particle size, the potential for separation in the mixing process is real.

Some of the questions regarding the use of 277-4 as a neutron poison in the ES-3100 were previously addressed regarding the use of BoroBond 4 in the RCSB. Radiography was performed on BoroBond 4 samples ranging in thickness from 1.0 to 1.5 in. Inspections revealed little or no visual differences, indicating uniformity of the BoroBond 4. For 277-4 where the B_4C grit is on the order of 100 μm, the potential for separation is reduced.

Table 6.9.3.3-1. Calculation of constituent weight-percentage values used in KENO V.a calculation models for as-manufactured 277-4 at minimum acceptable density and boron content

Source: G. A. Byington, *Mixing Weights and Elemental Composition of 277-4 Neutron Poison Used in the ES-3100*, DAC-PKG-801624-A001, BWXT Y-12, Y-12 National Security Complex, Jan. 25, 2006, Table 14.

Measurements from neutron transmission tests on BoroBond 4 ™ for determination of areal density indicated greater boron content than was physically present. This is due to the presence of elements besides the aluminum and boron (principally hydrogen, oxygen and other low and intermediate-Z elements). Given the similarity of 277-4 to BoroBond 4 ™ (a ceramic-cement composite shielding material, with a similar elemental composition, more uniform particle size, and the same boron content), the 75% credit for boron content applied in the ES-3100 criticality calculations is an adequate enough correction for the efficiency of the material.

Criticality calculations show boron content is adequate and k_{eff} is not dependent on absolute (microscopic) homogeneity. The boron concentration calculations presented here model an infinite array of ES-3100 packages with the boron concentration of Cat 277-4 uniformly varied inside the body weldment inner liner. While the Cat 277-4 described herein is an earlier formulation of the neutron-absorber material, the behavior characteristics being demonstrated for Cat 277-4 apply to the revised formulation, 277-4.

Credit for only 75% of the boron is taken in the specification of Cat 277-4. Each package in the array contains 2.774 kg of ^{235}U in broken metal form uniformly distributed inside the CV. The presence of just the hydrogenous cement matrix in the inner liner reduces k_{eff} to 1.132 from a value of 1.35 without the cement matrix. As an initial 1 wt % natural boron is added to the high alumina cement system (Table 6.9.3.3-6), the calculated k_{eff} based on 75% of the boron present drops significantly. Cat 277-4 with 4.2284 wt % natural boron in the minimum cast density of 100 lb/ft^3 (1.60 g/cm^3) has an acceptable mixture concentration, generating a k_{eff} of 0.88. The saturation value for boron content is reached at ~8 wt %. This near doubling of the boron content results in ~4% decrease in k_{eff} to an asymptotic value of ~0.85.

The density of Cat 277-4 is the sum of constituent densities: the boron density, the base-material density, and the water density. In the calculation model, the density of water in Cat 277-4 is 0.48210 g/cm^3 (not shown in Table 6.9.3.3-6). Canned spacers are omitted from the calculation model. Credit for only 75% of the boron is taken in each parametric calculation. The volume of the 277-4 in the body weldment inner liner cavity is 1.32708×10^4 cm^3.

Table 6.9.3.3-6. Effect of boron concentration on array neutron multiplication

NUREG-1609 recommended that only 75% of the minimum boron density be credited in criticality evaluation in order to address the issue of non-homogeneity of ^{10}B in the neutron-absorber material. The boron non-homogenity calculations presented here model an infinite array of ES-3100

packages with the boron concentration of Cat 277-4 varying along the vertical height of the body weldment inner liner. However, the total amount of boron in each package is fixed. Each package in the array contains 2.774 kg of ^{235}U in broken metal form uniformly distributed inside the CV. Two sets of calculations are evaluated with this model to address the effects of boron distribution in the ES-3100 inner liner.

In one set of cases, the inner cavity is divided vertically into three equal-volume regions. The density in one region is increased to 95% of the minimum boron density, while the boron density in the other two regions is decreased to 65%, thus preserving the amount of neutron-absorber material in the package. In the other set of cases, the inner cavity is divided vertically into four equal volume regions, but two regions are combined. This creates two quarter-sized regions and one half-size region. The density in the half-size region is increased to 95% of the minimum boron density, while the density in the quarter-sized regions is decreased to 55%, thus preserving the amount of neutron absorber in the package. In both sets of calculations, the high-density region was shifted upward in the package to examine the effect of boron distribution.

As shown in Figs. 6.9.3.3-2 and 6.9.3.3-3, the effect of non-homogeneity of boron in the ES-3100 liner on k_{eff} is not statistically significant. The "65% - 95% - 65%" nonhomogeneous boron distribution represents a relative standard deviation of 23.1% in boron concentration. Given the controls on method of manufacture and installation of the neutron-absorber material, these calculated conditions bound the expected physical distribution of boron with a large degree of conservatism.

Geometry characteristics of the ES-3100 system preclude the need for uniformity in boron areal density as a prerequisite for criticality safety control. The U.S. Nuclear Regulatory Commission provides crucial guidance in SFST-ISG-15 for controlling areal density in a geometry configuration where one-dimensional effects are significant, such as a distributed source separated by thin Boral sheets (aluminum and boron carbide) which range in thickness from 0.075 to 0.4 in. In this example, Boral aluminum sheets are placed between fissile fuel rods just a few inches away and only become efficient when the low-enriched fissile material is placed in a sea of hydrogenous moderator. The cylindrical thickness of the ES-3100 cast neutron-absorber material (Cat 277-4) is 1.12 in., which is about three times thicker than the largest Boral sheet. Its purpose in the ES-3100 is to provide criticality safety control for arrays of packages.

In the ES-3100, the proposed fissile mass loads are separated by at least one drum diameter (19.36 in.). Drawing M2E801580A031 in Appendix 1.3.7 shows the cross-section view of the many different layers of materials that are between the fissile mass loads in adjacent packages in an array. The direct neutron transport path between dispersed fissile material (assuming a neutron passes through the following thickness of materials at a normal angle to the closest neighboring package) is:

- fissile material,
- 0.100 in. Type 304 stainless-steel CV wall,
- air gap,
- 0.06 in. Type 304 stainless-steel inner liner wall,
- 1.12 in. of 277-4 neutron-absorber material,
- 0.06 in. Type 304 stainless-steel outer liner wall,
- 4.77 in. of Kaolite,
- 0.06 in. Type 304 stainless-steel outer drum wall, and
- air gap,

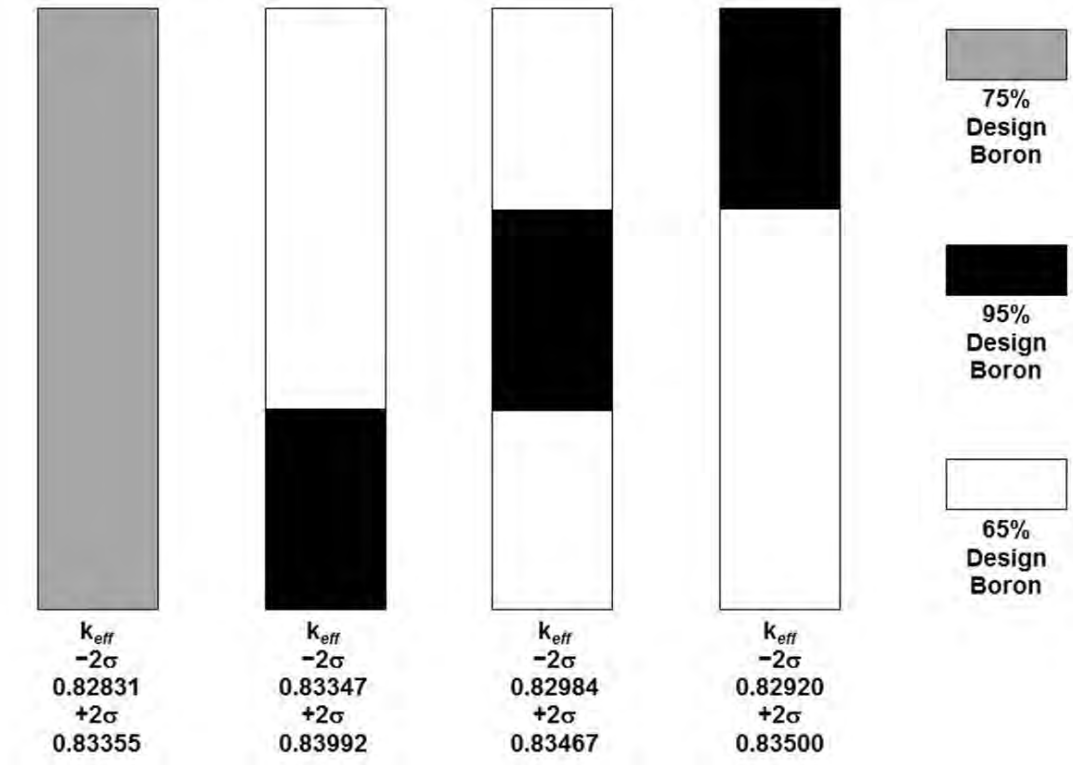

Fig. 6.9.3.3-2. Three equal-region models for evaluation of non-homogeneity in the boron distribution.

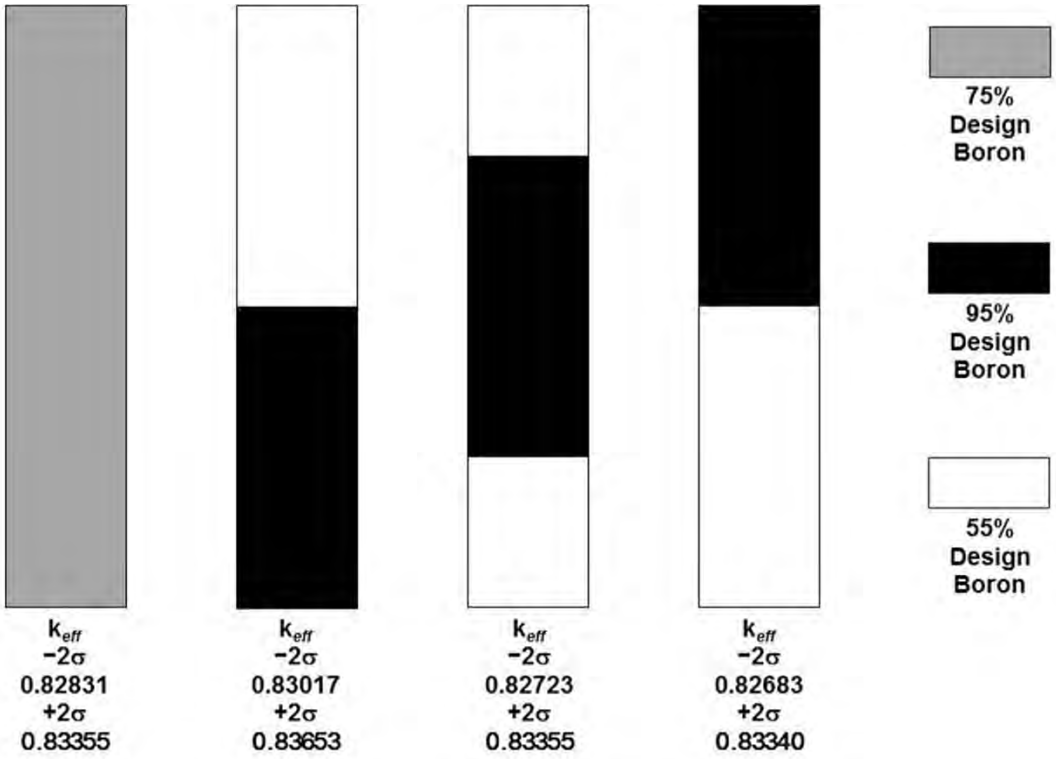

Fig. 6.9.3.3-3. Non-uniform region model for evaluation of non-homogeneity in the boron distribution.

followed by the reverse:

- 0.06 in. stainless-steel outer drum wall,
- 4.77 in. of Kaolite,
- 0.06 in. Type 304 stainless-steel outer liner wall,
- 1.12 in. of 277-4 neutron-absorber material,
- 0.06 in. Type 304 stainless-steel inner liner wall,
- air gap,
- 0.100 in. Type 304 stainless-steel CV wall, and
- back into a fissile material.

At the shortest distance between fissile materials, neutrons travel through the 1.12 in. (2.8448 cm) of 277-4 neutron-absorber material and 0.28 in. (0.7112 cm) of Type 304 stainless steel at least twice, with the high probability of several neutron scattering collisions along the way. Thus, the mean free path in the package is much smaller than the separation between the fissile material of adjacent packages.

In contrast to a Boral sheet application, the neutron-absorber component of the ES-3100 package physically represents a significant fraction of the total container volume and is large in comparison to the potential fissile material volume. Furthermore, the neutron-absorber component consists of boron dispersed throughout a hydraulic cement matrix with a high neutron scattering potential. The net result is that sensitivity to angular and spatial variations in the areal density of ^{10}B in the neutron-absorber volume is eliminated.

The calculation model for a 277-4 canned spacer was developed based on available information at the time of the initial design. The dimensions of the 277-4 filler are 4.13 in. for the diameter and 1.4 in. for the height with a resultant volume of 307.34 cm^3. Based on a density of 95.3886 lb/ft^3 (1.527971 g/cm^3), the amount of 277-4 represented in the calculation model is 469.61 g. As shown on Drawing M2E801580A043 (Appendix 1.3.7), the outer diameter of the stainless-steel can is 4.13 ± 0.09 in. and the height for the 277-4 filler is 1.37 ± 0.06 in. The wall thickness for the 30 gauge stainless steel is 0.012 in. The actual minimum volume of the 277-4 filler is 271.93 cm^3 based on this acceptance criteria. For cast material having a nominal density of 105 lb/ft^3 (1.68193 g/cm^3), the actual minimum amount of 277-4 present in a canned spacer is 457.36 g. An excess 12.25 g of neutron poison in the calculation model on which criticality safety is based is insignificant. Nevertheless, results of additional calculations are presented for demonstrating this fact.

A set of Cases **hciabmt12** establishing loading limits for broken metal were selected from Table 6.9.6-11. These cases based on the nominal 277-4 canned spacer were rerun using SCALE5 and are identified in Table 6.9.6-11d as reference Cases **5hciabmt12**. The corresponding cases for revised calculation model with 277-4 canned spacer sized per the minimal acceptance criteria are identified in Table 6.9.6-11d as Cases **5_401by131**. The minimum dimensions of the 277-4 filler in these cases are 4.01 in. for the diameter and 1.31 in. for the height; the amount of amount of 277-4 represented is 415 g. A statistically significant difference between case results for a configuration with the nominal canned spacer and one with the minimum-sized spacer occurs if the absolute value of the quantity "$\mathbf{(\Delta k_{eff}+2\sigma)/\sigma}$" is >3. As shown in Table 6.9.6-11d, the differences are statistically insignificant; therefore, loadings limits are adequate for content configurations with the canned spacer sized per the minimum acceptance criteria.

<u>The neutron-absorbing material will be fabricated under strict quality control and accepted for use under an NQA-1 compliant QA program.</u> The original equipment specification for the production of 277-4 neutron-absorber material used a proprietary mixture from the Thermo Electron Corporation that combined high alumina cement and a boron grit (Cat 277-4). The manufacturing process for the neutron

absorber was revised in order to obtain details necessary for material characterization and to achieve process control for ensuring consistency of absorber material among lots.

A two-part system of dry-blend components is now employed rather than relying on a single base material (a premixed powder of high alumina cement and boron grit). The vendor's proprietary high-alumina cement without boron grit (Cat 277-0) is mixed with boron carbide by the ES-3100 manufacturer under strict quality controls. A single batch is mixed on a per package basis. The boron carbide used in this process is strictly controlled. Boron carbide is specified as Type 1 material per ASTM C 750, "Nuclear-Grade Boron Carbide Powder." The particle size is controlled in accordance with JS-YMN5-801580-A003, Sect. 3.3.1.2.

The revised formulation designated "277-4" is produced through a quality-controlled batch process of dry blending, wet mixing, vibration casting, and timed cure (JS-YMN3-801580-A005, Appendix 1.3.5). The plan is to control the purity, boron carbide particle size, chemistry, measurements, weights, mixing, recording, casting, and testing using one batch per each shipping package (and its two companion spacer cans). A design analysis calculation shows all of the calculations used in mixing and determines (from the minimum acceptable chemical purities) the volumetric densities in g/cm^3 and an areal density in g/cm^3 of ^{10}B (DAC-PKG-801624-A001). These values will prove the acceptability of the mixing specifications.

An important part of this approach is a QA-approved 277-4 material verification and acceptance testing program. The applicant plans on performing 100% acceptance testing on the criticality safety significant properties of density, ^{10}B interaction (neutron absorption), and hydrogen content. The acceptance density shall be the as cast density in the drum to 105−5+10 lb/ft^3 and shall be determined as shown in Appendix 1.3.5. To test the other properties, two companion sample cans shall be cast from each batch used to cast a shipping container (the manufacturer will cast a fresh batch for each shipping container). The companion sample cans shall also have their density verified. The ^{10}B interaction will be tested in the manner described in Appendix A of the 277-4 specification (Appendix 1.3.5). Initially, a set of 277-4–certified cans will be cast using the proposed casting specification with the QA plan described previously. Then, on a companion sample can for each batch pour, a prompt gamma-ray neutron activation analysis (PGNAA) test will be used to neutronically test the ^{10}B for absorption. To pass the PGNAA test, the sample can results must be within the results obtained for the 277-4 certified standards, in units of Average Net Count rate (ANC/second) ±3 standard deviations. The second companion sample can will be used to test for hydrogen content using an LOD test as described in Appendix 1.3.5. Upon successful completion of the density, PGNAA, and LOD testing, the ES-3100 neutron-absorber material will be accepted for use.

6.9.3.4 Kaolite 1600

Kaolite 1600, manufactured by Thermal Ceramics of Augusta, Georgia [telephone number (404) 796-4200], is a super-lightweight, low thermal conductivity, castable material designed for backup insulation up to 1600°F. The material is obtained as a dry powder with the chemical composition given in Table 6.9.3.4-1. The powder is mixed with water in a water-to-powder ratio of 14.5 qt per 20-lb bag. The mixture is poured into the drum body weldment or top plug, vibrated to eliminate voids, and then dried and fired to form the finished product (Y/EN-5984). The density of the fired material is ~25 lb/ft^3. It is assumed that the wet mixture contains the maximum water possible. This value (14.5 qt per 20 lb) is therefore used to determine the maximum water content of the fired product,

$$S.G._{max} = \frac{14.5\ qt}{20\ lb\ dry} \times \frac{25\ lb}{ft^3} \times \frac{0.946\ L}{1\ qt} \times \frac{998.2\ g}{L} \times \frac{35.32\ ft^3}{10^6\ cm^3} = \frac{0.6045\ g}{cm^3}$$

Table 6.9.3.4-1. Kaolite 1600 chemical composition, percent fired basis

Component	Weight percent	Component	Weight percent
Al_2O_3	9.6	CaO	30.7
SiO_2	36.7	MgO	13.1
Fe_2O_3	6.7	Na_2O	2.0
TiO_2	1.2		

Tables 6.9.3.4-2 and 6.9.3.4-3 provide detailed information regarding the weight measurements taken during the casting of Kaolite 1600 for the production of a series of drum body weldment and top plug parts for a similar package (the CNS Model ES-2100). The mean values for the amount of Kaolite and water present after baking are 107.08 lb of Kaolite and 4.8 lb of water in the drum body weldment, and 16.99 lb of Kaolite and 0.58 lb of water in the top plug. An ES-2100 package contains, on the average, 124.07 lb (56,276.91 g) of Kaolite and 5.38 lb (2,440.32 g) of water. Given that the average volume is 5.72 ft^3, the average density of Kaolite is 22.63 lb/ft^3 (0.3625 g/cm^3).

The volume of the Kaolite region in the KENO models is 1.63417 × 5 cm^3. For NCT, the density of Kaolite is 0.34438 g/cm^3, and the density of water is 0.01493 g/cm^3. The data in Tables 6.9.3.4-2 and 6.9.3.4-3 indicate that the Kaolite may have as little as 1.90 lb (861.82 g) of water after baking (Part Serial Number 97) such that the corresponding density of water is 0.00527 g/cm^3. For the water-flooded HAC, the amount of water is assumed not to exceed the amount present before baking. The package would contain on the average 186.10 lb (84,413.1 g) of water such that the corresponding density is 0.51655 g/cm^3. The full range of NCT and HAC conditions would be covered by a variation of water in the Kaolite from 0 g/cm^3 to 0.51655 g/cm^3 in a calculation model.

The Kaolite components of ES-3100 shipping package had not been manufactured at the time this criticality safety evaluation was performed. Given the lack of production data for ES-3100 Kaolite, a material specification (mass and density) was derived from data for ES-2100 production units. This specification, denoted “as-manufactured” (AM) Kaolite, was used for the ES-3100 criticality calculations. This ES-2100 shipping package is similar in design to the ES-3100 currently being evaluated.

The Kaolite production process was re-evaluated and improved following the production of ES-3100 units (Y/DW-1890). Test samples were produced. These were classified into three groups: high density, medium density, and low density. The predominate number of samples fell into the medium density category (22.04 lb/ft^3), representing the expected, improved Kaolite production process (Y/DW-1890, Table 5). A material specification for use in criticality calculations was derived from the medium density “test sample” (TS) Kaolite data. However, the TS data are based on small sample volumes, whereas the AM data represents the entire package. Taking into consideration both the potential for scaling error and the uncertainty of how representative the test samples are of the manufactured ES-2100 units, the criticality safety packaging analysts chose to utilize the material specification derived from AM data rather than TS data in the criticality calculations for the ES-3100 safety analysis report for packaging.

[a] No explanation is given for the negative amount of water in Part 0. Also, the smaller percentage of water present in the top plug compared with to the drum body weldment is attributed to the larger surface-to-volume ratio, which results in better drying of the parts.

A set of criticality calculations was performed for each of the packaging material specifications (i.e., the TS and the AM Kaolite) using three package water contents to represent the range of NCT and HAC. Y-12 statisticians were asked to determine whether or not the observed differences in neutronic performance are statistically significant for a package modeled with the TS specification versus one modeled with the AM specification. The purpose of this discussion is to summarize this comparison (DAC-FS-900000-A014) and draw conclusions.

Criticality Calculations. Each case is rerun using a different starting random number in order to produce computed k_{eff} values that are statistically independent. Table 6.9.3.4-4 presents the random starting number, the mean value (k_{eff}) and corresponding standard error (s_i) computed for 10 individual runs of each case.

Three sets of criticality calculations were run for both the AM Kaolite and TS Kaolite. One set of calculations is for dry Kaolite (i.e., low water content, IS = 1E-04 sp gr water); another set is for normal moisture Kaolite (i.e., NCT water content); and the third set is for flooded Kaolite (i.e., high water content, IS = 1.0 sp gr water). These conditions span the range of NCT and HAC addressed in the criticality evaluation. An infinite array of packages was evaluated in order to eliminate any biases arising from spectral leakage effects in the reflector of the finite array. Each package was modeled having 36 kg of 100% enriched uranium in the form of 3.24-in.-diam cylinder content. The k_{eff} values for each KENO V.a case are based on 500,000 neutron histories produced by running for 215 generations with 2,500 neutrons per generation and truncating the first 15 generations of data.

Statistical evaluation. A review of KENO V.a calculation results was made to determine if a statistically significant difference exists between the mean k_{eff} for the TS Kaolite specification and the AM Kaolite material specifications used in the criticality evaluation of the ES-3100 shipping package. Case results were classified into three groups (i.e., low water content, medium water content, or high water content) depending on the amount of water present in the ES-3100 shipping package. The symbol "I" is used to specify the group. The mean difference and standard deviation for each of the three (3) sets of pair-wise differences was defined as follows:

(a) $d_i = (k_{effBi} - k_{effAi})/n$ and

(b) $s_{di} = \sqrt{[\, n\Sigma d_i^{\,2} - (\Sigma d_i)^2 \,] / n(n-1)}$ (conservatively defined for the t-test appropriate for small sample sizes)

where A_i denotes the TS by group classification, B_i the AM by group classification, and n the sample size of ten (10). It is reasonable to assume that the paired differences have been randomly selected from a normally distributed population of paired differences with mean μ_d and standard deviation σ_d. Therefore, the sampling distribution of

$$(d - \mu_d) / (s_d/\sqrt{n})$$

is a *t*-distribution having n-1 degrees of freedom.

The evaluation of the mean differences (d_i) for the 10 sets of cases is accomplished through hypothesis testing, a statistical tool used to provide evidence that a difference exists or does not exist. The ti values are 0.70, 10.0 and 0.95 for dry Kaolite, for NCT Kaolite, and for flooded Kaolite, respectively. A value of 3.25 is obtained from the standard table for critical values for the t distribution, from which the decision to accept or reject the null hypothesis H0 is made with a Type I error probability (α) of 0.01. For t <3.25, the Ho hypothesis is not rejected. Acceptance of the null hypothesis is the result of insufficient evidence to reject it. Thus, it can be concluded that the mean estimate of the difference of the AM Kaolite is not significantly different from the mean of the TS Kaolite for both dry and flooded Kaolite. For t >3.25, the Ho hypothesis is rejected. Therefore, it can be concluded that the mean estimate of the difference of the AM Kaolite is significantly different from the mean of the TS Kaolite for the normal moisture Kaolite. The mean k_{eff} for AM Kaolite is significantly greater than the mean k_{eff} of the TS Kaolite; therefore, the use of the AM specification in the ES-3100 criticality calculations is conservative and bounding. Details of the statistical evaluation are documented in Reference DAC-FS-900000-A014.

6.9.3.5 Packcrete

ES-3100 drum body assemblies and top plugs may be fabricated with Packcrete or Kaolite. Packcrete is a fireproof, lightweight, impact limiting, thermal insulating, cast refractory material. It is comprised of water, Airalon 3000 (air entraining agent), portland cement, and vermiculite as specified in SPC M801794-003 (Appendix 1.3.11) and SPC M801580-0003 (Appendix 1.3.12). The material is obtained as a dry powder with the chemical composition given in RP 802282-0002, *Packcrete Material Properties.* Only the major constituents in the dry powder were modeled with the weight percent of each component normalized to obtain 100% as shown in Table 6.9.3.5-1. Constituents less than 1% are ignored, and the water, which is a major constituent, is also ignored for the dry powder, since water is already varied in this analysis. The powder is mixed with water, with the mixture poured into a stainless-steel shell specified on Drawing M2E801580A002 (drum body weldment) and Drawing M2E801580A008 (top plug weldment). The filled weldements are vibrated to eliminate voids, and then dried and fired to form a finished product.

Table 6.9.3.5-1. Average Packcrete chemical composition, fired basis

Component	Before normalization (wt %)	Normalized (wt %)
Al_2O_3	7.59	8.93
SiO_2	24.61	28.96
Fe_2O_3	5.82	6.85
K_2O	1.90	2.54
CaO	35.63	41.93
MgO	7.26	8.55
SO_3	2.16	2.24
Total	84.97	100.00

As documented in RP 802282-0002, chemical analysis was performed on each sample taken during the initial production of Packcrete. A sample was taken from each 50 lb bag of material mixed. Properly cured Packcrete should have very little latent water, but it may have a significant amount of water of hydration. Dehydration testing was conducted on the samples to determine the water content.

The data of the evaluated samples were grouped as high-density dehydration data, medium-density dehydration data, and low-density dehydration data.

From dry mass data, the water composition in Packcrete ranges from a minimum of 10.16% to a maximum of 15.67%, with an average of 12.92%. The acceptable range for the baked density of Packcrete material is 22.4 ± 3 lb/ft^3 (19.4 to 25.4 lb/ft^3), while the acceptable range for the wet density of Packcrete material is 53.9 ± 5.6 lb/ft^3 (48.3 to 59.5 lb/ft^3).

In this analysis only the array calculations were performed. For these calculations, only the low density Packcrete and low density water was examined, since it has been shown in the Kaolite calculations that lower density materials are the most reactive for array calculations (due to the enhancement of interaction effects). An example of how these values were calculated is shown below. Although not calculated for single packages, an example calculating the maximum water density and dry Packcrete density is also provided below.

The maximum density of water remaining in the Packcrete is calculated by first multiplying the baked density (19.4, 22.4, or 25.4 lb/ft^3) by the water content (10.16 %, 12.92 %, or 15.67 %). This value is subtracted from the baked density to obtain the density of the dry Packcrete material. The maximum density of water is determined by subtracting the dry Packcrete material density from the maximum wet Packcrete density. An example of the calculation is found below for 25.4 lb/ft^3 at 15.67 % water content:

Dry Packcrete density: 25.4 lb/ft^3 × (1 - 0.1567) = 21.41982 lb/ft^3

Maximum density of water: 59.5 lb/ft^3 - 21.41982 lb/ft^3 = 38.08018 lb/ft^3.

The minimum density of water remaining in the Packcrete is calculated by first multiplying the baked density (19.4, 22.4, or 25.4 lb/ft^3) by the water content (10.16 %, 12.92 %, or 15.67 %). This value is subtracted from the baked density to obtain the density of the dry Packcrete material. The minimum density of water is determined by subtracting the dry Packcrete material density from the baked Packcrete density. An example of the calculation is found below for 19.4 lb/ft^3 at 10.16 % water content:

Minimum density of water: 19.4 lb/ft^3 × 0.1016 = 1.97104 lb/ft^3

Dry Packcrete density: 19.4 lb/ft^3 - 1.97104 lb/ft^3 = 17.42896 lb/ft^3.

All of the Kaolite calculations presented in this SARP were modeled with average Kaolite baked density for both single packages and arrays. The maximum amount of water was modeled in the Kaolite for the single package calculations and the minimum amount of water was modeled in the array calculations. The comparative calculations performed here will also use average density of both Kaolite and Packcrete.

Several series of calculations are performed in the analysis comparing Kaolite and Packcrete. In the first set of calculations, the maximum amount of water in both Kaolite and Packcrete was modeled. This value of water is the amount of water mixed with the dry constituent prior to baking. These calculations examined only single packages, since the maximum amount of water in Kaolite is more reactive in single package calculations than in array calculations. The results are found in Table 6.9.3.5-2.

From the results of Table 6.9.3.5-2 for single package calculations, there is no statistical difference between Kaolite and Packcrete at the average density with the maximum amount of water modeled in Kaolite and Packcrete.

Table 6.9.3.5-2. Comparative calculations Kaolite vs Packcrete for single package (maximum amount of water in Kaolite and Packcrete)

Description	Kaolite		Packcrete	
	Case	$k_{eff} + 2\sigma$	Case	$k_{eff} + 2\sigma$
Broken metal w/polyethylene	ncsrbmt11p_8_6_15	0.89242	ncsrbmt11ppckb_8_6_15	0.89088
Poly cyl and bars	ncsrcyct11p_17_1_15	0.89709	ncsrcyct11ppckb_17_1_15	0.89661
U_3Si compound	5ncsrdpu3st11_3_6_15	0.76239	5ncsrdpu3st11pckb_3_6_15	0.76119
4 kg oxide at 0.5 g/cm^3	ncsrltoxt11_6_8	0.78623	ncsrltoxt11pckb_6_8	0.78595

In the second set of calculations, the minimum amount of water is used. The amount of water modeled in the Kaolite calculations is based on the data from Table 6.9.3.4-2. For Packcrete, two calculations were performed using the minimum amount of water in the Packcrete samples and the minimum amount of water in the Kaolite samples. This was done because the minimum amount of water found in the Packcrete samples was greater than what was found in the Kaolite samples. This higher amount of water will reduce the interaction effects in the array calculations, resulting in a less reactive system. The results are found in Table 6.9.3.5-3.

Table 6.9.3.5-3. Comparative array calculations Kaolite vs Packcrete

Description	Case	Kaolite	Packcrete	
		$k_{eff} + 2\sigma$	$k_{eff} + 2\sigma$ [a]	$k_{eff} + 2\sigma$ [b]
Broken metal w/polyethylene	nciabmt11p_5_1_6_3	0.93426	0.87058	0.93718
U_3Si compound	5nciadpu3st11_3_4_3	0.93461	0.86636	0.93713
4 kg oxide at 0.5 g/cm^3	ncialdoxt11p_6_1_2	0.92405	0.86593	0.92544
15.5 kg oxide at 2 g/cm^3	ncf1oxt11_11_3	0.93250	0.88564	0.93165

[a] Minimum water density from Packcrete (ppckc).
[b] Minimum water density from Kaolite (ppckf).

When the Packcrete is modeled with the minimum amount of water from the samples documented in RP 802282-0002, the $k_{eff} + 2\sigma$ is lower than the original Kaolite cases. This is because the minimum amount of water from the samples is significantly higher than the Kaolite samples. This additional water is shown to reduce the amount of interaction between the ES-3100 packages. As seen from the results of Table 6.9.3.5-3 for array package calculations, modeling the Packcrete with the minimum amount of water based on the Packcrete samples is significantly less reactive than Kaolite modeled with the minimum amount of water based on the Kaolite samples. It is important to note that there were more Kaolite samples than Packcrete samples. To address this potential concern, additional cases were run using the minimum amount of water from the Kaolite cases in the Packcrete models for comparison purposes. From the results shown in Table 6.9.3.5-3, when modeling the minimum amount of water in the Packcrete the same as Kaolite, there is very little difference in the reactivity.

Additional calculations were performed modeling Kaolite and Packcrete with no water. Both were modeled at average density and with no water. This model will examine the effects that the dry constituents have on reactivity. The results are found in Table 6.9.3.5-4.

Table 6.9.3.5-4. Comparative array calculations for Kaolite vs Packcrete with no water

Description	Kaolite (with no water)		Packcrete (with no water)	
	Case	$k_{eff} + 2\sigma$	Case	$k_{eff} + 2\sigma$
Broken metal w/polyethylene	nciabmt11pnw_5_1_6_3	1.00341	nciabmt11ppcke_5_1_6_3	1.00534
U_3Si compound	5nciadpu3st11nw_3_4_3	1.00787	5nciadpu3st11pcke_3_4_3	1.00840
4 kg oxide at 0.5 g/cm^3	ncialdoxt11nw_6_1_2	0.98284	ncialdoxt11pcke_6_1_2	0.98613
15.5 kg oxide at 2 g/cm^3	ncf1oxt11nw_11_3	0.97964	ncf1oxt11pcke_11_3	0.97701

When modeling no water in Kaolite and Packcrete, there is no statistical difference in reactivity between the two. From the results of these calculations shown in Tables 6.9.3.5-3 and 6.9.3.5-4, the reactivity effects of the Kaolite and Packcrete are based on the amount of water in the Kaolite and Packcrete.

Based on the results of these calculations, it can be concluded that the calculations performed for Kaolite will also bound Packcrete.

6.9.3.6 Water

Water is used in various regions of the models to simulate HAC as an interstitial moderator and as a reflector. When used at full density, the density of water is 0.9982 g/cm^3 (NUREG/CR-0200, Rev. 6).

6.9.3.7 Calculation of Equivalent Water Mass for Polyethylene

In the calculation models for evaluation of NCT, water may be substituted for the polyethylene composition of bags present in the package. Based on hydrogen density, 1285.14 g of water are equivalent to 1000 g of polyethylene for nuclear criticality safety calculations. The equivalent water mass is calculated as follows:

$$1 \text{ kg polyethylene} = \frac{1000 \text{ g}}{0.92 \text{ g/cm}^3} = 1087.0197 \text{ cm}^3$$

$$\text{H number density} = \frac{(0.92)\,(4)\,(6.02252 \times 10^{23})}{(28.0312)\,(10^{24})} = 7.906502 \times 10^{-2} \text{ at/bn-cm}$$

$$\text{H in 1 kg} = (1087.0197 \text{ cm}^3)\,(7.906502 \times 10^{-2}) = 85.945234 \text{ at-cm}^2/\text{bn}$$

Hydrogen in 1 kg of polyethylene [$(CH_2)_2$, molecular weight = 28.0312; density = 0.92]:

Grams of water [H_2O, molecular weight = 18.0110; density = 0.9982] with hydrogen content equivalent to 1 kg of polyethylene:

$$\text{equivalent g of } H_2O = \frac{(85.945234)\,(18.0110)\,(10^{24})}{(2)\,(6.02252 \times 10^{23})} = 1285.1427 \text{ g}$$

Appendix 6.9.4
Qualification of a Neutron-absorber Material for the ES-3100

This page intentionally left blank.

Appendix 6.9.4
Qualification of a Neutron-absorber Material for the ES-3100

6.9.4.1 Introduction

277-4 is a formulation of Thermo Electron Corporation's Cat. 277-0, a boron carbide additive and water. 277-4 is a neutron radiation shielding product and is one of several materials in its class that have been evaluated as a candidate neutron-absorber system for a variety of nuclear criticality safety applications by the Y-12 National Security Complex (Y-12). This class of materials is characterized as a dispersion of $^{nat}B_4C$ particulate[1] throughout a hardened hydraulic cement or binder, resulting in a high-hydrogen, borated material system. It offers many advantages for typical Y-12 applications over other classes of materials such as borated aluminum because a neutron moderator and neutron absorber are both integral to the solid material system itself. The separate addition of another neutron moderating material such as water or polyethylene is not required in order for it to function effectively.

Computational methods of analysis in simple geometry permit direct comparison of neutron-absorber system performance for nuclear criticality safety applications. The measure of comparison is the neutron interaction potential between two parallel 0.745-cm-thick slabs of infinite extent of ^{235}U metal at a density of 18.81 g/cm^3. The slabs are separated by a variable thickness of material and reflected by a 60-cm thickness of the same material (Fig. 6.9.4.1-1). Each material is modeled as an idealized homogeneous mixture of elements based on nominal density and constituent proportions (Table 6.9.4.1-1). The result is expressed in terms of calculated k_{eff}[2] as influenced by the thickness of the candidate material between the two parallel slabs (see Fig. 6.9.4.1-2).

The least effective neutron-absorber material systems are those with low hydrogen content and low neutron absorption cross section (e.g., ordinary concrete). The performance of concrete that contains $^{nat}B_4C$ particulate (e.g., borated concrete) is improved, but it is still hindered by its low hydrogen content. This is a function of the proportion and type of cement in the typical concrete mixture (i.e., a low proportion of lime- and silica-based Portland cement). Ordinary water is also included for comparison because of its high hydrogen content, but its performance is also limited by a low total mass density and low neutron absorption cross section.

As expected, materials with high hydrogen content and high boron content (e.g., 277-4, borated ceramics, and borated polymers) are predicted to be the most effective neutron-absorber systems. Although the mechanical and thermal properties of such systems can vary significantly, their nuclear properties are dictated almost exclusively by the relative proportion and content of ^{10}B and H and the total mass density of the material system. These things being equal, the nuclear performance of any material in this class (i.e., 277-4, borated ceramics, and borated polymers) is representative of the others.

[1] 277-4 is an improved variant of the Cat 277 product ca. 2000 which was originally formulated as a dispersion of ^{nat}Borosilicate glass granules rather than the current practice of using $^{nat}B_4C$ particulate.

[a] The ^{10}B content of this material model for Cat 277 is based on its ca. 2000 formulation using crushed borosilicate glass rather than the current practice of using $^{nat}B_4C$ particulate. This particular formulation is roughly equivalent to ~2% $^{nat}B_4C$ particulate (i.e., equivalent ^{10}B content, by weight). For otherwise identical H and B-10 content, this difference is unimportant relative to its nuclear performance as an idealized homogeneous mixture of elements. However, the current use of more than 5% $^{nat}B_4C$ particulate (by weight) is preferred due to reasons relating to the method of preparation, chemical reaction, and placement of 277-4 and uniformity of ^{10}B distribution in the cured product. As with all the materials in this class, the amount of H and ^{10}B in the finished product is determined by the relative proportions of its major constituents, which are tailored to the requirements of the specific application.

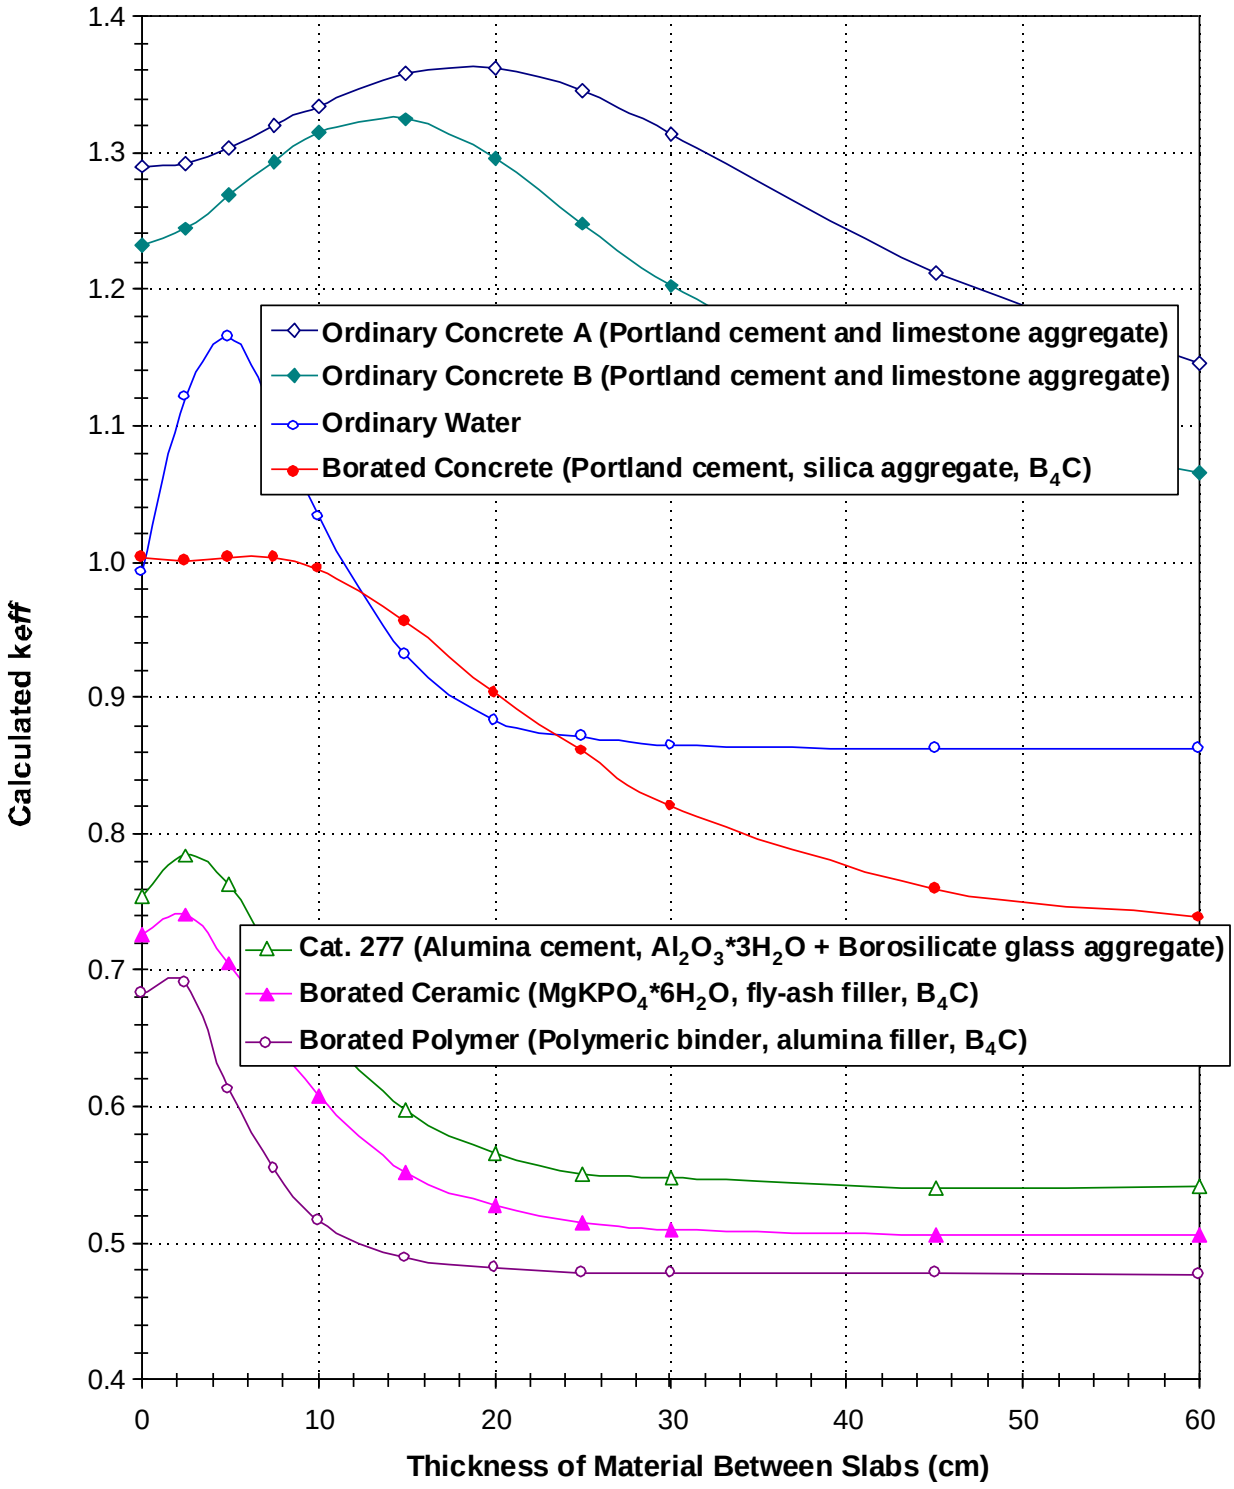

Fig. 6.9.4.1-2. The effect of various materials on neutron interaction between parallel slabs of ^{235}U metal of infinite extent.

6.9.4.2 Performance Testing

To investigate the performance of this class of neutron-absorbing materials further, Y-12 has studied neutron radiography and neutron transmission measurements on several samples of a borated ceramic. Like 277-4, the borated ceramic is also a dispersion of $^{nat}B_4C$ particulate throughout a hardened hydraulic crystalline solid material matrix for which the binder phase is $MgKPO_4 \cdot 6H_2O$ rather than the hydrates of CaO and Al_2O_3. In fact, the more finely divided $^{nat}B_4C$ particulate specified for 277-4 is a slight advantage over the modestly coarser particulate in the borated ceramic. As shown below in Table 6.9.4.2-1, the relative proportion and content of H and ^{10}B and their total mass density are very similar. The small differences between the nuclear properties of their associated low- and intermediate-Z elements (i.e., oxides of Mg, Al, P, K, and Ca) are negligible. Thus, performance and the most significant factors affecting performance are nearly identical for both materials, so the results of neutron radiography and neutron transmission for the borated ceramic samples are judged applicable to 277-4 specimens of similar dimension.

Table 6.9.4.2-1. Comparison of nominal values for 277-4 and borated ceramic samples subjected to neutron radiography and neutron transmission testing.

Attribute	Cat 277 original formulation ca. 2000	277-4 ES-3100 formulation as cured	Borated ceramic samples for testing
Principal binder phase(s)	Hydrates of CaO and Al_2O_3	Hydrates of CaO and Al_2O_3	$MgKPO_4 \cdot 6H_2O$
Neutron absorber	^{nat}Borosilicate glass granules	$^{nat}B_4C$ particulate	$^{nat}B_4C$ particulate
Particle Size	90 wt % <2360 μm 65 wt % <1180 μm 40 wt % <600 μm 15 wt % <102 μm 0 wt % <150 μm	100 wt % <102 μm	100 wt % <559 μm 90 wt % <356 μm 40 wt % <254 μm 3 wt % <122 μm 0 wt % <63 μm
Filler Material(s)	$Al_2O_3 \cdot 3H_2O$	$Al_2O_3 \cdot 3H_2O$	Class F Coal Fly-ash
Total Mass Density	1.68 g/cm^3	1.60 g/cm^3	1.91 g/cm^3
Total H_2O content	0.51 g/cm^3	0.51 g/cm^3	0.49 g/cm^3
Total ^{10}B content	0.005 g/cm^3	0.013 g/cm^3	0.012 g/cm^3

Samples were prepared from sectioned pieces of a single specimen from a vertically oriented mold measuring 10 × 10 × ~30 cm tall, as illustrated in Fig. 6.9.4.2-1 (nominally 4 × 4 × 12 in. tall). One specimen was prepared by the normal method of mixing and preparation for the borated ceramic material. Sectioning the first specimen resulted in two thick samples designated “1 of 2” and “2 of 2” which each measured 10-cm wide by ~30-cm long by ~2.4-cm thick (nominally 1-in. thick). A second specimen was prepared by abnormal methods intended to produce non-homogeneity (i.e., poorly mixed using retardants followed by excessive and extended vibration of the mold after installation). Sectioning this specimen resulted in two thin samples designated “062d1bc” and “062d1bd” which each measured 10-cm wide by ~30-cm long by ~1.2-cm thick (nominally 0.5-in. thick). The samples were delivered to the Breazeale Nuclear Reactor Building at Pennsylvania State University for inspection. Upon completion of inspection for all four samples as received, a thick sample “1 of 2” and a thin sample “062d1bc” were dehydrated by heating to 140°C to eliminate interference by hydrogen, and all four samples were tested again.

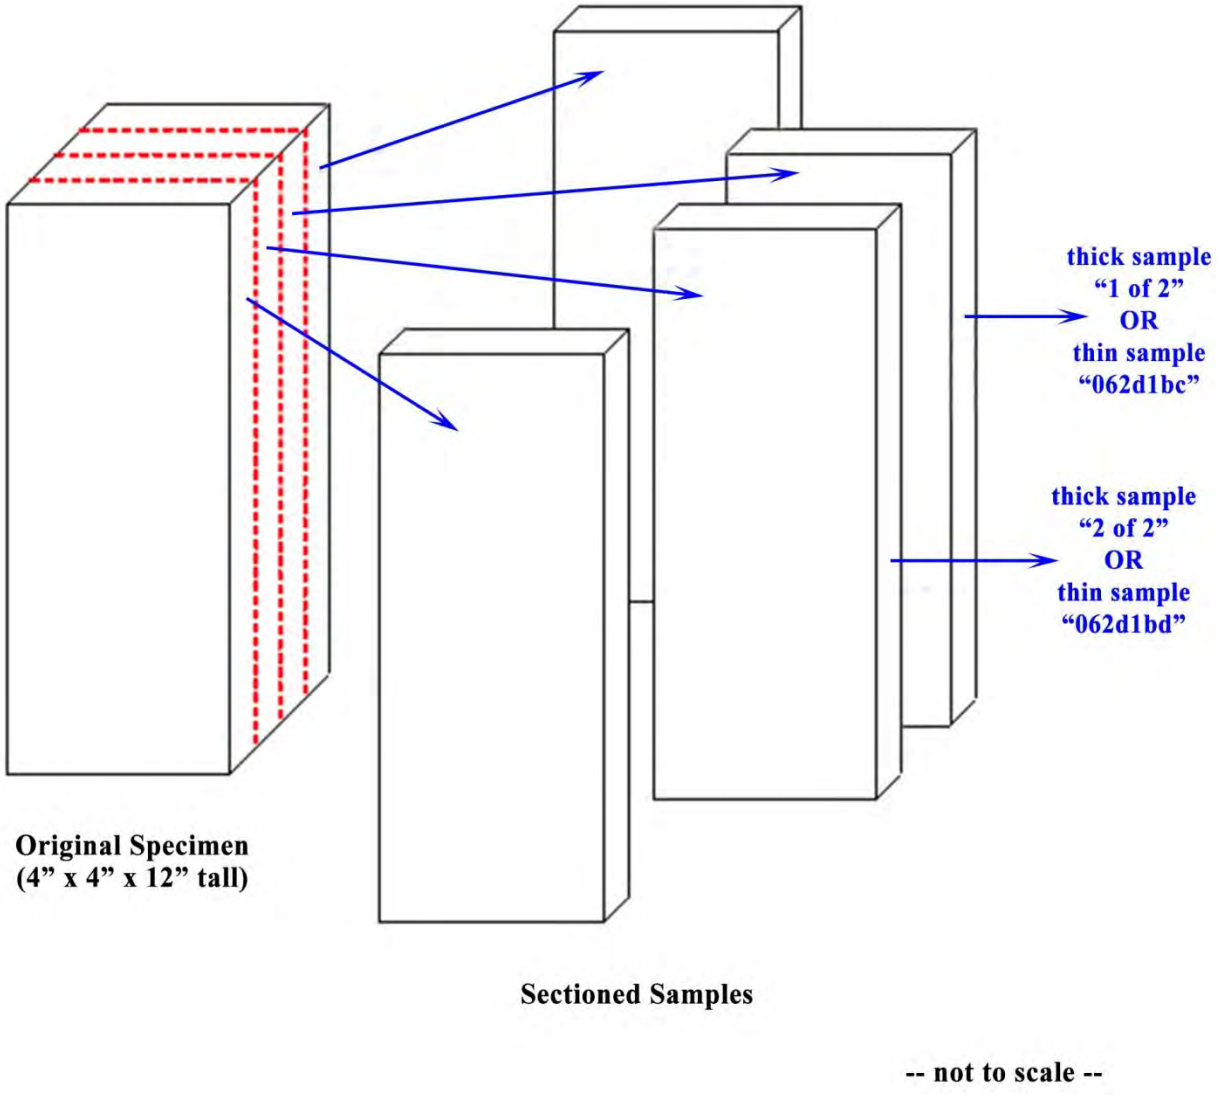

Fig. 6.9.4.2-1. Illustration of sectioning plan for borated ceramic samples for neutron radiography and neutron transmission measurements.

All four samples were qualitatively inspected for visual defects and subjected to neutron radiographic inspection. The inspections were intended to identify any variations in image luminance, which would indicate a variation in homogeneity and density. Neutron transmission measurements were calibrated to results for thin ZrB_2 reference coupons sandwiched with thick aluminum metal. The ^{10}B areal densities of the thin reference coupons ranged from 5.32 mg/cm^2 to 57.04 mg/cm^2 over a total ZrB_2 + Al reference thickness of 24.21–24.98 mm. By comparison, the thick samples contain an idealized ^{10}B areal density of 28.8 mg/cm^2 (i.e., 0.012 g/cm^3 over a 2.4-cm thickness), and the thin samples contain an idealized ^{10}B areal density of 14.4 mg/cm^2 (i.e., 0.012 g/cm^3 over a 1.2-cm thickness).

Radiographic examination of both thick samples "1 of 2" and "2 of 2" indicated uniformity of composition and density (see Fig. 6.9.4.2-2). Even after dehydration of thick sample "1 of 2," radioscopic examination indicated uniformity of composition and density. Initial neutron transmission results for both thick samples "1 of 2" and "2 of 2" indicated that neutron transmission was very low. In fact, the interference due to the hydrogen content implies an equivalent ^{10}B areal density measurement of ~67 ± 4 mg/cm^2. This is more than twice the actual physical value of 28.8 mg/cm^2. Only after thick sample of "1 of 2" is dehydrated and tested again do the results of neutron transmission measurements more accurately reflect the actual physical ^{10}B content. In fact, the average measured value of 27.419 mg/cm^2 at eleven points along the long axis of the dehydrated sample "1 of 2" is more than 95% of the actual physical value of 28.8 mg/cm^2 and varies no more than a few percent from one end to the other (see Tables 6.9.4.2-2 and 6.9.4.2-3).

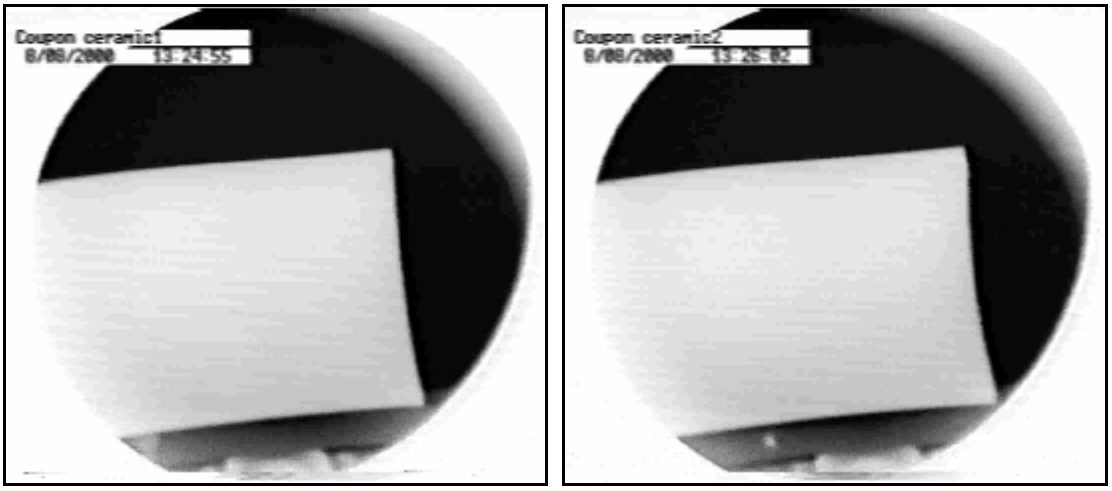

Fig. 6.9.4.2-2. Radiographic images of thick samples "1 of 2" (left) and "2 of 2" (right) indicating uniformity of composition and density.

Table 6.9.4.2-2. Results of neutron transmission measurements of thick samples

	Equivalent ^{10}B areal density (mg/cm^2)		
	End	**Center**	**End**
sample "1 of 2"	66.419	68.673	71.003
sample "2 of 2"	65.0	68.25	69.708
sample "1 of 2" (dehydrated)	27.586	27.191	28.555
sample "2 of 2" (re-test)	63.687	65.966	65.572

Table 6.9.4.2-3. Neutron transmission measurements of thick sample "1 of 2" after dehydration

Point of measurement (uniform intervals from one end to the other)	Equivalent ^{10}B areal density (mg/cm^2)	Deviation from average (%)
1	27.586	+0.6 %
2	26.909	-1.9 %
3	27.039	-1.4 %
4	27.358	-0.2 %
5	27.286	-0.5 %
6	27.191	-0.8 %
7	27.375	-0.2 %
8	27.179	-0.8 %
9	27.236	-0.7 %
10	27.897	-0.9 %
11	28.555	+4.1 %
Average	**27.419**	

Radiographic examination of both thin samples “062d1bc” and “062d1bd” indicates areas of nonuniformity and spots of lower neutron attenuation, along with greater dissimilarity between the samples themselves (see Fig. 6.9.4.2-3). Many of these areas and spots remained evident by radiographic examination even after dehydration of thin sample “062d1bc” and are attributed to physical voids revealed during visual inspection. Again, initial neutron transmission measurements implied a greater-than-actual equivalent ^{10}B areal density due to the interference of hydrogen (i.e., measured values averaged ~23.3 mg $^{10}B/cm^2$ rather than the actual value of 14.4 mg $^{10}B/cm^2$).

Measurements repeated after dehydration of sample “062d1bc” more correctly estimate the equivalent ^{10}B areal density to be ~11.1 mg/cm^2, which is ~77% of the actual physical ^{10}B content. Again, the relative values vary only a few percent from one end of the sample to the other (see Table 6.9.4.2-4). However, the measured values of a dehydrated sample in this case are known to be biased low. First, the total thicknesses of the ZrB_2 + Al reference coupons for calibration were ~24.21 to 24.98-mm compared to the 1.2-cm thickness of “062d1bc.” Second, the total mass density of the sample is ~1.4 to 1.5 g/cm^3 after dehydration compared to an Al mass density of ~2.7 g/cm^3 for the ZrB_2 + Al reference coupons. This indicates that even the performance of the thin samples (i.e., 1.2-cm thickness) exhibiting non-uniformity of composition and density is only marginally reduced from that of the idealized, homogeneous material model with respect to neutron absorber efficiency.

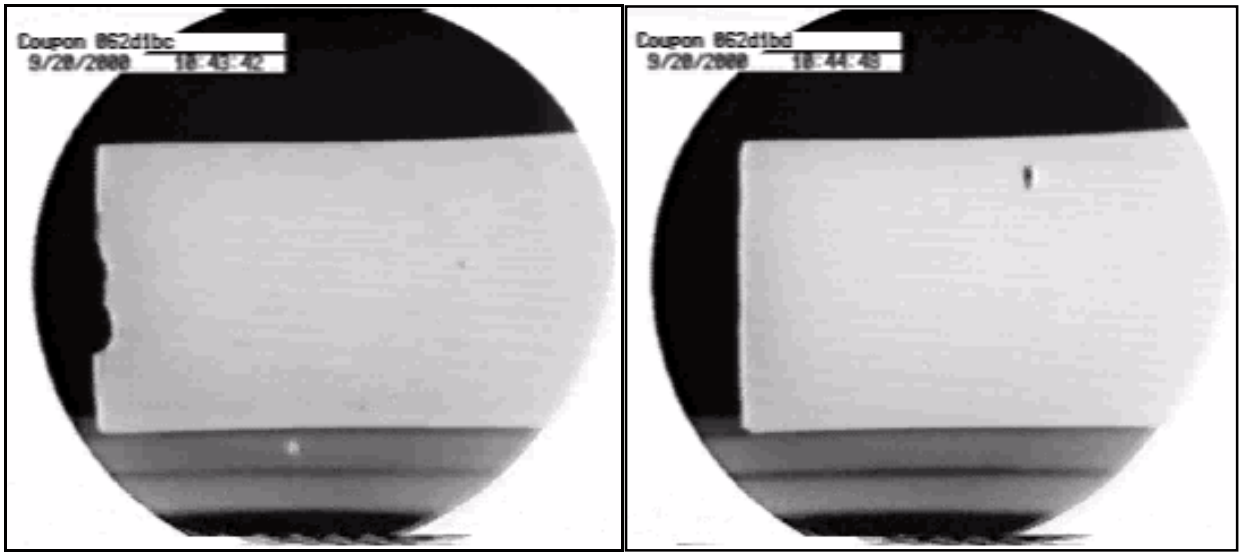

Fig. 6.9.4.2-3. Radiographic images of thin samples “062d1bc” (left) and “062d1bd” (right) indicating non-uniformity of composition and density and dissimilarity of samples.

6.9.4.2.3 Conclusions

Provided that 277-4 is prepared in a controlled manner to ensure the proper specification and proportioning of batch constituents, thorough mixing of the wet slurry, and correct placement and installation to prevent large physical voids, a credible technical justification exists to credit no less than 75% of the $^{nat}B_4C$ particulate and its other constituents, by weight, as an idealized homogeneous mixture for nuclear criticality safety analysis of the ES-3100. There is no evidence of non-homogeneity, neutron self-shielding effects, or neutron streaming effects in borated hydraulic cement or ceramic material systems for thicknesses of 2.4-cm or more. The qualification of 277-4 for use in the design and construction of the ES-3100 described herein is based on sound nuclear engineering principles and direct application of performance test results for such material systems.

Appendix 6.9.5
Miscellaneous Information and Data

Table 6.9.5.1 provides the atomic weights of the elements and isotopes of the materials used in this criticality safety evaluation. Atomic weights and isotopic weight percents of the naturally occurring materials are those taken from the Materials Information Processor in the SCALE Standard Composition Library.

Table 6.9.5.2 provides the molecular weights and weight percents of the corresponding elements and isotopes of the various compounds. The weight percents shown in this table are the input to KENO V.a (NUREG/CR-0200, Rev. 6).

Table 6.9.5.3 provides equations for determining atomic densities. These equations were derived based on the assumption that all constituents in the mixture are volume additive. Although these equations with their corresponding subscripts are for mixtures of elements, isotopes, or both, all except Equation (2) can be applied to compounds if the user substitutes certain subscript notations and meaning changes. For example, in Equations (1a) and (1b), the atomic weight becomes the molecular weight and the subscript "m" for mixture changes to the subscript "c" for compound. Likewise, in Equations (3a) and (3b), the atomic weight becomes the molecular weight, and the atom fraction (n_i) becomes the stoichiometric proportion of the elements making up the molecule. In Equations (3)–(5), the atom fraction (n_i) becomes the stoichiometric proportion (the element number subscript in the molecular formula), whose sum does not equal unity. Equation (2) is applicable only to the theoretical density of mixtures; it does not apply to the density of compounds.

Table 6.9.5.1. Atomic weights

Appendix 6.9.6
Abridged Summary Tables of Criticality Calculation Results

This appendix contains the summary tables for calculation results identified in Sects. 6.4, 6.5, 6.6, and 6.7 of this document. The CV calculation model is a modification of the water-reflected, single-unit package calculation model where the packaging regions external to the containment vessel are replaced with full density water. The index is as follows:

Cylinder Content

Table 6.9.6-1. Results for the 3.24 in.-diam cylinder HEU content in CV calculation model.

Table 6.9.6-1a. Results for cylinder C and D HEU content in CV calculation model.

Table 6.9.6-2. Results for the 3.24 in.-diam cylinder HEU content in bare and water reflected package calculation models.

Table 6.9.6-11d. Comparison of results for the 277-4 canned spacer under the nominal and minimal acceptance criteria for HEU broken metal content in ES-3100 HAC packaging calculation models

Note: Reference Cases **hciabmt12** selected from Table 6.9.6-11 are based for the nominal 277-4 canned spacer. These cases which establish loading limits were rerun with SCALE5, indicated as Cases **5hciabmt12** where case results are highlighted in yellow. The results for the corresponding Cases **5_401by131** for the 277-4 canned spacer sized per the minimal acceptance criteria are presented on the lines below. An absolute value of the quantity " **$(\Delta k_{eff}+2\sigma)/\sigma$** " >3 indicates that a statistically significant difference occurs between the case results.

5hciabmt12*	np (in.)	U (g)	^{235}U (g)	H_2O (g)	h/x	MOIFR	k_{eff}	σ	$k_{eff}+2\sigma$

Table 6.9.6-11d. Comparison of results for the 277-4 canned spacer under the nominal and minimal acceptance criteria for HEU broken metal content in ES-3100 HAC packaging calculation models

Note: Reference Cases **hciabmt12** selected from Table 6.9.6-11 are based for the nominal 277-4 canned spacer. These cases which establish loading limits were rerun with SCALE5, indicated as Cases **5hciabmt12** where case results are highlighted in yellow. The results for the corresponding Cases **5_401by131** for the 277-4 canned spacer sized per the minimal acceptance criteria are presented on the lines below. An absolute value of the quantity " **$(\Delta k_{eff}+2\sigma)/\sigma$** " >3 indicates that a statistically significant difference occurs between the case results.

5hciabmt12*	np (in.)	U (g)	^{235}U (g)	H_2O (g)	h/x	MOIFR	k_{eff}	σ	$k_{eff}+2\sigma$

Criticality Evaluation of Additional Content

This page intentionally left blank.

Appendix 6.9.8

Criticality Evaluation of Additional Content

This appendix presents the criticality safety evaluation of additional content for the ES-3100 package. Calculations presented herein were performed using the Monte Carlo CSAS25 criticality code sequence and 238-group ENDFB-V cross section library of SCALE 5.0 (NUREG/CR-0200, Rev. 7), executed on identical Hewlett Packard (HP) Model zx6000 Itanium workstations (CMODC and CMODD). Criticality calculations documented in Sects. 6.4–6.6 were performed using SCALE 4.4a (NUREG/CR-0200, Rev. 6) executed on an HP Model J5600 RISC workstation (CMODB). The obsolete CMODB with HP-UX 10.20 operating system was recently retired from service. No longer supported by the code developer, SCALE 4.4a is not portable to the updated computing platforms thus necessitating the use of SCALE 5.0.

SCALE5 incorporates minor improvements in the code modules for the Bondarenko and the Nordheim Integral Treatment processing of resonance cross sections and the KENO V.a module. Consequently, the USL used is validation dependent based on the SCALE-platform combination. The evaluation of the additional content based upon SCALE 5.0 calculations is documented in this appendix separate from the main body of Sect. 6 because this effort could not easily be folded into the existing SCALE 4.4a evaluation without inclusion of a patchwork of clarifications.

A variety of materials identified in Table 6.9.8.1-1 from various reactor programs, including bare, clad, or canned uranium metal alloy or oxide in various shapes as pellets, rods, plates, bundled components, fuel assemblies, and compounds will be shipped in the ES-3100 package.

6.9.8.1 Description of the Criticality Design

The design features of the ES-3100 package addressed in Sect. 6.1.1 are not changed. The same codes and standards addressed in Sect. 6.1.2 apply. No change is employed in the methodology for demonstrating maximum reactivity.

The criticality safety evaluation documented in this appendix is a cursory analysis of the proposed contents listed in Table 6.9.8.1-1. In addition to uranium compounds, these contents comprise a variety of reactor fuel components and scrap materials composed of clad HEU metal or metal hydride, HEU alloy or oxide, or clad HEU alloy. In most cases, the HEU present in the components or scrap represents a small portion of the total mass. Because the HEU fissile material mass loading limits for the ES-3100 are specified in terms of the ^{235}U mass (Table 6.2a), package loading capacities on the order of 35,200 g of content are conceivable as physical dimensions of the content permit. The shipping limits for the contents are derived limits bounded by limits established for similar content types evaluated in Sects. 6.4–6.6, or are less restrictive limits based on further investigation using explicit models of particular components and materials. The revised fissile mass loading limits for specific contents are presented in Table 6.9.8.1-2 for surface only modes of transportation. The CSI is assigned as described in Sect. 6.1.4.

6.9.8.2 The Additional Content for the ES-3100 Package

A variety of materials identified in Table 6.9.8.1-1 from various reactor programs, including bare, clad, or canned uranium metal alloy or oxide in various shapes as pellets, rods, plates, bundled components and fuel assemblies will be shipped in the ES-3100 package. The compounds of uranium identified in Table 6.9.8.1-1 included uranium tetrafluoride, uranyl fluoride, uranium carbide, and uranium nitride. The physical form of these uranium compounds is described as powder, beads, and ash. Both content moisture and content uniformity are not defined.

		≥40%, ≤60%	0	8.5 kg U_3Si-Al [k]	

[a] Content in solution form is not permitted for shipment in the ES-3100.
[b] All limits are expressed in g ^{235}U unless otherwise indicated.
[c] The mass loading limit cannot be rounded up.
[d] 277-4 can spacers as described on Drawing M2E801580A043 (Appendix 1.3.7) not required but are optional as dunnage.
[e] Non-uranium metallic constituents (e.g., aluminum, zirconium, or magnesium) are evaluated further in Appendix 6.9.11.
[f] As discussed in App. 6.9.11, the carbon limit of 921 g does not apply to HEU product oxide for ground transport.
[g] For SNAP $UZrH_x$, $x \leq 2$. For TRIGA $UZrH_x$, $x \leq 1.6$.
[h] Mass limits for alloys are evaluated further in Appendix 6.9.11.
[i] Mass limit is the most restrictive of the three values shown.
[j] Oxides of U-Zr are UO_2-Zr and UO_2-ZrO_2.
[k] No control on the amount of aluminum.

A general description of the Bulk Shielding Reactor-1 reveals that the core consisted of 30 subassemblies (MTR type stacked plates, 18 plates per subassembly), each subassembly with overall dimensions of 3.125 × 3 × 34.5 in., arranged into a parallelepiped with an active core ~15 × 18 × 24 in. The core contained 3,850-g ^{235}U (*Nuclear Reactor Plant Data*, Bulk Shielding Reactor, pp. 33–35).

A general description of the Oak Ridge Research Reactor reveals that the core consisted of 20–30 subassemblies (MTR type stacked plates, 19 plates per subassembly), each subassembly with overall dimensions of 3.015 × 3.15 × 38.375 in., arranged in 7 × 9 grid with an active core ~12 × 21 × 24 in. The core contained 3.5–4 kg ^{235}U (*Nuclear Reactor Plant Data*, Oak Ridge Research Reactor, pp. 102–110).

A general description of the Omega West Reactor reveals that the core consisted of 36 subassemblies (MTR type stacked plates, 18 plates per subassembly), each subassembly with overall dimensions of 2.966 × 3.069 × 30 in., arranged in 6 × 9 grid with an active core ~14 × 28 × 24 in. The core contained ~4-kg ^{235}U (Omega West Reactor).

Uranium tetrafluoride (UF_4), often called green-salt because of its characteristic color, is an intermediate product in the conversion of UF_6 to either uranium oxide (U_3O_8 or UO_2) or uranium metal. UF_4 is a solid composed of agglomerating particles with a texture similar to baking soda. It is non-volatile and non-hygroscopic, but only slightly soluble in water. After exposure to water, UF_4 slowly dissolves and undergoes hydrolysis, forming several possible uranium compounds and hydrogen fluoride (HF). The density of solid UF_4 is 6.7 g/cm^3.

Uranyl fluoride (UO_2F_2) is an intermediate product in the conversion of uranium hexafluoride (UF_6) to an uranium oxide. UO_2F_2 is a direct product of the reaction of UF_6 with moisture in the air. UO_2F_2 is very soluble in water and hygroscopic in air. It changes in color from brilliant orange to yellow after reacting with water. Deliquescence studies show that in room air (~50–60% relative humidity), deposits of UO_2F_2 reach an equilibrium point of hydration (H/U ≤ 4) with the formation of uranyl fluoride dihydrate ($UO_2F_2 \cdot 2H_2O$) [JE/ER-4]. UO_2F_2 is reported to be stable in air to 300°C, above which slow decomposition to U_3O_8 occurs. When heated to decomposition, UO_2F_2 emits toxic fluoride fumes. The densities for UO_2F_2 and $UO_2F_2 \cdot 2H_2O$ are 6.37 and 4.76 g/cm^3, respectively (Barber).

Uranium carbide is a hard refractive ceramic material. It comes in several stoichiometries (UC_x) such as uranium monocarbide (UC), uranium sesquicarbide (U_2C_3), and uranium dicarbide (UC_2). Typically, uranium carbide is used as a nuclear fuel in gas-cooled fast reactors. Uranium carbide is a dull, dark charcoal-gray or flat black colored powder. Theoretical densities for UC, U_2C_3, and UC_2 are 13.63, 12.7, and 11.3 g/cm^3, respectively.

Uranium nitride (UN) is a ceramic material with a high uranium density and melting point (2805°C). These properties make it suitable for both liquid-metal cooled reactor and in-core nuclear thermionic applications. One process for the production of UN powder is hydride-dehydride-nitride process where the starting material is oxide-free uranium metal. Material testing of isostatically pressed and sintered UN cylinders has revealed the presence of uranium sesquinitride (U_2N_3). The theoretical densities for UN and U_2N_3 are 14.32 and 11.24 g/cm^3, respectively. The fact that U_2N_3 has a lower density than UN and decomposes into UN and nitrogen gas at 900°C eliminates it as a potential reactor fuel (ORNL-4608).

Other uranium compounds consist primarily of finished tristructural-isotropic (TRISO) micro fuel particles; however, also included are pure/impure scrap materials generated during various stages of the manufacturing process. These materials have a ^{235}U assay $\leq$ 93.17% and are typically in a solid crystalline or granular form. A finished TRISO fuel particle consists of a kernel composed of UO_X (or sometimes UC or UCO) coated with four exterior layers of three isotropic materials. The four layers are a porous buffer layer made of carbon, followed by a dense inner layer of pyrolytic carbon (PyC), followed by a ceramic layer of SiC to retain fission products at elevated temperatures and to give the TRISO particle more structural integrity, followed by a dense outer layer of PyC. TRISO fuel particles are designed not to crack due to the stresses from processes (such as differential thermal expansion or fission gas pressure) at temperatures beyond 1600°C, and therefore can contain the fuel in the worst of accident scenarios in a properly designed reactor. TRISO fuel particles were originally developed in Germany for high-temperature gas-cooled reactors. Two current reactor designs are the pebble bed reactor (PBR) in which thousands of TRISO fuel particles are dispersed into graphite pebbles, and the prismatic-block gas-cooled reactor (such as the GT-MHR) in which the TRISO fuel particles are fabricated into compacts and placed in a graphite block matrix. Both of these reactor designs are very high temperature reactors (formally known as the high-temperature gas-cooled reactors).

The convenience cans, Teflon and polyethylene bottles, 277-4 canned spacers described in Sect. 6.2.2, and the packing materials described in Sect. 6.2.3 are not affected by inclusion of the package contents. Other than a reference made to Table 6.9.8.1-2, the Packing Content Loading Restrictions stated in Sect. 6.2.4 are unchanged.

6.9.8.3 General Considerations

General considerations expressed in Sect. 6.3 regarding both assumptions made about the ES-3100 packaging and the calculation methodology for the evaluation are maintained. No changes are required to the calculation models of the containment vessel (CV), the single-unit packaging (Sect. 6.3.1.1), the damaged packaging (Sect. 6.3.1.3), or the catastrophically-damaged packaging (Sect. 6.3.1.4). However, the array packaging calculation model used with some of the content models employs the explicit triangular-pitch geometry specification also used in the evaluation of small array configurations (Sect. 6.3.1.2). Both the ETP and the reduced diameter square-pitch configuration for simulating triangular pitch spacing in an array of packages yields acceptable (and comparable) results. Finally, the material properties specification for the content models are addressed in Sect. 6.9.8.3.2.

6.9.8.3.1 Model configuration for supplemental contents

Reactor Fuel Components and Scrap Materials

A variety of materials identified in Table 6.9.8.1-1 from various reactor programs include bare, clad or canned uranium metal alloy, and bare or clad HEU oxide. These items will be shipped in the ES-3100 package as pellets, rods, plates, bundled components and fuel assemblies. An assumed maximum of 500 g of polyethylene is included to represent hydrogenous packing material. Carbon coating on reactor fuel is not controlled. As shown in calculations in Appendix 6.9.11, adding carbon will reduce reactivity. In order to add carbon in the models, water must be removed to conserve volume. Water is a better moderator and reflector than carbon.

The calculation model for the U/Al fuel plates is based on the BR-2 MTR Type 2 fuel plate. Plate dimensions are 7.1 cm width × 0.1561 cm depth × 65.5 cm height based on data for the CNEA MTR Type 2 fuel. With an overall depth of 5.4627 cm, thirty-five BR-2 plates bundled together can be accommodated in the ES-3100 CV. Data for Bundle 29 provides the basis for the calculation model. The net weight is 7,309 g, the uranium mass is 525.19 g, and the ^{235}U mass is 473.09 g. Three loading configurations are analyzed for evaluation of the effect of plate separation. One configuration models a compact array of 35 fuel plates side-by-side inside the CV. The two other configurations model the plates with 0.06- and 0.12-cm separation between the plates. The bundle of plates intersect the CV wall at 0.18-cm separation between the plates.

The Massachusetts Institute of Technology (MIT) U/Al fuel plate aluminum cladding outer dimensions are 2.552-in. (6.48208-cm) wide × 0.08-in. (0.2032-cm) deep (thickness) × 23-in. (58.42-cm) high. An element consists of 15 MIT fuel plates with 0.082 in. (0.20828 cm) separation between plates for an overall depth (thickness) of 2.348 in. (5.96392 cm) for the 0.082-in. (as designed/built) separation. With the as-fabricated element/grid structure, only one MIT fuel element can be accommodated in the ES-3100 CV. If the MIT fuel plates were removed from the element structure and bundled together with no separation between plates, the bundle of plates would be ~1.2-in. (3.048-cm) thick. Since the designed separation distance between plates is slightly larger than the fuel plates themselves (0.082 and 0.080 in., respectively), up to 30 loose fuel plates could be bundled together; in this configuration, 30 plates would occupy approximately the same volume as 15 plates in the fuel element structure. For conservatism, the uranium is modeled as HEU at 94% enrichment [U(94)] and the remainder is modeled as aluminum. Given that ~525-g ^{235}U is present in the fuel element, the 3,597 g of U/Al in the 15 MIT fuel plates would contain 558.5-g U(94). For two sets of fuel element plates bundled together without the fuel element grid structure, the 30 fuel plates would have ~1,050-g ^{235}U [1,117-g U(94)]. The evaluation in Sect. 6.9.8.5.1 covers both a single intact MIT U/Al element with 15 fuel plates and a bundled arrangement of up to 30 MIT U/Al fuel plates.

A uranium silicide (U_3Si_2) fuel plate measures 2.79-in. (7.0866 cm) wide × 0.05-in. (0.127-cm) deep (thickness) × 25-in. (63.5-cm) high. The fuel is 0.02-in. thick with 0.015-in. thick cladding on all sides. A fuel element consists of twelve plates, each plate weighing 161.6 g and containing on average 12.5-g ^{235}U, 63.27-g U (19.7), 5.13-g Si, and 93.4 g of 6061-T0 aluminum cladding. The 12 fuel plates (net weight 1,942 g) bundled together contains 150-g ^{235}U [759-g U(19.7)]. A bundle of 36 fuel plates (net weight 5,825 g) contains 450-g ^{235}U [2,277-g U(19.7)]. U_3Si_2 fuel having similar dimensions and less fissile content is bounded by MIT U/Al fuel.

The evaluation of HEU oxide in Sects. 6.4.3, 6.5.3, and 6.6.3, focuses on product and skull oxides characterized as loose material with bulk densities ranging from 2.0 to 6.54 g/cm^3. Unlike bulk oxides, reactor components of HEU oxide consist of compressed, sintered pellets with densities approaching the theoretical 10.96 g/cm^3. Pellets measuring 1.25 in. in diameter and 3.5 in. in height are stacked into clad-tubing of various lengths. Calculation models consider both bare rods and rods clad with ~2-mil (0.002-in.) thickness of aluminum, stainless-steel or zirconium. Dimensions for a bare rod

are 1.8288 cm (0.7200 in.) in diameter and 63.5000 cm (25.0 in.) in length. Dimensions for a clad rod are 1.8388 cm (0.7239 in.) in diameter and 63.5100 cm (25.0039 in.) in length. Seven different rod arrangements shown in Figs. 6.9.8.3.1-1a through 6.9.8.3.1-1g are analyzed for determining the most reactive configuration. Twelve rods in the CV contain 19,308.9 g ^{235}U in 21,937.6 g UO_2. Additional cases were run with thorium oxide mixed with HEU oxide.

Other proposed contents are U/Al alloy fuel plates and Al-clad HEU fuel plates. Alloys of uranium are not explicitly evaluated in Sects. 6.4.1, 6.4.2, 6.5.1, 6.5.2, 6.6.1, and 6.6.2. Instead, the uranium alloy is conservatively assessed by counting the neutron scattering constituents (aluminum, molybdenum, zirconium, etc.) as multiplying media (^{235}U). When the aluminum alloy or aluminum component of a fuel plate is conservatively assumed to be 100 wt % ^{235}U, then the loading capacity is severely limited by limits given for HEU broken metal. The U/Al or aluminum clad plates are explicitly modeled as a homogenized mixture of 93% enriched uranium and aluminum distributed evenly throughout the plate.

A SNAP reactor fuel pin composed of $UZrH_2$ is ~1.25 in. in diameter and ~12.45 in. long. The calculation model for the TRIGA fuel ($UZrH_{1.6}$) was adapted for use by changing the pin dimensions, the enrichment to 93 wt % ^{235}U, and the hydrogen component from 1.6 to 2.0.

Uranium Compounds

UF_4, UO_2F_2, $UO_2F_2 \cdot 2H_2O$, U_3Si_2, and U_3Si powder are conservatively modeled as water soluble compounds like the UNH content (Sects. 6.4.4, 6.5.4, and 6.6.4). An assumed maximum of 500 g of polyethylene represents Teflon or polyethylene bottles, and hydrogenous material used for packing. A solution formed by UF_4, UO_2F_2, $UO_2F_2 \cdot 2H_2O$, U_3Si_2, or U_3Si powder dissolved in water fills the entire volume of the CV. The amounts of uranium compound and evaluation water in the CV determines the most reactive content condition. Both flooding of the CV and a partial load of uranium compound is required to achieve the most reactive configuration.

Uranium carbide, uranium nitride, and uranium silicide are known to have been fabricated into reactor fuel pellets, fuel plates, and cylinders as solid shapes. The physical form and the moisture content of these materials is not known. These uranium compounds are assumed to be a loose, granular or powdered material. UC, U_2C_3, UC_2, UN, U_3Si_2 , and U_3Si are conservatively modeled both as granular compounds like HEU oxide (Sects. 6.4.3, 6.5.3, and 6.6.3) and as water-soluble compounds like the UNH content (Sects. 6.4.4, 6.5.4, and 6.6.4). An assumed maximum of 500 g of polyethylene is included to represent hydrogenous packing material.

6.9.8.3.2 Content model material specifications

Material properties specification for the content models are presented in Table 6.9.8.3-1.

[a] The theoretical density input parameter is specified for each material such that the required (or desired) mass of material is represented in the KENO V.a calculation model. The mass of material is computed by KENO V.a as the product of the theoretical density input parameter times the volume fraction times the volume of the geometry region in which the material resides in the calculation model.

6.9.8.4 Computer Codes and Cross-Section Libraries

Calculations presented herein were performed using the Monte Carlo CSAS25 criticality code sequence and 238-group ENDFB-V cross section library of SCALE 5.0 (NUREG/CR-0200, Rev. 7), executed on identical Hewlett Packard (HP) Model zx6000 Itanium workstations (CMODC and CMODD) of the Y-12 Safety Analysis Engineering organization in Oak Ridge, Tennessee. Criticality calculations documented in Sects. 6.4–6.6 were performed using SCALE 4.4a (NUREG/CR-0200, Rev. 6) executed on an HP Model J5600 RISC workstation (CMODB). The obsolete CMODB with HP-UX 10.20 operating system was recently retired from service. SCALE 4.4a no longer supported by the code developer is not portable to the updated computing platforms thus necessitating the use of SCALE 5.0.

The SCALE 4.4a criticality codes and cross-section library are addressed in Sect. 6.3.3. The 238-group ENDF/B-V cross-section library used by SCALE 5.0 is unchanged from the previous version SCALE 4.4a. Also, most of the modular codes in CSAS25 control sequence of SCALE 5.0 are unchanged except for the cross-section processing functional module NITAWL-III.

NITAWL-III applies the Nordheim integral treatment to perform neutron cross-section processing in the resonance energy range for nuclides that have ENDF/B resonance parameter data. This technique involves the numerical integration of ENDF/B resonance parameters using a calculated flux distribution, which is based on the calculated collision density across each resonance and subsequent weighing of the reaction cross section to the desired broad group structure. In the CSAS sequence, NITAWL-III assembles the group-to-group transfer arrays from the elastic and inelastic scattering components and performs other tasks to produce a problem-dependent working cross-section library which can be used by KENO V.a.

As noted in the user manual, several extensions to the Nordheim calculation have been implemented into the algorithm contained in NITAWL-III:

- Elements containing more than one isotope can be treated.
- Self-shielding is applied to resonance scattering. Transfer matrices are adjusted.
- g-, f-, d-, and p-wave as well as s-wave levels can be treated.
- The asymptotic approximation for the flux in the thermal energy range is assumed to have a Maxwellian energy distribution.
- A refined procedure for generating the energy mesh over which reaction rates are integrated has been developed.

As with the SCALE 4.4a calculations, the k_{eff} values for each KENO V.a case are based on 500,000 neutron histories produced by running for 215 generations with 2,500 neutrons per generation and truncating the first 15 generations of data. The convergence of the KENO V.a calculation is related to trends in the average calculated k_{eff}. In general, the KENO V.a output table of k_{eff} by generation skipped is reviewed for trends. If no trends are observed, the calculation is accepted, and the reported value of k_{eff} is the one with the most neutron histories. There is usually no statistically significant difference between this result and the one with the smallest standard deviation.

No manual cross-section adjustment is performed for the criticality evaluation. Cross-section processing is performed automatically in the CSAS25 code sequence. Modeling the contents as precisely as possible improves the accuracy of cross-section processing.

The CSAS25 control module, the associated functional modules, the cross section library, and databases used in this evaluation reside in the verified configuration control area designated **/vcc/scale5** on CMODC and CMODD. Also, the computer input and output files for the criticality safety evaluation of the ES-3100 shipping package with the additional content reside in a configuration controlled area **/archive/sppkg_801940a002** on CMODC.

The criticality validation for SCALE 6.1.3 is based on benchmark experiments documented in the Organization for Economic Cooperation and Development (OECD) Handbook [NEA/NSC/DOC(95)03]. The USL without any safety margin—derived for the validation of CSAS5 control module of SCALE 6.1.3 with the multi-group V7-238-gr cross-section library run on ENGHPC workstation—is 0.9868 for thermal energy systems, 0.9852 for intermediate energy HEU systems, and 0.9886 for fast energy systems as documented in RP YAREA-F-0524. NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Using this safety margin, the USL for the calculations performed in this document would be 0.9368 for thermal energy systems, 0.9352 for intermediate energy systems, and 0.9386 for fast energy systems.

Calculations for U_3Si powder, U_3Si-Al powder, U_3Si_2-Al powder, and UO_2ThO_2 pellets were performed using the Monte Carlo CSAS5 and 238-group ENDF/B-VII (V7-238 gr) cross-section library of SCALE 6.1.3, executed on a Microway Parallel Linux Cluster ENGHPC at the Y-12 National Security Complex.

Several CSAS control modules are contained in SCALE 6.1.3. The CSAS control modules are designed to analyze systems containing fissile material and calculate the neutron multiplication factor (k_{eff}) of the system. The CSAS5 control module calls a series of utility modules and other functional modules to process the cross-section data before calling the KENO V.a functional module for calculating the k_{eff}. The modules associated with CSAS5 are:

- WORKER: This functional module interfaces between the AMPX master library contained in the SCALE code package and the AMPX working library used in KENO V.a.
- BONAMI: This functional module processes the unresolved resonance data contained in the master library and places it in the working library.
- PMC: This functional module uses point-wise continuous cross-section data to solve a one-dimensional equivalent problem producing a flux profile used for processing cross-section data.
- CENTRM: This functional module uses the flux profile calculated in PMC to collapse point-wise continuous cross-section data into the appropriate group structure producing a working library used in KENO V.a.
- KENO V.a: This functional module performs the three-dimensional Monte Carlo calculation using the cross-section library provided by the WORKER module.

The V7-238 gr cross-section library used to perform criticality calculations is a multigroup library containing 238 discrete neutron energy groups processed from the ENDF/B-VII continuous energy cross-section data.

The CSAS5 control module, the associated functional modules, the cross-section library, and databases used in this evaluation reside in the verified configuration control area designated **/vcc/scale6** on ENGHPC. The computer input and output files for the criticality safety evaluation of the ES-3100 package with the additional content also reside in a configuration control area **/wa9/archive/RP-801940-A001R3** on ENGHPC.

6.9.8.5 Single Package Evaluation (NCT and HAC)

The analyses presented in Sect. 6.4 demonstrate that the calculated $k_{eff} \pm 2\sigma$ values increase as a function of increasing MOIFR. Therefore, a fully flooded, reflected package is used to calculate the neutron multiplication factors for the single package analysis.

Reactor Fuel Components and Scrap Materials

6.9.8.5.1 U/Al fuel plates (Table 6.9.8.8-1a)

Uranium alloys may be loaded to the broken metal mass limits by assuming the mass of the alloy is all ^{235}U. An explicit evaluation is performed for deriving less restrictive limits for contents where the constituents of the alloy are predominately non-fissile.

The calculation model for bundled U/Al fuel plates at 93% enrichment is based on the BR-2 MTR Type 2 fuel plate described in Sect. 6.9.8.3.1. Four configurations were developed for the analysis. Case **5cvsrualfpt11p_1_1_15** represents a tight-packed bundle of 35 fuel plates side-by-side inside a flooded CV reflected on all sides by 30.48 cm water. A very small portion of the total 7,333 g of U/Al in a bundle is ^{235}U (~473 g). Cases **5cvsrualfpt11p_2_1_15**, **5cvsrualfpt11p_3_1_15**, and **5cvsrualfpt11p_4_1_15** model the plates with uniform spacing of 0.04 cm, 0.08 cm, and 0.116 cm separation between the plates, respectively. The calculated $k_{eff} \pm 2\sigma$ values range from 0.308 to 0.411. . 0.116 cm is the largest separation between the fuel plates that can be modeled without intersecting the CV.

Similarly, the NCT Cases **5ncsrualfpt11p_1_1_15**, **5ncsrualfpt11p_2_1_15**, **5ncsrualfpt11p_3_1_15,** and **5ncsrualfpt11p_4_1_15** model the U/Al plate configurations inside a flooded ES-3100 package with full water reflection. The calculated $k_{eff} \pm 2\sigma$ values range from 0.262 to 0.342. Comparison of NCT single package results with corresponding case results for the flooded, reflected CV demonstrates that ES-3100 packaging is not as an effective moderator as full water reflection.

HAC Cases **5hcsrualfpt12p_1_1_15**, **5hcsrualfpt12p_2_1_15**, **5hcsrualfpt12p_3_1_15**, and **5hcsrualfpt12p_4_1_15** model the U/Al plate configurations inside a damaged ES-3100 package with full water reflection. Comparison of HAC single package results with corresponding NCT results reaffirms that an insignificant difference is observed between the calculated $k_{eff} \pm 2\sigma$ values.

A single flooded, fully water reflected ES-3100 package, either undamaged or damaged, loaded with U/Al fuel plates (net weight 7,333 g) containing ~473 g of ^{235}U will remain adequately subcritical below the USL of 0.924.

Six loading configurations are analyzed for evaluation of the effect of plate separation for a 15-plate U/Al MIT fuel element. One configuration models a compact array of 15 fuel plates with no separation inside the CV. The five other configurations model the plates with 0.0508-, 0.127-, 0.20828-, 0.37338-, 0.442-, and 0.53594-cm. (maximum) separation between the plates. The two outermost plates would start to intersect the CV wall with larger separation distances between the plates.

Case **5cvcrmitfpt11p_1_1_15** represents a tight-packed bundle of 15 fuel plates face-to-face inside a flooded CV that is reflected on all sides by 30.48 cm of water. Cases **5cvcrmitfpt11p_2_1_15** through **5cvcrmitfpt11p_6_1_15** model the same plates with uniform spacing of 0.0508-, 0.127-, 0.20828-, 0.37338-, and 0.442-cm. separation between the plates, respectively. The calculated $k_{eff} \pm 2\sigma$ values range from 0.325 to 0.478. These same separation values are used in all of the other calculation models for the 15-plate MIT element evaluation.

Similarly, the NCT Cases **5ncsrmitfpt11p_1_1_15** through **5ncsrmitfpt11p_6_1_15** model the MIT fuel plate configurations inside a flooded ES-3100 package with full water reflection. The calculated $k_{eff} \pm 2\sigma$ values range from 0.300 to 0.426.

HAC Cases **5hcsrmitfpt12p_1_1_15** through **5hcsrmitfpt12p_6_1_15** model the MIT 15-plate configurations inside a damaged ES-3100 package with full water reflection. Comparison of HAC single package results with corresponding NCT results reaffirms that an insignificant difference is observed between the calculated $k_{eff} \pm 2\sigma$ values.

Two loading configurations are analyzed for evaluation of the effect of plate separation for a 30-plate bundle of MIT fuel. One configuration models a compact array of 30 fuel plates with no separation inside the CV. The other configuration models the plates with 0.119-cm. separation between the plates. The two outermost plates would start to intersect the CV wall with larger separation distances between the plates.

Case **5cvcr30mitfpt11p_1_1_15** represents a tight-packed bundle of 30 fuel plates face-to-face inside a flooded CV, which is reflected on all sides by 30.48-cm water. Case **5cvcr30mitfpt11p_6_1_15** models the same 30 plates with the maximum possible uniform spacing within the CV of 0.119-cm. separation between the plates. The calculated $k_{eff} \pm 2\sigma$ values for these two extremes are 0.354 and 0.451. These same separation values are used in all of the other calculation models for the evaluation of the 30-plate bundle of MIT U/Al fuel plates.

Similarly, the NCT Cases **5ncsr30mitfpt11p_1_1_15** and **5ncsrmitfpt11p_6_1_15** model the MIT fuel plate configurations inside a flooded ES-3100 package with full water reflection. The calculated $k_{eff} \pm 2\sigma$ values for these two extremes (tight-packed and maximum possible uniform spacing) are 0.263 and 0.369.

HAC Cases **5hcsr30mitfpt12p_1_1_15** and **5hcsr30mitfpt12p_6_1_15** model the MIT 30-plate bundle configurations inside a damaged ES-3100 package with full water reflection. Comparison of HAC single package results with corresponding NCT results reaffirms that an insignificant difference is observed between the calculated $k_{eff} \pm 2\sigma$ values.

A single flooded, fully water reflected ES-3100 package, either undamaged or damaged, loaded with a single MIT element consisting of 15 U/Al fuel plates (net weight 3,597 g) containing ~525 g of ^{235}U, or loaded with a bundle of up to 30 MIT fuel plates (net weight 7,194 g) containing ~1,050 g of ^{235}U, will remain adequately subcritical below the USL of 0.93680.

6.9.8.5.2 Reactor components of HEU oxide (Table 6.9.8.8-2)

Twelve UO_2 oxide rods in a CV are modeled to determine whether the clad or unclad rods are the most reactive. Case **5cvsroxt11_1_4_1_15** models unclad UO_2 rods as shown in Fig. 6.9.8.3.1-1d, while Case **5cvsroxt11p_1_4_1_15** models unclad UO_2 rods with 500 g of polyethylene. Case **5cvsroxt11_1_4_2_15** models Al-clad UO_2 rods. Case **5cvsroxt11_1_4_3_15** models Zr-clad rods. Case **5cvsroxt11_1_4_4_15** is for unclad UO_2 rods. The calculated $k_{eff} \pm 2\sigma$ values for unclad, Al-clad, SS304-clad, and Zr-clad UO_2 rods with no polyethylene range from 0.799 to 0.801. The unclad UO_2 rods are the most reactive configuration. Comparing the fuel rods with polyethylene, the CV and single package cases are slightly more reactive and the array calculations are essentially the same. All cases were well below the USL.

The single unit analysis is performed with unclad rods modeled in the various rod arrangements shown in Figs. 6.9.8.3.1-1a through 6.9.8.3.1-1g. For NCT Cases **5ncsroxt11_1_1_1_15** through **5ncsroxt11_1_7_1_15,** the calculated $k_{eff} \pm 2\sigma$ values range from 0.604 to 0.745. For HAC Cases **5hcsroxt12_1_1_1_15** through **5hcsroxt12_1_7_1_15**, the calculated $k_{eff} \pm 2\sigma$ values range from 0.603 to 0.750. Configuration "**UO2_D**" shown in Fig. 6.9.8.3.1-1d is the most reactive one represented by Cases **5ncsroxt11_1_4_1_15** and **5hcsroxt12_1_4_1_15**. A single flooded, fully water reflected ES-3100 package with up to 12 clad or unclad UO_2 fuel rods, each containing ~1,609 g of ^{235}U are adequately subcritical, below the USL of 0.924. Case **5ncsroxt11p_1_4_1_15** with unclad UO_2 rods with 500 g of polyethylene, are adequately subcritical, below the USL of 0.93520, with no difference between fuel rods with or without polyethylene.

Additional calculations were performed to exam the effect that ThO_2 would have on the UO_2 fuel rods. In this model, UO_2 is replaced with UO_2 in increments of 10% up to all of the fuel rod composed of ThO_2. The results of these calculations are found in Table 6.9.8.8-2. As more ThO_2 is substituted for UO_2, reactivity decreases. This is expected since thorium is not fissile, and as such has no subcritical limits in any ANSI/ANS standards or handbook data.

6.9.8.5.3 $UZrH_2$ fuel (Table 6.9.8.8-3)

SNAP fuel elements are modeled as 12.45-in.-tall cylinders of $UZrH_2$. The analysis assumes that three SNAP fuel elements each are packed into both the bottom and middle can locations, rather than the fuel being size reduced to fit into 10-in. or 8-3/4 in.-tall convenience cans. The top can location is assumed void. For calculations where canned spacers are modeled, two canned spacers are assumed present in the CV. For configurations where canned spacers are not used, the $UZrH_2$ content is assumed stacked end-to-end. The three cylinders of the active fuel are modeled in triangular-pitch configuration within a radial boundary of 4.25 in. The pitch used in the criticality calculation models for the NCT and HAC ground transport is 4.9809 cm (1.96 in.). Five hundred grams of polyethylene is modeled to represent the maximum amount of hydrogenous packing material in the CV.

NCT Cases **5ncsrsnapp_93_1_15_15** and **5ncsrsnapp_93_1_1_15** model the $UZrH_2$ cylinders inside a flooded or dry CV in flooded ES-3100 packaging under full water reflection. The calculated $k_{eff} \pm 2\sigma$ values are 0.571 and 0.283, respectively. Cases **5ncsrsnapp_93_2_15_15** and **5ncsrsnapp_93_2_1_15** model the presence of canned spacers. The calculated $k_{eff} \pm 2\sigma$ values are 0.544 and 0.264, respectively. Case **5ncsrsnap_93_1_1_15** (without polyethylene) has a $k_{eff} \pm 2\sigma$ values of 0.568, which is slightly less reactive than the polyethylene case.

HAC Cases **5hcsrsnapp_93_1_15_15** and **5hcsrsnapp_93_1_1_15** model the $UZrH_2$ cylinders inside a flooded or dry CV in flooded damaged ES-3100 packaging under full water reflection. The calculated $k_{eff} \pm 2\sigma$ values are 0.571 and 0.285, respectively. The 1.4-in.-thick canned spacers are modeled in Cases **5hcsrsnapp_93_2_15_15** and **5hcsrsnapp_93_2_1_15**. The calculated $k_{eff} \pm 2\sigma$ values are 0.545 and 0.265, respectively. Comparison of HAC single package results with corresponding NCT results reaffirms that an insignificant difference is observed between the calculated $k_{eff} \pm 2\sigma$ values. Case **5hcsrsnap_93_1_1_15** (without polyethylene) has a $k_{eff} \pm 2\sigma$ values of 0.569, which is slightly less reactive than the polyethylene case.

10 CFR 71.55(d)(2) requires the geometric form of a package's content not be substantially altered under the NCT. Also, 10 CFR 7155(e)(1) requires that the package be adequately subcritical under HAC with the package contents in the most reactive credible configuration. However, conclusions about damage to the fuel content cannot be extrapolated from test data because a mock (test weight) content rather than actual SNAP content is evaluated in the NCT and HAC tests of 10 CFR 71.71 and 10 CFR 71.73. Consequently, one way for addressing these requirements is to model the content in an extremely damaged condition and make a determination of subcriticality through a series of criticality calculations. Case **5ncsr9355d2p_1_15_15** models the $UZrH_2$ homogenized with the water of a flooded CV and dispersed over the free volume of the CV, where the undamaged ES-3100 packaging is flooded and reflected by 30.48 cm of water. Similarly, Case **5ncsrs9355d2p_1_1_15** and 5ncsrs9355d2p_1_15_15 models the $UZrH_2$ dispersed over the free volume of a dry CV of the ES-3100 packaging. The calculated $k_{eff} \pm 2\sigma$ values are 0.191 and 0.679, respectively.
Cases **5ncsr9355d2p_2_15_15** and **5ncsr9355d2p_2_1_15** model the presence of the canned spacers. The calculated $k_{eff} \pm 2\sigma$ values for these cases are 0.647 and 0.182, respectively. These results indicate that extremely damaged content is more reactive than the unaltered configuration. Nevertheless, each set of cases is adequately below the USL of 0.9352 and the requirement of 10 CFR 71.55(d)(2) is satisfied. Given that changes external to the CV due to HAC do no result in an appreciable change in neutron multiplication for the single package, similar results are expected for the cases demonstrating compliance

with 10 CFR 71.55(e)(1). Conclusions regarding compliance with 10 CFR 71.55(d)(2) equally apply regarding compliance with 10 CFR 71.55(e)(1).

A single flooded, fully water reflected ES-3100 package, either undamaged or damaged, loaded with $UZrH_2$ (net weight 11,164 g) containing ~857 g ^{235}U will remain adequately subcritical below the USL 0.93520.

6.9.8.5.4 UZr fuel plates

As an alloy, UZr fuel plates may be loaded to the broken metal mass limits by assuming the mass of the alloy is all uranium.

Uranium Compounds

UF_4, UO_2F_2, and $UO_2F_2 \cdot 2H_2O$ are conservatively modeled as water soluble compounds like the UNH content (Sects. 6.4.4, 6.5.4, and 6.6.4). UC, U_2C_3, UC_2, and UN are conservatively modeled both as granular compounds like HEU oxide (Sects. 6.4.3, 6.5.3, and 6.6.3) and as water-soluble compounds like the UNH content (Sects. 6.4.4, 6.5.4, and 6.6.4). An assumed maximum of 500 g of polyethylene represents Teflon or polyethylene bottles, and hydrogenous material used for packing.

6.9.8.5.5 UF compounds (Tables 6.9.8.8-5a, 6.9.8.8-5b)

Consider the flooded, water reflected CV with the UF_4 content in solution and homogenized with 500 g polyethylene. The UF_4 content ranges from 24,000 to 1,000 g. For Cases **5cvcrpuf4t11_24_15** through **5cvcrpuf4t11_1_15** (Table 6.9.8.8-5a), the $k_{eff} \pm 2\sigma$ values range from 0.863 to 0.709 and optimum concentration occurs at ~11,000 g UF_4 ($k_{eff} \pm 2\sigma = 0.890$).

Consider a single, flooded ES-3100 package loaded with UF_4 content in solution and homogenized with 500 g polyethylene. The UF_4 content ranges from 24,000 to 1,000 g. For Cases **5ncsrpuf4t11_24_15** through **5ncsrpuf4t11_1_15**, the $k_{eff} \pm 2\sigma$ values range from 0.747 to 0.629 and optimum concentration occurs at ~9,000 g UF_4 ($k_{eff} \pm 2\sigma = 0.783$). Given that the water-reflected CV is more reactive than the water-reflected package, the result for Case **5cvcrpuf4t11_11_15** is reported [10 CFR 71.55(b)].

Consider the flooded, water reflected CV with the UO_2F_2 content in solution and homogenized with 500 g polyethylene. The UO_2F_2 content ranges from 24,000 to 1,000 g. For Cases **5cvcrpuofct11_24_15** through **5cvcrpuofct11_1_15** (Table 6.9.8.8-5b), the $k_{eff} \pm 2\sigma$ values range from 0.851 to 0.710 and optimum concentration occurs at ~8,000 g UO_2F_2 ($k_{eff} \pm 2\sigma = 0.887$). Consider $UO_2F_2 \cdot 2H_2O$ content in solution and homogenized with 500 g polyethylene. The $UO_2F_2 \cdot 2H_2O$ content ranges from 24,000 to 1,000 g. For Cases **5cvcrpuofhct11_24_15** through **5cvcrpuofhct11_1_15** (Table 6.9.8.8-5b), the $k_{eff} \pm 2\sigma$ values range from 0.898 to 0.696 and optimum concentration occurs at ~14,000 g $UO_2F_2 \cdot 2H_2O$ ($k_{eff} \pm 2\sigma = 0.907$). Given that $UO_2F_2 \cdot 2H_2O$ is more reactive than UO_2F_2, calculations with $UO_2F_2 \cdot 2H_2O$ are bounding.

Consider a single, flooded ES-3100 package loaded with $UO_2F_2 \cdot 2H_2O$ content in solution and homogenized with 500 g polyethylene. For Cases **5ncsrpuofhct11_24_15** through **5ncsrpuofhct11_1_15** (Table 6.9.8.8-5b), the $k_{eff} \pm 2\sigma$ values range from 0.787 to 0.614 and optimum concentration occurs at ~14,000 g $UO_2F_2 \cdot 2H_2O$ ($k_{eff} \pm 2\sigma = 0.798$). The water-reflected CV is more reactive than the water-reflected package; therefore the result for Case **5cvcrpuofhct11_14_15** is reported [10 CFR 71.55(b)].

6.9.8.5.6 UC and UN compounds (Tables 6.9.8.8-6a, 6.9.8.8-6b)

Consider the flooded, water reflected CV with 500 g polyethylene homogenized with bulk saturated UC, U_2C_3, UC_2, or UN compound. These uranium compounds are evaluated over the range from 10,000 to 1,000 g. For Cases **5cvcrpuct11_1_10** through **5cvcrpuct11_1_1** (Table 6.9.8.8-6a), the $k_{eff} \pm 2\sigma$ values for UC content decrease from 0.945 to 0.648. For Cases **5cvcrpuct11_2_10** through **5cvcrpuct11_2_1**, the $k_{eff} \pm 2\sigma$ values for U_2C_3 decrease from 0.910 to 0.643. For Cases **5cvcrpuct11_3_10** through **5cvcrpuct11_3_1**, the $k_{eff} \pm 2\sigma$ values for UC_2 decrease from 0.901 to 0.637. For Cases **5cvcrpunt11_10** through **5cvcrpunt11_1** (Table 6.9.8.8-6b), the $k_{eff} \pm 2\sigma$ values for UN decrease from 0.909 to 0.646.

Consider a single ES-3100 package loaded with 500 g polyethylene homogenized with bulk saturated UC, U_2C_3, UC_2, or UN compound. These uranium compounds are evaluated over the range from 10,000 to 1,000 g. For Cases **5ncsrpuct11_1_10_15** through **5ncsrpuct11_1_1_15** (Table 6.9.8.8-6a), the $k_{eff} \pm 2\sigma$ values for UC content decrease from 0.814 to 0.575. For Cases **5ncsrpuct11_2_10_15** through **5ncsrpuct11_2_1_15**, the $k_{eff} \pm 2\sigma$ values for U_2C_3 decrease from 0.811 to 0.575. For Cases **5ncsrpuct11_3_10_15** through **5ncsrpuct11_3_1_15**, the $k_{eff} \pm 2\sigma$ values for UC_2 decrease from 0.802 to 0.570. For Cases **5ncsrpunt11_10_15** through **5ncsrpunt11_1_15** (Table 6.9.8.8-6b), the $k_{eff} \pm 2\sigma$ values for UN content decrease from 0.814 to 0.574. The water-reflected CV cases are more reactive than the corresponding cases for the water-reflected package.

Consider a single ES-3100 package loaded with 500 g polyethylene homogenized with 2,000 g bulk saturated UC or UN compound. The water inside the CV is varied from the flooded to the dry condition. For Cases **5ncsrpuct11_1_2_15** through **5ncsrpuct11_1_2_1** (Table 6.9.8.8-6a), the $k_{eff} \pm 2\sigma$ values for UC content decrease from 0.657 to 0.617. For Cases **5ncsrpunt11_2_15** through **5ncsrpunt11_2_1** (Table 6.9.8.8-6b), the $k_{eff} \pm 2\sigma$ values for UN content decrease from 0.657 to 0.615. These cases reveal that the addition of water in the void region of the CV above the homogenized water saturated content has little effect on neutron multiplication.

6.9.8.5.7 U_3Si_2 and U_3Si_2-Al powder (Tables 6.9.8.8-7a, 6.9.8.8-7b)

Consider the flooded, water-reflected CV loaded with 500-g polyethylene homogenized with bulk saturated U_3Si_2. This content is evaluated from 13,000- to 7,000-g U_3Si_2 over a density range of 7 to 2 g/cm^3. For Cases **5cvcrpdusit11_8_7_13_15** through **5cvcrpdusit11_8_2_13_15** (Table 6.9.8.8-7a), the $k_{eff} \pm 2\sigma$ values for U_3Si_2 content increase from 0.849 to 0.920 as the density decreases. For Cases **5cvcrdpust11_8_7_13_15** through **5cvcrdpust11_8_2_13_15** where the same content is dispersed over the internal volume of the CV, $k_{eff} \pm 2\sigma = 0.929$. The uniform configuration—a column of 8656-g water is mixed with 13-kg U_3Si_2 and 500-g polyethylene—is more reactive than the discrete configuration—13-kg U_3Si_2 (plus 5,490-g saturation water) and 500-g polyethylene separated from the 3,166 g of water filling the remaining volume of the CV.

For Cases **5cvcrdpusttt11_8_7_13_15** through **5cvcrpdusit11_8_7_7_15** (Table 6.9.8.8-7a), the $k_{eff} \pm 2\sigma$ values for U_3Si_2 content decrease from 0.929 to 0.915 as the mass of U_3Si_2 decreases from 13- to 7-kg U_3Si_2 .

For Cases **5cvcrpdusit11_8_7_13_15** through **5cvcrpdusit11_1_7_13_15** (Table 6.9.8.8-7a), the $k_{eff} \pm 2\sigma$ values decrease from 0.849 to 0.624 as the enrichment decreases from 100 to 19.7% in the content (13-kg U_3Si_2 plus 5,490-g saturation water and 500-g polyethylene). Similarly for Cases **5cvcrdpust11_8_7_13_15** through **5cvcrdpust11_1_7_13_15**, the $k_{eff} \pm 2\sigma$ values decrease from 0.929 to 0.763 where this content is dispersed over the CV. The same trend is evident in Cases **5cvcrdpust11_8_7_7_15** through **5cvcrdpust11_1_7_7_15** for a reduced amount of content, the $k_{eff} \pm 2\sigma$ values decrease from 0.915 to 0.724.

For Cases **5cvcrdpustt11_1_7_13_15** through **5cvcrpdusit11_1_7_7_15** (Table 6.9.8.8-7a), the $k_{eff} \pm 2\sigma$ values for U_3Si_2 content decrease from 0.763 to 0.724 as the mass of U_3Si_2 decreases from 13- to 7-kg U_3Si_2 at 19.7% enrichment.

Consider a single ES-3100 package loaded with 500-g polyethylene homogenized with bulk saturated U_3Si_2. This content is evaluated from 13,000- to 7,000-g U_3Si_2 over a density range of 7 to 2 g/cm^3. For Cases **5ncsrpdusit11_8_7_13_15** through **5ncsrpdusit11_8_2_13_15** (Table 6.9.8.8-7b), the $k_{eff} \pm 2\sigma$ values for U_3Si_2 content increase from 0.769 to 0.820 as the density decreases. For Cases **5ncsrdpust11_8_7_13_15** through **5ncsrdpust11_8_2_13_15** where the same content is dispersed over the internal volume of the CV, $k_{eff} \pm 2\sigma = 0.824$. For Cases **5ncsrdpust11_8_7_13_15** through **5ncsrdpust11_8_7_7_15** (Table 6.9.8.8-7b), the $k_{eff} \pm 2\sigma$ values for U_3Si_2 content decrease from 0.824 to 0.809 as the mass of U_3Si_2 decreases from 13- to 7-kg U_3Si_2.

For Cases **5ncsrpdusit11_8_7_13_15** through **5ncsrpdusit11_1_7_13_15** (Table 6.9.8.8-7b), the $k_{eff} \pm 2\sigma$ values decrease from 0.769 to 0.521 as the enrichment decreases from 100 to 19.7% in the content (13-kg U_3Si_2 plus 5,490-g saturation water and 500-g polyethylene). Similarly for Cases **5ncsrdpust11_8_7_13_15** through **5ncsrdpust11_1_7_13_15**, the $k_{eff} \pm 2\sigma$ values decrease from 0.824 to 0.662 where this content is dispersed over the CV. The same trend is evident in Cases **5ncsrdpust11_8_7_7_15** through **5ncsrdpust11_1_7_7_15** for a reduced amount of content, the $k_{eff} \pm 2\sigma$ values decrease from 0.809 to 0.633.

The same trend observed for the flooded reflected CV is apparent for the flooded reflected package; however, the water-reflected CV cases are more reactive than the corresponding cases for the water-reflected package. The result for Case **5cvcrdpust11_8_7_7_15** (Table 6.9.8.8-7a) is reported [10 CFR 71.55(b)].

Additional calculations were performed to determine the effect aluminum would have on the reactivity of U_3Si_2 powder. Parametric studes were performed for U_3Si_2 powder at an enrichment of 100%, varying the amount of aluminum from none up to 4 kg. The aluminum is modeled at the same bulk density as U_3Si_2, which is 2 g/cm^3. The results of these calculations can be found in Table 6.9.8.8-7a. As aluminum powder at the same bulk density as U_3Si_2 is added, reactivity decreases. Thus, the limits and controls for U_3Si_2 would bound this loading.

6.9.8.5.8 U_3Si and U_3Si-Al powder (Tables 6.9.8.8-7a, 6.9.8.8-7b)

Consider the flooded, water-reflected CV loaded with 500-g polyethylene homogenized with bulk saturated U_3Si. This content is evaluated from 4,000- to 14,000-g U_3Si at a density of 2 g/cm^3, since this density has shown to be the most reactive from previous calculations for compounds (see above sections). The results of these cases can be found in Table 6.9.8.8-7a. For U_3Si powder with 500 g of polyethylene at enrichment of 40% in a dry CV, for a CSI = 0, the most reactive case below the USL of 0.9352 is Case **cvcrdpus3sit11_2_6_1**, with a $k_{eff} + 2\sigma$ value of 0.826 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9368 is Case **cvcrdpu3sit11_2_6_1**, with a $k_{eff} + 2\sigma$ value of 0.706 for 14 kg of U_3Si. For a flooded CV, the most reactive case below the USL of 0.9352 is Case **cvcrdpus3sit11_2_6_15**, with a $k_{eff} + 2\sigma$ value of 0.829 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9352 is Case **cvcrdpu3sit11_2_6_15**, with a $k_{eff} + 2\sigma$ value of 0.838 for 14 kg of U_3Si.

For 60% enrichment in a dry CV, the most reactive case below the USL of 0.9352 is Case **cvcrdpus3sit11_3_6_1**, with a $k_{eff} + 2\sigma$ value of 0.859 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9352 is Case **cvcrdpu3sit11_3_6_1**, with a $k_{eff} + 2\sigma$ value of 0.738 for 14 kg of U_3Si. For a flooded CV, the

most reactive case below the USL of 0.9352 is Case **cvcrdpus3sit11_3_6_15**, with a k_{eff} + 2σ value of 0.860 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9352 is Case **cvcrdpu3sit11_3_6_15**, with a k_{eff} + 2σ value of 0.871 for 14 kg of U_3Si.

The results for Cases **cvcrdpu3sit11_2_6_15** and **cvcrdpu3sit11_3_6_15** (Table 6.9.8.8-7a) are reported [10 CFR 71.55(b)].

Consider a single ES-3100 package loaded with 500-g polyethylene homogenized with bulk saturated U_3Si. This content is evaluated from 4,000- to 14,000-g U_3Si at a density of 2 g/cm^3 since this density has shown to be the most reactive from previous calculations for compounds (see previous sections). The results of these cases can be found in Table 6.9.8.8-7b. For U_3Si powder with 500 g of polyethylene at enrichment of 40% in a dry CV, for a CSI = 0, the most reactive case below the USL of 0.9352 is Case **ncsrdpus3sit11_2_6_1**, with a k_{eff} + 2σ value of 0.716 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9352 is Case **ncsrdpu3st11_2_6_1**, with a k_{eff} + 2σ value of 0.563 for 14 kg of U_3Si. For a flooded CV, the most reactive case below the USL of 0.9352 is Case **ncsrdpus3sit11_2_6_15**, with a k_{eff} + 2σ value of 0.719 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9352 is Case **ncsrdpu3st11_2_6_15**, with a k_{eff} + 2σ value of 0.729 for 14 kg of U_3Si.

For 60% enrichment in a dry CV, the most reactive case below the USL of 0.9352 is Case **ncsrdpus3sit11_3_6_1**, with a k_{eff} + 2σ value of 0.751 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9352 is Case **ncsrdpu3st11_3_6_1**, with a k_{eff} + 2σ value of 0.597 for 14 kg of U_3Si. For a flooded CV, the most reactive case below the USL of 0.9352 is Case **ncsrdpus3sit11_3_6_15**, with a k_{eff} + 2σ value of 0.752 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9368 is Case **ncsrdpu3st11_3_6_15**, with a k_{eff} + 2σ value of 0.762 for 14 kg of U_3Si.

The results for Cases **ncsrdpu3st11_2_6_15** and **ncsrdpu3st11_3_6_15** (Table 6.9.8.8-7b) are reported [10 CFR 71.55(b)].

From the additional calculations performed to determine the effect aluminum would have on the reactivity of U_3Si_2 powder, we can conclude that this analysis will bound aluminum in U_3Si powder as well. Thus, the limits and controls for U_3Si would bound this loading.

6.9.8.6 Array Package Evaluation (NCT and HAC)

The analyses presented in Sects. 6.5 and 6.6 demonstrate that maximum reactivity occurs in an array of packages when the CV is flooded (MOCFR = 1.0) and the ES-3100 packaging is dry (MOIFR = 1e-04). A water fraction of MOIFR = 1e-04 pertains specifically to NCT or HAC packages where both the neutron poison of the body weldment liner inner cavity and the Kaolite are dry and both the recesses of the package external to the CV and the interstitial space between drums of the array do not contain any residual moisture.

The analyses presented in Sects. 6.4, 6.5, and 6.6 demonstrate that an insignificant difference is observed between the calculated k_{eff} ± 2σ values for undamaged packages in NCT and damaged packages in HAC. Therefore, the HAC array analysis is redundant and not fully developed in this appendix.

Reactor Fuel Components and Scrap Materials

6.9.8.6.1 U/Al fuel plates (Tables 6.9.8.8-1a, 6.9.8.8-1b)

As stated in Sect. 6.9.8.5.1, an explicit evaluation is performed for deriving less-restrictive loading limits for contents where the constituents of the U-Al alloy are predominately non-fissile. The infinite array packaging calculation model for bundled U/Al fuel plates at 93% enrichment is based on the BR-2 MTR Type 2 fuel plate described in Sect. 6.8.8.3.1. NCT Cases **5nciaualfpt11p_1_1_3**, **5nciaualfpt11p_2_1_3**, **5nciaualfpt11p_3_1_3, and 5nciaualfpt11p_4_1_3** model infinite arrays of undamaged ES-3100 packages with the U/Al plates uniformly spaced at 0.0 cm, 0.04 cm, 0.08 cm, and 0.116 cm separation between plates. The ES-3100 packaging is dry, while the CV with content is flooded. A water fraction of MOIFR = 1e-04 signifies dry NCT packaging where both the neutron poison of the body weldment liner inner cavity and the Kaolite are dry (in the as-manufactured condition) and both the recesses of the package external to the CV and the interstitial space between drums of the array do not contain any residual moisture. The calculated $k_{eff} \pm 2\sigma$ values range from 0.316 to 0.403.

HAC Cases **5hciaualfpt12p_1_1_3** through **5hciaualfpt12p_4_1_3** model the U/Al plate configurations inside damaged ES-3100 packages. The calculated $k_{eff} \pm 2\sigma$ values range from 0.315 to 0.403. Comparison of HAC array package results with corresponding HAC results reaffirms the insignificant difference observed between the calculated $k_{eff} \pm 2\sigma$ values.

Given that the results indicate adequate subcriticality below the USL of 0.924, ES-3100 packages loaded with U/Al fuel plates (net weight 7,333 g) containing ≤473 g of ^{235}U may be shipped under a CSI = 0.

The infinite array NCT Cases **5nciamitfpt11p_1_1_3** through **5nciamitfpt11p_6_1_3** model the MIT U/Al single element/15-plate configurations inside a flooded ES-3100 package with full water reflection. The calculated $k_{eff} \pm 2\sigma$ values range from 0.342 to 0.478.

HAC Cases **5hciamitfpt12p_1_1_3** through **5hciamitfpt12p_6_1_3** model the MIT single element/15-plate configurations inside a damaged ES-3100 package with full water reflection. Comparison of HAC single package results with corresponding NCT results reaffirms that an insignificant difference is observed between the calculated $k_{eff} \pm 2\sigma$ values.

The infinite array NCT Cases **5ncia30mitfpt11p_1_1_3** and **5ncia30mitfpt11p_6_1_3** model the 30 MIT U/Al fuel plates configurations inside a flooded ES-3100 package with full water reflection. The calculated $k_{eff} \pm 2\sigma$ values are 0.363 and 0.439.

HAC Cases **5hcia30mitfpt12_1_1_3** and **5hcia30mitfpt12_6_1_3** model the MIT 30-plate configurations inside a damaged ES-3100 package with full water reflection. Comparison of HAC single package results with corresponding NCT results reaffirms that an insignificant difference is observed between the calculated $k_{eff} \pm 2\sigma$ values.

Given that the results indicate adequate subcriticality below the USL of 0.924, ES-3100 packages loaded with one MIT U/Al element with 15 fuel plates (net weight 3,597 g) containing ~525-g ^{235}U or up to 30 bundled MIT U/Al fuel plates (net weight 7,194 g) containing ~1,050 g of ^{235}U may be shipped under a CSI = 0.

6.9.8.6.2 Reactor components of HEU oxide (Table 6.9.8.8-2)

Unclad UO_2 rods are used in the infinite array analysis like the single unit analysis. Each rod arrangement (Figs. 6.9.8.3.1-1a through 6.9.8.3.1-1g) is evaluated for confirmation that Configuration "**UO2_D**" is the most reactive one. For NCT Cases **5nciaoxt11_1_1_1_3** through **5nciaoxt11_1_7_1_3**, the calculated $k_{eff} \pm 2\sigma$ values range from 0.715 to 0.885. For HAC Cases **5hciaoxt12_1_1_1_15** through **5hciaoxt12_1_7_1_15,** the calculated $k_{eff} \pm 2\sigma$ values range from 0.708 to 0.877. The most reactive configuration is **UO2_D** represented by Cases **5nciaoxt11_1_4_1_15** and **5hciaoxt12_1_4_1_15**. Calculation results for the configurations evaluated indicate adequate subcriticality below the USL of 0.924. The ES-3100 packages loaded with 12 UO_2 (net weight 21,938 g) containing ≤ 19,308 g of ^{235}U may be shipped under a CSI = 0. Cases **5nciaoxt11_1_4_1_15** and **5hciaoxt12_1_4_1_15** were rerun with 500 g of polyethylene as was calculated in the CV and single unit cases. The calculated values for Cases **5nciaoxt11p_1_4_1_15** and **5hciaoxt12p_1_4_1_15** are adequately below the USL of 0.924, with little difference between fuel rods with or without polyethylene.

6.9.8.6.3 $UZrH_2$ fuel (Table 6.9.8.8-3)

NCT Cases **5nciasnapp_93_1_15_3** and **5nciasnapp_93_1_1_3** model infinite arrays of undamaged ES-3100 packages with $UZrH_2$ cylinders inside a flooded or dry CVs. The calculated $k_{eff} \pm 2\sigma$ values are 0.622 and 0.350, respectively. Cases **5nciasnapp_93_2_15_3** and **5nciasnapp_93_2_1_3** model the presence of canned spacers. The calculated $k_{eff} \pm 2\sigma$ values are 0.596 and 0.337, respectively.

HAC Cases **5hciasnapp_93_1_15_3** and **5hciasnapp_93_1_1_3** model infinite arrays of damaged ES-3100 packages with $UZrH_2$ cylinders inside a flooded or dry CVs. The calculated $k_{eff} \pm 2\sigma$ values are 0.6220 and 0.351, respectively. The 1.4-in.-thick canned spacers are modeled in Cases **5hciasnapp_93_2_15_3** and **5hcsrsnapp_93_2_1_3**. The calculated $k_{eff} \pm 2\sigma$ values are 0.595 and 0.336, respectively. Comparison of HAC single package results with corresponding NCT results reaffirms that an insignificant difference is observed between the calculated $k_{eff} \pm 2\sigma$ values.

Case **5ncia9355d2p_1_15_3** models infinite arrays of dry, undamaged ES-3100 packages with the $UZrH_2$ homogenized with the water of a flooded CV and dispersed over the free volume of the CV. Similarly, Case **5ncia9355d2p_1_1_3** models the $UZrH_2$ dispersed over the free volume of a dry CV of the dry ES-3100 packaging. The calculated $k_{eff} \pm 2\sigma$ values are 0.7878 and 0.2476, respectively. Cases **5ncia9355d2p_2_15_15** and **5ncia9355d2p_2_1_1**5 model the presence of the canned spacers. The calculated $k_{eff} \pm 2\sigma$ values for these cases are 0.7414 and 0.2331, respectively. These results indicate that extremely damaged content is more reactive than the unaltered configuration. Nevertheless, each set of cases is adequately below the USL of 0.924 and the requirement of 10 CFR 71.55(d)(2) is satisfied. Given that changes external to the CV due to HAC do no result in an appreciable change in neutron multiplication for the single package, similar results are expected for the cases demonstrating compliance with 10 CFR 71.55(e)(1). Conclusions regarding compliance with 10 CFR 71.55(d)(2) equally apply regarding compliance with 10 CFR 7155(e)(1).

Additional array cases were performed to exam the effect that 500 g of polyethylene will have on SNAP fuel elements. The original cases were rerun using SCALE 6.1.3 with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. Only the most reactive cases were rerun. The results of these cases are found in Tables 6.9.8.6-1 and 6.9.8.6-2.

Table 6.9.8.6-1. NCT Arrays, SNAP fuel, with and without 500-g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
5nciasnap_93_1_15_3	3 cylinders per can, two cans, no spacers or polyethylene	0.61809	0.00093	0.61995
5nciasnapp_93_1_15_3	3 cylinders per can, two cans, no spacers, 500 g polyethylene	0.62060	0.00068	0.62196
5nciasnap_93_2_15_3	3 cylinders per can, two cans, with spacers, no polyethylene	0.58957	0.00078	0.59113
5nciasnapp_93_2_15_3	3 cylinders per can, two cans, with spacers, 500 g polyethylene	0.59447	0.00062	0.59571

Table 6.9.8.6-2. HAC Arrays, SNAP fuel, with and without 500-g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
5hciasnap_93_1_15_3	3 cylinders per can, two cans, no spacers or polyethylene	0.61697	0.00068	0.61833
5hciasnapp_93_1_15_3	3 cylinders per can, two cans, no spacers, 500 g polyethylene	0.62101	0.00067	0.62235
5hciasnap_93_2_15_3	3 cylinders per can, two cans, with spacers, no polyethylene	0.58937	0.00063	0.59063
5hciasnapp_93_2_15_3	3 cylinders per can, two cans, with spacers, 500 g polyethylene	0.59389	0.00067	0.59523

From the result of the single package cases for SNAP fuel, modeling 500 g of polyethylene surrounding the HEU metal is slightly more reactive than no polyethylene.

Given that the results indicate adequate subcriticality below the USL of 0.924, ES-3100 packages loaded with $UZrH_2$ (net weight 11,164 g) containing ≤ 857 g ^{235}U may be shipped under a CSI = 0.

6.9.8.6.4 UZr fuel plates

As stated in Sect. 6.9.8.5.4, UZr fuel plates may be loaded to the broken metal mass limits by assuming the mass of the alloy is all ^{235}U.

6.9.8.6.5 UF compounds (Tables 6.9.8.8-5a, 6.9.8.8-5b)

Cases **5nciapuf4t11_24_1** through **5nciapuf4t11_24_15** (Table 6.9.8.8-5a) model infinite arrays of ES-3100 packages each loaded with 24,000 g UF_4 in solution and homogenized with 500 g polyethylene. The $k_{eff} \pm 2\sigma$ values decrease from 0.981 to 0.765 as the packaging external to the CV and the interstitial space between the packages of the array floods. Comparison of results for Cases **5ncsrpuf4t11_24_15** through **5nciapuf4t11_24_15** confirms that flooded packages in a flooded array are nearly neutronically isolated from each other.

Consider an array of flooded ES-3100 packages loaded with UF_4 content in solution and homogenized with 500 g polyethylene. The UF_4 content ranges from 5,000 to 1,000 g. For Cases **5nciapuf4t11_5_3** through **5nciapuf4t11_1_3**, the $k_{eff} \pm 2\sigma$ value decreases from 0.947 to 0.738.

Given that the results indicate adequate subcriticality below the USL of 0.924, ES-3100 packages loaded with 3000 g UF_4 containing ≤ 2,267 g ^{235}U may be shipped under a CSI = 0.

Cases **5nciapuofhct11_24_1** through **5nciapuofhct11_24_15** (Table 6.9.8.8-5b) model infinite arrays of ES-3100 packages each loaded with 24,000-g $UO_2F_2 \cdot 2H_2O$ in solution and homogenized with 500-g polyethylene. The $k_{eff} \pm 2\sigma$ values decrease from 1.048 to 0.813 as the packaging external to the CV and the interstitial space between the packages of the array floods. Comparison of results for Cases **5ncsrpuofhct11_24_15** and **5nciapuofhct11_24_15** confirms that flooded packages in a flooded array are nearly neutronically isolated from each other.

Consider an array of flooded ES-3100 packages loaded with $UO_2F_2 \cdot 2H_2O$ content in solution and homogenized with 500 g polyethylene. The $UO_2F_2 \cdot 2H_2O$ content ranges from 5,000 to 1,000 g. For Cases **5nciapuofhct11_5_3** through **5nciapuofhctt11_1_3**, the $k_{eff} \pm 2\sigma$ value decreases from 0.949 to 0.719.

Given that the results indicate adequate subcriticality below the USL of 0.924, ES-3100 packages loaded with 3000 g $UO_2F_2 \cdot 2H_2O$ containing ≤ 2,067 g ^{235}U may be shipped under a CSI = 0.

6.9.8.6.6 UC and UN compounds (Tables 6.9.8.8-6a, 6.9.8.8-6b)

As shown in Table 6.9.8.8-6a, UC content bounds the other forms of uranium carbide compounds. Consider an array of flooded ES-3100 packages loaded with UC content homogenized with 500 g polyethylene. For Cases **5nciapuct11_1_10_3** through **5nciapuct11_1_1_3**, the UC content is conservatively modeled as granular compound like HEU oxide. Over the range of 10,000 to 1,000 g UC, the $k_{eff} \pm 2\sigma$ value decreases from 0.914 to 0.577. For Cases **5nciadpuct11_1_10_15_3** through **5nciadpuct11_1_1_15_3**, the UC content is conservatively modeled as a water-soluble compound dispersed over the free volume of the CV, like the UNX, UF_4, UO_2F_2, and $UO_2F_2 \cdot 2H_2O$ contents. Over the range of 10,000 to 1,000 g UC, the $k_{eff} \pm 2\sigma$ value decreases from 1.031 to 0.785.

Given that the UC content may not be well characterized as bulk material like the HEU oxide content, the latter model is used for establishing the loading limits. On the basis of calculation results indicating adequate subcriticality below the USL of 0.924, ES-3100 packages loaded with 2,000 g UC, U_2C_3, or UC_2 containing ≤ 1,903 g ^{235}U may be shipped under a CSI = 0.

Consider an array of flooded ES-3100 packages loaded with UN content homogenized with 500 g polyethylene. For Cases **5nciapunt11_10_3** through **5nciapuct11_1_3**, the UN content is conservatively modeled as granular compound like HEU oxide. Over the range of 10,000 to 1,000 g UN, the $k_{eff} \pm 2\sigma$ value decreases from 0.927 to 0.578. For Cases **5nciadpunt11_10_15_3** through **5nciadpunt11_1_15_3**, the UN content is conservatively modeled as a water-soluble compound dispersed over the free volume of the CV. Over the range of 10,000 to 1,000 g UN, the $k_{eff} \pm 2\sigma$ value decreases from 1.027 to 0.780.

Given that the UN content may not be well characterized as bulk material like the HEU oxide content, the latter model is used for establishing the loading limits. On the basis of calculation results indicating adequate subcriticality below the USL of 0.924, ES-3100 packages loaded with 2,000 g UN containing ≤ 1,888 g ^{235}U may be shipped under a CSI = 0.

6.9.8.6.7 U_3Si_2 powder (Table 6.9.8.8-7c)

Consider an infinite array of ES-3100 packages loaded with saturated bulk U_3Si_2 content homogenized with 500 g of polyethylene in flooded CVs. The packaging external to the CVs and the interstitial void space between packages in the infinite array is assumed dry for maximizing neutronic interaction. For Cases **5nciapdusit11_8_7_13_3** through **5nciapdusit11_8_2_13_3** (Table 6.9.8.8-7c) where

13 kg of U_3Si_2 content is evaluated over a density range of 7 to 2 g/cm^3, the $k_{eff} \pm 2\sigma$ values increase from 0.831 to 0.963 as the density decreases. For Cases **5nciadpust11_8_7_13_3** through **5nciadpust11_8_2_13_3** where this same content is dispersed over the internal volume of the CV, $k_{eff} \pm 2\sigma = 1.037$. In the latter set of cases, the density of the saturated content does not have an effect on neutron multiplication because the amount of water within which the content is dispersed is constant.

For Cases **5nciapdusit11_8_2_13_3** through **5nciapdusit11_8_2_7_3** (Table 6.9.8.8-7c), the $k_{eff} \pm 2\sigma$ values for U_3Si_2 content decrease from 0.964 to 0.863 as the mass of U_3Si_2 decreases from 13 to 7 kg. Similarly for Cases **5nciadpust11_8_7_13_3** through **5nciadpust11_8_7_7_3** (Table 6.9.8.8-7c), the $k_{eff} \pm 2\sigma$ values decrease from 1.037 to 1.006. While the discrete configuration modeled in Cases **5nciapdusit11** indicates that potentially high content loadings can be achieved, the uniform configuration modeled in Cases **5nciadpust11** indicates the contrary.

For Cases **5nciapdusit11_8_2_13_3** through **5nciapdusit11_1_2_13_3**, the $k_{eff} \pm 2\sigma$ values decrease from 0.964 to 0.739 as the enrichment decreases from 100 to 19.7% in the content (13-kg U_3Si_2 plus 5,490-g saturation water and 500-g polyethylene). For Cases **5nciadpust11_8_7_13_3** through **5nciadpust11_1_7_13_3** where content is dispersed over the internal volume of the flooded CV, the $k_{eff} \pm 2\sigma$ values decrease from 1.037 to 0.7993.

The last set of cases presented in Table 6.9.8.8-7c ranks the results for the uniform content configuration model Cases **5nciadpust11** and corresponding discrete configuration model Cases **5nciapdusit11** according to decreased neutron multiplication factor. Given that the U_3Si_2 content may not be as well characterized as bulk HEU oxide content, the uniform model is used for establishing the loading limits. On the basis of calculation results indicating adequate subcriticality below the USL of 0.924, ES-3100 packages may be shipped under a CSI = 0 for:

(A) loading not exceeding 7-kg U_3Si_2 at enrichments ≥40% but ≤ 60% and

(B) loading not exceeding 13-kg U_3Si_2 at enrichments ~19.7 but < 40%.

Additional calculations were performed to determine the effect aluminum would have on the reactivity of U_3Si_2 powder. Parametric studes were performed for U_3Si_2 powder at an enrichment of 100%, varying the amount of aluminum from none up to 4 kg. The aluminum is modeled at the same bulk density as U_3Si_2, which is 2 g/cm^3. The results of these calculations can be found in Table 6.9.8.8-7c. As aluminum powder at the same bulk density as U_3Si_2 is added, reactivity decreases. Thus, the limits and controls for U_3Si_2 would bound this loading.

6.9.8.6.8 U_3Si powder (Table 6.9.8.8-7c)

Consider an infinite array of ES-3100 packages loaded with saturated bulk U_3Si content homogenized with 500 g of polyethylene in flooded CV. The packaging external to the CVs and the interstitial void space between packages in the infinite array is evaluated at a range of interstitial water moderation up to fully flooded. As expected, the dry condition was the most reactive for maximizing neutronic interaction. For U_3Si powder with 500 g of polyethylene at enrichment of 40% in a flooded CV, for a CSI = 0, the most reactive case below the USL of 0.9352 is Case **nciapdu3sit11_2_6_2**, with a $k_{eff} + 2\sigma$ value of 0.839 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9352 is Case **nciapdu3st11_2_6_2**, with a $k_{eff} + 2\sigma$ value of 0.904 for 14 kg of U_3Si.

For 60% enrichment in a flooded CV, the most reactive case below the USL of 0.9352 is Case **nciapdu3sit11_3_6_2**, with a $k_{eff} + 2\sigma$ value of 0.889 for 14 kg of U_3Si. For when U_3Si powder is dispersed over the internal volume of the CV, the most reactive case below the USL of 0.9368 is Case **nciapdu3st11_3_4_2**, with a $k_{eff} + 2\sigma$ value of 0.936 for 8.5 kg of U_3Si.

On the basis of calculation results indicating adequate subcriticality below the USL, ES-3100 packages may be shipped under a CSI = 0 for:

(A) loading not exceeding 8.5-kg U_3Si at enrichments ≥40% but ≤ 60% and

(B) loading not exceeding 14-kg U_3Si at enrichments ~19.7 but < 40%.

From the additional calculations performed to determine the effect aluminum would have on the reactivity of U_3Si_2 powder found in Section 6.9.8.5.7 (Table 6.9.8.8-7a), we can conclude that this analysis will bound aluminum in U_3Si powder as well. Thus, the limits and controls for U_3Si would bound this loading.

6.9.8.7 Benchmark Experiments and the Criticality Validation

The criticality validation for SCALE 5.0 is a repetition of the SCALE 4.4a validation based on benchmark experiments documented in the Organization for Economic Cooperation and Development (OECD) Handbook [NEA/NSC/DOC(95)03]. Validation cases for SCALE 4.4a were executed on an HP Model J5600 RISC workstation under the HP-UX 10.20 operating system. For SCALE 5.0, these same validation cases were executed on an HP Model zx6000 Itanium workstation (CMODC).

The validation of CSAS25 control module of SCALE 5.0 with the 238-group ENDF/B-V cross-section library is documented in Y/DD-1220 and Y/DD-1221. Like Y/DD-896/R1, Y/DD-1220 addresses the establishment of bias, bias trends, and uncertainty associated with the use of SCALE 5.0 for performance of criticality calculations. Like Y/DD-972R1, Y/DD-1221 addresses determining USL and for incorporating uncertainty and margin into this USL.

SCALE5 incorporates minor improvements in the code modules for the Bondarenko and the Nordheim Integral Treatment processing of resonance cross sections and the KENO V.a module. Consequently, the USL used is validation dependent based on the SCALE-platform combination. The evaluation of the contents based upon SCALE 5.0 calculations is documented in this appendix separate from the main body of Chap. 6 because this effort could not easily be folded into the existing SCALE 4.4a evaluation without inclusion of a patchwork of clarifications.

The USL is based on the non-parametric statistics-based lower tolerance limit (LTL) for greater than 0.99/99% where there is a probability of greater than 0.99 that 99% of the population is greater than a specified result, reduced by additional margin. From Table 1 of Y/DD-1221, the LTL combining bias and bias uncertainty is 0.974 for uranium systems, including HEU metal. Tables 4.2, 4.3, and 4.4 of Y/DD-1220 list the maximum (positive) and minimum (negative) biases for HEU (metal, compound, solution), IEU (metal, compound) and LEU (compound, solution) systems. Since the positive bias is conservatively treated as a "zero" bias in the validation analysis, the negative bias is applied to determine the USL for the systems. The minimum bias given for HEU, IEU, and LEU systems is given as −0.0230, −0.0055 and −0.0260, respectively.

The minimum bias given for HEU systems in Table 4.2 of Y/DD-1220 is -0.1423. However, this result is from one of the four k-infinite models which are somewhat different than the usual benchmark experiments. As discussed in Sect. 5.3 of Y/DD-1220, the four outlier results are for benchmark experiments that were modeled as infinite in extent, thereby amplifying the effects of imperfections in cross section data. The models also required additional interpretation and adjustment from the actual finite experimental configuration to create an infinite benchmark model. After eliminating outlier models from the bias determination, the minimum bias was determined to be -0.023 for HEU systems.

The global minimum bias results for these systems (−0.0260) is applied to all uranium enrichments. Ordinarily, the USL would be 0.954 where an additional margin of subcriticality of 0.02 is subtracted from the LTL of 0.974. However, NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Thus, the USL is equal to 0.95 plus the minimum bias (−0.026), giving a value of 0.924.

The criticality validation for SCALE 6.1.3 is based on benchmark experiments documented in the Organization for Economic Cooperation and Development (OECD) Handbook [NEA/NSC/DOC(95)03]. The USL without any safety margin—derived for the validation of CSAS5 control module of SCALE 6.1.3 with the multi-group V7-238-gr cross-section library run on ENGHPC workstation—is 0.9852 for intermediate energy HEU systems as documented in RP YAREA-F-0524. NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Using this safety margin, the USL for the calculations performed in this document would be 0.9368 for thermal energy systems, 0.9352 for intermediate energy systems, and 0.9386 for fast energy systems.

6.9.8.8 Calculation Results Tables

Tables 6.9.8.8-1a through 6.9.8.8-7c contain a summary of the calculation results for the additional contents to be shipped in the ES-3100 shipping package. Table 6.9.8.8-4 has been omitted until such time when the Uranium Zirconium alloys are explicitly modeled. Currently these content items are to be treated as broken metal and shipped under these limits accordingly.

Appendix 6.9.9
Criticality Evaluation for Increasing the Fissile Loading Limit for HEU Oxide

This page intentionally left blank.

Appendix 6.9.9
Criticality Evaluation for Increasing the Fissile Loading Limit for HEU Oxide

This appendix presents the criticality safety evaluation for increasing the fissile loading limit for highly enriched uranium (HEU) oxide content in the ES-3100 package using SCALE5 as the criticality analysis tool. Calculations presented herein were performed using the Monte Carlo CSAS25 [Criticality Safety Analysis Sequence] code and 238-group ENDFB-V cross section library of SCALE 5.0 (NUREG/CR-0200, rev. 7), executed on identical Hewlett Packard (HP) Model zx6000 Itanium workstations (CMODC and CMODD). Criticality calculations documented in Sects. 6.4 – 6.6 were performed using SCALE 4.4a (NUREG/CR-0200, rev. 6) executed on an HP Model J5600 RISC workstation (CMODB). The obsolete CMODB with HP-UX 10.20 operating system was recently retired from service. No longer supported by the code developer, SCALE 4.4a is not portable to the new computing platforms, thus necessitating the use of SCALE 5.0.

SCALE5 incorporates minor improvements in the code modules for the Bondarenko and the Nordheim Integral Treatment processing of resonance cross sections and the KENO V.a module. Consequently, the upper subcritical limit (USL) used is validation dependent based on the SCALE-platform combination. The criticality evaluation based upon SCALE 5.0 calculations is documented in this appendix separate from the main body of Sect. 6 because this new work could not easily be folded into the existing SCALE 4.4a evaluation without inclusion of a patchwork of clarifications.

6.9.9.1 Description of the Criticality Design

The design features of the ES-3100 package addressed in Sect. 6.1.1 are not changed. The same codes and standards apply. No change is employed in the methodology addressed in Sect. 6.1.2 for demonstrating maximum reactivity. The shipping limit for an ES-3100 package with HEU product oxide content having a bulk density $\geq$2.0 g/cm^3 is increased from 9,682 g ^{235}U to 12,323 g ^{235}U by specifying a CSI = 0.4. The CSI is assigned as described in Sect. 6.1.3. This administrative limit restricts the size of an array of packages, maintaining subcriticality for both the Normal Conditions of Transport (NCT) and Hypothetical Accident Conditions (HAC).

6.9.9.2 HEU Oxide Content for the ES-3100 Package

The criticality safety evaluation documented in this appendix pertains to HEU product oxide as described in Sect. 6.2.1, and Appendices 6.9.1 and 6.9.3. The convenience cans described in Sect. 6.2.2 and the packing materials described in Sect. 6.2.3 are not affected by the new fissile loading limit. The packing content loading restrictions stated in Sect. 6.2.4 are unchanged.

6.9.9.3 General Considerations

General considerations expressed in Sect. 6.3 regarding both assumptions made about the ES-3100 packaging and the calculation methodology for the evaluation are maintained. No changes are required to the calculation models of the containment vessel (CV), the single-unit packaging (Sect. 6.3.1.1), the infinite array and finite array packaging (Sect. 6.3.1.2), the damaged packaging (Sect. 6.3.1.3), or the catastrophically-damaged packaging (Sect. 6.3.1.4). The material properties specification for the HEU product oxide (Sect. 6.3.2) does not change.

6.9.9.4 Computer Codes and Cross-Section Libraries

Calculations presented in this appendix were performed using the Monte Carlo CSAS25 code and 238-group ENDFB-V cross section library of SCALE 5.0 (NUREG/CR-0200, rev. 7), executed on identical Hewlett Packard (HP) Model zx6000 Itanium workstations (CMODC and CMODD) of the Y-12 Safety

Analysis Engineering organization in Oak Ridge, Tennessee. Criticality calculations documented in Sects. 6.4–6.6 were performed using SCALE 4.4a (NUREG/CR-0200, rev. 6) executed on an HP Model J5600 RISC workstation (CMODB). The obsolete CMODB with HP-UX 10.20 operating system was recently retired from service. No longer supported by the code developer, SCALE 4.4a is not portable to the new computing platforms, thus necessitating the use of SCALE 5.0.

The SCALE 4.4a criticality codes and cross-section library are addressed in Sect. 6.3.3. The 238-group ENDF/B-V cross-section library used by SCALE 5.0 is unchanged from the previous version SCALE 4.4a. Also, most of the modular codes in CSAS25 control sequence of SCALE 5.0 are unchanged except for the cross-section processing functional module NITAWL-III.

NITAWL-III applies the Nordheim integral treatment to perform neutron cross-section processing in the resonance energy range for nuclides that have ENDF/B resonance parameter data. This technique involves the numerical integration of ENDF/B resonance parameters using a calculated flux distribution, which is based on the calculated collision density across each resonance and subsequent weighing of the reaction cross section to the desired broad group structure. In the CSAS code, NITAWL-III assembles the group-to-group transfer arrays from the elastic and inelastic scattering components and performs other tasks to produce a problem-dependent working cross-section library which can be used by KENO V.a.

As noted in the user manual, several extensions to the Nordheim calculation have been implemented into the algorithm contained in NITAWL-III:

- Elements containing more than one isotope can be treated.
- Self-shielding is applied to resonance scattering. Transfer matrices are adjusted.
- g-, f-, d-, and p-wave as well as s-wave levels can be treated.
- The asymptotic approximation for the flux in the thermal energy range is assumed to have a Maxwellian energy distribution.
- A refined procedure for generating the energy mesh over which reaction rates are integrated has been developed.

As with the SCALE 4.4a calculations, the k_{eff} values for each KENO V.a case are based on 500,000 neutron histories produced by running for 215 generations with 2,500 neutrons per generation and truncating the first 15 generations of data. The convergence of the KENO V.a calculation is related to trends in the average calculated k_{eff}. In general, the KENO V.a output table of k_{eff} by generation skipped is reviewed for trends. If no trends are observed, the calculation is accepted, and the reported value of k_{eff} is the one with the most neutron histories. There is usually no statistically significant difference between this result and the one with the smallest standard deviation.

No manual cross-section adjustment is performed for the criticality evaluation. Cross-section processing is performed automatically in the CSAS25 code. Modeling the contents as precisely as possible improves the accuracy of cross-section processing.

The CSAS25 control module, the associated functional modules, the cross section library, and databases used in this evaluation reside in the verified configuration control area designated **/vcc/scale5** on CMODC and CMODD. Also, the computer input and output files for the criticality safety evaluation of the ES-3100 shipping package with the additional/new content reside in a configuration control area **/archive/ylf717_Rev3PC1** on CMODC.

6.9.9.5 Single Package Evaluation (NCT and HAC)

The analysis presented in Sect. 6.4 demonstrates that $k_{eff} + 2\sigma$ increases with increasing MOIFR. Therefore, a model of a fully flooded, reflected package is used to calculate neutron multiplication factors for the single package analysis. The reference analysis reveals that a continuous decrease in $k_{eff} + 2\sigma$ occurs with decreasing fissile mass when density is held constant. Also, $k_{eff} + 2\sigma$ increases as the bulk density decreases for a fixed fissile mass, which is due to the increased moderation of the HEU oxide.

Cases **5ncsrpdoxt11_1_*n*_14** (Table 6.9.9.8-2) represents the NCT model of an ES-3100 package with 14 kg of HEU oxide (12,323 g ^{235}U). The parameter "***n***" ranging from 1 to 5, signifies oxide density values of 2.0, 3.0, 4.0, 5.0, and 6.54 g/cm^3, respectively. The $k_{eff} + 2\sigma$ values ranging from 0.810 to 0.752 are well below the USL value of 0.924.

Case **5cvcrpdoxt11_1_1_14_15)** (Table 6.9.9.8-1) models a reflected CV with 14 kg of HEU oxide at 2.0 g/cm^3. The $k_{eff} + 2\sigma$ value is ~0.1 greater in the reflected CV than in the corresponding reflected, flooded single package (Case **5cvcrpdoxt11_1_1_14_15)**. This result is consistent with the reference evaluation of Sect. 6.4.

Cases **5hcsrpdoxt12_1_*n*_14** (Table 6.9.9.8-2) represents the HAC model of the damaged ES-3100 package, where the outer dimensions of the package are reduced accordingly and the entire package is flooded except the neutron poison of the body weldment liner inner cavity. The $k_{eff} + 2\sigma$ values range from 0.811 to 0.757. The changes in both the outer dimensions of the package and the compositions of the Kaolite and 277-4 due to HAC result in a ≤0.004 change in the neutron multiplication factor, also consistent with the reference evaluation of Sect. 6.4.

6.9.9.6 Array Package Evaluation (NCT and HAC)

The infinite array analyses presented in Sects. 6.5 and 6.6 demonstrate that the CSI is 0.0 for ES-3100 packages having product oxide content with a bulk density ≥2.0 g/cm^3 and with a maximum of 9,682 g ^{235}U. Case result presented in Table 6.9.9.8-3 substantiate this conclusion.

The array analyses presented in Sects. 6.5 and 6.6 also demonstrate maximum reactivity occurs in an array of packages when both the CV is flooded (MOCFR = 1.0) and the ES-3100 packaging is dry (MOIFR = 1e-04). A water fraction of MOIFR = 1e-04 pertains specifically to NCT or HAC packages where both the neutron poison of the body weldment liner inner cavity and the Kaolite are dry and both the recesses of the package external to the CV and the interstitial space between drums of the array do not contain any residual moisture. Therefore, the ES-3100 package model consisting of dry packaging and flooded CV is used for the finite array package analysis as required for establishing a non-zero CSI value.

Cases **5ncf1pdoxt11_1_*n*_15_3** through **5ncf1pdoxt11_1_*n*_11_3** (Table 6.9.9.8-4) represent a 13 × 13 × 6 array of NCT packages. The content mass ranges from 15 kg of HEU oxide (13,203 g ^{235}U) to 11 kg of HEU oxide (9,682 g ^{235}U). Case parameter "***n***" ranging from 1 to 5, signifies oxide density values of 2.0, 3.0, 4.0, 5.0, and 6.54 g/cm^3, respectively. Likewise, Cases **5hcf2pdoxt12_1_*n*_15_3** through **5hcf2pdoxt12_1_*n*_11_3** (Table 6.9.9.8-4) represent a 9 × 9 × 4 array of HAC packages. These finite array configurations support the assignment of a CSI = 0.4. (Cases **5ncf1pdoxt11_1_1_15_3** and **5hcf2pdoxt12_1_1_15_3** are not evaluated because the capacity of the convenience cans is exceeded for the 15 kg oxide loading at a density of 2.0 g/cm^3.)

As expected, the neutron multiplication factor for the finite array configurations of ES-3100 packages with HEU product oxide decreases as a function of decreasing ^{235}U mass. Also, calculation results for the parametric cases reveal the same continuous increase in the $k_{eff} + 2\sigma$ values with decreasing bulk density as observed in both the single package calculation results (Sect. 6.4.3) and infinite array calculation results (Table 6.9.9.8-4). Given that the $k_{eff} + 2\sigma$ values are below the USL of 0.924, ES-3100

packages may be shipped under a CSI = 0.4 for ES-3100 packages having HEU product oxide content with a bulk density ≥2.0 g/cm^3 and with a maximum of 12,323 g ^{235}U.

6.9.9.7 Benchmark experiments and the criticality

The criticality validation for SCALE 5.0 is a repetition of the SCALE 4.4a validation based on benchmark experiments documented in the Organization for Economic Cooperation and Development (OECD) Handbook. [NEA/NSC/DOC(95)03] Validation cases for SCALE 4.4a were executed on an HP Model J5600 RISC workstation under the HP-UX 10.20 operating system. For SCALE 5.0, these same validation cases were executed on an HP Model zx6000 Itanium workstation (CMODC).

The validation of CSAS25 control module of SCALE 5.0 with the 238-group ENDF/B-V cross-section library is documented in Y/DD-1220 and Y/DD-1221. Like Y/DD-896/R1, Y/DD-1220 addresses the establishment of bias, bias trends, and uncertainty associated with the use of SCALE 5.0 for performance of criticality calculations. Like Y/DD-972R1, Y/DD-1221 addresses determining USL and for incorporating uncertainty and margin into this USL.

SCALE 5.0 incorporates minor improvements in the code modules for the Bondarenko and the Nordheim Integral Treatment processing of resonance cross sections and the KENO V.a module. Consequently, the USL used is validation dependent based on the SCALE-platform combination. The evaluation of additional/new contents based upon SCALE 5.0 calculations is documented in this appendix separate from the main body of Chap. 6 because this new work could not easily be folded into the existing SCALE 4.4a evaluation without inclusion of a patchwork of clarifications.

The USL is based on the non-parametric statistics-based lower tolerance limit (LTL) for greater than 0.99/99% where there is a probability of greater than 0.99 that 99% of the population is greater than a specified result, reduced by additional margin. From Table 1 of Y/DD-1221, the LTL combining bias and bias uncertainty is 0.974 for uranium systems, including HEU metal. Tables 4.2, 4.3, and 4.4 of Y/DD-1220 list the maximum (positive) and minimum (negative) biases for HEU (metal, compound, solution), IEU (metal, compound) and LEU (compound, solution) systems. Since the positive bias is conservatively treated as a "zero" bias in the validation analysis, the negative bias is applied to determine the USL for the systems. The minimum bias given for HEU, IEU, and LEU systems is −0.0230, −0.0055 and −0.0260, respectively.

The minimum bias given for HEU systems in Table 4.2 of Y/DD-1220 is -0.1423. However, this result is from one of the four k-infinite models which are somewhat different than the usual benchmark experiments. As discussed in Sect. 5.3 of Y/DD-1220, the four outlier results are for benchmark experiments that were modeled as infinite in extent, thereby amplifying the effects of imperfections in cross section data. The models also required additional interpretation and adjustment from the actual finite experimental configuration to create an infinite benchmark model. After eliminating outlier models from the bias determination, the minimum bias was determined to be -0.023 for HEU systems.

The global minimum bias results for these systems (−0.0260) is applied to all uranium enrichments. Ordinarily, the USL would be 0.954 where an additional margin of subcriticality of 0.02 is subtracted from the LTL of 0.974. However, NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Thus, the USL is equal to 0.95 plus the minimum bias (−0.026), giving a value of 0.924.

6.9.9.8 Calculation results tables for additional/new contents

Tables 6.9.9.8-1 through 6.9.9.8-4 contain a summary of the calculation results for the additional/new contents to be shipped in the ES-3100 shipping package.

Appendix 6.9.10
Criticality Evaluation of HEU Oxide Product Content for Air Transportation

This page intentionally left blank.

Appendix 6.9.10
Criticality Evaluation of HEU Oxide Product Content for Air Transportation

Highly enriched uranium (HEU) product oxides (UO_2, UO_3, and U_3O_8), HEU product oxides mixed with thorium oxide, HEU product oxides mixed with zirconium oxide, and HEU product oxides mixed with thorium metal are evaluated as ES-3100 package contents for ground transport in Sects. 6.4 through 6.6. The criticality safety evaluation presented in this appendix is required for the approval of these oxides as a package content under the air transport mode. This analysis is simply an extension of the analysis presented in Sect. 6.7 for HEU metal. The catastrophically damaged package calculation models for HEU described in Sect. 6.3.1.4 for metal content were modified to address HEU product oxide under the air transport mode. Calculations presented in this appendix were performed using the Monte Carlo CSAS5 criticality code sequence and 238-group ENDF/B-VII (V7-238 gr) cross-section library of SCALE 6.1.3.

The criticality validation for SCALE 6.1.3 is based on benchmark experiments documented in the Organization for Economic Cooperation and Development (OECD) Handbook [NEA/NSC/DOC(95)03]. The USL without any safety margin—derived for the validation of CSAS5 control module of SCALE 6.1.3 with the multi-group V7-238-gr cross-section library run on ENGHPC workstation—is 0.9852 for intermediate energy HEU systems and 0.9868 for thermal energy systems as documented in RP YAREA-F-0524 (note there were no fast systems in these calculations). NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Using this safety margin, the USL for the calculations performed in this document would be 0.9368 for thermal energy systems, 0.9352 for intermediate energy systems, and 0.9386 for fast energy systems.

6.9.10.1 Description of the Criticality Design

Changes to the design features of the ES-3100 package addressed in Sect. 6.1.1 are not required for air transport. However, the total free water permitted in the Kaolite is limited to 12 lb (5,443.1 g) as in the case of HEU metal content assuming the containment vessel (CV) well and other void spaces external to the CV are dry. The codes and standards addressed in Sect. 6.1.2 apply to HEU product oxide as a package content for air transport. Moreover, the methodology for demonstrating maximum reactivity is not changed. The fissile mass loading limits for these contents are presented in Tables 6.9.10.1-1 through 6.9.10.1-4 and 6.2b for the air mode of transportation. Finally, the assignment of the criticality safety index (CSI) as to the ES-3100 package as described in Sect. 6.1.4 is unchanged.

6.9.10.2 The HEU Product Oxide Contents for the ES-3100 Package for Air Transport

HEU product oxide content for shipment by air in the ES-3100 is identified in Table 6.9.10.1-1. Physically, these uranium oxides (UO_2, UO_3, and U_3O_8) are non-rigid, bulk material in loose, granular, or powdered form. These oxides may also be mixed with ThO_2, ZrO_2, and thorium metal and are evaluated under different limits. Both content moisture and content uniformity are undefined. The convenience cans, Teflon and polyethylene bottles, 277-4 canned spacers described in Sect. 6.2.2, and the packing materials described in Sect. 6.2.3 are not affected by inclusion of HEU product oxide as a package content for air transport. The Packing Content Loading Restrictions stated in Sect. 6.2.4 are unchanged.

Table 6.9.10.1-1. HEU product oxide content loadings limits [a, b, c, d]

Detailed description	Assay (wt % ^{235}U)	^{235}U wt (g)
5.0 g/cm^3 ≤ density ≤ 6.54 g/cm^3	≤100	7,570
4.0 g/cm^3 ≤ density < 5.0 g/cm^3	≤100	6,020
3.0 g/cm^3 ≤ density < 4.0 g/cm^3	≤100	4,750
2.0 g/cm^3 ≤ density < 3.0 g/cm^3	≤100	3,380
1.5 g/cm^3 ≤ density < 2.0 g/cm^3	≤100	2,770
1.0 g/cm^3 ≤ density < 1.5 g/cm^3	≤100	2,150

[a] The mass loading limit cannot be rounded up.
[b] Content in solution form is not permitted for shipment in the ES-3100. Content may be a combination of UO_2, UO_3, U_3O_8, U_3O_8-Al, UO_2-Mg.
[c] 277-4 can spacers as described on Drawing M2E801580A043 (Appendix 1.3.7) are not required but are optional.
[d] Non-uranium metallic constituents (e.g., aluminum , zirconium, or magnesium) are evaluated further in Appendix 6.9.11.

Table 6.9.10.1-2. HEU product oxide mixed with thorium oxide content loadings limits [a, b, c, d]

Detailed description	Assay (wt % ^{235}U)	^{235}U wt (g)
5.0 g/cm^3 ≤ density ≤ 6.54 g/cm^3	≤100	7,570
4.0 g/cm^3 ≤ density < 5.0 g/cm^3	≤100	6,020
3.0 g/cm^3 ≤ density < 4.0 g/cm^3	≤100	4,480
2.0 g/cm^3 ≤ density < 3.0 g/cm^3	≤100	2,460
1.5 g/cm^3 ≤ density < 2.0 g/cm^3	≤100	1,580
1.0 g/cm^3 ≤ density < 1.5 g/cm^3	≤100	1,140

[a] The mass loading limit cannot be rounded up.
[b] Content in solution form is not permitted for shipment in the ES-3100. Content may be a combination of product oxides (UO_2, UO_3, U_3O_8) mixed with ThO_2.
[c] 277-4 can spacers as described on Drawing M2E801580A043 (Appendix 1.3.7) are not required but are optional.
[d] Non-uranium metallic constituents (e.g., aluminum , zirconium, or magnesium) are evaluated further in Appendix 6.9.11.

Table 6.9.10.1-3. HEU product oxide mixed with zirconium oxide content loadings limits [a, b, c, d]

Detailed description	Assay (wt % ^{235}U)	^{235}U wt (g)
5.0 g/cm^3 ≤ density ≤ 6.54 g/cm^3	≤100	7,570
4.0 g/cm^3 ≤ density < 5.0 g/cm^3	≤100	6,020
3.0 g/cm^3 ≤ density < 4.0 g/cm^3	≤100	3,120
2.0 g/cm^3 ≤ density < 3.0 g/cm^3	≤100	1,490
1.5 g/cm^3 ≤ density < 2.0 g/cm^3	≤100	830
1.0 g/cm^3 ≤ density < 1.5 g/cm^3	≤100	700

[a] The mass loading limit cannot be rounded up.
[b] Content in solution form is not permitted for shipment in the ES-3100. Content may be a combination of product oxides (UO_2, UO_3, U_3O_8) mixed with ZrO_2.
[c] 277-4 can spacers as described on Drawing M2E801580A043 (Appendix 1.3.7) are not required but are optional.
[d] Non-uranium metallic constituents (e.g., aluminum , zirconium, or magnesium) are evaluated further in Appendix 6.9.11.

Table 6.9.10.1-4. HEU product oxide mixed with thorium metal content loadings limits [a, b, c, d]

Detailed description	Assay (wt % ^{235}U)	^{235}U wt (g)
5.0 g/cm^3 ≤ density ≤ 6.54 g/cm^3	≤100	7,570
4.0 g/cm^3 ≤ density < 5.0 g/cm^3	≤100	6,020
3.0 g/cm^3 ≤ density < 4.0 g/cm^3	≤100	4,660
2.0 g/cm^3 ≤ density < 3.0 g/cm^3	≤100	2,550
1.5 g/cm^3 ≤ density < 2.0 g/cm^3	≤100	1,710
1.0 g/cm^3 ≤ density < 1.5 g/cm^3	≤100	1,180

[a] The mass loading limit cannot be rounded up.
[b] Content in solution form is not permitted for shipment in the ES-3100. Content may be a combination of product oxides (UO_2, UO_3, U_3O_8) mixed with Th metal.
[c] 277-4 can spacers as described on Drawing M2E801580A043 (Appendix 1.3.7) are not required but are optional.
[d] Non-uranium metallic constituents (e.g., aluminum , zirconium, or magnesium) are evaluated further in Appendix 6.9.11.

6.9.10.3 General Considerations

The general considerations expressed in Sect. 6.3 regarding both the calculation methodology for the ground and air transport modes, and the assumptions made about the ES-3100 packaging regarding geometry and material composition are unchanged. Only modifications to the calculation models for the catastrophically damaged package (Sect. 6.3.1.4) were required for evaluating HEU product oxide as a package content in the air transport mode.

6.9.10.3.1 Model configuration

The general modeling technique for the ES-3100 package described in Sect. 6.3.1, the single-unit packaging calculation models (Sect. 6.3.1.1), the infinite array and finite array packaging calculation models (Sect. 6.3.1.2), and the calculation models for damaged packages (Sect. 6.3.1.3) are specific to the ground transport. Only the content portion of the six calculation models for the catastrophically damaged package specific to HEU metal as a package content under the air transport (Sect. 6.3.1.4) were appropriately modified for evaluating HEU product oxide as a package content in the air transport mode. This was accomplished by replacing the homogeneous mixture of HEU metal and 500 g of polyethylene in the original models with a homogeneous mixture of water-saturated HEU oxide and 500 g of polyethylene. The 500-g polyethylene represents a limit on Teflon or polyethylene bottles as well as hydrogenous packing material. Given the requirement that CVs be flooded in the ground transport analysis; credit for product oxide quality (dryness) is not taken in the air transport analysis either. The HEU product oxide is assumed water-saturated in the air transport analysis.

The general arrangements of materials depicted in Figs. 6.11–6.16 (Sect. 6.1.3.4) remains the same for the HEU metal and HEU product oxide content configurations. Note that model dimensions are presented in the calculation results summary tables rather than depicted in these figures. Changes in dimensions of each model resulting from switching content from HEU metal to HEU product oxide content are slight and not visible in the figures. Consequently, revised figures were not drawn for HEU product oxide; instead, Figs. 6.11–6.16 are referenced accordingly in this appendix.

The content description for the HEU product oxide given in Table 6.9.10.1 provides the basis for the calculation model. The 7.57 kg ^{235}U will be shown to be the largest amount allowable for air transport in Table 6.9.10.9-1 for 5.0 g/cm^3 and higher densities at 100% enrichment. There are three major oxides

of uranium—UO_2, UO_3 , and U_3O_8. UO_3 and U_3O_8 are bounded by calculations using UO_2 for two reasons: (1) for the same net weight, there is more ^{235}U in UO_2 than in UO_3 or U_3O_8 and (2) for the same ^{235}U content, the UO_3 and U_3O_8 have more oxygen atoms per uranium atom and, therefore, have lower uranium densities. However, the neutron scattering and absorption in the additional oxygen is a minor effect compared to reactivity changes due to the uranium mass/density differences. For this reason, Table 6.9.10.9-1 contains only a few calculations of UO_3 and U_3O_8 at the 6-kg oxide net weight amount included to demonstrate that the UO_2 is obviously bounding for the other two oxides.

HEU product oxide evaluated for ground transport in Sects. 6.4.3, 6.5.3, and 6.6.3 is characterized as non-hydroscopic or mildly hydroscopic, non-rigid, bulk material in clumped, loose, granular, or powdered form having a bulk density ranging from 1.0 to 6.54 g/cm^3. Oxide impurity (unidentified constituents) is treated as ^{235}U [Sect. 6.2.4, Item 8]. This same criteria is applied in the criticality evaluation for the air transport mode. Given the requirement that CVs be flooded in the ground transport analysis, credit for product quality (dryness) is not taken in the air transport analysis either. The HEU product oxide is assumed water-saturated.

As explained in Sect. 6.3.1.4, the air-transport calculation models incorporate features exhibiting the worst-case assumptions made regarding the geometric arrangement of the packaging and package contents. No credit is taken for the geometric form of the package content. Spherical geometry is used to represent the ultimate configuration of the ES-3100 package which undergoes catastrophic destruction.

The criticality analysis for air transport does not credit the ES-3100 for maintaining the geometrical configuration of the packaged content. Fissile material is configured spherical in shape for optimization of neutron multiplication. Also, the criticality analysis does not credit the ES-3100 packaging for structural integrity of the containment and the confinement. Therefore, the reactivity "enhancing" materials of the packaging may be interspersed with the fissile material content. A calculation model in which the fissile material is homogenized with moderating material is an appropriate representation because the form of HEU product uranium oxide being shipped consists of a bulk material in clumped, loose, granular, or powdered form. However, homogenization of fissile material with moderating material is not performed with exclusive preference given to specific constituents of the moderating material. Selective removal of the neutron-absorbing materials of the package (i.e., Kaolite and stainless steel) accompanied by retention of the moderating constituents of the neutron-absorbing material (i.e., bound water in the Kaolite) for enhancing content reactivity is not a credible condition.

Concerning the "no water inleakage" condition of 10 CFR 71.55(f)(1) and (f)(2), the focus is on the Kaolite region of the ES-3100 package. The 53,419 g of dry-baked Kaolite in the drum body weldment and drum top plug consists of 51,214.9 g of vermiculite-cement constituents and 2,204.7 g of bound water. For establishing the loading limits for air transport, the total **free** water permitted in wet Kaolite was conservatively evaluated up to 15 lb (6,803.8 g). As in the case of HEU metal content, this limit assumes that the CV well and other void spaces external to the CV are dry.

A set of six calculation models are constructed in order to determine the worst case or most reactive configuration with consideration given to the efficiency of moderators, loss of neutron absorbers, rearrangement of packaging components and contents, geometry changes, and temperature effects. In each case, fissile material content in the core consists of HEU product oxide saturated with water (e.g., 2,448.1-g H_2O for UO_2 from 1.0 to 5.0 g/cm^3) and homogenized with 500-g polyethylene which models the allowed hydrogenous packing material.

Model 1 (Fig. 6.11, Sect. 6.3.1.4) represents the fissile material content configured into a spherical core with a 20.0-cm thick water reflector. All ES-3100 packaging material (Kaolite, stainless steel, 277-4 neutron poison, etc.) is excluded from Model 1. The fissile material content considered in the calculation model consists of a specific material form: HEU product oxide (6- to 14-kg UO_2 containing

5,281- to 12,323-g ^{235}U). The presence of hydrogenous packing material inside the CV is also addressed in this calculation model where 500 g of polyethylene is used to represent a maximum amount of hydrogenous packing material allowed in the ES-3100. From the parametric studies for 6-kg HEU product oxide (5,281-g ^{235}U) homogenized with 500 g of polyethylene, the radius of the core is 6.3861 cm. HEU product oxide is assumed to be saturated with water that is 2,448.1-g H_2O for UO_2 at 2.0 g/cm^3. From the results of these parametric studies, UO_2 was shown to be the most reactive HEU product oxide, and the bulk density of 2.0 g/cm^3 was also shown to be the most reactive density (the lowest density evaluated in this study). Thus, UO_2 is used in all subsequent air transport calculations, and these lower density HEU product oxide densities evaluated here will bound the higher density HEU product oxides evaluated.

The parametric variation of both the ^{235}U mass and the density of the water-saturated oxide in Model 1 is used to establish a reference point for the evaluation neutron reflection and absorption effects on k_{eff} provided by the stainless steel and Kaolite packaging materials, which are addressed separately in Models 2 and 3. Case names for Model 1 are designated with the prefix "5atdorxx." The "xx" in alphanumeric prefix indicates calculations were run at a specific oxide density, with 50 for calculations at 5.0 g/cm^3 and 15 for calculations at 1.5 g/cm^3 respectively, UO_2 is shown to be the most reactive uranium oxide; therefore, the oxide content is modeled as UO_2 at various densities ranging from 1.0 to 6.54 g/cm^3. Details are provided in Table 6.9.10.9-1 for each density evaluated.

Model 2 (Fig. 6.12, Sect. 6.3.1.4) represents a spherical core of Model 1 blanketed by a variable-thickness shell of stainless steel and a 20.0-cm-thick water reflector external to the shell. The shell at maximum thickness corresponds to the 66,133-g stainless steel of the CV and the liner and drum assembly Case names in Table 6.9.10.9-1 for Model 2 are designated with the prefix "5atdosrxx."

Model 3 (Fig. 6.13, Sect. 6.3.1.4) is configured the same as Model 2 with the exception that instead of stainless steel, the variable-thickness shell is composed of dry Kaolite in one set of cases and wet Kaolite in the other set. Dry Kaolite from inside the body weldment outer liner and the drum top plug consists of 51,214.3-g vermiculite-cement and 2,204.8-g bound water. Wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite and up to 6,803.9-g free water—moisture which dampens the Kaolite and may also be present in the CV well. Because the Kaolite is constrained within the liners of the ES-3100 packaging, the Kaolite density rather than its volume changes when water is added to the material. The radius of the core is the same as in Model 2, for a homogeneous mixture of HEU product oxide, 2,448.1 g of saturation water, and 500 g of polyethylene. Case names for Model 3 designated with the prefix "5atdodkrxx" are for HEU product oxide content with a dry Kaolite shell (Kaolite only contains bound water), while case names designated with the prefix "5atdo15krxx" are for HEU product oxide content with a wet Kaolite having 15-lb free water. The parametric variation of shell thickness/composition in Models 2 and 3 is performed for the purpose of evaluating the effect on k_{eff} of neutron reflection and absorption provided by each packaging material.

Models 1–3 for water-saturated HEU product oxide evaluate scenarios where containment and confinement of the content are assumed but the physical shape of the packaging is destroyed. Models 4–6 evaluate scenarios where the package content blends with the other materials of the packaging in the air transport accident given the physical form of the HEU product oxide is bulk material in clumped, loose, granular, or powdered form.

Model 4 (Fig. 6.14, Sect. 6.3.1.4) depicts a spherical core of HEU product oxide and 2,448.1 g of saturation water homogenized with wet Kaolite (variable amount) and hydrogenous packing materials from inside the CV represented by 500 g of polyethylene. A 20-cm-thick water reflector blankets the spherical core. All other ES-3100 packaging material (stainless steel, 277-4 neutron poison, etc.) is excluded from Model 4. The core is homogenized containing HEU product oxide, saturation water for the oxide at that particular density, 500 g of polyethylene and wet Kaolite. The amount of water in wet

Kaolite ranges from 2,204.7-g bound water in baked-dry Kaolite to 9,008.6 g (2,204.7-g bound plus 15-lb free water). Case names in Table 6.9.10.9-1 for Model 4 are designated with the prefix "5athop15krxx" for the HEU product oxide.

Model 5 (Fig. 6.15, Sect. 6.3.1.4) is an extension of Model 3 applied to HEU product oxide contents. Excess water from wet Kaolite is homogenized with the fissile material in the core along with the water of saturation and the hydrogenous packing materials (modeled as polyethylene). The core is a homogeneous mixture of HEU product oxide, saturation water for the oxide at that particular density, 500 g of polyethylene, and 0.0 g of free water from wet Kaolite. The corresponding exterior Kaolite shell contains 7,646.8 g (2,204.7-g bound plus 12-lb free water) of water homogenized with the 51,214.9 g of vermiculite-cement constituents. The corresponding exterior shell of dry Kaolite contains 2,204.7 g of bound water and 51,214.9 g of vermiculite-cement constituents. Case names in Table 6.9.10.9-1 for Model 5 are designated with the prefix "5athopw12krxx" for 12-lb free water in the Kaolite.

Model 6 (Fig. 6.16, Sect. 6.3.1.4) is configured similar to Model 4 with the exception that only a partial amount of HEU product oxide resides in the homogenized core. The remainder of the fissile material is modeled as a shell external to the spherical core and internal to the 20.0-cm-thick water reflector. A series cases is run with suffixes "**_f_a_b**" is run where the first number "**f**"designates variable water mass in the fissile core region, the second number "**a**" designates oxide mass in the fissile core, and the third number "**b**"designates oxide mass in shell around the core. For Cases **5athop15korxx_f_a_b**, the amount of water-saturated HEU oxide in the homogenized core is varied in increments for **"a**. The unsaturated HEU product oxide removed from the core to form the shell adjacent to the core correspondingly increases depending on the oxide density for "**b**. For maximization of reactivity, it is assumed that all the saturation water present in the oxide remains in the core. The effect of varying the free water in the core is evaluated in cases designated by the suffix "**f**." In Cases **5athop15korxx_1_a_b**, the saturated water in the oxide plus both the free water and bound water in Kaolite. In Cases **5athop15kor_5_a_b**, the water represents the saturated water in the oxide plus the bound water in Kaolite. Case names in Table 6.9.10.9-2 for Model 6 are designated with the prefix "5athop15korxx" for the HEU product oxide contents. Model 6 addresses potential redistribution of fissile material consisting of HEU product oxide content. The parametric variation of shell thickness in Model 6 is performed for the purpose of evaluating the effect on k_{eff} of moderation efficiency of the core and enhanced neutron multiplication of the shell.

Models 1–6 are applicable to air transport of the ES-3100 package given that the physical integrity of the fissile content following the air-transport accident cannot be established and that the physical form of fissile material content is oxide.

6.9.10.3.2 Content model material specifications for HEU product oxide

The material properties for the ES-3100 package addressed in Sect. 6.3.2 remain unchanged for the air transport analysis. However, additional specification data is provided in Table 6.9.10.3-1 for addressing the HEU product oxide content modeled in the air-transport analysis.

6.9.10.4 Computer Codes and Cross-Section Libraries

This information is discussed in the introductory section of this appendix.

Table 6.9.10.3-1. Material compositions for HEU product oxide content calculation models for air transport

Material	Mix. No.	Theoretical density input parameter (g/cm3) a	Volume fraction	Constituent	Weight fraction
Uranium oxide (UO_2)	1	10.96000	1.0	O	11.9827

[a] The theoretical density input parameter is specified for each material such that the required (or desired) mass of material is represented in the KENO V.a calculation model. The mass of material is computed by KENO V.a as the product of the theoretical density input parameter times the volume fraction times the volume of the geometry region in which the material resides in the calculation model.

6.9.10.5 Single Package Evaluation (NCT and HAC)

The evaluation of a single ES-3100 package with HEU product oxide content for Normal Conditions of Transport (NCT) and Hypothetical Accident Conditions (HAC) in the ground mode of transportation is presented in Sect. 6.4.3, while the evaluation of a catastrophically damaged package in air transport mode is addressed in Sect. 6.9.10.7.

6.9.10.6 Array Package Evaluation (NCT and HAC)

The evaluation of arrays of packages in NCT and in HAC for the ground transport mode are presented in Sects. 6.5.3 and 6.6.3, respectively. The array evaluations are not required by 10 CFR 71.55(f) for the air mode of transportation. However, the CSI established for the ground transport mode establishes the maximum number of packages which can be loaded onto an aircraft for criticality safety purposes.

6.9.10.7 Fissile Material Packages with HEU Product Oxide for Air Transport

As discussed in Sect. 6.7, a series of calculations are performed for determining the most reactive configuration of the content and surrounding packaging material in an ES-3100 package that undergoes catastrophic destruction. Subcriticality is demonstrated after due consideration of such aspects as the efficiency of moderator, loss of neutron absorbers, rearrangement of packaging components and contents, geometry changes and temperature effects. Details of the six calculation models used in this evaluation are described in Sect. 6.9.10.3.1. In this section, HEU oxide, HEU oxide with thorium oxide, HEU oxide with zirconium oxide, and HEU oxide with thorium metal are evaluated, with the density of the HEU oxide and additional material evaluated at 5.0, 4.0, 3.0, 2.0, 1.5, and 1.0 g/cm^3. The results of these calculations are found in Tables 6.9.10.9-2 through 6.9.10.9-9.

Model 1 (Fig. 6.11, Sect. 6.3.1.4) represents fissile material content configured into a spherical core with a 20.0-cm-thick water reflector taking no credit for the geometry or structure of the container. In addition, all ES-3100 packaging material (Kaolite, stainless steel, 277-4 neutron poison, etc.) is excluded from Model 1. The parametric variation of both the ^{235}U mass and the density of the oxide along with its corresponding saturation water in Model 1 is used to establish a reference point for the evaluation of neutron reflection and absorption effects on k_{eff} provided by the stainless steel and Kaolite packaging materials, which are addressed separately in Models 2 and 3. The purpose of the variations in Model 1 is to identify the most reactive oxide (UO_2, UO_3, or U_3O_8) mass at a corresponding density (from 1.0 to 6.54 g/cm^3) for water-saturated HEU product oxide. For the parametric study cases, in Cases **5atdor_1_5_6** through **5atdor_1_5_14** (Table 6.9.10.9-1), the $k_{eff} + 2\sigma$ values increase from 0.751 to 0.871 as the mass of saturated HEU product oxide increases from 6-kg UO_2 (5,281-g ^{235}U) to 14-kg UO_2 (12,323-g ^{235}U) at 6.54 g/cm^3. In Cases **5atdor_1_1_6** through **5atdor_1_5_6** for UO_2, Cases **5atdor_2_1_6** through **5atdor_2_5_6** for U_3O_8, and Cases **5atdor_3_1_6** through **5atdor_3_5_6** for UO_3, the densities of the three oxides are varied from 2 to 6.54 g/cm^3. These contents are most reactive at minimum density where the $k_{eff} + 2\sigma$ values range from 0.671 for UO_3 (**Case 5atdor_3_5_6**) to 0.917 for UO_2 (**Case 5atdor_1_1_6**). UO_2 is the most reactive of the product oxides evaluated and is used in all subsequent HEU oxide calculations.

Cases **5atdor*** (HEU oxide, Table 6.9.10.9-2), **atdothr*** (HEU oxide and ThO_2, Table 6.9.10.9-4), **atdozrr*** (HEU oxide and ZrO_2, Table 6.9.10.9-6), and **atdothmr*** (HEU oxide and thorium metal, Table 6.9.10.9-8), calculate a range of oxide masses from 1.0 to 5.0 g/cm^3. The maximum oxide masses that are below the USL are found in Table 6.9.10.4. Note that for ThO_2, ZrO_2, and thorium metal calculations at densities less than 2.0 g/cm^3, the total amount of HEU oxide and material mixed with HEU oxide that is evaluated is limited by the volume of the CV.

Model 2 (Fig. 6.12, Sect. 6.3.1.4) represents a spherical core of water-saturated HEU product oxide and polyethylene (Model 1) blanketed by a variable thickness shell of stainless steel, with a 20.0-cm-thick water reflector external to the shell. The shell at maximum thickness corresponds to the 66,133-g stainless steel of the CV and the liner and drum assembly. For calculations at 2.0 g/cm^3, the thickness of the stainless steel shell is varied from zero to 4.6944 cm in Cases **5atdosr_1** through **5atdosr_11** (Table 6.9.10.9-1). The maximum $k_{eff} + 2\sigma$ is 0.915 for 6 kg of HEU product oxide and zero stainless-steel thickness. The $k_{eff} + 2\sigma$ values decrease to a minimum of 0.863 at 1.84-cm stainless-steel shell thickness (Case **5atdosr_4**). The $k_{eff} + 2\sigma$ values increase to within 0.02 of the maximum at the maximum stainless steel thickness (Case **5atdosr_11**). The overall effect of adding the stainless steel of the ES-3100 packaging to the configuration is the reduction in the neutron multiplication factor for the system. The $k_{eff} + 2\sigma$ values are substantially below the USL of 0.924.

Cases **5atdosr*** (HEU oxide, Table 6.9.10.9-2), **atdothsr*** (HEU oxide and ThO_2, Table 6.9.10.9-4), **atdozrsr*** (HEU oxide and ZrO_2, Table 6.9.10.9-6), and **atdothmsr*** (HEU oxide and thorium metal, Table 6.9.10.9-8), calculate a range of oxide masses from 1.0 to 5.0 g/cm^3. The maximum oxide masses that are below the USL are found in Table 6.9.10.5.

Model 3 (Fig. 6.13, Sect. 6.3.1.4) is configured the same as Model 2 with the exception that instead of stainless steel, the variable-thickness shell is composed of dry Kaolite (Cases **5atdodrk_1** through **5atdodkr_6**) or wet Kaolite (Cases **5atdo15rk_1** through **5atdo15kr_6**). Dry Kaolite from inside the body weldment outer liner and the drum top plug consists of 51,214.9-g vermiculite-cement and 2,204.7-g bound water. Wet Kaolite to a maximum of 60,223 g consists of the dry Kaolite and up to 6,803.8-g free water—moisture which dampens the Kaolite and may also be present in the CV well. Because the Kaolite is constrained within the liners of the packaging, the Kaolite density rather than its volume changes when water is added to the material. Consequently, the shell thickness in Model 3 does not change as free water is added. The $k_{eff} + 2\sigma$ decreases from 0.915 to 0.719 for dry Kaolite (Cases **5atdodkr_1** through **5atdodkr_6**) and decreases from 0.916 to 0.729 for wet Kaolite (Cases **5atdo15kr_1** − **5atdo15kr_6**). NCT Kaolite of the ES-3100 packaging or wet Kaolite is not as effective a reflector as 20 cm water surrounding the core.

For Model 3 with dry Kaolite, Cases **5atdodkr*** (HEU oxide, Table 6.9.10.9-2), **atdothdkr*** (HEU oxide and ThO_2, Table 6.9.10.9-4), **atdozrdkr*** (HEU oxide and ZrO_2, Table 6.9.10.9-6), and **atdothmdkr*** (HEU oxide and thorium metal, Table 6.9.10.9-8), calculate a range of oxide masses from 1.0 to 5.0 g/cm^3. The maximum oxide masses that are below the USL is found in Table 6.9.10.6. For Model 3 for wet Kaolite, Cases **5atdo15kr*** (HEU oxide, Table 6.9.10.9-2), **atdoth15kr*** (HEU oxide and ThO_2, Table 6.9.10.9-4), **atdozr15kr*** (HEU oxide and ZrO_2, Table 6.9.10.9-6), and **atdothm15kr*** (HEU oxide and thorium metal, Table 6.9.10.9-8), calculate a range of oxide masses from 1.0 to 5.0 g/cm^3. The maximum oxide masses that are below the USL are found in Table 6.9.10.7.

[a] The keff + 2σ value is above the USL; however, Model 5 is more reactive configuration resulting in lower limits.

Model 4 (Fig. 6.14, Sect. 6.3.1.4) represents a spherical core of water-saturated HEU product oxide and polyethylene (Model 1) homogenized with wet Kaolite. A 20-cm-thick water reflector blankets the spherical core. All other ES-3100 packaging material (stainless steel, 277-4 neutron poison, etc.) is excluded from Model 4. In Cases **5athop15kr_1** through **5athop15kr_5** (Table 6.9.10.9-3), $k_{eff} + 2\sigma$ increases from 0.51089 to 0.60192 as free water is added to the 15-lb limit. Again, the core radius is constant with changing moisture conditions because the volume of the porous Kaolite constrained within the liners of the packaging does not change appreciably as the material is dried out or absorbs water. Small amounts of free water in the Kaolite can have a significant moderating effect if introduced to the fissile core.

For Model 4, Cases **5atdodkr*** (HEU oxide, Table 6.9.10.9-2), **atdothdkr*** (HEU oxide and ThO_2, Table 6.9.10.9-4), **atdozrdkr*** (HEU oxide and ZrO_2, Table 6.9.10.9-6), and **atdothmdkr*** (HEU oxide and thorium metal, Table 6.9.10.9-8), calculate a range of oxide masses from 1.0 to 5.0 g/cm^3. The maximum oxide masses that are below the USL are found in Table 6.9.10.8.

Model 5 (Fig. 6.15, Sect. 6.3.1.4) is an extension of Model 3 applied to HEU product oxide contents. Excess water from wet Kaolite is homogenized with the spherical core of water-saturated HEU product oxide and polyethylene (Model 3), with a maximum of 12 lb free water from the Kaolite is evaluated. Since the HEU product oxide masses used in Model 1 for use in the calculations for Model 5 are well above the USL, parametric studies were performed to determine the highest HEU product oxide that is below the USL as were performed in Model 1. The results of these calculations for Cases **5athopw12kr*** (HEU oxide, Table 6.9.10.9-2), **athothpw12kr*** (HEU oxide and ThO_2, Table 6.9.10.9-4), **athozrpw12kr*** (HEU oxide and ZrO_2, Table 6.9.10.9-6), and **athothmpw12kr*** (HEU oxide and thorium metal, Table 6.9.10.9-8), calculate a range of oxide masses from 1.0 to 5.0 g/cm^3. The maximum oxide masses that are below the USL are found in Table 6.9.10.9. For the UO_2-ThO_2, UO_2-ZrO_2, and UO_2 thorium metal, HEU oxide for densities of 5.0 and 4.0 g/cm^3 were more reactive without the thorium and zirconium.

Model 6 (Fig. 6.16, Sect. 6.3.1.4) is configured similar to Model 4 with the exception that only a partial amount of HEU product oxide resides in the homogenized core; the remainder of the unsaturated HEU product oxide is modeled as a shell external to the spherical core and internal to the 20.0 cm thick water reflector. The oxide masses evaluated in Models 2 through 4 are calculated here.

For Model 6, Cases **5athop15kor*** (HEU oxide, Table 6.9.10.9-2), **athothp15kor*** (HEU oxide and ThO_2, Table 6.9.10.9-4), **athozrp15kor*** (HEU oxide and ZrO_2, Table 6.9.10.9-6), and **athothmp15kor*** (HEU oxide and thorium metal, Table 6.9.10.9-8), calculate a range of oxide masses from 1.0 to 5.0 g/cm^3. The maximum oxide masses that are below the USL are found in Tables 6.9.10.10a through 6.9.10.10d.

The bounding model for the air transport of HEU oxide is Model 5 (Table 6.9.10.9), which was shown to be significantly more reactive than the other models. For oxides with ThO_2, ZrO_2, and thorium metal, the bounding model for the air transport of oxides is Model 5 (Table 6.9.10.9) for densities down to 2.0 g/cm^3 and Model 1 (Table 6.9.10.4) for densities of 1.5 and 1.0 g/cm^3.

6.9.10.8 Benchmark Experiments and the Criticality Validation

This information is discussed in Sect. 6.9.8.7. The USL is 0.924 for calculations run using SCALE 5. For the updated cases for 1.0, 1.5, 3.0 through 5.0 g/cm^3 for Models 1 through 6 and 2.0 g/cm^3 for Models 4, 5, and 6, the benchmark experiments and criticality validation is discussed in Appendix 6.9.10.

6.9.10.9 Calculation Results Tables for HEU Product Oxide Contents for Air Transport

Tables 6.9.10.9-1 and 6.9.10.9-2 contain a summary of the calculation results for the HEU product oxide contents to be shipped by air transport as contents in the ES-3100 shipping package.

Table 6.9.10.9-1. Results for HEU oxide content for air transportation (Models 1–3)

Appendix 6.9.11
Criticality Evaluation of the Removal of Carbon Limits for Oxides; Removal of Cladding Limits; and Uranium Tetrafluoride at a Criticality Safety Index of 2.0

This page intentionally left blank.

Appendix 6.9.11
Criticality Evaluation of the Removal of Carbon Limits for Oxides; Removal of Cladding Limits; and Uranium Tetrafluoride at a Criticality Safety Index of 2.0

This appendix presents the criticality safety evaluation of several modifications to the limits for the ES-3100 package. This appendix evaluates the removal of the carbon restriction for all HEU oxides (i.e., eliminating the 921-g carbon limit). Furthermore, based on evaluations in this appendix, HEU broken metal cladding restrictions are not required for ground and air transport. Cladding is also not controlled for research reactor fuel elements and components that are shown to be bounded by HEU bulk oxide (U_3O_8-Al, oxides of U-Zr, and UO_2-Mg). Studies on the effect of cladding on fuel pellets are also examined. Lastly, this appendix evaluates uranium tetrafluoride (UF_4) at CSI of 2.0.

Calculations presented in this appendix are performed using the Monte Carlo Criticality Safety Analysis Sequence (CSAS), CSAS5 code module (KENO V.a), and the 238-group ENDF/B-VII cross-section library of the Standardized Computer Analysis for Licensing Evaluation (SCALE) 6.1.1 (ORNL/TM-2005/39). Criticality calculations documented in Sects. 6.4–6.6 were performed using SCALE 4.4a (NUREG/CR-200, Rev. 6) executed on an Hewlett Packard (HP) Model J5600 RISC Workstation (CMODB). This system has been retired from service, and the SCALE 4.4a version of the code is no longer supported by the Radiation Safety Information Computational Center at the Oak Ridge National Laboratory.

6.9.11.1 Description of the Criticality Design

The design features of the ES-3100 package addressed in Sect. 6.1.1 are not changed. The same codes and standards addressed in Sect. 6.1.2 apply.

6.9.11.2 Additional or Revised Content Description for the ES-3100 Package

The materials identified in Table 6.4 are used in this analysis. The only changes from Table 6.4 would be the addition of carbon to UO_2 calculations. The amount of carbon modeled in these calculations is varied from 0 to 5000 g in 1000-g increments. The amount of UO_2 modeled in these calculations is also varied in increments of 1000 g except for the HEU oxide CSI 0.4 calculations in which UO_2 is varied in increments of 250 g. The theoretical density of carbon (2.27 g/cm^3) is used in these calculations. The various amounts of cladding for broken metal is analyzed for both ground and air transport. Cladding is also evaluated for research reactor fuel elements and components that are shown to be bounded by HEU bulk oxide (U_3O_8-Al, oxides of U-Zr, and UO_2-Mg) in Table 6.9.8.1-2.

6.9.11.3 General Considerations

General considerations expressed in Sect. 6.3 regarding assumptions made about the ES-3100 packaging and the calculation methodology for the evaluation is maintained. No changes are required to the calculation models of the containment vessel (CV), the single-unit packaging (Sect. 6.3.1.1), the damaged packaging (Sect. 6.3.1.3), or the material properties specifications (Sect. 6.3.2) except for the analysis of carbon in HEU oxides.

6.9.11.3.1 Model configuration for supplemental contents

Unless stated otherwise, the materials and models used in this analysis are the same as described in Sect. 6.3. The only difference is adding carbon in UO_2 and evaluating UF_4 at a CSI of 2.0.

In this analysis, UO_2 is evaluated with varying amount of carbon. Only UO_2 is evaluated because this is shown as the most reactive oxide in Sect. 6.4.3. Calculations are performed substituting various

amounts of carbon for equal amounts oxide as well as adding carbon to a fixed amount of oxide. These calculations are performed using the same input decks used in the HEU UO_2 evaluation in this safety analysis report for packaging (SARP). The methodologies used for the calculations in this appendix are also used for the rest of the analyses in this SARP. In this SARP—no changes are made in the ES-3100 material content models except for carbon, and no changes are made to the ES-3100 container model. Oxide cases are run with 500 g of polyethylene mixed with the oxide.

6.9.11.3.2 Content model material specification

Material property specifications for this material are presented in Table 6.4.

6.9.11.4 Computer Codes and Cross-Section Libraries

KENO V.a calculations are performed using CSAS5 in SCALE 6.1.1 on the Microway Parallel Linux Cluster ENGHPC01 in the Y-12 Engineering organization in Oak Ridge, Tennessee. The upper subcritical limit (USL) without any safety margin for running SCALE 6.1.1 on this workstation is 0.985 (which covers all HEU systems with enrichments > 60%) as documented in RP YAREA-F-0455. NUREG/CR-5661 provides guidance that the USL should be established with a minimum margin of subcriticality of 0.05. Using this safety margin, the USL for the calculations performed in this appendix would be 0.935.

Several CSAS control modules are contained in SCALE6.1. The CSAS control modules are designed to analyze systems containing fissile material and calculate the neutron multiplication factor (k_{eff}) of the system. This validation is only applicable to the CSAS5 control module that uses the KENO V.a functional module. Prior to entering the KENO V.a functional module, the CSAS5 control module calls a series of utility modules and other functional modules to process the cross-section data. This validation used the 238-group ENDF/B-VII cross-section library. This is a multigroup library containing 238 distinct neutron energy groups based on the ENDF/B-VII library. The CSAS5 control module executes several functional modules to process the cross-section data used in KENO V.a. These programs are:

- WORKER: This functional module interfaces between the AMPX master library contained in the SCALE code package and the AMPX working library used in KENO V.a.
- BONAMI: This functional module processes the unresolved resonance data contained in the master library and places it in the working library.
- PMC: This functional module uses point-wise continuous cross-section data to solve a one dimensional equivalent problem producing a flux profile used for processing cross-section data.
- CENTRM: This functional module uses the flux profile calculated in PMC to collapse point-wise continuous cross-section data into the appropriate group structure producing a working library used in KENO V.a.
- KENO V.a: This functional module performs the three dimensional Monte Carlo calculation using the cross-section library provided by the WORKER module.

This validation covers the execution of the CSAS5 control module and the functional modules that are executed by it.

6.9.11.5 CV and Single Package Evaluation

Calculations are performed for the fully reflected CV and fully reflected single unit [for both Normal Conditions of Transport (NCT) and Hypothetical Accident Conditions (HAC)] with the specific gravity of water inside the CV varied from dry to fully flooded for the CV cases and evaluated as fully flooded for the single-unit cases. The CV is analyzed only for fully flooded because full flooding of the CV is shown to be the most reactive configuration.

6.9.11.5.1 UO_2 and carbon

In the reflected CV cases, calculations are performed examining various amounts of oxide mixed with 500 g of polyethylene and carbon ranging from 0 to 5000 g in 1000-g increments. In Tables 6.9.11.1–6.9.11.3, the fully reflected CV is modeled fully flooded and dry at various uranium and carbon masses. The single package cases are examined in Tables 6.9.11.8–6.9.11.10. Note that the shaded sections of these tables (and those that follow) are masses that would not fit inside the CV at that density, while "N/A" entries in the tables denote where additional calculations are not necessary.

Table 6.9.11.1. ES-3100 results for UO_2 at a bulk density of 2 g/cm^3, reflected CV, varying amounts of carbon, CV fully flooded and dry

MOCFR	Oxide mass (kg)	Case cvcrpdoxt11a_	$k_{eff} + 2\sigma$ [a]					
			No carbon (ω = 1)	1 kg carbon (ω = 2)	2 kg carbon (ω = 3)	3 kg carbon (ω = 4)	4 kg carbon (ω = 5)	5 kg carbon (ω = 6)

1.0	13	1_13_ω_15	0.9042	0.8863	0.8726	0.8563	0.8232	0.8299
1.0	12	1_12_ω_15	0.9031	0.8846	0.8654	0.8479	0.8360	0.8207
1.0E-20	19	1_19_ω_1	0.9225					
1.0E-20	18	1_18_ω_1	0.9171	0.9065				
1.0E-20	17	1_17_ω_1	0.9137	0.9017	0.8911			
1.0E-20	16	1_16_ω_1	0.9136	0.8978	0.8878	0.8707		
1.0E-20	15	1_15_ω_1	0.9103	0.8938	0.8811	0.8684	0.8552	
1.0E-20	14	1_14_ω_1	0.9075	0.8888	0.8754	0.8620	0.8460	0.8325
1.0E-20	13	1_13_ω_1	0.9012	0.8866	0.8722	0.8563	0.8405	0.8256
1.0E-20	12	1_12_ω_1	0.9012	0.8811	0.8634	0.8502	0.8360	0.8190

[a] The shaded sections are masses that would not fit inside the CV at that density.

From Table 6.9.11.1 for 2-g/cm^3 bulk density oxide, the volume of oxides with masses >19 kg would not fit inside the CV. Oxide masses of 15 kg and higher with a significant amount of carbon added would also not fit inside the CV. The same volumetric limitation is found for oxide masses of 23 kg and higher for 3-g/cm^3 bulk density oxide.

Table 6.9.11.2. ES-3100 results for UO_2 at a density of 3 g/cm^3, reflected CV, varying amounts of carbon, CV fully flooded and dry

From the results found in Tables 6.9.11.1–6.9.11.3 for a fully flooded and dry reflected CV, the most reactive cases are those with no carbon mixed with the oxide. In both scenarios, substituting carbon for oxide and adding carbon to a fixed amount of oxide resulted in a decrease of reactivity. For example, when substituting 1000 g of carbon for 1000 g of oxide at 4-g/cm^3 bulk density for a total mass (oxide and carbon) of 24 kg in a flooded CV (Cases **cvcrpdoxt11a_3_24_1_15**, **cvcrpdoxt11a_3_23_2_15**, **cvcrpdoxt11a_3_22_3_15**, **cvcrpdoxt11a_3_21_4_15**, **cvcrpdoxt11a_3_20_5_15**, and **cvcrpdoxt11a_3_19_6_15** from Table 6.9.11.7), the reactivity decreases from $k_{eff} + 2\sigma$ of 0.909 to 0.810. When adding carbon to 24 kg of oxide (Cases **cvcrpdoxt11a_3_24_1_15**, **cvcrpdoxt11a_3_24_2_15**, **cvcrpdoxt11a_3_24_3_15**, **cvcrpdoxt11a_3_24_4_15**, **cvcrpdoxt11a_3_24_5_15**, and **cvcrpdoxt11a_3_24_6_15**), the reactivity decreases from $k_{eff} + 2\sigma$ of 0.909 to 0.832. In both scenarios, the reactivity of this system decreases. Substitution of carbon for oxide has the highest decrease in reactivity as opposed to just adding carbon to a fixed amount of oxide.

In the reflected single-unit cases for both NCT and HAC, calculations are performed examining uranium oxide with varying amounts of carbon ranging from 0 to 5000 g in 1000-g increments. The ES-3100 package is fully reflected with the specific gravity of water in the CV (MOCFR) modeled as fully flooded because this is shown in Tables 6.9.11.1–6.9.11.3 as the most reactive configuration. The results are shown in Tables 6.9.11.4–6.9.11.6.

20	3_20_ω	0.8018	0.7797	0.7564	0.7333	0.7124	0.6957

From the results found in the Tables 6.9.11.4–6.9.11.6 as in the CV cases shown in Tables 6.9.11.1–6.9.11.3, substituting carbon for oxide and adding carbon to a fixed amount of oxide resulted in a decrease of reactivity. The substitution of carbon for oxide results in the highest decrease in reactivity as opposed to adding carbon to a fixed amount of oxide. All cases in Tables 6.9.11.4–6.9.11.6 are well below the comparative fully flooded and reflected CV cases shown in Tables 6.9.11.1–6.9.11.3.

6.9.11.5.2 Cladding for broken metal

In the broken metal reflected CV cases, calculations are performed examining various amounts of cladding materials (stainless steel, aluminum, zirconium, and nickel). Two reflected CV calculation models are rerun using cladding. The first model is "**cvr3sqa**," which evaluated the broken metal explicitly as small cubes. The second model, "**cvr3lhac**," evaluated the broken metal homogeneously mixed within the rectangular lattices formed by the unit cells of the small cubes. This "**cvr3lhac**" model is the basis for the limits found in Table 6.1.c. The maximum amount of cladding is evaluated for both models that would fit around the small cube without intersection the adjacent cubes. The single package cases are not examined because the CV cases are shown to be the most reactive. The results are found in Tables 6.9.11.7 and 6.9.11.8.

Table 6.9.11.7. ES-3100 results for broken metal cubes with various amounts of cladding CV fully reflected and flooded 27,743.2-g ^{235}U

0.1508	28_4_ω	0.82467	0.82152	0.82317	0.82490
0.2032	28_5_ω	0.81595	0.81376	0.81514	0.81585
0.2446	28_6_ω	0.80975	0.80727	0.80756	0.80975

a The "N/A" entries denote where additional calculations are not necessary.
SS304 = Type 304 stainless steel.

From the results found in Tables 6.9.11.7 and 6.9.11.8 for a fully flooded and reflected CV, the most reactive cases are those with no cladding material either surrounding the broken metal or intermixed with the broken metal. The more cladding material is added to the broken metal, the more the reactivity of this system is decreased. The single-unit package is not evaluated because it has been shown that the reflected and flooded CV model is bounding.

6.9.11.5.3 Cladding for U_3O_8-Al, oxides of U-Zr, and UO_2-Mg reactor fuel elements and components

For the research reactor fuel elements and components (U_3O_8-Al, oxides of U-Zr, and UO_2-Mg), the bulk oxide cases are rerun modeling varying amounts of cladding material (stainless steel, aluminum, zirconium, and nickel) in a reflected CV with the CV fully flooded. Only the 24-kg bulk oxide cases are rerun for these calculations. The amount of cladding material is varied from none up to 1.5 L for 3.0 g/cm^3 and up to 2.5 L for 4 g/cm^3 calculations. The 2.0-g/cm^3 cases are not run because 24 kg of UO_2 at this density will not fit inside the CV. The results are found in Table 6.9.11.9.

Table 6.9.11.9. ES-3100 results for bulk oxide with various amounts of cladding CV fully reflected and flooded 24 kg UO_2 (21,1242-g ^{235}U)

Clad volume (L)	Case cvcrpdoxt11c_	$k_{eff} + 2\sigma$ [a]			
		SS304 (ω = 1)	Aluminum (ω = 2)	Zirconium (ω = 3)	Nickel (ω = 4)
Bulk density 3.0 g/cm^3					
0.0	2_1_ω	**0.91714**	N/A	N/A	N/A
0.5	2_2_ω	0.89736	0.89736	0.89736	0.89753
1.0	2_3_ω	0.88099	0.87694	0.87975	0.87955
1.5	2_4_ω	0.86201	0.85852	0.86214	0.85886
Bulk density 4.0 g/cm^3					
0.0	3_1_ω	**0.90905**	N/A	N/A	N/A
0.5	3_2_ω	0.88574	0.88348	0.88574	0.88574
1.0	3_3_ω	0.86509	0.86178	0.86250	0.86423
1.5	3_4_ω	0.84416	0.84001	0.84511	0.84274
2.0	3_5_ω	0.82535	0.82009	0.82563	0.82460
2.5	3_6_ω	0.80823	0.80209	0.80762	0.80513

[a] The "N/A" entries denote where additional calculations are not necessary.
SS304 = Type 304 stainless steel.

From the results found in Table 6.9.11.9 for a fully flooded and reflected CV, the most reactive case is with no cladding material intermixed with the bulk oxide. The more cladding material is added to the bulk oxide, the more the reactivity of this system is decreased. The single-unit package is not evaluated because it has been shown that the reflected and flooded CV model is bounding.

6.9.11.5.4 Cladding for fuel pellets

The evaluation involving HEU fuel pellets in rods is performed using the analysis found in Sect. 6.9.8.3.1 as the basis for the next set of calculations. In this section, 12 fuel pellet rods are evaluated inside the CV. These fuel pellets in the shape of rods are modeled as UO_2 at a density of 10.96 g/cm^3

with a diameter of 1.8288 cm and length of 63.5 cm. The SARP evaluated the fuel pellet rods with 0.005-cm-thick aluminum, stainless steel, and zirconium cladding surrounding the fuel pellet rod as well as no cladding. The "UO2_D" model (Fig. 6.9.8.3.1-1d) is shown to be the most reactive configuration for the fuel rods (Table 6.9.8.8-2). The analysis in this appendix modified the "UO2_D" model by varying the cladding thickness up to 0.45-cm thick and adding nickel as cladding material. The results are found in Table 6.9.11.10. These calculations examine the effect of cladding on high density HEU oxide fuel.

Table 6.9.11.10. ES-3100 results for fuel pellet rods with various amounts of cladding CV fully reflected and flooded 27,743.2-g ^{235}U

Clad thickness (cm)	Case 5cvsroxt11c_	$k_{eff} + 2\sigma$ [a]			
		SS304 (ω = 1)	Aluminum (ω = 2)	Zirconium (ω = 3)	Nickel (ω = 4)
0.0	1_ω	**0.80118**			
0.05	2_ω	0.78499	0.79184	0.79419	0.77725
0.10	3_ω	0.76727	0.78347	0.78415	0.75428
0.15	4_ω	0.75077	0.77116	0.77298	0.73055
0.20	5_ω	0.75004	0.75941	0.76237	0.70619
0.25	6_ω	0.70952	0.74496	0.74696	0.68138
0.30	7_ω	0.68972	0.72921	0.73497	0.65613
0.35	8_ω	0.66924	0.71227	0.71956	0.63118
0.40	9_ω	0.64547	0.69589	0.70424	0.60577
0.45	10_ω	0.62212	0.67797	0.68446	0.58020

[a] The shaded sections are masses that would not fit inside the CV at that density.
SS304 = Type 304 stainless steel.

From the results found in Table 6.9.11.10 for a fully flooded and reflected CV, the most reactive case is with no cladding material surrounding each fuel pellet rod. The more cladding material is added to each fuel pellet rod, the more the reactivity of this system is decreased. The single-unit package is not evaluated because it has been shown that the reflected and flooded CV model is bounding.

6.9.11.6 Array Package Evaluation (NCT and HAC)

The analyses presented in Sects. 6.5 and 6.6 demonstrate that maximum reactivity occurs in an array of packages when the CV is flooded (MOCFR of 1.0). Calculations are performed for various size arrays (for both NCT and HAC) with the CV modelled as fully flooded because full flooding of the CV is shown to be the most reactive configuration in Sects. 6.5 and 6.9.11.5.

6.9.11.6.1 UO_2 and carbon

The next set of calculations evaluated the ES-3100 package loaded with oxide with varying amounts of carbon in an infinite array with the CV fully flooded. Calculations for both NCT and HAC are performed varying the amount of carbon from 0 to 5000 g in 1000-g increments at various UO_2 masses. Only calculations with a specific gravity of 1.0E-20 outside the CV (MOIFR) are shown because this specific gravity is shown to be the most reactive. The results of the calculations are found in Tables 6.9.11.11–6.9.11.16 for NCT and HAC cases. The results show that the carbon mixed with oxide does not require any control.

Table 6.9.11.11. ES-3100 results for UO_2 at a density of 2 g/cm^3, infinite array, varying amounts of carbon, CV fully flooded, NCT

From the results found in the Tables 6.9.11.11–6.9.11.16, as in the CV and single package cases shown in Tables 6.9.11.1–6.9.11.6, substituting carbon for oxide and adding carbon to a fixed amount of oxide resulted in a decrease of reactivity. The substitution of carbon for oxide results in the highest decrease in reactivity as opposed to adding carbon to a fixed amount of oxide.

6.9.11.6.2 Cladding for broken metal

The ES-3100 package is evaluated loaded with broken metal with varying amounts of cladding material [SS304 (stainless steel, Type 304), aluminum, zirconium, and nickel] in an infinite array with the CV fully flooded. The case for 2774 g of broken metal at 100% enrichment is used for these calculations because this case is the basis for the limits for broken metal for CSI 0.0 (Table 6.1c). Calculations for the NCT are performed varying the amount of cladding material from none to 6.0-cm thick. The amount of cladding that is evaluated in this section is larger than what is evaluated for the CV cases because the amount of fissile material analyzed in the array cases is significantly less than the CV cases, which allows for more cladding material to be added to the CV. Only calculations with a specific gravity of 1.0E-20 outside the CV (MOIFR) are shown in this section because this specific gravity is shown to be the most reactive.

The HAC cases are not examined because the behavior of the system would be the same due to the only differences in these models are the outer diameter of the drum, the increase of the density of the Kaolite inside the drum, and essentially no difference in the reactivity between NCT and HAC (k_{eff} + 2σ of 0.904 for NCT and 0.905 for HAC from Table 6.1c). The results of the calculations are found in Table 6.9.11.17.

Table 6.9.11.17. ES-3100 results for broken metal with various amounts of cladding CV fully reflected and flooded

Clad thickness (cm)	Case nciabmt11c_	k_{eff} + 2σ [a]			
		SS304 (ω = 1)	Aluminum (ω = 2)	Zirconium (ω = 3)	Nickel (ω = 4)
0.0	1_ω	**0.90406**	N/A	N/A	N/A
0.0506	2_ω	0.90365	0.90304	0.90364	0.90224
0.1016	3_ω	0.90219	0.90319	0.90253	0.90249
0.1508	4_ω	0.90212	0.90066	0.90268	0.90104
0.2032	5_ω	0.90008	0.90210	0.90150	0.89994
0.2446	6_ω	0.89904	0.90043	0.90099	0.89884
1.0	7_ω	0.88358	0.89024	0.89169	0.87866
2.0	8_ω	0.84395	0.86485	0.86666	0.83612
4.0	10_ω	0.71260	0.75712	0.76546	0.68986
6.0	12_ω	0.47076	0.51865	0.53007	0.44871

[a] The "N/A" entries denote where additional calculations are not necessary.
SS304 = Type 304 stainless steel.

From the results found in the Table 6.9.11.17, as in the CV cases (Tables 6.9.11.7 and 6.9.11.8), adding cladding material to broken metal results in a decrease of reactivity. From these calculations, it can be concluded that for stainless steel, aluminum, zirconium, and nickel based cladding, these materials do not need to be controlled for criticality safety purposes.

6.9.11.6.3 Cladding for U_3O_8-Al, oxides of U-Zr, and UO_2-Mg research reactor fuel elements and components

The next set of calculations evaluates the ES-3100 package loaded with research reactor fuel elements and components. This is modeled with varying amounts of cladding material in an infinite array with the CV fully flooded. Only calculations with a specific gravity of 1.0E-20 outside the CV (MOIFR) are shown because this specific gravity is shown to be the most reactive. These contents are shown to be bounded by the bulk oxide analysis evaluated in this SARP. The HEU oxide model used in these calculations is UO_2 at a bulk density of 2.0 g/cm^3 mixed with 500 g of polyethylene with the void spaces inside the oxide filled with water. The 9.682-kg ^{235}U cases are rerun adding cladding to the oxide matrix because this case is the basis for the limits for bulk oxide for CSI 0.0 (Table 6.2a). The HAC cases are not examined since the behavior of the system would be the same due to the only differences in these models are the outer diameter of the drum and the increase of the density of the Kaolite inside the drum. The results of the calculations are found in Table 6.9.11.18.

Table 6.9.11.18. ES-3100 results for oxide research reactor fuel elements and components with various amounts of cladding at 2.0 g/cm^3

Volume (L)	Case nciapdoxt11c_	$k_{eff} + 2\sigma$ [a]			
		SS304 (ω = 1)	Aluminum (ω = 2)	Zirconium (ω = 3)	Nickel (ω = 4)
0.0	1_1_ω	**0.91889**	N/A	N/A	N/A
0.5	1_2_ω	0.89322	0.89297	0.89436	0.89385
1.0	1_3_ω	0.86928	0.87076	0.87378	0.86813
1.5	1_4_ω	0.84743	0.84974	0.85300	0.84612
2.0	1_5_ω	0.82769	0.83251	0.83501	0.82331
3.0	1_7_ω	0.79572	0.80417	0.80824	0.78927
4.0	1_9_ω	0.77617	0.79397	0.79556	0.76332

[a] The "N/A" entries denote where additional calculations are not necessary.
SS304 = Type 304 stainless steel.

From the results found in the Table 6.9.11.18, as in the CV cases (Table 6.9.11.9), adding cladding material to oxides resulted in a decrease of reactivity.

6.9.11.6.4 Cladding for Fuel Pellets

This analysis evaluated the ES-3100 package loaded with HEU fuel pellets modeled as rods as in Sect. 6.9.11.5.6. Calculations are performed varying the types and amounts of cladding material as in the reflected and flooded CV cases but for an infinite array of ES-3100 packages. Only calculations with a specific gravity of 1.0E-20 outside the CV (MOIFR) are shown because this specific gravity is shown to be the most reactive. The HAC cases are not examined because the behavior of the system would be the same due to the only differences in these models are the outer diameter of the drum and the increase of the density of the Kaolite inside the drum. The results of the calculations are found in Table 6.9.11.19.

Table 6.9.11.19. ES-3100 results for fuel pellet rods with various amounts of cladding CV fully flooded infinite array

Clad thickness (cm)	Case 5nsiaoxt11c_	$k_{eff} + 2\sigma$ [a]			
		SS304 (ω = 1)	Aluminum (ω = 2)	Zirconium (ω = 3)	Nickel (ω = 4)
0.0	1_ω	**0.86743**	N/A	N/A	N/A
0.050	2_ω	0.85245	0.85959	0.86152	0.84563
0.100	3_ω	0.83506	0.84831	0.85155	0.82322
0.150	4_ω	0.81643	0.83892	0.83852	0.79969
0.200	5_ω	0.79691	0.82402	0.82557	0.77464
0.300	7_ω	0.75648	0.79220	0.79599	0.72561
0.400	9_ω	0.71180	0.75478	0.75858	0.67644
0.450	10_ω	0.68895	0.73640	0.73757	0.65268

[a] The "N/A" entries denote where additional calculations are not necessary.
SS304 = Type 304 stainless steel.

From the results found in Table 6.9.11.19, the most reactive cases are those with no reflector material surrounding the fuel pellet rod. The more cladding material is added to the fuel pellet rod, the more the reactivity of this system is decreased.

6.9.11.5 Air Transport for Broken Metal

In these calculations, the air transport models are re-evaluated examining the effect of cladding material on these models. For broken metal, Models 1 through 6 are rerun with stainless steel, aluminum, zirconium, and nickel cladding (Tables 6.9.11.20–6.9.11.25). The cladding is homogeneously mixed with the fissile material in all of these models except for Model 6, which homogeneously mixes part of the cladding with fissile material and surrounds the fissile material with the rest of the cladding. A more detailed description of these models is found in Sect. 6.3.1.4 with a brief summary of the models described in this section.

In this analysis, Model 1 is a spherical homogeneous mixture of 10-kg ^{235}U, 500 g of polyethylene, and cladding material surrounded by 20 cm of water. The type and volume of cladding material is varied from none to 5 L in volume.

Model 2 is a spherical homogeneous mixture of 10-kg ^{235}U and 500 g of polyethylene surrounded by cladding material instead of stainless steel, which is surrounded by 20 cm of water. The type and thickness and of cladding material is varied from none to 5.0 cm.

Model 3 a spherical homogeneous mixture of 10-kg ^{235}U, 500 g of polyethylene, and cladding material that is surrounded by wet Kaolite, which is surrounded by 20 cm of water. The amount of Kaolite surrounding the fissile material is varied from none to 60,223.4 g of wet Kaolite (53,419.6 g of dry-baked Kaolite plus 6,803.8 g of free water). The type and volume of cladding material is varied from none to 5 L in volume. If no Kaolite is modeled, Model 3 is the same as Model 1.

Model 4 is a spherical homogeneous mixture of 7-kg ^{235}U, 500 g of polyethylene, wet Kaolite, and cladding material, which is surrounded by 20 cm of water. The amount of water in the Kaolite region is varied from 2,204.7 g in baked-dry Kaolite to 9,008.6 g in wet Kaolite. The type and volume of cladding material is varied from none to 5 L in volume.

Model 5 is a spherical homogeneous mixture of 7-kg ^{235}U, 500 g of polyethylene, excessive moisture from the Kaolite, and cladding material that is surrounded by Kaolite, which is surrounded by 20 cm of water. The amount of water from the Kaolite region in the fissile material region is varied from 2,204.7 g in baked-dry Kaolite to 9,008.6 g in wet Kaolite. The type and volume of cladding material is varied from none to 5 L in volume.

Model 6 is a spherical homogeneous mixture of part of 7-kg ^{235}U, 500 g of polyethylene, wet Kaolite, and part of the cladding material surrounded by a homogeneous mixture of the remaining 7-kg ^{235}U and remaining cladding material, which is surrounded by 20 cm of water. The type and volume of cladding material is varied from none to 5 L in volume.

The most reactive configurations of the models are presented in the tables below. The results of the calculations are found in Tables 6.9.11.20–6.9.11.25.

[a] The "N/A" entries denote where additional calculations are not necessary.
SS304 = Type 304 stainless steel.

From the results found in the Table 6.9.11.25, adding stainless steel and nickel cladding results in a decrease in reactivity. Adding aluminum and zirconium cladding results in either no increase or a decrease in reactivity. All cases are well below the USL.

6.9.11.6 UF_4 at CSI 2.0

This section discusses the calculations for the array calculations for UF_4 at a CSI of 2.0. For a CSI of 2.0, the array size for NCT is 7 × 7 × 3. The results of these calculations are found in Table 6.9.11.26. The CV and single package models were evaluated in Sect. 6.9.8.5.5 and were shown to be below the USL for up to 24-kg UF_4 (Table 6.9.8.8-5a for calculation results). From Sect. 6.9.8.6, the analyses presented in Sects. 6.4, 6.5, and 6.6 demonstrate that an insignificant difference is observed between the calculated $k_{eff} \pm 2\sigma$ values for undamaged packages in NCT and damaged packages in HAC. Therefore, the HAC array analysis is redundant and not performed.

Table 6.9.11.26. ES-3100 results for UF_4, 7×7×3 array, CSI 2.0, CV fully flooded, NCT

24	24_ω	0.85500	N/A	N/A	N/A	N/A	N/A

[a] The "N/A" entries denote where additional calculations are not necessary.

From the results found in Table 6.9.11.26 for a 7 × 7 × 3 array (CSI of 2.0) with NCT, the most reactive configuration is for 13 kg of UF_4 with no interstitial water between the packages. This case is below the USL (Case **5ncf3puf4t11_13_1** with $k_{eff} + 2\sigma$ of 0.870).

6.9.11.7 Conclusions

For uranium oxides, there are no limits on amount of carbon that may be mixed with the oxide; thus, all carbon limitations are removed.

From the calculations performed in this appendix, it is shown that for broken metal and research reactor fuel elements and components bounded by bulk oxide, no cladding is the most reactive configuration. As cladding is added to the fissile material, reactivity decreases. In the air transport models, reactivity decreases as cladding is added to the fissile material, except for Model 6 where reactivity increases slightly but remained well below the USL. Thus, it can be concluded that for stainless steel, aluminum, zirconium, and nickel based cladding, these materials do not need to be controlled for criticality safety purposes.

Uranium metal loadings in this package may contain quantities of alloying constituents, none of which are fissile. These constituents act a diluent when mixed with HEU metal. Calculations are performed in Sects. 6.9.11.5.4 and 6.9.11.6.4 for broken metal evaluated uranium homogeneously mixed with various amounts of aluminum, steel, zirconium, or nickel. Adding these materials to the uranium metal resulted in a decrease in reactivity for both single-unit and array calculations. Furthermore, TID-7016 (Sect. 3.1, p. 71) states that when ^{235}U, ^{233}U, or plutonium metal is mixed with any element from $11 \leq Z$ (atomic number) ≤ 83 (from sodium to bismuth), the amount of fissile material required to go critical increases. If the system was shown to be subcritical without the alloying material, then adding alloying material would increase the amount of fissile material required to go critical, thus diluting the system and resulting in a less reactive system. Therefore, alloying materials of any element from $11 \leq Z \leq 83$ do not require any criticality safety controls.

For UF_4 at a CSI of 2.0, the maximum amount of UF_4 per ES-3100 package is 24 kg (18.136-kg ^{235}U).

7. PACKAGE OPERATIONS

Radioactive material packages shall be operated in accordance with applicable U.S. Nuclear Regulatory Commission (NRC), U.S. Department of Transportation (DOT), and other federal, state, and local regulations to protect the health and safety of the public, workers, and the environment. Furthermore, the packages shall be operated according to a quality assurance (QA) plan approved by the U.S. Department of Energy (DOE), Office of Environmental Management; or DOE, National Nuclear Security Administration (DOE/NNSA); as appropriate.

The user is responsible for following the established NRC regulations for packaging, preparation for shipment, and transportation of radioactive materials given in Title 10, Part 71, of the Code of Federal Regulations (CFR) [10 CFR 71] as well as DOT regulations for packaging and shipment of hazardous materials given in Title 49 CFR. DOE nuclear facility users are responsible for implementing DOE regulations given in Title 10, Parts 830 and 835, of the CFR in addition to directives conveyed in DOE Order (O) 232.2A, DOE O 414.1D, and DOE O 460.1D or DOE O 461.1C, as appropriate.

Specific operational criteria for the ES-3100 package with highly enriched uranium (HEU) content are presented in this section. Where appropriate, facility management may authorize the adjustment of the explicit implementation sequence in this section to accommodate facility-specific workflow logistics and operational requirements. The package user shall develop detailed, written site-specific operating procedures based on the Certificate of Compliance (CoC), the criteria contained herein, and the facility's operational requirements. These procedures shall be in accordance with 10 CFR 71, Subparts A, G, and H; DOT and DOE regulations; and applicable state, tribal, and local regulations not preempted by DOT. The operating procedures should also describe interim activities to be performed if the package is to be temporarily stored prior to shipment. Storage incident to transportation shall be in accordance with the facility Safety Analysis Report (10 CFR 830) or the Transportation Safety Document (TSD) [DOE O 460.1D or DOE O 461.2, as applicable].

The package operations should be consistent with maintaining occupational radiation exposures as low as reasonably achievable (ALARA) [10 CFR 71.87(i)] in addition to addressing applicable safety aspects or activities such as personal protection (radiation, chemical, and physical); contamination or radiation surveys; nuclear criticality safety; provisions for reporting safety concerns associated with the packaging or its use; and the records and reporting requirements cited in Appendix 7.5.1. The user of the packaging shall:

1. have authorization to acquire, package, or transport radioactive, fissile, or special nuclear materials;

2. have the latest CoC and safety analysis report for packaging (SARP) for the ES-3100 package with HEU content, and comply with all actions and restrictions therein;

3. be registered as a user of the ES-3100 packaging with DOE;

4. comply with the applicable requirements of the DOT regulations in Title 49 CFR, Parts 107, 171–180, and 390–397, as appropriate to the mode of transport (10 CFR 71.5); and

5. have a site-approved QA program that meets the requirements of 10 CFR 71, Subpart H.

The ES-3100 package description is presented in Sect. 1.2 with a schematic shown in Fig. 1.1, and an exploded view of the packaging components is presented in Fig. 1.2. The ES-3100 certification drawing can be found in Appendix 1.3.1. The packaging design drawings (Appendix 1.3.7) provide material lists, dimensions, safety components, welding requirements, and gasket requirements. The largest nominal gross shipping weight of the ES-3100 package with bulk HEU content is 187.81 kg (414.05 lb) and the maximum allowable gross weight is 190.5 kg (420 lb).

The ES-3100 is handled using industry-standard drum-handling equipment. When using a forklift, the ES-3100 can be placed on the tines of the forklift from below, or it is designed for a forklift pincher assembly that can be used to grasp the exterior of the drum assembly. Forklift gripping forces of up to 5400 lb can be used with no detrimental effects on the package (Sect. 1.2.1.1).

The site-specific operating procedures, which include the facility's operational requirements, shall ensure that:

1. All appropriate documents have been reviewed by operating personnel and are available for further review, if necessary.

2. Certified equipment is used (e.g., torque wrenches, instrumentation, scales, lifting hardware, and radiation survey instruments) in accordance with the site-approved QA program.

3. Segregated work stations, curtains, lead blankets, personnel protective equipment, or other equipment is used, as necessary, to protect workers and nearby personnel from radioactive material hazards.

4. Appropriate material handling equipment is available and approved for use (e.g., forklifts, hoists, and drum handlers). Operating controls shall be implemented for any forklift pincher assembly to limit clamping forces on the drum body (i.e., $\leq$ 5400 lb).

5. Appropriate provisions to decontaminate packages and packaging components are provided consistent with ALARA principles.

6. During routine package operations, adhesive-backed items such as labels, tags, stickers, tape, or document holders can be affixed to the package stainless-steel surfaces. Unless directed otherwise in this chapter, the placement of adhesive-backed items over painted identification markings on the package will be avoided. Given that commercially available plain vinyl tape and vinyl-type transportation labels are readily removable and leave a minimal adhesive residue, an adhesive-backed item that is not readily removable or leaves an excessive adhesive residue upon removal (resulting in increased maintenance time and expense) will be placed on plain vinyl tape, which is affixed to the package surface.

   Note: The Y-12 ES-3100 Program Manager or the Y-12 ES-3100 packaging engineer may authorize relief from these adhesive-backed item requirements on a per shipment basis. A copy of the Y-12 authorization shall be included with the shipping papers.

7. An optional radio-frequency identification (RFID) monitoring system tag may be secured to the drum assembly in accordance with the applicable requirements of ANL/DIS-09-5. The mounting bracket for the RFID monitoring system tag shall provide the equivalent contact area of a drum washer and the thread engagement for the drum hex nuts shall remain unchanged. When attached, the RFID tag will extend beyond the outside diameter of the drum body, and controls shall be implemented to avoid damage to the RFID tag.

Care should be exercised to control the packaging components when they are removed to ensure that parts are kept with the packaging and not mixed with other loose parts or parts from other packagings. Other preparations should be made to minimize damage or loss of packaging components. The drum and CV are marked with their serial numbers. The numbers are used to control these parts and to accumulate their respective operational and maintenance histories. Applicable serial numbers of packaging components should be verified to ensure that these components are maintained together. Loose parts (e.g., hex nuts, washers, and O-rings) may be reused if it can be shown that they were the parts that were removed and that no damage to the parts has occurred. Otherwise, they shall be discarded and replaced with certified parts. In order to maintain configuration control of the packaging components, the user shall ensure that there are no unauthorized modifications and no substitution of components with unauthorized components. The user may replace certain parts identified in Table 7.1, and the certification of all replacement parts must be traceable. The user shall document any part replacement identifying it to a specific packaging by model and serial number.

Table 7.1. Replacement parts for the ES-3100 packaging

Part	Description	Material	Specification/ Data Sheet [a]
ES-3100 drum assembly (Drawing M2E801580A001, Appendix 1.3.7)			
Drum lid hex nut	5/8-11 UNC-2B hex nut	Silicon bronze	ASTM F 467 per ASME B18.2.2 M2E801580A005-3
Drum lid washer	0.812-in. ID × 1.375-in. OD × 0.25-in.-thick	Stainless steel	ASTM A 240 or ASTM A 276 M2E801580A005-4
Nylon plug	Vent-hole plug (installed around circumference of the drum body and on top of the top plug)	Nylon 6/6	Micro Plastic, Inc. Part 62MP0312 or equivalent M2E801580A002-8 M2E801580A008-7
Silicone rubber pads (CV bottom, CV flange, and plug)		Silicone rubber 22 ± 5 Shore A	M2E801580A009-1 M2E801580A009-2 M2E801580A009-3
Aluminum tape	Duct tape, low temperature (−40 to +250°F), 2-in. wide	Aluminum foil	M2E801580A002-11 McMaster-Carr Part 7616A21 or equivalent
ES-3100 containment vessel assembly (Drawing M2E801580A011, Appendix 1.3.7)			
Outer O-ring	5.859-in. ID × 0.139-in. diam cross section	Ethylene propylene diene monomer (EPDM)	ASTM D 2000, M2E801580A013-2
Inner O-ring	5.359-in. ID × 0.139-in. diam cross section	EPDM	ASTM D 2000, M2E801580A013-1
Modified VCO [b] threaded plug with O-ring	Leak-test-port plug	Brass	Volunteer Industrial P/N 04-2126 M2E801580A011-6

[a] All items beginning with"M2E" or "M8" are part numbers and the parts are shown on the corresponding drawings in Appendix 1.3.7.
[b] VCO—Vacuum coupling O-ring.

If packaging components are stored for an extended period of time, they may be bagged. The packaging components (i.e., complete assembly or individual parts) will be stored in weather-protected indoor facilities and transferred between facilities in an enclosed conveyance for protection from environmental elements. Generally, the exterior surface of the packaging components will remain relatively clean; however, each user will include provisions in the operating procedures to clean packaging components as necessary. Additionally, special precautions should be taken to protect the packaging from inadvertent contamination by radioactive materials. In radiological contamination areas, the packaging or package should be placed onto surfaces that are covered with a disposable covering, such as plastic or paper, to minimize the transfer of contamination.

The reference to nonfixed (removable) surface contamination is repeated throughout the various operating sections. It is essential that radiation exposure be minimized to protect the health and safety of the public, workers, and the environment. As the package is prepared to enter the public domain, the surface contamination level of the package and the conveyance will be maintained ALARA.

All personnel who support and/or perform packaging, transfer and transportation operations will be appropriately trained and qualified in accordance with the site-approved QA program; 49 CFR 171.1; and 49 CFR 172, Subpart H, as appropriate. Auditable training records will be maintained in accordance with site record retention requirements. The Y-12 National Security Complex (Y-12) ES-3100 Program Manager and the Y-12 ES-3100 packaging engineer must be apprised of all planned users of the ES-3100 package to ensure proper operational training has been performed.

7.1 PACKAGE LOADING

This section addresses the operational criteria relating to the preparation for loading, loading of contents, and preparation for transport of the ES-3100 package. Implementation of the operational criteria in this section along with the conditions of the CoC and the requirements of 10 CFR 71.5 will ensure that the package is properly prepared for transport.

7.1.1 Preparation for Loading

The user shall develop detailed operating procedures which include, at a minimum, the process steps listed below for content and packaging preparation activities.

7.1.1.1 Content preparation

Operating personnel shall ensure that:

1. The HEU material has been verified as being within the limits specified in this SARP and the CoC for content form, material mass, material dimensions, uranium content, and ^{235}U enrichment as presented in Sect. 1.2.2. The contents shall be verified using accountability records and weight measurements.

   Note: A radiation survey of the contents may be conducted prior to loading to measure the content dose rate. The measured dose rate should be compared with known or calculated values. This is not a requirement and generally should only be performed if there are shielding concerns.

2. Packing materials (e.g., convenience cans or bottles; polyethylene, nylon, or Teflon bags; silicone can pads; can spacers; stainless-steel scrubbers) are visually inspected for signs of moisture, corrosion, or physical damage.

3. If the contents are broken HEU metal and alloy, proceed to Step 4. For all other contents, proceed to Step 7.

4. For proper handling of broken HEU metal and alloy, pyrophoric concerns will be addressed by one of the following options:

   a. Treat all broken HEU metal and alloy content as pyrophoric and proceed to Step 6; or

   b. Determine whether or not the broken HEU metal and alloy content is pyrophoric in accordance with Step 5.

5. For pyrophoric categorization of broken HEU metal and alloy content, the specific surface area of the metal pieces (surface area to mass ratio) is evaluated. If the specific surface area is $\leq$1.00 cm^2/g, then the metal pieces are not pyrophoric and are acceptable for loading according to Step 7. If the specific surface area is >1.00 cm^2/g or if the specific surface area cannot be evaluated, characterize the metal using the following methods:

   a. Solid-metal pieces that are clearly larger than 3/8 in. in every dimension do not require additional size-grading determinations and are acceptable for loading according to Step 7.

   b. Items which are unacceptable by definition (Sect. 1.2.2), such as powders, foils, wires, and turnings, will be rejected and do not require additional size-grading determinations. These items will be loaded according to Step 6.

   c. Any items that are not obviously larger than the 3/8 in. in every dimension must be size-graded using a 3/8-in. (9.5-mm) mesh sieve as follows:

      Note: With facility management approval, equivalent size-grading methods may be used [e.g., 3/8-in. (9.5 mm) mesh screens, visual comparison to size standards, etc.].

      i. Any item that falls through the sieve must be rejected and will be loaded according to Step 6.

      Note: Operators need to be alert to items which may not fall through the sieve but can be rejected based on the following criteria:

      - Long, thin shapes such as wires and turnings may not fall through the sieve when shaken. If the wire or turning could be picked up and poked through the mesh it must be rejected, even if it did not fall through unassisted.

      - Wires or turnings may form a tangled ball which will not fall through the sieve. If the wire or turning could be separated and poked through the sieve, it must be rejected.

      - Foils, thin chips or shards (any item less than 1/8-in. thick) must be rejected.

      ii. The metal pieces that are not rejected by the criteria above are acceptable for loading according to Step 7.

6. Load the rejected broken HEU metal and alloy content in a sealed container under an inert cover gas (e.g., argon or nitrogen).

   Note: The sealed container with an inert atmosphere will be leaktight as defined in ANSI N14.5-1997.

7. All contents are loaded in appropriate cans, bottles, or bags with associated packing material in accordance with the allowable loading limits and restrictions specified in Sect. 1.2.2.

7.1.1.2 Packaging preparation

Operating personnel shall ensure that:

1. A valid leak-test sticker is present on the drum to ensure that the required periodic maintenance (Sect. 8.2) and leak testing has been performed.

2. For planning purposes, the following conditions will be satisfied:

   a. The package will arrive at its destination prior to the expiration of the CoC;

   b. The package must be loaded in the approved conveyance and the conveyance operator must take custody of the package prior to the leak-test expiration date [recorded on the leak-test label (see Fig. 8.1) on the exterior of the drum]; and

   c. When shipping HEU oxides or uranyl nitrate crystals (UNX), the shipper must verify that the shipment can be completed within the time period allotted [2 or 4 months from CV closure for UNX crystals (Table 1.3a) or 1 year from CV closure for HEU oxides (Table 1.3)].

3. The level of nonfixed radioactive contamination on the external surfaces of the packaging is ALARA and within the limits specified in 49 CFR 173.443 for alpha-, beta-, and gamma-emitting radionuclides or the user's site-specific criteria (whichever is more stringent).

4. The exterior surface of the packaging is visually inspected for signs of moisture, corrosion, or physical damage and is in good condition.

5. If installed on the empty packaging, the tamper-indicating devices (TIDs) are removed when authorized.

6. The drum hex nuts and washers are removed.

   Note: If the optional RFID monitoring system tag is installed, remove the RFID tag in accordance with the applicable requirements of ANL/DIS-09-5.

7. The drum lid is removed.

8. Site-approved lifting hardware is attached to the top plug threaded lifting holes and the top plug is removed.

9. Accessible portions of the interior of the drum body and top plug are visually inspected for signs of moisture, corrosion, or physical damage and are in good condition.

10. The silicone rubber CV flange pad is removed from the top of the CV.

    Note: A contamination survey of the exposed drum liner and top of the CV may be conducted if there are contamination concerns.

11. The silicone rubber CV flange pad and plug pad are visually inspected for signs of moisture and physical damage. There are no significant gouges, cuts, tears, or nondesign voids in the pads.

    Note: Refer to Sect. 8.2.5.6 for silicone rubber pad rejection criteria.

12. The top of the CV is visually inspected for signs of moisture, corrosion, or physical damage and is in good condition. There are no visible signs of damage and the CV sealing lid is secure.

13. The swivel hoist ring is installed in the CV sealing lid and torqued to 16.27 ± 1.36 N·m (12 ± 1 ft-lb) [Drawing M2E801580A011, Appendix 1.3.7].

14. The CV is lifted from the drum body using the swivel hoist ring and site-approved lifting equipment, and the exterior surface of the CV is visually inspected for signs of moisture, corrosion, or physical damage.

15. Comparisons of the serial number etched on the following locations are in agreement:

    a. trefoil data plate located on the side of the drum body,
    b. side of the CV body,
    c. top of the CV sealing lid, and
    d. top of the CV lid closure nut.

16. The leak-test labels are present on the drum and the CV with the recorded expiration date.

17. The drum liner is visually inspected for signs of moisture, corrosion, or physical damage.

18. The aluminum foil tape applied over the neutron-absorbing material cavity fill and vent holes (four places) located on the drum liner lower shelf (Drawing M2E801580A002, Appendix 1.3.7) is visually inspected for damage such as tears, holes, or loose edges.

19. The silicone rubber CV bottom pad is installed in the bottom of the drum cavity. If necessary, the CV bottom pad is removed and visually inspected for signs of moisture and physical damage. There are no significant gouges, cuts, tears, or nondesign voids in the pad.

    Note: Refer to Sect. 8.2.5.6 for silicone rubber pad rejection criteria.

20. In order to support the CV during disassembly and loading operations, users have two options:

    a. Install a site-approved support plate on the top of the drum body and lower the CV into the drum body with the CV flange resting on the support plate; or

    b. Lower the CV into a site-approved support stand.

21. The swivel hoist ring is removed from the CV sealing lid.

22. The CV lid assembly is removed and placed on a protective surface to prevent scratching of the sealing surface.

    Note: A contamination survey of the CV interior surfaces may be conducted if there are contamination concerns.

23. Any packing materials (e.g., convenience cans or bottles; polyethylene, nylon, or Teflon bags, silicone rubber can pads; can spacers; stainless-steel metal scrubbers), if present, are removed from the CV.

24. The interior of the CV is visually inspected for signs of moisture, corrosion, or physical damage and is in good condition.

25. Isopropyl alcohol and lint-free gloves, cloths, or swabs are used to clean the CV interior surface, as necessary.

7.1.2 Loading of Contents

The user shall develop detailed operating procedures which include, at a minimum, the process steps listed below for loading content into the CV. Operating personnel shall ensure that:

1. The CV has been emptied of radioactive contents as far as practical.

2. The O-rings and the O-ring grooves on the CV flange are protected from damage during loading operations.

3. The HEU content and associated packing materials (e.g., convenience cans or bottles; polyethylene, nylon, or Teflon bags; silicone rubber can pads; can spacers; stainless-steel metal scrubbers) are prepared for loading in accordance with the requirements of Sect. 1.2.2. The weight of the CV payload (HEU content including all packing materials) shall not exceed 40.82 kg (90 lb).

4. The CV payload is loaded into the CV body in accordance with Sect. 1.2.2.

7.1.2.1 CV assembly and leak testing

The user shall develop detailed operating procedures which include, at a minimum, the process steps listed below for preparing the CV for closure and leak testing. Operating personnel shall ensure that:

1. The CV O-rings and sealing surfaces are cleaned and inspected as follows:

   Note: The O-rings are retained in half-dovetail grooves and may be removed from the CV flange grooves as necessary to facilitate cleaning and inspection activities. Exercise care during removal and installation to avoid damage to the O-rings and O-ring grooves.

   a. Clean the sealing surfaces and O-rings, as required, with isopropyl alcohol and lint-free gloves, cloths, or swabs.

   b. Visually inspect the sealing surfaces for foreign matter, nicks, and scratches. If nicks or scratches are found, review Sect. 8.2.2 for evaluation criteria.

   c. Visually inspect the inner and outer O-rings for roughness, porosity, or surface defects. Damaged O-rings may be replaced with certified replacement O-rings (Table 7.1) subject to the requirements of Sect. 8.1.5.1 and the following:

      i. If the outer O-ring is damaged and requires replacement, then it can be replaced without performing the maintenance leakage rate testing (Sect. 8.2.2).

      Note: The outer O-ring is not part of the containment boundary. The outer O-ring functions as a seal to create the annulus between the O-rings in support of preshipment leak testing.

      ii. If the inner O-ring is damaged and requires replacement, the HEU content shall be removed (see Steps 14-16 in Sect. 7.2.2), and the leakage testing of the containment boundary shall be performed in accordance with Sect. 8.2.2 by qualified personnel.

      Note: Although only the inner O-ring is installed during the leakage testing (Sect. 8.2.2), both O-rings will be replaced during periodic maintenance in accordance with Sect. 8.2.3.1.

2. The O-rings are lubricated as necessary with a thin coat of Super-O-Lube and inserted into the CV flange grooves.

3. The CV lid closure nut threads are visually inspected for damage and foreign matter. If necessary, clean the threads with lint-free gloves, cloths, or swabs.

4. A thin coat of Krytox grease, Grade 240 AC, is applied as necessary to the CV lid closure nut threads (Drawing M2E801580A011, Appendix 1.3.7).

5. The CV lid assembly is positioned over the CV body with the two alignment pins in the CV flange engaged in the slots on the underside of the CV lid assembly.

6. The CV lid closure nut is torqued to 162.7 ± 6.78 N·m (120 ± 5 ft-lb) [Drawing M2E801580A011, Appendix 1.3.7].

   Note: If the content is HEU oxide or uranyl nitrate crystals (UNX), the seal date is recorded (see Sect. 7.1.1.2, Step 2c).

7. The annulus between the CV O-rings is leak tested to either (1) a leakage rate of not more than the reference air leakage rate, L_R, or (2) no detected leakage when tested to a sensitivity of at least 1×10^{-3} ref-cm^3/s in accordance with the requirements of ANSI N14.5-1997, Subclause 7.6, Preshipment leakage rate test. The preshipment leak-test procedure shall meet the requirements of ANSI N14.5-1997 and the site-approved QA program. Y-12 Product Specification Procedure Y51-01-B2-R-074, *Shipping Container Leak Test* (Appendix 7.5.2) is provided as an example preshipment leak-test procedure. It should be noted that the leakage rate acceptance criteria stated in Procedure Y51-01-B2-R-074 is lower (i.e., more conservative) than the ANSI N14.5-1997 requirements noted above for a preshipment leak test. Operating personnel shall perform the following at a minimum:

   a. Ensure that the preshipment leak testing is performed in accordance with procedures that meet the criteria presented above and that the results are properly documented.

   b. Ensure that leak-test instrumentation has been properly calibrated.

   c. Remove the modified VCO threaded brass plug from the CV lid assembly leak-test port.

      Note: If the plug O-ring is not retained on the VCO threaded plug during plug removal, then use caution when extracting the plug O-ring to prevent damage of the leak-test port O-ring sealing surface.

   d. Connect the leak-test equipment to the leak-test port.

   e. Perform the preshipment leak test under isothermal conditions.

   f. Disconnect the leak-test equipment.

   g. Install the modified VCO threaded brass plug in the CV lid assembly leak-test port.

Following a successful preshipment leak test, the CV is ready to be loaded into the drum body assembly per Sect. 7.1.2.2. However, if the preshipment leak test fails to reach the required vacuum/pressure or fails the leak test, then the following measures should be taken: (1) review the operating procedures; (2) check the leak-test equipment and connections; (3) check the test gauges and instrumentation including verification of calibration and certification records, as necessary; and (4) verify

isothermal test conditions. The user is also cautioned to allow sufficient time after applying the required vacuum or pressure for the O-ring annulus to reach thermal equilibrium.

The CV lid assembly shall be removed if none of the measures described above reveal the root cause for the leak-test failure. Care should be taken to control all parts on removal and then Steps 1-7 specified above shall be repeated. If the preshipment leak test fails again, the HEU content shall be removed by performing Steps 14–16 in Sect. 7.2.2. The packaging and O-rings shall be tagged as "potential" nonconforming parts and returned to the packaging maintenance organization for closer examination and disposition.

7.1.2.2 Drum closure

The user shall develop detailed operating procedures which include, at a minimum, the process steps listed below for preparing the drum assembly for closure. Operating personnel shall ensure that:

1. The CV assembly with HEU content was prepared for loading into the drum body assembly in accordance with Sect. 7.1.2.1.

2. The loaded CV, top plug, drum lid, plug pad, CV bottom pad, CV flange pad, drum nuts and washers, TIDs, and optional RFID monitoring system tag are available.

3. The swivel hoist ring is installed in the CV sealing lid and torqued to 16.27 ± 1.36 N·m (12 ± 1 ft-lb) [Drawing M2E801580A011, Appendix 1.3.7].

4. The loaded CV is lifted using the swivel hoist ring and site-approved lifting equipment.

5. If the CV was loaded while supported in the drum body, then remove the site-approved support plate.

6. The loaded CV is lowered into the drum body cavity and the swivel hoist ring is removed.

7. The CV flange pad is placed over the top of the CV and the plug pad is placed on the top shelf of the drum liner (Drawing M2E801580A001, Appendix 1.3.7).

8. The nylon plug is installed in the top plug vent hole and site-approved lifting hardware is attached to the top plug threaded lifting holes.

9. The top plug is installed in the drum (Drawing M2E801580A001, Appendix 1.3.7) and the lifting hardware is removed.

10. The drum weld studs and hex nut threads are visually inspected for damage and foreign matter. If necessary, clean the threads with lint-free gloves, cloths, or swabs.

11. The drum lid is positioned over the drum with the holes in the lid aligned with the weld studs and the TID lugs, and the lid is lowered into position.

12. The eight 5/8-11 UNC-2B hex nuts with washers (Drawing M2E801580A005, Appendix 1.3.7) are installed and the nuts are torqued to 40.67 ± 6.78 N·m (30 ± 5 ft-lb) [Drawing M2E801580A001, Appendix 1.3.7]. **An impact wrench shall not be used.**

    Note: An optional RFID monitoring system tag may be installed in accordance with the applicable requirements of ANL/DIS-09-5.

13. A nylon plug is installed in each of the four drum vent holes (Drawing M2E801580A002, Appendix 1.3.7).

14. As required by site-specific requirements, either one or two TIDs are attached through the drum TID links.

15. The gross weight of the package does not exceed 190.5 kg (420 lb).

16. All "EMPTY" or inappropriate labels previously affixed to the drum body in conformance with 49 CFR 172, Subpart E are removed, obliterated, or covered. Leak-test labels should not be removed. The drum body is cleaned as necessary including the removal of any adhesive residue from removed labels.

17. The level of nonfixed radioactive contamination on the external surfaces of the package is ALARA and within the limits specified in 49 CFR 173.443 for alpha-, beta-, and gamma-emitting radionuclides or the user's site-specific criteria (whichever is the most stringent).

18. The maximum radiation level at the package surface is measured. In addition, the maximum radiation level at 1 m from the external surface shall be measured to establish the transport index (TI) for the package. The radiation levels should be compared with the expected levels (Chap. 5), as appropriate, and evaluated against the allowable radiation levels prescribed in 10 CFR 71.47 and 49 CFR 173.441.

19. The package is labeled in accordance with 49 CFR 172, Subpart E, and the user shall particularly note the requirements of 49 CFR 172.403, *Class 7 (radioactive) material*.

    Note: All labels shall be vinyl type or placed on plain vinyl tape and applied to the packaging to facilitate removal during maintenance.

20. The package is marked in accordance with 49 CFR 172, Subpart D. The user shall particularly note the requirements of 49 CFR 172.301, *General marking requirements for non-bulk packagings*, and 49 CFR 172.310, *Class 7 (radioactive) materials*.

    Note: For enriched uranium content in the ES-3100, which in aggregate is less than a Type B quantity of material, the proper shipping name and identification number etched on the data plate (Drawing M2E801580A010, Appendix 1.3.7) are appropriate provided that the shipping papers indicate the hazardous material description (e.g., Type A quantity of material) contained in the Type B(U)F packaging.

21. The DOE CoC number [USA/9315/B(U)F-96 (DOE)] is marked on the drum body by one of the following methods:

    a. **Preferred method.** The NRC CoC number [USA/9315/B(U)F-96] will be covered with opaque vinyl tape and the package will be marked near the data plate with the DOE CoC number in letters at least ½-in. high.

    b. **Alternate method.** A "(DOE)" marking in letters at least ½-in. high will be added adjacent to right-hand side of the data plate in line with the NRC CoC number.

    c. **Alternate method.** The DOE CoC number is marked on the data plate in accordance with Drawing M2E801580A010, Appendix 1.3.7.

7.1.3 Preparation for Transport

The transfer of the package to an onsite storage or staging area prior to offsite shipment shall be accomplished in accordance with the facility Safety Analysis Report or the TSD, as applicable. The criticality safety index (CSI) may vary from 0–3.2 for the authorized content and fissile mass loading limits (Table 1.3). Because the dose rate (and therefore the TI) presented in Chap. 5 is conservative,

the actual TI, which is measured at the time of shipment, should be lower than the maximum calculated TI value for the HEU content (TI = 6.2 for 36 kg of HEU metal and TI = 5.1 for 24 kg of HEU oxide (Tables 5.1 and 5.2, respectively). These TI values are greater than or equal to the TI values for the other authorized content and fissile mass loading limits (Sect. 5.1.1).

In support of criticality safety evaluations (Sect. 6.3.1.4) and due to the potential exposure to environmental elements during transfer or handling operations, all packages prepared for air transport will be appropriately covered with an industry-standard drum cover or other waterproof cover to protect against water from entering the drum cavity. After loading in the aircraft, the drum covering may be removed to facilitate tie down of the package.

7.1.3.1 Package transfer or handling

The user shall develop detailed operating procedures which include, at a minimum, the process steps listed below for preparing the package for transfer or handling. Operating personnel shall ensure that:

1. The level of nonfixed radioactive contamination on the external surfaces of the package is ALARA and within the limits specified in 49 CFR 173.443 for alpha-, beta-, and gamma-emitting radionuclides or the user's site-specific criteria (whichever is more stringent).

2. Appropriate package labels are affixed to the package's surface and TIDs are properly installed.

3. Placement restrictions associated with onsite handling, storage, staging, or transfer of radioactive materials for onsite operations are identified. These activities are governed by the applicable requirements of the TSD (DOE O 460.1D or DOE O 461.2, as appropriate) and the facility Safety Analysis Report (10 CFR 830).

4. All packages prepared for air transport will be appropriately covered with an industry-standard drum cover or other waterproof cover to protect against water from entering the drum cavity. After loading in the aircraft, the drum covering may be removed to facilitate tie down of the package.

7.1.3.2 Decontamination

As the package is prepared to enter the public domain, the surface contamination level of the package will be maintained ALARA. The user shall develop detailed operating procedures for decontaminating packages that consider, at a minimum, the items listed below:

1. The drum is austenitic stainless steel.
2. The drum nuts are silicon bronze.
3. The drum vent holes are covered with nylon plugs (Drawing M2E801580A002, Appendix 1.3.7).
4. The labels and markings on the drum must remain legible.

7.1.3.3 Requirements prior to shipment

The shipper shall notify the receiver of the scheduled shipment [49 CFR 173.22(c)] and verify that the receiver has agreed to accept the shipment. If needed, the shipper shall provide any special instructions to the receiver to safely open the package (10 CFR 71.89), including special tools and precautions for handling or unloading. In addition, the shipper will submit appropriate documentation to the receiver to ensure that the physical characteristics and hazards of the HEU content are conveyed (49 CFR 172, Subpart C).

Before each shipment, the shipper shall ensure that the appropriate routine determinations (10 CFR 71.87) and the quality control requirements (49 CFR 173.475) have been satisfied. Detailed operating procedures shall provide evidence that the requirements stated above are met and ensure that:

1. The package has been loaded properly and preparation for shipment has been followed, witnessed, and checked.

2. When shipping HEU oxides or UNX, the shipper provides the receiver with the date that the CV was sealed. The shipper must verify that the shipment can be completed within the time period allotted [2 or 4 months for UNX crystals (Table 1.3a) or 1 year for HEU oxides (Table 1.3)].

3. All records for the shipment are prepared and maintained (Sect. 7.5.1.1) [10 CFR 71.91(a)].

4. The shipping papers including the appropriate shipper's certification (declaration) statement are prepared in accordance with 49 CFR 172, Subpart C.

5. The placarding requirements of 49 CFR 172, Subpart F, are addressed.

6. The emergency response information in accordance with 49 CFR 172, Subpart G, is addressed.

7. As determined by 49 CFR 172.800, security plans are developed in accordance with 49 CFR 172, Subpart I.

7.1.3.4 Securing to the approved conveyance

The package shall be secured against movement within the conveyance in which it is being transported under conditions normally incident to transportation. The user shall develop detailed operating procedures that include, at a minimum, the process steps listed below for loading and securing the package on the approved conveyance. Operating personnel shall ensure that:

1. An approved conveyance is used in accordance with the CoC-authorized mode of transport.

2. Reasonable precautions such as wheel chocking are taken to prevent motion of the conveyance during package loading.

3. The package must be loaded in the approved conveyance and the conveyance operator must take custody of the package prior to the leak-test expiration date [recorded on the leak-test label (see Fig. 8.1) on the exterior of the drum].

4. The consignment is positioned on the conveyance under the direction of qualified personnel in such a way that the weight is properly distributed over the width and length of the conveyance.

5. The ends, sides, or doors of the conveyance are not relied upon to prevent shifting of loads.

6. The package is secured in the conveyance using blocking, bracing, and tie-down equipment that meet industry-standard practices to prevent shifting during Normal Conditions of Transport (NCT) [49 CFR 173.448(a); 49 CFR 175.88(c) and 49 CFR 177.842(d)].

7.2 PACKAGE UNLOADING

Placement restrictions associated with onsite handling, storage, staging, or transfer of radioactive materials for onsite operations will be identified. These activities are governed by the

applicable requirements of the TSD (DOE O 460.1D or DOE O 461.2, as appropriate) and the facility Safety Analysis Report (10 CFR 830).

If HEU oxide or UNX are being shipped, the receiver shall check the seal time and date before opening the container (shipment time restrictions for these contents are discussed in Sect. 1.2.2.8). The receiver shall open the CV prior to the seal time expiring or take special precautions in accordance with the facility Safety Analysis Report requirements when handling and opening the container. Special precautions are associated with the potential buildup of >5 mol % hydrogen in the CV (Appendix 3.5.4). Typical precautions may include, but are not limited to, elimination of ignition sources, gradually opening the CV in a well-ventilated area, or opening the CV in an inert glove box.

7.2.1 Receipt of Package from Carrier

The user shall develop detailed operating procedures that include, at a minimum, the process steps listed below for receiving a package and performing contamination and radiation surveys of the package. Operating personnel shall ensure that:

1. Documentation is received that conveys the physical characteristics and hazards of the package including any special instructions provided in accordance with Sect. 7.1.3.3.

2. When offered by the carrier for delivery, the TIDs on the conveyance (if required) and on the package are examined for signs of tampering. The general appearance of the conveyance and the package are noted.

3. The shipping papers are compared with the consignment, and the package is accepted.

4. The enclosed cargo space of the conveyance is examined for moisture and free liquids. If present, they will be surveyed for contamination and removed.

5. The external surfaces of the package are surveyed for removable radioactive contamination and radiation levels (10 CFR 835.405).

    a. The package nonfixed surface contamination levels are within the limits specified in 49 CFR 173.443 for alpha-, beta-, and gamma-emitting radionuclides or the user's site-specific criteria (whichever is more stringent).

    b. The radiation levels do not exceed the limits specified in 10 CFR 71.47 and 49 CFR 173.441.

6. The conveyance restraint gear was properly used to secure the package.

7. Appropriate labeling and marking of the package is checked for compliance.

8. The package restraint gear is removed and the package is removed from the conveyance.

9. The package is visually inspected for exterior surface damage during shipping or handling.

    Note: If the package surface is damaged, a nonconformance tag shall be completed and attached to the package for subsequent maintenance (10 CFR 71.131).

All users shall include provisions for reporting safety concerns associated with the packaging or its use. The user shall comply with reporting requirements in accordance with DOE O 232.2A, which delineates specific reporting periods in accordance with the category of the occurrence. In addition to the requirements of Sect. 7.5.1.3, incidents requiring notification include the following:

1. Nonfixed radioactive surface contamination is in excess of the limits specified in 49 CFR 173.443.

2. Radiation levels are in excess of the limits specified in 10 CFR 71.47 and 49 CFR 173.441.

3. Discrepancies exist between the shipping papers and the consignment.

4. TIDs are found to be compromised.

5. Adverse conditions are found (i.e., entrapped moisture, noncompliant items/conditions, or visible damage that may significantly reduce the package performance).

7.2.2 Removal of Contents

The user shall develop detailed operating procedures that include, at a minimum, the process steps listed below for removing the contents from the package. Operating personnel shall ensure that:

1. Appropriate labels and markings for the content are affixed to the exterior surface of the drum body.

2. The TIDs remain intact until authorized for removal.

   Note: Notify DOE in accordance with DOE O 232.2A if they are found to be compromised.

3. The drum hex nuts and washers are removed.

   Note: If the optional RFID monitoring system tag is installed, remove the RFID tag in accordance with the applicable requirements of ANL/DIS-09-5.

4. The drum lid is removed.

5. Accessible portions of the top plug and interior of the drum body are visually inspected for signs of moisture, corrosion, or physical damage and are in good condition.

6. Site-approved lifting hardware is attached to the top plug threaded lifting holes, and the top plug is removed.

7. The silicone rubber CV flange pad is removed from the top of the CV.

8. A contamination survey of the exposed drum liner and top of the CV is conducted to determine if there was a release of radioactive material.

   Note: If the nonfixed surface contamination levels exceed the limits specified in 49 CFR 173.443 for alpha-, beta-, and gamma-emitting radionuclides, notify DOE in accordance with DOE O 232.2A.

9. The top of the CV is visually inspected for signs of moisture, corrosion, or physical damage and is in good condition.

10. The swivel hoist ring is installed in the CV sealing lid and torqued to 16.27 ± 1.36 N·m (12 ± 1 ft-lb) [Drawing M2E801580A011, Appendix 1.3.7].

11. The CV is lifted from the drum body using the swivel hoist ring and site-approved lifting equipment and the external surfaces of the CV are visually inspected for signs of moisture, corrosion, or physical damage.

12. In order to support the CV during disassembly and unloading operations, users have two options:

a. Install a site-approved support plate on the top of the drum body and lower the CV into the drum body with the CV flange resting on the support plate; or

b. Lower the CV into a site-approved support stand.

13. The swivel hoist ring is removed from the CV sealing lid.

14. The CV lid assembly is removed and placed on a protective surface to prevent scratching of the sealing surface.

    Note: A contamination survey of the CV interior surface may be conducted if there are contamination concerns.

15. The O-rings and the O-ring grooves on the CV flange are protected from damage.

16. The HEU content and associated packing materials (e.g., convenience cans or bottles; polyethylene, nylon, or Teflon bags; silicone rubber can pads; can spacers; stainless-steel metal scrubbers) are removed from the CV in accordance with site-specific radioactive material handling procedures.

    Note: A contamination survey of the CV interior surfaces and packing materials may be conducted if there are contamination concerns.

17. The HEU content and shipping configuration are compared with the applicable information on the shipping papers and the conditions of approval in the CoC. Instances in which the conditions of approval in the CoC were not observed in making a shipment shall be reported in accordance with Sect. 7.5.1.3.

7.3 PREPARATION OF EMPTY PACKAGE FOR TRANSPORT

General requirements for shipping an empty packaging are provided in 49 CFR 173.428, *Empty Class 7 (radioactive) materials packaging*. The user shall develop detailed operating procedures which include, at a minimum, the process steps listed below to prepare an empty package for transport. Operating personnel shall ensure that:

1. The package has been emptied of radioactive contents as far as practical and the CV internal contamination level does not exceed 100 times the limits in 49 CFR 173.443(a).

2. Isopropyl alcohol and lint-free gloves, cloths, or swabs are used to clean the CV as necessary.

3. The CV sealing surfaces are visually checked for foreign matter, nicks, and scratches. If nicks or scratches are found, review Sect. 8.2.2 for evaluation criteria.

4. The O-rings are free from debris and have not been damaged. The O-rings can be cleaned with isopropyl alcohol and wiped with lint-free gloves, cloths, or swabs.

5. The O-rings are lubricated as necessary with a thin coat of Super-O-Lube and inserted into the CV flange grooves.

6. The CV lid closure nut threads are visually inspected for damage and foreign matter. If necessary, clean the threads with lint-free gloves, cloths, or swabs.

7. A thin coat of Krytox grease, Grade 240 AC, is applied as necessary to the CV lid closure nut threads (Drawing M2E801580A011, Appendix 1.3.7).

8. The CV lid assembly is positioned over the CV body with the two alignment pins in the CV flange engaged in the slots on the underside of the CV lid assembly.

9. The CV lid closure nut is torqued to 162.7 ± 6.78 N·m (120 ± 5 ft-lb) [Drawing M2E801580A011, Appendix 1.3.7].

10. The modified VCO threaded brass plug is installed in the CV lid assembly leak-test port.

11. The CV, top plug, drum lid, plug pad, CV bottom pad, CV flange pad, drum nuts and washers, TIDs, and optional RFID monitoring system tag (depending on site-specific requirements) are available.

12. The aluminum foil tape applied over the neutron-absorbing material cavity fill and vent holes (four places) located on the drum liner lower shelf (Drawing M2E801580A002, Appendix 1.3.7) is visually inspected for damage such as tears, holes, or loose edges.

13. The swivel hoist ring is installed in the CV sealing lid and torqued to 16.27 ± 1.36 N·m (12 ± 1 ft-lb) [Drawing M2E801580A011, Appendix 1.3.7].

14. The CV is lifted using the swivel hoist ring and site-approved lifting equipment.

15. If the CV was supported in the drum body, then remove the site-approved support plate.

16. The CV bottom pad is installed in the bottom of the drum cavity.

17. The CV is lowered into the drum body cavity and the swivel hoist ring is removed.

18. The CV flange pad is placed over the top of the CV and the plug pad is placed on the top shelf of the drum liner (Drawing M2E801580A001, Appendix 1.3.7).

19. The nylon plug is installed in the top plug vent hole and site-approved lifting hardware is attached to the top plug threaded lifting holes.

20. The top plug is installed in the drum (Drawing M2E801580A001, Appendix 1.3.7) and the lifting hardware is removed.

21. The drum weld studs and hex nut threads are visually inspected for damage and foreign matter. If necessary, clean the threads with lint-free gloves, cloths, or swabs.

22. The drum lid is positioned over the drum with the holes in the lid aligned with the weld studs and the TID lugs, and the lid is lowered into position.

23. The eight, 5/8-11 UNC-2B, hex nuts with washers (Drawing M2E801580A005, Appendix 1.3.7) are installed and the nuts are torqued to 40.67 ± 6.78 N·m (30 ± 5 ft-lb) [Drawing M2E801580A001, Appendix 1.3.7]. **An impact wrench shall not be used.**

    Note: An optional RFID monitoring system tag may be installed in accordance with the applicable requirements of ANL/DIS-09-5.

24. A nylon plug is installed in each of the four drum vent holes (Drawing M2E801580A002, Appendix 1.3.7).

25. If required by site-specific requirements, TIDs are attached through the drum TID links.

26. Any inappropriate labels previously affixed to the drum body in conformance with 49 CFR 172, Subpart E are removed, obliterated, or covered. Leak-test labels should not be removed. The drum body is cleaned as necessary including the removal of any adhesive residue from removed labels.

27. The level of nonfixed radioactive contamination on the external surfaces of the package is ALARA and within the limits specified in 49 CFR 173.443(a) for alpha-, beta-, and gamma-emitting radionuclides or the user's site-specific criteria (whichever is more stringent).

28. The "EMPTY" label prescribed in 49 CFR 172.450 is affixed to the drum.

    Note: All labels shall be vinyl type or placed on plain vinyl tape and applied to the packaging to facilitate removal during maintenance.

29. The "Radioactive Material, Type B(U) Package, Fissile UN3328" marking on the ES-3100 data plate is covered with opaque vinyl tape, and the package is marked "UN2908" in accordance with 49 CFR 173.428.

30. The radiation level at any point on the external surface of the package does not exceed 0.5 mrem/h.

31. The package is prepared for shipment as specified in 49 CFR 173.422.

7.4 OTHER OPERATIONS

There are no additional special controls unique to this package.

Appendix 7.5.1
Records and Reporting Requirements

7.5.1.1 Records for each shipment

A record of each shipment shall be maintained for a period of 3 years after the shipment in accordance with Title 10, Part 71, Sect. 91(a), of the Code of Federal Regulations (CFR) [10 CFR 71.91(a)]. As specified in 10 CFR 71.91(c), records are only valid if stamped, initialed, or signed and dated by authorized personnel, or otherwise authenticated. These records shall include:

1. The identification of the packaging by model and serial number.
2. Verification that there were no significant defects in the packaging as shipped.
3. Type and quantity of radioactive material in each package and total quantity for each shipment.
4. Date of the shipment.
5. Any special controls exercised.
6. Name and address of the transferee (receiver).
7. Address to which the shipment was made.
8. Results of the determinations required by 10 CFR 71.87 and 49 CFR 173.475 (including documentation of replacement parts) and conditions of approval in the Certificate of Compliance (CoC).

If requested, records of the package shipping history or other information shall be forwarded to the Y-12 National Security Complex in support of recertification efforts. Additionally, each packaging user shall maintain a file of procedures and operating records associated with the ES-3100. These records shall be available for the U.S. Department of Energy (DOE) Headquarters Certifying Official audits and appraisals upon reasonable notice.

7.5.1.2 Records of packaging history

Users shall maintain sufficient written records to furnish evidence of the quality of packagings for a period of three years after the life of the packaging to which they apply in accordance with 10 CFR 71.91(d). As specified in 10 CFR 71.91(c), records are only valid if stamped, initialed, or signed and dated by authorized personnel, or otherwise authenticated. Inspection, tests, and audit records must identify the packaging by model and serial number, the inspector, the type of observation, the results, the acceptability, and the action taken in connection with any deficiencies noted. These records shall include:

1. Results of determinations required by 10 CFR 71.85 and 49 CFR 173.474.
2. Design, fabrication, and assembly records.
3. Results of reviews, inspections, tests, and audits.
4. Results of monitoring work performance and materials analyses.
5. Results of maintenance, modification, and repair activities.

The user shall permit the DOE Headquarters Certifying Official, or designee, at all reasonable times to inspect the radioactive material, packaging, premises, and facilities in which the radioactive material or packaging is used, provided, constructed, fabricated, tested, stored, or shipped [10 CFR 71.93(a)]. Authorized users shall perform any tests deemed necessary or appropriate by the DOE Headquarters Certifying Official in accordance with 10 CFR 71.93(b).

7.5.1.3 Reports

Users shall include provisions in their operating procedures for reporting safety concerns associated with the packaging or its use. The user shall comply with 10 CFR 71.95 by providing written notification to the DOE Headquarters Certifying Official in accordance with DOE O 232.2A for the following:

1. Instances where there is a significant reduction in the effectiveness of the packaging during use.

2. Details of any defects with safety significance of the packaging after first use.

3. Instances in which the conditions of approval in the CoC were not observed in making a shipment.

In addition, the U.S. Department of Transportation will be notified of hazardous materials incidents during loading, unloading, and temporary storage operations in accordance with 49 CFR 171.15 and 171.16, as appropriate. The user shall particularly note the requirements of 49 CFR 171.15(b)(2) and 49 CFR 171.16(a)(2) and (4).

1 APPLICABILITY AND SCOPE

To provide instructions for operating the shipping container leak test stations. The VTI Smart Station consists of a touch screen PC, printer, two MKS vacuum gauges, reference volume, vacuum pump, automatic valve manifold, and temperature sensor mounted on a rolling cart. Either one of the systems may be used to perform leak tests on shipping containers.

Applies to the leak test of the O-ring seal found in leak testable inner containers. The VTI Smart Station is capable of determining a leak rate of 1.0×10^{-4} atm-cm^3/sec.

The Orifice Leak Test Station correlates the pressure drop across an orifice as compared to the pressure drop across the orifice when a calibrated leak is installed.

The VTI Smart Station performs a pressure (vacuum) rate of rise test using air as the test gas with the part under vacuum.

Program: WC

2 PRECAUTIONS AND LIMITATIONS

A. Use of standard tools and equipment, as needed, is acceptable without being listed in the tooling/equipment list.

B. The VTI Smart Station leak rate is displayed with the units of measure of "atm-cc/s" which is equivalent to "atm-cm^3/sec."

3 ACCEPTANCE CRITERIA

A. Container has passed the leak test **WHEN** the test result is PASS.

4 PREREQUISITE ACTIONS

4.1 Special Tools, Test Equipment, Parts and Supplies

Supervisor

[1] Ensure the following equipment is available:

- Leak Tester (Appendix A)
- Test Cap
- FAIL Test Standard Leak
- O-ring lube
- Container Leak Test Adapter.

4.2 Field Preparations

Assemblyperson

NOTE *Facility Instrument Air may be connected to the VTI Smart Station via quick disconnect (if equipped) in lieu of on-board compressor.*

[1] Verify leak tester vacuum pump oil level is between minimum and maximum line on gauge.

[2] **IF** the leak tester vacuum pump is **NOT** between the minimum and maximum line on the gauge, **THEN** notify Supervisor.

[3] Ensure printer is ready (i.e., turned on, has paper and ink) for operation.

[4] Ensure leak tester is turned on.

[5] **IF** system was started from power off condition, **THEN** ensure MKS Baratron transducer is allowed at least four (4) hours warm up time.

[6] Verify certification sticker(s) is **NOT** expired.

4.3 Approvals and Notifications

Supervisor

[1] Obtain permission from the Shift Manager to start the Performance Section of this procedure.

5 PERFORMANCE ACTIVITIES

5.1 VTI Smart Station

5.1.1 VTI Smart Station - System Functional Check

Assemblyperson

NOTE 1 *The operator may log in to the leak tester, as necessary, by entering login password.*

NOTE 2 *After the login password is entered, a "Manual Commands" screen may display momentarily, but the screen is not used.*

NOTE 3 *If "Welcome to HP Product Assistant" screen appears, the operator may clear this screen and continue.*

NOTE 4 *A system functional check is to be performed prior to the first leak test of the day/shift in order to verify proper function of the leak tester. Two test volumes (one PASS test and one FAIL test) are run to ensure acceptable operation.*

NOTE 5 *Operator I.D. time limit may expire. Operator I.D. may be re-entered, as necessary.*

[1] **IF** system functional check has already been performed during the current shift, **THEN GO TO** Section **5.1.2**, *VTI Smart Station – Leak Testing.*

[2] Ensure pigtail at back of leak tester is installed.

[3] Perform a PASS function test as follows:

- **[a]** Ensure free end of pigtail is capped.
- **[b]** Double touch VTI icon, as needed.
- **[c]** Enter Operator ID (badge number).
- **[d]** Enter "DT22" in the location designated for Package Model.
- **[e]** Enter "CAP" in the location designated for serial number.
- **[f]** Press the "Start Test" icon.
- **[g]** **IF** alarm lights (e.g., evac. fault or settle press, etc.) activate during test, **THEN** press "ABORT TEST" icon **AND** notify Supervisor.
- **[h]** Receive the printout of the test results.
- **[i]** **IF** result is FAIL (the first attempt), **THEN REPEAT** Steps **5.1.1[3]** - **5.1.1[3][h]** to perform test again.
- **[j]** **IF** result is FAIL (the second attempt), **THEN** notify Supervisor.
- **[k]** **IF** result is PASS, **THEN GO TO** Step **5.1.1[4]**.

5.1.1 VTI Smart Station - System Functional Check (cont.)

Assemblyperson

[4] Perform a FAIL function test as follows:

[a] Remove cap from free end of pigtail.

[b] Connect the FAIL Test Standard Leak (labeled "FAIL") to the free end of the pigtail.

[c] Double touch VTI icon, as needed.

[d] Enter Operator ID (badge number).

[e] Enter "DT22" in the location designated for Package Model.

[f] Enter "FAIL" and the serial number on the standard leak tag (if applicable) in the location designated for serial number.

[g] Press the "Start Test" icon.

[h] **IF** alarm lights (e.g., evac. fault or settle press) activate during test, **THEN** press "ABORT TEST" icon **AND** notify Supervisor.

[i] Receive the printout of the test results.

[j] **IF** result is PASS (the first attempt), **THEN REPEAT** Steps **5.1.1[4]** - **5.1.1[4][i]** to perform test again.

[k] **IF** result is PASS (the second attempt), **THEN** notify Supervisor.

[l] **IF** result is FAIL, **THEN** remove FAIL Test Standard Leak **AND GO TO** Step **5.1.2**.

5.1.2 VTI Smart Station – Leak Testing

Assemblyperson

NOTE 1 *The operator may log in to the leak tester, as necessary, by entering login password.*

NOTE 2 *After the login password is entered, a "Manual Commands" screen may display momentarily, but the screen is not used.*

NOTE 3 *If "Welcome to HP Product Assistant" screen appears, the operator may clear this screen and continue.*

NOTE 4 *Operator I.D. time limit may expire. Operator I.D. may be re-entered, as necessary.*

[1] Ensure the leak test port plug has been removed from the test port on the container to be tested.

[2] Ensure flexible hose from the VTI Smart Station to the container test port, (using the container leak test adapter if necessary is connected).

[3] Double touch VTI icon, as needed.

[4] Enter Operator ID (badge number).

[5] Enter Package Model (e.g., DT22, ES 3100, etc).

[6] Enter Serial Number (last five digits of inner container serial number).

[7] Press "Start Test" icon.

[8] **IF** alarm occurs, **THEN** press "ABORT TEST" icon, **AND** notify Supervisor.

[9] **IF** test results printout is "FAIL," **THEN** perform the following:

- **[a]** Clean **OR** replace O-ring at the end of the pigtail **AND** add O-ring lube, as necessary.
- **[b]** Check pigtail for leaks at leak tester connection **AND** repair or replace, using new metal sealing washer, as necessary.
- **[c]** Notify Supervisor for determination on whether to **RETURN TO** Step **5.1.2[2] OR** disconnect drum **AND** exit procedure.

5.1.2 VTI Smart Station – Leak Testing (cont.)

Assemblyperson

[10] **IF** test result is PASS, **THEN** perform the following:

[a] Attach leak test printout to the associated container documentation.

[b] Verify the serial number of the container matches the serial number of the container on the printout.

[c] Disconnect pigtail from container.

[d] **IF** additional containers will be leak tested, **THEN REPEAT** Steps **5.1.2[1] – 5.1.2[10][c]** until all containers are leak tested.

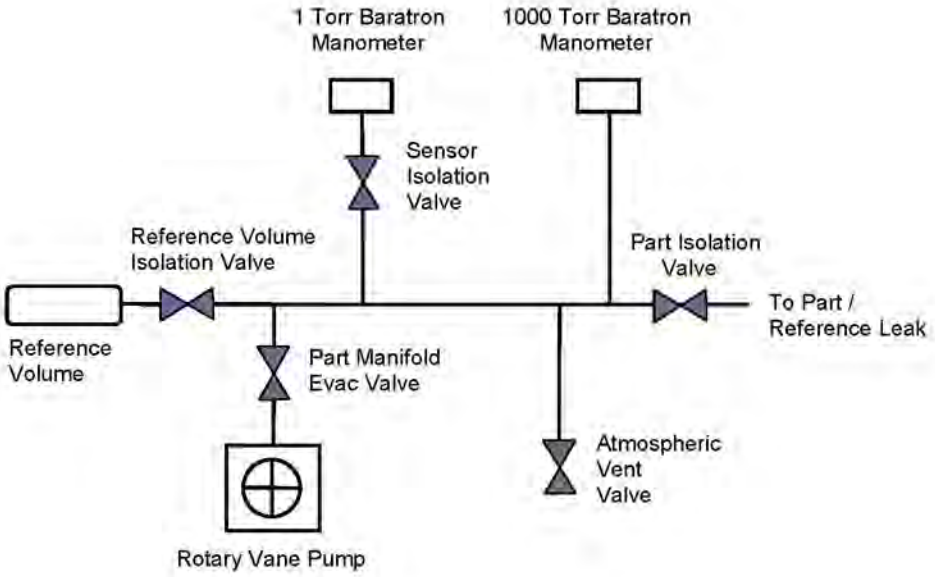
[e] Install cap onto pigtail.

6 POST-PERFORMANCE ACTIVITIES

6.1 Extended Shutdown

Assemblyperson

[1] **IF** placing the VTI Smart Station into extended shutdown, **THEN** turn off all power to VTI Smart Station.



7 RECORDS

No records are generated by the performance of this procedure.

8. ACCEPTANCE TESTS AND MAINTENANCE PROGRAM

Radioactive material packagings shall be fabricated, procured, and maintained in accordance with applicable U.S. Nuclear Regulatory Commission (NRC), U.S. Department of Transportation (DOT), and other federal, state, and local regulations to protect the health and safety of the public, the workers, and the environment. The basis of the ES-3100 acceptance tests and maintenance requirements is primarily established in the design drawings and equipment specifications that are applied to the packaging components during design and fabrication. The packaging must continue to meet these requirements during its useful lifetime. Acceptance tests and maintenance activities are used to ensure that the design requirements and the conditions of approval in the Certificate of Compliance (CoC) are satisfied in addition to ensuring the integrity of the packaging components with respect to the structural, thermal, containment, shielding, and criticality evaluations in this safety analysis report for packaging (SARP). Furthermore, the packagings shall be fabricated, procured, and maintained according to a quality assurance (QA) plan approved by the U.S. Department of Energy (DOE), Office of Environmental Management; or DOE, National Nuclear Security Administration (DOE/NNSA), as appropriate.

The user is responsible for following the established NRC regulations for packaging, preparation for shipment, and transportation of radioactive materials given in Title 10, Part 71, of the Code of Federal Regulations (CFR) [10 CFR 71] as well as DOT regulations for packaging and shipment of hazardous materials given in Title 49 CFR. DOE nuclear facility users are responsible for implementing DOE regulations given in Title 10, Parts 830 and 835, of the CFR in addition to directives conveyed in DOE Order (O) 232.2A, DOE O 414.1D, and DOE O 460.1D or DOE O 461.1C, as appropriate.

Specific acceptance testing and maintenance criteria for the ES-3100 are presented in this section. Where appropriate, facility management may authorize the adjustment of the explicit implementation sequence in this section to accommodate facility-specific workflow logistics and operational requirements. The packaging owner and user shall develop detailed, written site-specific procedures based on the CoC and the criteria contained herein. These procedures shall be in accordance with 10 CFR 71, Subparts A, G, and H; DOT and DOE regulations; and applicable state, tribal, and local regulations not preempted by DOT.

The packaging acceptance testing and maintenance operations should be consistent with maintaining occupational radiation exposures as low as reasonably achievable (ALARA) [10 CFR 71.87(i)] in addition to addressing applicable safety aspects or activities such as personal protection (radiation, chemical, and physical); contamination or radiation surveys; provisions for reporting safety concerns associated with the packaging or its use; and the records and reporting requirements cited in Appendix 7.5.1.

The ES-3100 packaging description is presented in Sect. 1.2 with a schematic shown in Fig. 1.1 and an exploded view of the packaging components presented in Fig. 1.2. The ES-3100 certification drawing can be found in Appendix 1.3.1. The packaging design drawings (Appendix 1.3.7) provide material lists, dimensions, safety components, welding requirements, and gasket requirements. The maximum gross weight of the ES-3100 package is 190.5 kg (420 lb).

The requirements for fabricating, procuring, and maintaining the packaging are presented in this section. Nonconforming conditions or deficiencies will be appropriately dispositioned to satisfy the applicable design requirements in accordance with 10 CFR 71.131. Rework or repair authorization for packaging components would include applicable nondestructive examinations and pressure/leak testing

as specified in the design requirements. Fabrication requirements for the ES-3100 components are listed on the design drawings (Appendix 1.3.7) and the following specifications:

1. JS-YMN3-801580-A002, *ES-3100 Drum Assembly* (Appendix 1.3.2);

2. JS-YMN3-801580-A001, *ES-3100 Containment Vessel* (Appendix 1.3.3);

3. JS-YMN3-801580-A003, *Manufacturing Process Specification for Casting Kaolite 1600TM into the ES-3100 Shipping Package* (Appendix 1.3.4);

4. JS-YMN3-801580-A005, *Casting Catalog No. 277-4 Neutron Absorber for the ES-3100 Shipping Package* (Appendix 1.3.5);

5. SPC-M801580-0002, *ES-3100 Ethylene Propylene Diene Monomer (EPDM) Containment Vessel (CV) O-rings* (Appendix 1.3.9);

6. SPC M801580-0004, *Heavy Can Spacers* (Appendix 1.3.10);

7. SPC M801794-0003 *Packcrete Preliminary Lot Qualification* (Appendix 1.3.11);

8. SPC M801580-0003 *ES-3100 Packcrete Final Lot Qualification and Production Processing* (Appendix 1.3.12).

The containment vessel (CV) is designed and built to meet American Society of Mechanical Engineers *Boiler and Pressure Vessel Code* (ASME Code), Sect. III, Div. 1, Subsection NB. The ES-3100 includes the following packaging components/assemblies:

1. A drum assembly: body weldment, lid weldment, top plug weldment, CV bottom pad, CV flange pad, plug pad, hex nuts, washers, and paint (Drawing M2E801580A001, Appendix 1.3.7); with a data plate and a trefoil data plate (Drawing M2E801580A010, Appendix 1.3.7).

2. A CV assembly: CV body assembly; CV lid assembly (sealing lid, closure nut, and retaining ring); O-rings; brass VCO (vacuum coupling O-ring) threaded plug; and swivel hoist ring (Drawing M2E801580A011, Appendix 1.3.7).

3. Packing materials, as appropriate: convenience cans or bottles; polyethylene, nylon, or Teflon bags; metal scrubbers; silicone rubber can pads (Drawing M2E801580A024, Appendix 1.3.7); and heavy can spacer assemblies (Drawing M2E801580A043, Appendix 1.3.7).

Care should be exercised to control the packaging components when they are removed to ensure that parts are kept with the packaging and not mixed with other loose parts or parts from other packagings. Other preparations should be made to minimize damage or loss of packaging components. The drum assembly and containment vessel are marked with serial numbers. The numbers are used to control these parts and to accumulate their respective operational and maintenance histories. Applicable serial numbers of packaging components should be verified to ensure that these components are maintained together. Loose parts (e.g., hex nuts, washers, O-rings) may be reused if it can be shown that they were the parts that were removed and that no damage to the parts has occurred. Otherwise, they shall be discarded and replaced with certified parts. In order to maintain configuration control of the packaging components, the user shall ensure that there are no unauthorized modifications and no substitution of components with unauthorized components. The certification of all replacement parts must be traceable. The user shall document any part replacement identifying it to a specific packaging by model and serial number.

The ES-3100 is handled using industry-standard drum-handling equipment. When being moved using a forklift, it can be placed on the tines of the forklift from below. The ES-3100 is also designed for a forklift pincher assembly that can be used to grasp the exterior of the drum assembly. Forklift gripping forces of up to 5400 lb can be used with no detrimental effects on the packaging (Sect. 1.2.1.1).

Site-specific maintenance procedures including the facility's operational requirements shall ensure the following:

1. All appropriate documents have been reviewed by operating personnel and are available for further review, if necessary.

2. Certified equipment is used (e.g., torque wrenches, instrumentation, scales, lifting hardware, and radiation survey instruments) in accordance with the site-approved QA program.

3. Segregated work stations, curtains, lead blankets, personnel protective equipment, or other equipment are used, as necessary, to protect workers and nearby personnel from radioactive material hazards.

4. Appropriate material handling equipment is available and approved for use (e.g., forklifts, hoists, drum handlers). Operating controls shall be implemented for any forklift pincher assembly to limit clamping forces on the drum body (i.e., ≤ 5400 lb).

5. Appropriate provisions to decontaminate packaging components are provided consistent with ALARA principles.

All personnel who support and/or perform fabrication, assembly, testing, and maintenance operations will be appropriately trained and qualified in accordance with the site-approved QA program; 49 CFR 171.1; and 49 CFR 172, Subpart H, as appropriate. Auditable training records will be maintained in accordance with site record retention requirements.

8.1 ACCEPTANCE TESTS

Before the first use of the packaging, the owner shall determine that the packaging has been fabricated in accordance with the approved design including the preliminary determinations (10 CFR 71.85), the quality control for construction of packaging (49 CFR 173.474), and the conditions of approval in the CoC. Guidance provided in NUREG/CR-6314, *Quality Assurance Inspections for Shipping and Storage Containers*, for conducting QA inspections of packaging suppliers may be used as necessary. Acceptance test requirements in Sect. 8.1 are derived from the design drawings and equipment specifications, and their determinations shall be present in the owner's or appropriate supplier's fabrication records as described in Sect. 7.5.1.2. The minimum certification requirements are shown on the ES-3100 certification drawing (Appendix 1.3.1).

The design drawings and specifications indicate the applicable inspections, testing, records, and reports required to properly document the quality of the packaging. The minimum acceptance test and inspection requirements for the packaging components (Tables 8.1 and 8.2) and packing materials (Table 8.3) are presented in the following sections. Prior to first use of the packaging, the user, packaging suppliers, or both shall meet these requirements.

Table 8.1. Acceptance tests for the drum assembly

Component [a]	Inspection	Structural and pressure tests	Leak tests
Double open head drum	Material certification [b], gauging [c], marking, liquid penetrant, weld examinations [d], corrosion, dents	Tensile, percent elongation, yield point, chemistry, pneumatic pressure test [e]	NA [f]
Weld studs	Part certifications, gauging	Tensile, percent elongation, yield point, chemistry	NA
Inner liner weldment	Material certification, weld examinations, gauging	Tensile, percent elongation, yield point, chemistry	NA
Flat cover (drum bottom)	Material certification, gauging	Tensile, percent elongation, yield point, chemistry	NA
Lid weldment	Material certification, weld examinations, gauging	Tensile, percent elongation, yield point, chemistry	NA
Top plug weldment	Material certification, weld examinations, gauging	Tensile, percent elongation, yield point, chemistry	NA
Kaolite 1600 or Packcrete insulation	C of C [g], damage	NA	NA
Cat 277-4 neutron-absorber material	C of C, damage	NA	NA
Hex nuts	C of C, gauging, damage	NA	NA
Washers	C of C, damage	NA	NA
TID [h] lugs	C of C, damage	NA	NA
Data plate and trefoil data plate	Material certification, gauging, marking	NA	NA
Nylon plug	C of C	NA	NA
Paint	C of C, color comparison	NA	NA
Aluminum tape	C of C, damage	NA	NA
Silicone rubber pads (CV bottom pad, CV flange pad, and plug pad)	C of C, damage, marking	NA	NA
RFID monitoring system [i]	NA	NA	NA

[a] ES-3100 drum assembly components (Drawing M2E801580A001, Appendix 1.3.7).
[b] Material certification – Certified quantitative data (physical, mechanical, chemical, functional, dimensional, and/or visual) demonstrating compliance with the drawing/specification requirements.
[c] Gauging refers to dimensional inspections for height, width, thickness, diameter, position, edge breaks, and surface finish.
[d] Weld examinations in accordance with Sect. 8.1.2.
[e] Pneumatic pressure test in accordance with Sect. 8.1.3.3.
[f] NA—Not applicable.
[g] C of C—Certificate of Conformance. A document signed or otherwise authenticated by an authorized individual certifying the degree to which items or services meet the specified requirements.
[h] TID—Tamper-indicating device.
[i] An optional radio-frequency identification (RFID) monitoring system tag may be secured to the drum assembly in accordance with the applicable requirements of ANL/DIS-09-5.

Table 8.2. Acceptance tests for the CV assembly

Component [a]	Inspection	Structural and pressure tests	Leak tests
Body assembly and lid assembly (as applicable)	Material certification [b], gauging [c], marking, liquid penetrant, weld examinations, qualification tests, corrosion, scratches	Tensile, percent elongation, yield point, chemistry, hydrostatic pressure test [d]	Helium leak test [e]
Inner O-ring	Material certification, gauging, packaging, marking	Shore A durometer, elongation	NA [f]
Outer O-ring	Material certification, gauging, packaging, marking	Shore A durometer, elongation	NA
External retaining ring	C of C [g], damage	NA	NA
Modified VCO [h] threaded plug with O-ring	C of C, damage	NA	NA

[a] ES-3100 CV assembly components (Drawing M2E801580A011, Appendix 1.3.7).
[b] Material certification – Certified quantitative data (physical, mechanical, chemical, functional, dimensional, and/or visual) demonstrating compliance with the drawing/specification requirements.
[c] Gauging refers to dimensional inspections for height, width, thickness, diameter, position, edge breaks, and surface finish.
[d] Hydrostatic pressure test in accordance with Sect. 8.1.3.3.
[e] Leakage test in accordance with Sect. 8.1.4.
[f] NA—Not applicable.
[g] C of C—Certificate of Conformance. A document signed or otherwise authenticated by an authorized individual certifying the degree to which items or services meet specified requirements.
[h] VCO—Vacuum coupling O-ring.

Table 8.3. Acceptance tests for packing materials

Component [a]	Inspection	Structural and pressure tests	Leak tests
Silicone rubber pad [b] (can pad)	C of C [c], damage, marking	NA [d]	NA
Heavy can spacer assembly [e]	Material certification [f], sample pour	NA	NA
Convenience cans	C of C, damage	NA	NA
Convenience bottles	C of C, damage	NA	NA
Polyethylene, nylon, or Teflon bags	C of C, damage	NA	NA
Metal scrubbers	C of C	NA	NA

[a] ES-3100 CV packing materials, as appropriate (see Sect 1.2.2.4).
[b] Drawing M2E801580A024, Appendix 1.3.7.
[c] C of C—Certificate of Conformance. A document signed or otherwise authenticated by an authorized individual certifying the degree to which items or services meet specified requirements.
[d] NA—Not applicable.
[e] Packing material, as appropriate, not part of CV (Drawing M2E801580A043, Appendix 1.3.7).
[f] Material certification – Certified quantitative data (physical, mechanical, chemical, functional, dimensional, and/or visual) demonstrating compliance with the drawing/specification requirements.

8.1.1 Visual Inspections and Measurements

Visual inspections with the unaided eye of all pertinent features of the packaging shall be performed during fabrication. There shall be no cracks, pinholes, uncontrolled voids, or other defects that could significantly reduce the effectiveness of the packaging [10 CFR 71.85(a)]. These inspections include paint color; surface condition; marking content; gauging (toleranced dimensions, positioning, edge breaks, surface finish); and welding. The required inspections are summarized in Tables 8.1–8.3.

8.1.1.1 Paint color

Paint color, which is not a safety item, is used to identify, segregate, and document packagings. The acceptance criteria for paint color are given in the drawings (Appendix 1.3.7). Incorrect or incomplete application of paint is cause for rejection. An application of incorrect letters or misspelled words is also cause for rejection.

8.1.1.2 Surface condition

The surfaces of the drum assembly and CV shall be visually inspected for penetrations, dents, and corrosion. Dents >1-in. deep in the drum body will be cause for the drum body to be reworked to remove the dent. The CV surfaces must be in accordance with the dimensional requirements on the drawings (Appendix 1.3.7). Penetrations (e.g., cracks, pinholes, other defects) in the drum or CV will be cause for the component to be rejected.

The packaging components (i.e., complete assembly or individual parts) will be stored in weather-protected indoor facilities. However, before acceptance of any component, accessible surfaces shall be inspected for corrosion. The presence of surface corrosion on any component will be cause for further inspection. If the corrosion can be easily wiped off and no pitting is apparent beneath it, the component is acceptable. If the corrosion cannot be easily wiped off, if scaling is present, or if pitting is observed, the component must undergo a dimensional inspection, including nondestructive examinations as necessary, to determine the extent of the damage before the packaging component can be used. If the corrosion has compromised the structural integrity of the component (i.e., the component no longer meets dimensional or surface finish criteria for a new part as specified on the design drawings), then the component shall be rejected.

8.1.1.3 Marking packaging components

Markings on the packaging components provide traceability for the fabrication, operation, and maintenance of the packaging components. All markings (e.g., model number, serial numbers, instructions, identification) shall be compared with the acceptance criteria (e.g., paint color, etching, dimensions) for markings on the design drawings (Appendix 1.3.7) or equipment specifications, as appropriate. Incorrect or incomplete marking is cause for rejection.

8.1.1.4 Gauging

The ES-3100 design drawings list the dimensions/tolerances; positions (e.g., bolt holes, grooves, leak-test port); edge breaks; and surface finishes. A “Diamond I” or “Diamond S” symbol is used on the drawings or equipment specifications to designate significant dimensions or features, which are specifically inspected and documented in the inspection reports. Inspection of gauging features will be performed on dimensions to ensure that each component meets the applicable tolerances, which are provided on the drawings. Gauging outside the tolerance is cause for rejection.

8.1.2 Weld Examinations

As discussed in Sect. 2.3, *Fabrication and Examination*, all welded or weld-repair surfaces shall be visually examined by a qualified weld examiner for indications of inclusions, cracks, or porosity using a written weld examination procedure. Weld examiners are qualified to perform weld inspections in accordance with the techniques specified on the applicable design drawings and equipment specifications. Weld symbols are provided on the design drawings indicating for each weld the type of weld and dimensions of weld. These weld symbols are interpreted in accordance with American Welding Society (AWS) A2.4. For a detailed description of the drum assembly and CV manufacturing requirements, see the appropriate equipment specification and the following SARP sections:

Drum Assembly [JS-YMN3-801580-A002 (Appendix 1.3.2)]

- Section 2.3.1.1, Drum assembly fabrication.
- Section 2.3.2.1, Examination of the drum assembly fabrication.

Containment Vessel [JS-YMN3-801580-A001 (Appendix 1.3.3)]

- Section 2.3.1.2, Containment boundary fabrication.
- Section 2.3.2.2, Examination of the containment vessel fabrication.

8.1.3 Structural and Pressure Tests

Structural tests for the drum and CV include mechanical properties and chemical tests to ensure that the correct materials are used. The CV is hydrostatically pressure tested to ensure that the supplier's fabrication meets the requirements. These tests are discussed below. The drum body is pressure tested (Sect. 8.1.3.3) in accordance with the QA provisions in Military Specification MIL-D-6054F, *Drum, Metal—Shipping and Storage*.

8.1.3.1 Mechanical property tests

The design drawings or equipment specifications specify the requirements for the packaging materials. The mechanical properties and specifications for these materials are discussed in Sect. 2.2.1 and summarized in Tables 2.12–2.17. Visual examination and mechanical property testing requirements for the O-rings are discussed in Sect. 8.1.5.1. An out-of-specification property is cause for rejection.

8.1.3.2 Chemical tests

Tests shall be performed to determine the chemical properties of the packaging materials. The acceptance criteria and their sensitivity are provided in the appropriate national material standard specified on the design drawings (Appendix 1.3.7). An out-of-specification chemical property is cause for rejection. Material that cannot be traced to the mill or heat-treatment lot shall be rejected.

8.1.3.3 Pressure tests

The CV assembly shall be hydrostatically pressure tested at 150 ± 5 psig per Sect. 3.6 of JS-YMN3-801580-A001 (Appendix 1.3.3). Visible indication of a leak on the exterior surface of the CV is cause for rejection. This testing exceeds the regulatory requirement in 10 CFR 71.85(b) [1.5 × maximum normal operating pressure] and the requirement stipulated in ASME Code, Sect. III, Div. 1, NB-6200 (1.25 × design pressure). The CV maximum normal operating pressure is 15.576 psig (Appendix 3.5.1) and the CV design pressure is 101.5 psig (DAC-M900000-0003).

The drum pressure test is performed in accordance with Drawing M2E801580A004 (Appendix 1.3.7) to verify the integrity of the welded seam. Typically, one sample drum in each lot fabricated is pressure tested (MIL-D-6054F, Para. 4.6.1). The pressure test is performed prior to the drilling of the four vent holes with the opened ends of the drum sealed. This test is observed by the owner during the First Article Evaluation of the drum. To conduct the pressure test, the drum is pressurized with air to 10 psig as specified in MIL-D-6054F. The compressed air supply line is closed, but the pressure gauge is left connected to the drum. The initial pressure is recorded. All joints and seams are coated with a bubble-supporting film. The drum is turned so that all surfaces may be observed for leakage. Five minutes after the initial pressure is recorded, the final gauge pressure is recorded. If a loss of pressure is observed and no leaks were detected by bubbles, the bubble-supporting film operation is repeated to find any leaks that were not detected initially. Any evidence of leakage is cause for rejection.

8.1.4 Leakage Tests

Following the hydrostatic pressure test, a leak test of the containment boundary shall be performed with the inner O-ring installed in accordance with American National Standards Institute (ANSI) N14.5-1997, Subclause 7.3, *Fabrication leakage rate test*, as prescribed in Sect. 3.7 of JS-YMN3-801580-A001 (Appendix 1.3.3). This leak testing demonstrates that the CV is fabricated properly and that the containment boundary is "leaktight." An integrated air leakage rate exceeding 1×10^{-7} ref-cm^3/s (or equivalent) is cause for rejection. Per ANSI N14.5-1997, the test procedure shall have a sensitivity of 5×10^{-8} ref-cm^3/s (one-half the reference air leakage rate) or equivalent.

As required in JS-YMN3-801580-A001 (Appendix 1.3.3), the containment vessel leakage rate testing will be performed by trained and qualified personnel using certified equipment and written leak-test procedures in accordance with the applicable sections of ANSI N14.5-1997. Y-12 Product Specification Procedure Y51-01-B2-R-140, *He Leak Testing in B2* (Appendix 8.3.1) is provided as an example leak-test procedure.

In addition, a leakage rate test will be performed at initial fabrication on the fully assembled CV with both O-rings installed to demonstrate the functionality of the leak-test port and sealing capability of the outer O-ring. The leak testing acceptance criterion is that the CV shall not have an air leakage rate $>1 \times 10^{-4}$ ref-cm^3/s. Y-12 Product Specification Procedure Y51-01-B2-R-074, *Shipping Container Leak Test* (Appendix 7.5.2) is provided as an example leak-test procedure.

8.1.5 Component and Material Tests

8.1.5.1 Containment vessel O-rings

The O-ring visual inspection and mechanical tests are described below. Additionally, the fabrication leak test (Sect. 8.1.4), the periodic and maintenance leak tests (Sect. 8.2.2), and the preshipment leak test (Sect. 7.1.2.1) verify the functionality of the O-rings.

Visual inspection

A visual inspection of the O-ring surface shall be performed. The surface shall be smooth, nonporous, and free of skin defects. O-rings that do not meet these requirements shall be rejected.

Each O-ring shall be packaged separately to provide traceability. Each O-ring package shall be marked with the O-ring identification number, lot number, cure date, compound number, and established expiration date. The material identification numbers shall be assigned uniquely to each lot and to each size of O-ring. The identifications shall be adequate to trace the O-rings to their raw material

master batch. Improper packaging or marking is cause for rejection. Additionally, no O-ring shall be installed after the established expiration date noted on the manufacturer's packaging.

Mechanical properties

The O-ring material mechanical properties and acceptance criteria shall be in accordance with SPC-M801580-0002 (Appendix 1.3.9) for EPDM O-rings.

8.1.5.2 Valves and pressure-relief devices

The ES-3100 packaging does not incorporate any valves or pressure-relief devices.

8.1.5.3 Neutron-absorber material

The Cat 277-4 neutron-absorber material is specifically designed for criticality safety. Acceptance testing for the Cat 277-4 procurement, preparation, and casting is described in JS-YMN3-801580-A005 (Appendix 1.3.5).

8.1.6 Shielding Tests

No gamma or neutron radiation shielding features are integral to the packaging.

8.1.7 Thermal Tests

A thermal acceptance test is not required for the passive thermal features of this packaging. The maximum decay heat generated by the radioactive material is 5 W (Sects. 1.2.2.7 and 3.1.2), which is negligible. The QA and technical requirements for weighing, mixing, pouring, vibrating, curing and baking the Kaolite 1600 thermal insulation is described in JS-YMN3-801580-A003 (Appendix 1.3.4). The QA and technical requirements for weighing, mixing, pouring, vibrating, curing and baking the Packcrete material are described in SPC M801794-0003 (Appendix 1.3.11) and SPC M801580-0003 (Appendix 1.3.12).

8.1.8 Miscellaneous Tests

No additional tests are required prior to the use of the ES-3100 packaging.

8.2 MAINTENANCE PROGRAM

The ES-3100 maintenance program ensures that the packaging continues to meet the design requirements and the conditions of approval in the CoC. Periodic maintenance inspections and testing requirements verify that the performance of the packaging has not deviated or degraded during use from the authorized configuration. Incidental maintenance activities and routine determinations/quality control requirements (10 CFR 71.87 and 49 CFR 173.475) are authorized and performed during package operations as described in Sect. 7 of this SARP.

Although Subclause 7.5.2 of ANSI N14.5-1997 states that the periodic leakage rate testing shall be conducted within 12 months prior to each shipment, periodic maintenance of the ES-3100 packaging shall be performed on a 2-year basis as discussed in Sect. 4.4. Periodic maintenance is not required during a period of nonuse (i.e., extended storage or inactivity). The user shall verify that the ES-3100 periodic leakage rate testing (ANSI N14.5-1997, Subclause 7.5) and any necessary maintenance leakage rate testing (ANSI N14.5-1997, Subclause 7.4) [including any required corrective maintenance associated

with noncompliant conditions] have been performed within the 2-year period prior to shipment to ensure full compliance with the containment requirements of 10 CFR 71.

Maintenance requirements presented in Sect. 8.2 shall be considered as minimum requirements, and their determinations shall be included in the owner's or user's packaging maintenance records as described in Sect 7.5.1.2. Packaging components may be repaired, reworked, or replaced in accordance with the requirements specified in 10 CFR 71.131 and Sect. 9.3.15.

8.2.1 Structural and Pressure Tests

The ES-3100 packaging does not require any structural tests or pressure tests during periodic maintenance. Welding and structural repair/rework of the containment vessel or drum assembly would involve operations that are considered beyond the scope of routine maintenance.

8.2.2 Leakage Tests

The fabrication leak test (Sect. 8.1.4) must be performed before the first use of the packaging and the periodic leak test is performed on a 2-year basis thereafter while the packaging is in use. The maintenance leak test is performed following the structural repair/rework or replacement of a containment boundary component (e.g., weld repair or inner O-ring replacement).

The user shall develop detailed maintenance procedures which include, at a minimum, the process steps listed below for CV leak testing. Maintenance personnel shall ensure that:

1. The CV periodic maintenance has been performed in accordance with Sect. 8.2.5.2 and the O-ring grooves and sealing surfaces are cleaned, as necessary, with isopropyl alcohol and lint-free gloves, cloths, or swabs.

2. Certified replacement O-rings are obtained in accordance with Sect. 8.2.3.1 and the O-rings are cleaned, as necessary, with isopropyl alcohol and lint-free gloves, cloths, or swabs.

3. The inner O-ring is lubricated with a thin coat of Super-O-Lube and inserted into the CV flange groove.

   Note: Only the inner O-ring is installed during the maintenance or periodic leakage rate testing of the containment boundary.

4. The leak-test fixture is installed as follows:

   a. The leak check flange assembly (Drawing T2E801827A008, Appendix 1.3.7) is positioned over the CV body and lowered into the CV flange.

   b. The leak check flange O-ring has been installed in the O-ring groove.

   c. The CV lid assembly is placed on top of the leak check flange assembly.

      Note: The above fixture installation sequence assumes the use of a leak check flange assembly (Drawing T2E801827A008, Appendix 1.3.7). With facility management approval, an alternate leak-test fixture and installation sequence may be used.

5. The CV is leak tested with the inner O-ring installed in accordance with ANSI N14.5-1997, Subclause 7.4, *Maintenance leakage rate test*, or Subclause 7.5, *Periodic leakage rate test*, to demonstrate that the containment boundary is "leaktight." An integrated air leakage rate exceeding 1×10^{-7} ref-cm^3/s (or equivalent) is cause for rejection. Per ANSI N14.5-1997, the test procedure shall have a sensitivity of 5×10^{-8} ref-cm^3/s (one-half the reference air leakage rate) or equivalent. Maintenance personnel shall ensure the following, at a minimum:

    a. The leak testing is performed by trained and qualified personnel in accordance with the requirements of ANSI N14.5-1997 and the site-approved QA program.

        Note: Y51-01-B2-R-140 (Appendix 8.3.1) is provided as an example leak-test procedure.

    b. Leak-test instrumentation has been properly calibrated.

    c. The leak-test equipment is connected to the leak-test port in the leak check flange assembly.

    d. The leak test is performed under isothermal conditions.

        Note: If the leak test fails, the following measures should be performed: (1) review the operating procedures; (2) check the leak-test equipment and connections; and (3) check the test gauges and instrumentation including verification of calibration and certification records, as necessary. If none of these measures reveal the root cause for the leak-test failure, the following inspections should be considered: (1) visually inspect the O-rings per Sect. 8.2.3.1; (2) visually inspect the O-ring grooves and sealing surfaces per Sect. 8.2.5.2; (3) visually inspect the containment boundary; and (4) perform other nondestructive examinations, as appropriate.

6. Following successful completion of the leak test, the leak-test equipment is disconnected.

7. The CV lid assembly and the leak check flange assembly (or approved alternate leak-test fixture) are removed from the CV body.

8. The outer O-ring is lubricated with a thin coat of Super-O-Lube and inserted into the CV flange groove.

9. The CV lid closure nut threads are visually inspected for foreign matter. If necessary, clean the threads with lint-free gloves, cloths, or swabs and apply a thin coat of Krytox grease, Grade 240 AC, to the threads, as required [Drawing M2E801580A011, Appendix 1.3.7].

10. The CV lid assembly is positioned over the CV body with the two alignment pins in the CV flange engaged in the slots on the underside of the CV lid assembly.

11. The CV lid closure nut is hand tightened.

12. The CV lid assembly has a brass VCO threaded plug installed in the leak-test port.

13. The expiration date (2 years from the leak-test date) and either the signature or badge number of the person who performed the testing or certified the test results shall be entered on two copies of a leak-test label (see example label in Fig. 8.1). One label will be attached to the exterior surface of the CV, and the second label will be attached to the exterior surface of the drum. The leak-test label must contain organization information, "LEAK TEST APPROVED," "DO NOT REMOVE," expiration date, and either the name or badge number of the person (who performed the testing or certified the test results), at a minimum.

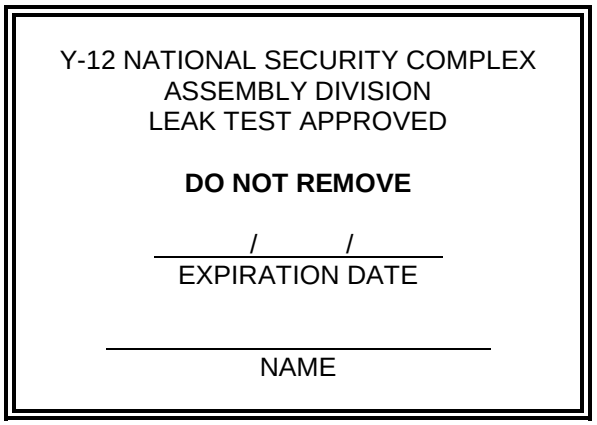

Fig. 8.1. Example label for use on the exterior surface of the containment vessel and the drum.

14. An optional radio-frequency identification (RFID) monitoring system tag may be secured to the drum assembly in accordance with the applicable requirements of ANL/DIS-09-5.

    Note: The mounting bracket for the RFID monitoring system tag shall provide the equivalent contact area of a drum washer and the thread engagement for the drum hex nuts shall remain unchanged.

8.2.3 Component and Material Tests

8.2.3.1 Containment vessel O-rings

The inner and outer O-rings will be replaced during periodic maintenance of the packaging. Certified replacement O-rings (see Sect. 8.1.5.1) are visually inspected for defects such as roughness, porosity, and surface defects. Defective O-rings are discarded. Replacement O-rings (stored in sealed containers) will have an established expiration date marked on the O-ring manufacturer's packaging, and no O-rings shall be installed after the established expiration date.

8.2.3.2 Thermal insulation and neutron-absorber material

Since the Kaolite or Packcrete insulation and Cat 277-4 are encapsulated within the stainless-steel liner, no damage or deterioration is expected. However, the drum, liner, internal flange, flat cover, and top plug shall all be visually inspected for tears or punctures or other defects that would allow for the escape of insulating or neutron-absorbing material. The drum assembly and top plug will be weighed prior to first use and during periodic maintenance to evaluate density variations in the insulation (Kaolite 1600 or Packcrete) or the Cat 277-4. For the purpose of weight comparisons, the drum does not include the lid, pads, nuts, or washers. Weights recorded during periodic maintenance will be compared to the recorded weights prior to first use, and the packaging components will be rejected and evaluated for rework if the weight change of the drum is >10 lb or the weight change of the top plug is >2 lb.

8.2.4 Thermal Tests

There are no periodic maintenance thermal test requirements for the passive thermal features of this packaging.

8.2.5 Miscellaneous Tests

8.2.5.1 Visual inspection for corrosion

The ES-3100 packaging will be stored in weather-protected indoor facilities; thus, surface corrosion is not expected. However, during periodic maintenance inspections, accessible surfaces shall be visually inspected for corrosion, moisture, and damage. The observation of surface corrosion on any component will be cause for further inspection. If the corrosion can be easily wiped off and no pitting is apparent beneath it, the package is acceptable for use. If the corrosion cannot be easily wiped off, if scaling is present, or if pitting is observed, the component must undergo a dimensional inspection, including nondestructive examinations as necessary, to determine the extent of the damage before the packaging component can be used. If the corrosion has compromised the structural integrity of the component (i.e., the component no longer meets dimensional or surface finish criteria for a new part as specified on the design drawings), then the component shall be rejected.

8.2.5.2 Containment vessel maintenance

The CV must be removed from the drum assembly for periodic maintenance inspections. After removing the CV lid assembly, interior and exterior CV surfaces shall be examined for signs of moisture, corrosion, or physical damage. Any CV exhibiting signs of moisture inside will be tagged and segregated until the cause is determined and corrected and the CV has been successfully reinspected. If physical damage has compromised the structural integrity of the CV [i.e., the component no longer meets dimensional requirements specified on the design drawings (Appendix 1.3.7) or JS-YMN3-801580-A001 (Appendix 1.3.3)] the component shall be rejected. Repair/rework authorization of damaged surfaces would include any nondestructive examinations and pressure/leak-test requirements in accordance with the design requirements. A repaired component shall meet the established acceptance criteria in Sect. 8.1.

The CV closure nut and CV flange threads shall be cleaned, as necessary, and visually inspected for damage. Minor defects such as small nicks or burrs may be smoothed with a thread file; however, components with damaged threads (evidence of cross-threading, or flattened threads) or excessive wear (visually apparent rounding of the fastener threads) are cause for rejection. Repair/rework of damaged threads on the CV closure nut or body flange would involve operations that are considered beyond the scope of routine maintenance.

The CV sealing lid leak-test port and brass VCO plug threads shall be cleaned, as necessary, and visually inspected for damage. Minor defects such as small nicks or burrs may be smoothed with a thread file or chased with a tap or die, as appropriate; however, components with damaged threads (as determined by the criteria noted above) must be replaced with certified replacement parts. Repair/rework of damaged threads on the CV sealing lid leak-test port would involve operations that are considered beyond the scope of routine maintenance.

The CV lid assembly (Drawing M2E801580A014, Appendix 1.3.7) will be evaluated to ensure that the CV closure nut rotates freely on the CV sealing lid. If there is excessive binding or varying resistance, the external retaining ring will be removed, and the CV lid assembly will be disassembled. The contact surface between the CV sealing lid and closure nut will be cleaned and lubricated with a thin film of Krytox grease, Grade 240 AC (Drawing M2E801580A011, Appendix 1.3.7). The CV sealing lid, closure nut, and external retaining ring will be assembled per Drawing M2E801580A014 (Appendix 1.3.7), and a thin coat of Krytox grease, Grade 240 AC, will be applied to the CV closure nut threads.

If installed, the O-rings will be removed from the CV flange grooves. The sealing surfaces of the CV sealing lid and CV flange grooves will be cleaned, as necessary, with isopropyl alcohol and lint-free

gloves, cloths, or swabs. The O-ring grooves and sealing surfaces will be visually inspected for foreign matter, nicks, and scratches. If nicks or scratches are found, the affected sealing surfaces may be smoothed with a stone or with fine sandpaper to return them to specification. Surface defects or imperfections that impact containment performance and cannot be removed without taking the component out of dimensional specification constitute cause for rejection of the component. Welding and structural repair/rework of the CV would involve operations that are considered beyond the scope of routine maintenance.

8.2.5.3 Subsystem maintenance

Touch-up paint that complies with drawing requirements should be applied to worn or faded packaging markings as necessary. The data plate and trefoil data plate (Drawing M2E801580A010, Appendix 1.3.7) shall be visually examined for legibility of all required information, and the plates will be securely attached to the drum as shown in Drawing M2E801580A031 (Appendix 1.3.7). Interior and exterior surfaces of the drum body shall be visually inspected for signs of moisture, corrosion, or physical damage. Defects in the drum assembly (e.g., tears, broken welds, dents >1-in. deep) are cause for rejection and possible reporting in accordance with Sect. 7.5.1.3.

8.2.5.4 Drum fastener inspection

The drum lid fasteners (5/8-11 UNC-2B silicon-bronze hex nuts and stainless-steel weld studs) shall be cleaned as necessary and visually inspected for damage. Minor defects such as small nicks or burrs may be smoothed with a thread file or chased with a tap, as appropriate; however, fasteners with damaged threads (evidence of cross-threading, or flattened threads) or excessive wear (visually apparent rounding of the fastener threads) must be replaced with certified replacement parts. In addition, the drum hex nuts will be inspected for proper certification markings. If there is any question about the certification status of the hex nuts, all suspect parts shall be replaced with certified replacement parts. Welding and structural repair/rework of a drum weld stud would involve operations that are considered beyond the scope of routine maintenance.

8.2.5.5 Valves and pressure-relief devices

The ES-3100 packaging does not incorporate any valves or pressure-relief devices.

8.2.5.6 Miscellaneous

The silicone rubber pads (Drawing M2E801580A009, Appendix 1.3.7) shall be visually inspected during periodic maintenance to verify that there are no signs of moisture and no significant gouges, cuts, tears, or nondesign voids in the pads that would cause them to be unusable. A silicone rubber pad shall be considered unusable if the following conditions are observed: (1) a through-section cut or tear that extends beyond half of the radial pad width or (2) a gouge or nondesign void larger than 1/2 in. diameter and deeper than 1/8 in. or one half of the pad thickness, whichever is less. Defective pads shall be rejected and replaced

1 APPLICABILITY AND SCOPE

To provide instructions for operating the helium leak test stations in Building 9204-2. The leak stations consist of Veeco MS-50 or MS-50GT leak detectors, vacuum pumps, pressure gauges, and the connecting valve manifold. This system has a multiple unit capability which allows the system operator to pump down the other units while running a leak test. Although there are multiple roughing pump valves, multiple manifold valves, and multiple vacuum gauges, during Section **5**, *Performance Activities*, **NO** specific valve number alpha designator is given. These valves and gauges are referred to as "valve (gauge) associated with the part under test" to allow the operator to perform a leak test on whichever unit roughs down first.

Applies to leak test equipment used to determine leak rates. The equipment, as currently set-up, is sensitive to Helium leak rates as low as 1×10^{-8} cc/sec.

The component to be tested is first vacuum evacuated. Then the component's exterior surfaces are exposed to a helium atmosphere. The atmosphere internal to the part is then valved into the leak detector to check for the presence of helium. A gross leak is indicated by a severe leak rate that exceeds the value normally encountered for the component being tested, and in some instances, may also exceed the pumping capacity of the vacuum system. A gross leak may be the result of an unacceptable part or a poor quality vacuum test connection.

Program: WC (Weapons Container)

2 PRECAUTIONS AND LIMITATIONS

Industrial Hygiene

A. Nitrile gloves SHALL be worn when using organic solvents (isopropyl alcohol, Right Stuff, etc.).

Industrial Safety

B. Safety shoes SHALL be worn while performing material activities detailed in this procedure.

C. Leather gloves or approved work gloves SHALL be worn, as needed, for work requiring tooling.

Radiological Control (RADCON)

D. RADCON SHALL perform any surveys requested or surveys that are deemed necessary by RADCON.

3 ACCEPTANCE CRITERIA

A. The acceptance criteria for helium leak testing each container is listed in the applicable container refurbishment procedure or work request (e.g., DT-20, DT-22, DT-23, DPP-2, ES-2100, ES-3100, etc.).

4 PREREQUISITE ACTIONS

4.1 Special Tools, Test Equipment, Parts and Supplies

Supervisor or Assemblyperson

[1] Ensure the following equipment is available, as necessary:

- Adhesive tape
- Helium supply bottle with regulator and tubing
- LT-283, LT-285, LT-286, LT-287, or other Leak Test Station(s)
- Leak Test flange for package
- Low Vacuum Source (Shop-Vac®, Wet-Vac™), or equivalent
- Plastic bags.

4.2 Field Preparations

Assemblyperson

[1] Ensure all equipment, fixtures, and accessories are:

- Operable
- Current on required inspection and/or maintenance
- Determined to be in good condition.

[2] Ensure helium supply bottle pressure is 200 psig or greater.

[3] Ensure certification stickers are attached and **NOT** expired on the following:

- Internal Standard Leak
- Pump A Vacuum
- Pump C Vacuum
- Temperature Sensor.

[4] Ensure the printer is on **AND** Leak Rate Results forms are in the paper tray.

[5] Ensure the Leak Detector is set to the test reject point (recipe) related to the acceptance criteria listed in the applicable container refurbishment procedure for the container being tested **OR** check with Packaging Engineer for equivalent detector reject point (recipe) if refurbishment procedure acceptance criteria is not listed in this chart.

Conversion Table	
Acceptance Criteria from Refurbishment Procedure	**Leak Detector Test Reject Point (Recipe)**
≤ 1.0 X 10^{-5} atm-cc/sec of helium	1.0 X 10^{-5} atm-cc/sec of helium
≤ 1.0 x 10^{-5} std-cc/sec helium	1.0 X 10^{-5} atm-cc/sec of helium
≤ 2.0 X 10^{-7}cc/s of helium	1.0 X 10^{-7} atm-cc/sec of helium
≤ 1 × 10^{-7} ref-cm^3/s - air	1.0 X 10^{-7} atm-cc/sec of helium
≤ 1.9 X 10^{-7} cc/s of helium	1.0 X 10^{-7} atm-cc/sec of helium
Atm cc/sec, cc/s, std-cc/sec, and ref- cm^3/s are nominally equal	

5 PERFORMANCE ACTIVITIES

Assemblyperson

NOTE 1 *Section 5.1, Helium Leak Testing Using the MS-50 Leak Test Station, will be used when leak testing with the Veeco MS-50 Leak Test Station.*

NOTE 2 *Section 5.2, Helium Leak Testing Using the MS-50GT Leak Test Station, will be used when leak testing with the Veeco MS-50GT Leak Test Station.*

NOTE 3 *While multiple containers may be in process concurrently on one leak test station, each container must be processed through its respective sub-section before moving to another sub-section.*

NOTE 4 *There are four Veeco Leak Test stations in the Container Refurbishment areas (LT-283, LT-285, LT-286, LT-287). Equipment valve number labels will consist of the appropriate Leak Test system ID and the valve number (e.g., LT-283-PV-101A, LT-286-PV-102A, etc.). For consistency, the Leak Test system ID numbers will be omitted from the label numbers in the procedure leaving only the ending valve numbers (e.g., PV-101A, PV-102A, etc.).*

[1] Notify Supervisor if maintenance is needed for any leak detection equipment.

5.1 Helium Leak Testing Using the MS-50 Leak Test Station

5.1.1 Performing the MS-50 Operational Check

Assemblyperson

NOTE 1 *Any leak detector may be interchanged with any applicable manifold system (i.e., LD 283 may be used with manifold system 284, etc.). The Supervisor gives direction for interchanging manifold systems.*

NOTE 2 *A Veeco operational check is performed by Maintenance, as necessary.*

NOTE 3 *The Veeco MS-50GT leak detector may be used at any of the above listed manifold stations if the respective Veeco LD is down for service. The Supervisor gives direction on making the substitution.*

5.1.1 Performing the MS-50 Operational Check (cont.)

Assemblyperson

[1] Ensure the following valves are CLOSED:

- PV-110, LEAK DETECTOR ISOLATION
- PV-101A, TEST POINT A PUMP ISOLATION
- PV-102A, TEST POINT A LD ISOLATION
- PV-101B, TEST POINT B PUMP ISOLATION
- PV-102B, TEST POINT B LD ISOLATION
- PV-101C, TEST POINT C PUMP ISOLATION
- PV-102C, TEST POINT C LD ISOLATION
- PV-101D, TEST POINT D PUMP ISOLATION
- PV-102D, TEST POINT D LD ISOLATION.

NOTE *The vertically arranged blue soft-keys (numbered 1-5) correspond to settings and selections that appear on the CRT.*

[2] Ensure the roughing pumps are running.

[a] **IF** the roughing pumps will **NOT** turn on, **THEN** notify the Supervisor.

[3] **IF** the Veeco is turned off, **THEN** turn on the Veeco.

[a] **IF** the Veeco will **NOT** turn on, **THEN** notify the Supervisor.

[4] **IF** Veeco is in SLEEP MODE, **THEN** press any key to wake it up.

[5] Verify the READY TO TEST screen is displayed.

[6] **IF** the FIL ON/OFF LED light is off, **THEN** press the FIL ON/OFF key **AND** wait 15 seconds.

[a] **IF** the FIL ON/OFF LED light **DOES NOT** illuminate after 15 seconds, **THEN** notify the Supervisor.

5.1.2 Pumping Down the Containers With the MS-50 Leak Test Station

Assemblyperson

NOTE 1 *Section 5.1.2 may be performed concurrently with other sections in the procedure.*

NOTE 2 *Multiple containers may be pumped down at one time.*

[1] Ensure the following valves are CLOSED:

- PV-101A, TEST POINT A PUMP ISOLATION
- PV-102A, TEST POINT A LD ISOLATION
- PV-101B, TEST POINT B PUMP ISOLATION
- PV-102B, TEST POINT B LD ISOLATION
- PV-101C, TEST POINT C PUMP ISOLATION
- PV-102C, TEST POINT C LD ISOLATION
- PV-101D, TEST POINT D PUMP ISOLATION
- PV-102D, TEST POINT D LD ISOLATION.

[2] **IF** test line(s) are capped, **THEN** remove cap.

[3] Ensure each Containment Vessel's (CV) Leak Test Flange is connected to the following station test line(s), as necessary:

- Test Point A
- Test Point B
- Test Point C
- Test Point D.

NOTE *The bag will be placed on the CV during the respective container refurbishment operating procedure.*

[4] Ensure the CV to be leak tested is fully encapsulated within a plastic bag.

[5] Ensure the PV-101 pump isolation valve(s) associated with the CV to be tested is opened to evacuate CV using the roughing pump.

NOTE *All remaining CVs will continue to be pumped down, with their PV-101 pump isolation valves remaining open.*

[6] **WHEN** the Granville Phillips (GP) vacuum gauge reads maximum vacuum (less than 15 mTorr), **THEN** close the PV-101 pump isolation valve for the CV being tested.

[7] Ensure the PV-101 pump isolation valves remain open for all remaining CVs being pumped down.

5.1.3 Leak Testing the Containers With the MS-50 Leak Test Station

Assemblyperson

NOTE *Leaks may be repaired and the test repeated, as directed by the Supervisor.*

[1] Select Containment Vessel (CV) to be tested.

[2] Remove as much air as possible from the bag, using a Shop-Vac® (Wet-Vac™), or other vacuum source.

[3] Insert the helium fill tube near the bottom of the bag, **AND** secure, as needed.

[4] Ensure the display screen shows READY TO TEST **AND** the appropriate REJECT POINT is displayed.

- **[a]** **IF** the appropriate REJECT POINT is **NOT** displayed, **THEN** perform the following steps:
  - **[i]** Press 5, SETTINGS/HELP on READY TO TEST screen.
  - **[ii]** Press 3, SELECT UP, **OR** 4, SELECT DOWN, on HELP/SETTINGS menu, **UNTIL** TEST RECIPE field is highlighted.
  - **[iii]** Press 2, CHANGE, to access SELECT TEST RECIPE menu.
  - **[iv]** Press 3, SELECT UP, or 4, SELECT DOWN, to specify test recipe with the appropriate REJECT point.
  - **[v]** Press 5, EXIT, to return to test mode.

[5] Ensure ALL of the PV-102 leak detector (LD) isolation valves are closed to isolate the manifold from the leak detector (i.e., upper valves).

[6] Ensure PV-110, LEAK DETECTOR ISOLATION, is OPEN.

NOTE 1 *The READY TO TEST light on the screen goes away when the START button is pressed.*

NOTE 2 *Pressing START a second time after testing begins will halt testing.*

[7] Press **AND** hold START button **UNTIL** leak test begins (this will allow the piping from the VEECO to the leak detector isolation valve to be pumped down by the VEECO before the isolation valve is opened).

NOTE *One CV will be tested at a time. The remaining PV-102 isolation valves for the CVs being pumped down remain closed.*

[8] Open the PV-102 LD isolation valve associated with the CV under test.

5.1.3 Leak Testing the Containers With the MS-50 Leak Test Station (cont.)

Assemblyperson

NOTE 1 *The test start time begins when the plastic bag is full of helium.*

NOTE 2 *To ensure a helium atmosphere, a slight purge of helium may be necessary to keep the bag inflated during testing. Helium must flow into the bag and be purged from a point below the CV being tested throughout the test. This continuous purge may be at a lower helium pressure than the pressure used to inflate the bag.*

[9] Open the Helium Tank Valve **AND** fill the plastic bag with Helium **UNTIL** the bag is full of helium (puffed up).

NOTE *Helium will diffuse through the O-ring in 10 minutes. Testing longer than this can cause a false failed test due to the diffusion process.*

[10] Wait for at least two minutes (minimum time to ensure detector stability) for test to complete.

NOTE *Step **5.1.3[11]** is performed when the CV fails the leak test.*

[11] **IF** LEAK RATE is more than the REJECT set point and the REJECT message is displayed, **THEN** end the test by performing the following:

- **[a]** **WHEN** the leak test time is complete, **THEN** press **AND** hold VENT button **UNTIL** test ends.
- **[b]** Ensure the leak test results are printed.
- **[c]** Close the PV-102 LD isolation valve associated with the CV under test.
- **[d]** Close the Helium Tank Valve.
- **[e]** Ensure the PV-110 is CLOSED.
- **[f]** Ensure the associated PV-101 pump isolation valve is OPEN (to allow the manifold to pump down):
  - PV-101A, TEST POINT A PUMP ISOLATION
  - PV-101B, TEST POINT B PUMP ISOLATION
  - PV-101C, TEST POINT C PUMP ISOLATION
  - PV-101D, TEST POINT D PUMP ISOLATION.

5.1.3 Leak Testing the Containers With the MS-50 Leak Test Station (cont.)

Assemblyperson

[g] **IF** this is the FIRST **OR** SECOND leak test attempt **AND** the CV **DOES NOT** pass the leak test, **THEN** perform the following:

[i] Remove **AND** clean the O-Ring(s).

[ii] **IF** testing an ES-3100 container, **THEN** lubricate the O-ring(s).

[iii] Re-install the O-Ring(s).

[iv] **GO TO** Step **5.1.2[4]**.

[h] **IF** this is the THIRD leak test attempt **AND** the CV **DOES NOT** pass the leak test, **THEN** contact the Supervisor.

Supervisor

NOTE *The Supervisor contacts the Packaging Engineer after the third failed attempt to leak test the Containment Vessel. The Packaging Engineer will determine whether to test the CV again.*

[i] Contact the Packaging Engineer for disposition instructions **AFTER** three failed attempts.

Assemblyperson

[ii] **IF** directed, **THEN** place a UCN-11738, Tag: *Nonconforming Material*, on the Containment Vessel **AND** set the container aside for disposition.

NOTE *Step **5.1.3[12]** is performed when the CV passes the leak test **AND** may be performed at any time **AFTER** the ACCEPT is displayed.*

[12] **IF** the LEAK RATE is less than the REJECT set point **AND** the ACCEPT is displayed, **THEN** end the test by performing the following:

[a] **WHEN** the leak test time is complete, **THEN** press **AND** hold the VENT button **UNTIL** the test ends.

[b] Ensure the leak test results are printed.

[c] Close the Helium Tank Valve.

[d] Remove helium tube.

5.1.3 Leak Testing the Containers With the MS-50 Leak Test Station (cont.)

Assemblyperson

[e] Close the PV-102 leak detector (LD) isolation valve associated with the CV under test.

[f] Ensure the following is recorded on the Leak Rate Results form **AND** attached to the part card:

- Internal Standard Leak SAP # and Expiration Date
- Pump A Vacuum SAP # and Expiration Date
- Pump C Vacuum SAP # and Expiration Date
- Temperature Sensor SAP # and Expiration Date.

[13] **IF** there are remaining CV(s) that have been roughed down (i.e., pumped down) for testing, **THEN GO TO** Step **5.1.2[1]**.

[14] Ensure the helium is turned off.

[15] Ensure the PV-110 is CLOSED.

[16] Disconnect CV(s) from leak test station line(s).

[17] Replace cap(s).

[18] Ensure ALL PV-101 pump isolation valves **AND** PV-102 LD isolation valves are OPEN to evacuate the test lines:

- PV-101A, TEST POINT A PUMP ISOLATION
- PV-102A, TEST POINT A LD ISOLATION
- PV-101B, TEST POINT B PUMP ISOLATION
- PV-102B, TEST POINT B LD ISOLATION
- PV-101C, TEST POINT C PUMP ISOLATION
- PV-102C, TEST POINT C LD ISOLATION
- PV-101D, TEST POINT D PUMP ISOLATION
- PV-102D, TEST POINT D LD ISOLATION.

[19] Ensure the roughing pumps are running.

[a] **IF** roughing pumps are **NOT** running, **THEN** contact Supervisor.

5.2 Helium Leak Testing Using the MS-50GT Leak Test Station

NOTE 1 *Section 5.1, Helium Leak Testing Using the MS-50 Leak Test Station, will be used when leak testing with the Veeco MS-50 Leak Test Station.*

NOTE 2 *Section 5.2, Helium Leak Testing Using the MS-50GT Leak Test Station, will be used when leak testing with the Veeco MS-50GT Leak Test Station.*

5.2.1 Performing the MS-50GT Operational Check

Assemblyperson

NOTE 1 *Any leak detector may be interchanged with any applicable manifold system (i.e., LD 283 may be used with manifold system 284, etc.). The Supervisor gives direction for interchanging manifold systems.*

NOTE 2 *A Veeco operational check is performed by Maintenance, as necessary.*

NOTE 3 *There are four Veeco Leak Test stations in the Container Refurbishment areas (LT-283, LT-285, LT-286, LT-287). Equipment valve number labels will consist of the appropriate Leak Test system ID and the valve number (e.g., LT-283-PV-101A, LT-286-PV-102A, etc.). For consistency, the Leak Test system ID numbers will be omitted from the label numbers in the procedure leaving only the ending valve numbers (e.g., PV-101A, PV-102A, etc.).*

NOTE 4 *The Veeco MS-50GT leak detector may be used at any of the above listed manifold stations if the respective Veeco LD is down for service. The Supervisor gives direction on making the substitution.*

[1] Ensure the following valves are CLOSED:

- PV-110, LEAK DETECTOR ISOLATION
- PV-101A, TEST POINT A PUMP ISOLATION
- PV-102A, TEST POINT A LD ISOLATION
- PV-101B, TEST POINT B PUMP ISOLATION
- PV-102B, TEST POINT B LD ISOLATION
- PV-101C, TEST POINT C PUMP ISOLATION
- PV-102C, TEST POINT C LD ISOLATION
- PV-101D, TEST POINT D PUMP ISOLATION
- PV-102D, TEST POINT D LD ISOLATION.

5.2.1 Performing the MS-50GT Operational Check (cont.)

Assemblyperson

NOTE *The MS-50GT uses touch screen technology rather than soft-key buttons.*

[2] Ensure the roughing pumps are running.

[a] **IF** the roughing pumps will **NOT** turn on, **THEN** notify the Supervisor.

[3] **IF** the Veeco is turned off, **THEN** turn on the Veeco.

[a] **IF** the Veeco will **NOT** turn on, **THEN** notify the Supervisor.

[4] **IF** the Veeco is in SLEEP MODE, **THEN** press any key to wake it up.

[5] Verify the green START button is illuminated.

[6] Press MORE, followed by CALIBRATE (on bottom of screen).

5.2.2 Pumping Down the Containers With the MS-50GT Leak Test Station

Assemblyperson

[1] Ensure the following valves are CLOSED:

- PV-101A, TEST POINT A PUMP ISOLATION
- PV-102A, TEST POINT A LD ISOLATION
- PV-101B, TEST POINT B PUMP ISOLATION
- PV-102B, TEST POINT B LD ISOLATION
- PV-101C, TEST POINT C PUMP ISOLATION
- PV-102C, TEST POINT C LD ISOLATION
- PV-101D, TEST POINT D PUMP ISOLATION
- PV-102D, TEST POINT D LD ISOLATION.

[2] **IF** test line(s) are capped, **THEN** remove cap.

[3] Ensure each Containment Vessel's (CV) Leak Test Flange is connected to the following station test line(s), as necessary:

- Test Point A
- Test Point B
- Test Point C
- Test Point D.

NOTE *The bag will be placed on the CV during the respective container refurbishment operating procedure.*

[4] Ensure the CV to be leak tested is fully encapsulated within a plastic bag.

[5] Ensure the PV-101 pump isolation valve(s) associated with the CV to be tested is opened to evacuate the CV using the roughing pump.

NOTE *All remaining CVs will continue to be pumped down, with their PV-101 pump isolation valves remaining open.*

[6] **WHEN** the Granville Phillips (GP) vacuum gauge reads maximum vacuum (less than 15 mTorr), **THEN** close the PV-101 pump isolation valve for the CV being tested.

[7] Ensure the PV-101 pump isolation valves remain open for all remaining CVs being pumped down.

5.2.3 Leak Testing the Containers With the MS-50GT Leak Test Station

Assemblyperson

NOTE *Leaks may be repaired and the test repeated, as directed by the Supervisor.*

[1] Select the Containment Vessel (CV) to be tested.

[2] Remove as much air as possible from the bag, using a Shop-Vac® (Wet-Vac™), or other vacuum source.

[3] Insert the helium fill tube near the bottom of the bag, **AND** secure, as needed.

[4] Verify the green START button is illuminated **AND** the appropriate REJECT POINT is displayed.

- **[a]** **IF** the appropriate REJECT POINT is **NOT** displayed, **THEN** perform the following steps:
  - **[i]** Press RECIPE.
  - **[ii]** Press LOAD.
  - **[iii]** Enter recipe number.
  - **[iv]** Press ENTER.
  - **[v]** Press LEAK RATE to return to home screen.

[5] Ensure ALL of the PV-102 leak detector (LD) isolation valves are closed to isolate the manifold from the vacuum pump (i.e., upper valves).

[6] Ensure the PV-110, LEAK DETECTOR ISOLATION, is OPEN.

NOTE 1 *The READY TO TEST light on the screen goes away when the START button is pressed.*

NOTE 2 *Pressing START a second time after testing begins will halt testing.*

NOTE 3 *Pressing and holding the START button will allow the piping from the VEECO to the leak detector isolation valve to be pumped down by the VEECO before the isolation valve is opened.*

[7] Press **AND** hold START button **UNTIL** leak test begins.

NOTE *One CV will be tested at a time. The remaining PV-102 isolation valves for the CVs being pumped down remain closed.*

[8] Open the PV-102 LD isolation valve associated with the CV under test.

5.2.3 Leak Testing the Containers With the MS-50GT Leak Test Station (cont.)

Assemblyperson

NOTE 1 *The test start time begins when the plastic bag is full of helium.*

NOTE 2 *To ensure a helium atmosphere, a slight purge of helium may be necessary to keep the bag inflated during testing. Helium must flow into the bag and be purged from a point below the CV being tested throughout the test. This continuous purge may be at a lower helium pressure than the pressure used to inflate the bag.*

[9] Open the Helium Tank Valve **AND** fill the plastic bag with Helium **UNTIL** the bag is full of helium (puffed up), indicating that the test start time begins now.

NOTE *Helium will diffuse through the O-ring in 10 minutes. Testing longer than this can cause a false failed test due to the diffusion process.*

[10] Wait for at least two minutes (minimum time to assure detector stability) for test to complete.

NOTE *Step **5.2.3[11]** is performed when the CV fails the leak test.*

[11] **IF** the LEAK RATE is more than the REJECT set point **AND** the screen displays a red "thumbs down" symbol (upper right-hand corner of screen), **THEN** end the test by performing the following:

- **[a]** **WHEN** the leak test time is complete, **THEN** press **AND** hold the VENT button **UNTIL** test ends.
- **[b]** Ensure the leak test results are printed.
- **[c]** Close the PV-102 LD isolation valve associated with the CV under test.
- **[d]** Close the Helium Tank Valve.
- **[e]** Ensure the PV-110 is CLOSED.
- **[f]** Ensure the associated PV-101 pump isolation valve is OPEN (to allow the manifold to pump down):
  - PV-101A, TEST POINT A PUMP ISOLATION
  - PV-101B, TEST POINT B PUMP ISOLATION
  - PV-101C, TEST POINT C PUMP ISOLATION
  - PV-101D, TEST POINT D PUMP ISOLATION.

5.2.3 Leak Testing the Containers With the MS-50GT Leak Test Station (cont.)

Assemblyperson

[g] **IF** this is the FIRST **OR** SECOND leak test attempt **AND** the Containment Vessel **DOES NOT** pass the leak test, **THEN** perform the following:

[i] Remove, clean, **AND** re-install the O-Ring(s).

[ii] **GO TO** Step **5.2.2[4]**.

[h] **IF** this is the THIRD leak test attempt **AND** the Containment Vessel **DOES NOT** pass the leak test, **THEN** contact the Supervisor.

Supervisor

NOTE *The Supervisor contacts the Packaging Engineer after the third failed attempt to leak test the Containment Vessel. The Packaging Engineer will determine whether to test the CV again.*

[i] Contact the Packaging Engineer for disposition instructions for three failed attempts **AND** set container aside for disposition.

Assemblyperson

[ii] **IF** directed, **THEN** place a UCN-11738, Tag: *Nonconforming Material*, on the Containment Vessel, **AND** set container aside for disposition.

NOTE *Step **5.2.3[12]** is performed when the CV passes the leak test.*

[12] **IF** the LEAK RATE is less than the REJECT set point **AND** the screen displays a green "thumbs up" symbol (upper right-hand corner of screen), **THEN** end the test by performing the following:

[a] **WHEN** the leak test time is complete, **THEN** press **AND** hold the VENT button **UNTIL** the test ends.

[b] Ensure leak test results are printed.

[c] Close the Helium Tank Valve.

[d] Remove helium hose

[e] Close the PV-102 LD isolation valve associated with the CV under test.

[f] Ensure the following is recorded on the Leak Rate Results form **AND** attached to the part card:

- Internal Standard Leak SAP # and Expiration Date
- Pump A Vacuum SAP # and Expiration Date
- Pump C Vacuum SAP # and Expiration Date
- Temperature Sensor SAP # and Expiration Date.

5.2.3 Leak Testing the Containers With the MS-50GT Leak Test Station (cont.)

Assemblyperson

[13] **IF** there are remaining CV(s) that have been roughed down (i.e., pumped down) for testing, **THEN GO TO** Step **5.2.2[1]**.

[14] Ensure the helium is turned off.

[15] Disconnect CV(s) from the leak test station test line(s).

[16] Replace cap(s) on leak test station test line(s).

[17] Ensure PV-110 is CLOSED.

[18] Ensure ALL PV-101 pump isolation valves **AND** PV-102 LD isolation valves are OPEN to evacuate the test lines:

- PV-101A, TEST POINT A PUMP ISOLATION
- PV-102A, TEST POINT A LD ISOLATION
- PV-101B, TEST POINT B PUMP ISOLATION
- PV-102B, TEST POINT B LD ISOLATION
- PV-101C, TEST POINT C PUMP ISOLATION
- PV-102C, TEST POINT C LD ISOLATION
- PV-101D, TEST POINT D PUMP ISOLATION
- PV-102D, TEST POINT D LD ISOLATION.

[19] Ensure the roughing pumps are running.

[a] **IF** the roughing pumps are **NOT** running, **THEN** contact the Supervisor.

6 RECORDS

All records generated as a result of this procedure are maintained in accordance with E-PROC-3114, *Records Management*.

9. QUALITY ASSURANCE

This chapter of the safety analysis report for packaging (SARP) describes the ES-3100 package quality assurance (QA) requirements that apply to packaging-related activities necessary for the design, fabrication, assembly, testing, maintenance, repair, modification, and use in accordance with applicable U.S. Nuclear Regulatory Commission (NRC), U.S. Department of Transportation (DOT), and other federal, state, and local regulations to protect the health and safety of the public, workers, and the environment. This package must comply with the NRC requirements specified in Title 10 of the Code of Federal Regulations (CFR), Part 71 (10 CFR 71), *Packaging and Transportation of Radioactive Material,* including DOT regulations in Title 49 CFR as cited in 10 CFR 71.5. Furthermore, packaging-related activities shall be performed according to a QA program approved by the U.S. Department of Energy (DOE), Office of Environmental Management; or National Nuclear Security Administration (NNSA), as appropriate. Title 10 CFR 71.101 requires the establishment, maintenance, and implementation of a QA program that satisfies each of the applicable criteria of 10 CFR 71, Subpart H. The applicable criteria shall be executed in a graded approach to an extent that is commensurate with their respective importance to safety.

As used in 10 CFR 71, QA comprises all planned and systematic actions necessary to provide adequate confidence that a system or component will perform satisfactorily in service. Consequently, QA includes quality control, which comprises those QA actions related to control of the physical characteristics and quality of the material or component to predetermined requirements.

9.1 INTRODUCTION

The Packaging and Transportation QA Program has been established at Y-12 in accordance with QAP-Y-91-273860-1, *Packaging and Transportation Quality Assurance Program Plan* (QAPP), which has been approved by the National Nuclear Security Administration (NNSA), Office of Packaging and Transportation (OPT) and endorsed by the DOE Certifying Official. The program was designed and implemented using a graded approach to selectively apply the QA requirements contained in 10 CFR 830, *Nuclear Safety Management*; U.S. Department of Energy (DOE) O 414.1D, *Quality Assurance*; 10 CFR 71; ASME NQA-1, *Quality Assurance Requirements for Nuclear Facility Applications*; and DOE O 460.1D, *Hazardous Materials Packaging and Transportation Safety* or DOE O 461.1C, *Packaging and Transportation for Offsite Shipment of Materials of National Security Interest*, as applicable. The U.S. Nuclear Regulatory Commission (NRC) regulations for packaging, preparation for shipment, and transportation of radioactive materials are given in 10 CFR 71, and DOT regulations for packaging and shipment of hazardous materials are given in Title 49 CFR. DOE nuclear facility users are also responsible for implementing DOE regulations given in 10 CFR 830 and 835, *Occupational Radiation Protection*, in addition to directives conveyed in DOE O 414.1D and DOE O 460.1D or DOE O 461.1C, as applicable. (References to DOE O 460.1D and DOE O 461.1C are used in this chapter because these orders are incorporated into the current conformed contract. However, when this SARP was released the associated QAPP, which has been updated to reference the latest order revisions, is currently under NNSA OPT review.)

The QA requirements and quality control provisions of the program apply to packaging-related activities and services necessary for the design, purchase, fabrication, handling, shipping, storing, cleaning, assembly, inspection, testing, operation, maintenance, repair, and modification of Type B and fissile material packagings for offsite transportation. These requirements are incorporated into an integrated body of packaging activities established to ensure quality. Achieving quality of design, conformance, and performance that meets or exceeds all packaging standards is the essential purpose of this program.

9.2 SCOPE

The design agency (Y-12) and owner of the ES-3100 packaging will implement a QA program that addresses the following QA elements of 10 CFR 71, Subpart H, as well as appropriate suspect/counterfeit item and software quality assurance requirements:

- § 71.103, *Quality assurance organization*;
- § 71.105, *Quality assurance program*;
- § 71.106, *Changes to quality assurance program;*
- § 71.107, *Package design control*;
- § 71.109, *Procurement document control*;
- § 71.111, *Instructions, procedures, and drawings*;
- § 71.113, *Document control*;
- § 71.115, *Control of purchased material, equipment, and services*;
- § 71.117, *Identification and control of materials, parts, and components*;
- § 71.119, *Control of special processes*;
- § 71.121, *Internal inspection*;
- § 71.123, *Test control*;
- § 71.125, *Control of measuring and test equipment*;
- § 71.127, *Handling, storage, and shipping control*;
- § 71.129, *Inspection, test, and operating status*;
- § 71.131, *Nonconforming materials, parts, or components*;
- § 71.133, *Corrective action*;
- § 71.135, *Quality assurance records*; and
- § 71.137, *Audits*.

In accordance with their site-approved QA program, authorized users of the ES-3100 packaging must address the following QA elements, as a minimum:

- § 71.103, *Quality assurance organization*;
- § 71.105, *Quality assurance program*;
- § 71.106, *Changes to quality assurance program;*
- § 71.111, *Instructions, procedures, and drawings*;
- § 71.113, *Document control*;
- § 71.115, *Control of purchased material, equipment, and services*;
- § 71.117, *Identification and control of materials, parts, and components*;
- § 71.121, *Internal inspection*;
- § 71.123, *Test control*;
- § 71.125, *Control of measuring and test equipment*;
- § 71.127, *Handling, storage, and shipping control*;
- § 71.129, *Inspection, test, and operating status*;
- § 71.131, *Nonconforming materials, parts, or components*;
- § 71.133, *Corrective action*;
- § 71.135, *Quality assurance records*; and
- § 71.137, *Audits*.

Additional QA elements may also be addressed as commensurate with the user scope of responsibility (i.e., if authorized for packaging-related design, fabrication, maintenance, repair, or modification activities). All providers of items and/or services must demonstrate that they meet the applicable QA requirements for their respective work scope. Each user of the ES-3100 package must also develop an appropriate site-approved QA plan and related implementing documentation.

9.3 QUALITY ASSURANCE PLAN

The QA requirements from 10 CFR 71, Subpart H are to be selectively applied using a graded approach to the specific packaging programs being developed and implemented. This selective application requires that the detail and magnitude of resources expended for a packaging-related activity be commensurate with the activity's importance to safe and reliable operations, environmental compliance, safeguards and security, programmatic mission, and/or other packaging-specific requirements. As stated in NRC Regulatory Guide 7.10, "structures, systems, and components important to safety mean the features of a Type B or fissile material package that are intended to (1) maintain the conditions required to safely transport the package contents; (2) prevent damage to the package during transport; or (3) provide reasonable assurance that the radioactive contents can be received, handled, transported, and retrieved without undue risk to the health and safety of the public or the environment."

In conjunction with the overall QA Program (E-SD-0002, *Quality Assurance Program Description)*, the QAPP identifies the management system that applies to ES-3100 packages for offsite transportation and describes the method of control over those structures, systems, and components (SSCs) and activities that are important to safety. Section 9.3.1 – 9.3.19 discuss how these requirements are implemented at Y-12 for the ES-3100 package.

9.3.1 Quality Assurance Organization

As described in Sect. 1 of the QAPP, the organizations ultimately responsible for QA within the Y-12 offsite packaging and transportation program are: (1) Packaging and Transportation Engineering (PTE); (2) Production Operations; (3) Quality; (4) Program Integration; and (5) Transportation and Traffic Management. Other Y-12 organizations have QA functions in support of the organizations identified above. An organization chart that depicts PTE and its relationship with the functional and technical support groups that provide items and services or that conduct other activities in support of radioactive material packagings is provided in Fig. 9.1.

PTE is responsible for the development of the QAPP and quality requirements for packaging components designed at Y-12. The PTE Manager has the responsibility for the technical leadership of the program. The PTE organization is part of the Y-12 Engineering division, which reports to the Vice President of Mission Engineering (Fig. 9.1). They also ensure that packagings fully comply with the applicable regulations, requirements, and standards. PTE and the Y-12 QA organizations ensure that the quality of packagings is maintained throughout the design, testing, fabrication, and maintenance processes. PTE is the design authority and primary contact for all packaging-related activities and services necessary for the design, purchase, fabrication, handling, shipping, storing, cleaning, assembly, inspection, testing, operation, maintenance, repair, and modification of Y-12 Type B and fissile material packagings, such as the ES-3100. PTE provides requested technical assistance for other Type B radioactive material packages. The complete description of the engineering roles and responsibilities is described in Y17-69-PE-335PD, *Packaging and Transportation Engineering Program Description*.

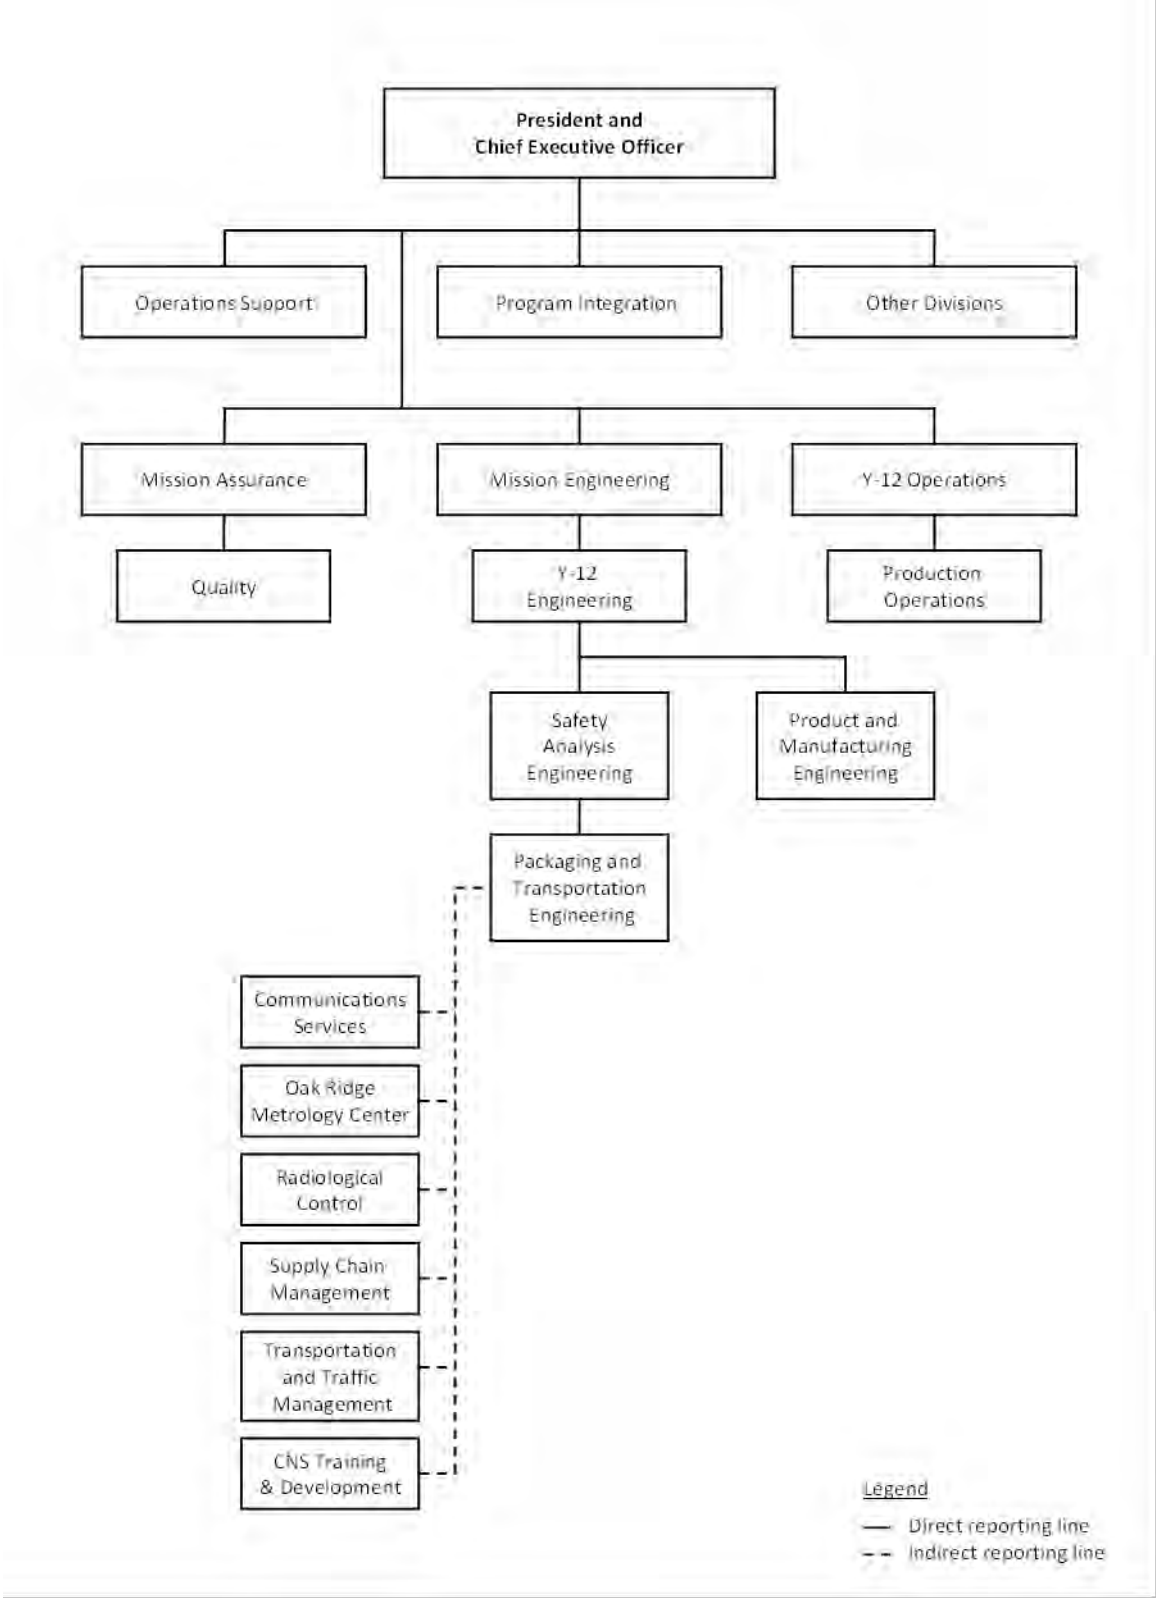

Fig. 9.1. Y-12 Packaging and Transportation Engineering organizational support.

In conjunction with Program Integration management, the PTE Manager plans, schedules, and assigns work activities and also obtains adequate funding to accomplish program goals and milestones. Production Operations conducts packing, maintenance, loading, and material handling activities with qualified personnel. Production Operations activities related to packaging are controlled by procedures approved by PTE and overseen by the Quality organization. Production Operations reports to the Vice President and Y-12 Site Manager, is funded by the program integration organizations, and receives technical support from PTE and quality oversight from the Quality organization. Production Operations is responsible for complying with implementing procedures, instructions, and/or checklists for loading, unloading, and maintenance of the packagings. Production Operations has the primary responsibility for the proper use of the package.

The Quality organization is responsible for the management and execution of the overall QA Program (E-SD-0002). The Quality organization is also responsible for providing qualified personnel for assessments and oversight for operations, supplier evaluations, and independent component inspections. The Quality Senior Director reports to the Vice President of Mission Assurance.

Program Integration management provides the funding for the daily maintenance and compliance activities necessary to ensure that the Y-12 packaging and transportation program complies with NRC, DOT, and DOE regulations. These activities include DOE order compliance, programmatic training, assessments, QA, investigations, packaging maintenance, and user support. The Vice President of Program Integration reports to the Chief Executive Officer.

The Transportation and Traffic Management organization provides compliance oversight to ensure compliance with DOE orders and federal, state, and local laws for the offsite shipment of radioactive materials. Other organizations provide services to PTE as shown in Fig. 9.1. Every individual and organization that produces an item, performs an activity, or provides a service for radioactive material packagings has direct responsibility for the quality of that item, activity, or service. Every organization using a package is responsible for ensuring proper procedures, training, and qualifications are in place.

9.3.2 Quality Assurance Program

Through the effective implementation of the QA program, Y-12 management provides control over activities affecting the quality of identified materials and components of the ES-3100 packaging to the extent commensurate with their importance to safety and, as necessary, to ensure conformance to the approved design of the packaging used to ship radioactive material. The QA program also provides for activities affecting quality to be accomplished under suitably controlled conditions.

The QA program is implemented by the preparation, review, approval, and use of implementing procedures. These procedures provide a system of checks and balances to ensure a safe, reliable, quality product. Each user of the ES-3100 package must also develop an appropriate site-approved QA program and related implementing documentation.

At Y-12, a graded approach is used to selectively apply QA requirements to the ES-3100 packaging components and any related services and activities in accordance with 10 CFR 71.105. The purpose of the graded approach is to select the QA controls and appropriate verification actions to be applied to the various packaging to the various packaging items, services and activities consistent with the extent of their importance to health and safety or to a significant environmental event.

The graded approach is consistent with that defined in NRC Regulatory Guide 7.10. This process involves (1) classifying packaging SSCs as "important to safety" or "not important to safety"; (2) grouping SSCs classified as "important to safety" into quality categories; and (3) specifying the applicable level of QA effort for each category. Approved procedures provide instructions to analyze packaging SSCs to determine whether their functions or physical characteristics are essential to safety, and they provide the criteria for grouping SSCs into one of the following quality categories as defined below. Table 9.1 shows the typical level of QA effort for each element of 10 CFR 71, Subpart H, relative to the graded safety-related quality categories. Each packaging component is graded by the Quality Category Committee using the quality category definitions in a manner similar to the procedure described in NRC Regulatory Guide 7.10, Appendix A. The results of the quality category grading for ES-3100 packaging components are given in Table 9.2, and the correlation between the NRC Regulatory Guide 7.10–based quality categories and the Y-12 quality levels (based on ASME NQA-1) is presented in the QAPP.

- **Category A** (critical to safe operation) components whose failure or malfunction will directly result in an unacceptable condition of containment, shielding, or nuclear criticality.
- **Category B** (major impact on safety) components whose failure or malfunction will indirectly result in an unacceptable condition of containment, shielding, or nuclear criticality (if the primary event occurred in conjunction with a secondary event, another failure, or an environmental event).
- **Category C** (minor impact on safety) components whose failure or malfunction does not result in an unacceptable condition of containment, shielding, or nuclear criticality regardless of other failures in this category.
- **NITS** (not important to safety).

Training and qualifications are required for personnel within Y-12 performing packaging activities related to design, fabrication, testing, procurement, loading, unloading, leak testing, quality oversight, transportation, and record keeping. Each activity is evaluated, and the proper training plan is developed and documented in accordance with E-PROC-3028, *Enterprise Training and Qualification Program.* Vendors performing packaging activities will require training or qualifications in accordance with the established contract. Activities involving special processes as defined in 10 CFR 71, Subpart H, may require specialized qualifications in accordance with established approved training requirements or through a nationally recognized standard such as the American Society for Nondestructive Testing, ASME, or American National Standards Institute.

The management assessment process is designed to focus on the compliance and flow down of contractual requirements, including applicable standards and codes, how those requirements are implemented in procedures, and the measurement of implementation effectiveness. Management assessments are conducted by members of the line organization or program to evaluate and determine whether packaging-related activities are properly focused on achieving desired results. These assessments serve as a periodic self-analysis tool and include reviewing the processes, systems, and programs that are important to the specified mission, goals, and objectives as well as identifying areas for continuous improvement. The assessment process includes provisions to appropriately evaluate all aspects of the Y-12 packaging process, determine how well the management system meets specified requirements, and assess methods to safely perform packaging-related activities.

Table 9.1. Typical level of quality assurance effort by graded quality category

10 CFR 71, Subpart H, level of quality assurance effort	Graded quality category		
	A	B	C
§ 71.103, *Quality assurance organization*			
– Quality assurance program established	✓	✓	✓
– Responsibilities defined	✓	✓	✓
– Quality assurance functions executed	✓	✓	✓
– Reporting levels established	✓	✓	✓
– Management endorsement	✓	✓	✓
§ 71.105, *Quality assurance program*			
– 10 CFR 71, Subpart H, compliant quality assurance program	✓	✓	
– Written procedures and instructions	✓	✓	✓
– Activities affecting quality are appropriately controlled and performed by trained personnel	✓	✓	✓
– Management review	✓	✓	✓
§ 71.107, *Package design control*			
– Most stringent Codes and Standards	✓		
– Formal test for complex items (first article evaluation)	✓		
– Codes and Standards	✓	✓	
– Formal engineering design process (control of design inputs, outputs, reviews, verifications, testing, changes/deviations, analyses, and interfaces)	✓	✓	
– Software quality assurance	✓	✓	
– Catalog/off-the-shelf components			✓
– Design change approval required for certifier controlled design conditions	✓	✓	✓
§ 71.109, *Procurement document control*			
– Traceability	✓	✓	
– Qualified supplier lists	✓	✓	
– Suppliers and subtier suppliers meet the applicable provisions of 10 CFR 71, Subpart H–*Quality Assurance*	✓	✓	
– Commercial grade dedication of items or services	✓	✓	
– Catalog/off-the-shelf components			✓
§ 71.111, *Instructions, procedures, and drawings*			
– Written and controlled	✓	✓	
– Quantitative or qualitative acceptance criteria	✓	✓	
– Controlled changes and deviations for certifier controlled design conditions	✓	✓	✓
§ 71.113, *Document control*			
– Controlled issuance	✓	✓	
– Controlled changes and deviations	✓	✓	

Table 9.1. Typical level of quality assurance effort by graded quality category

10 CFR 71, Subpart H, level of quality assurance effort	Graded quality category		
	A	B	C
§ 71.115, *Control of purchased material, equipment, and services*			
– Source evaluation and selection	✓		
– Inspections, audits, or surveillances at supplier facilities in accordance with specified requirements	✓	✓	
– Objective evidence of quality furnished by the supplier	✓	✓	
– Commercial grade dedication of items or services	✓	✓	
– Documentary evidence provided to ensure that material, equipment, and services conform to the procurement documents and specified requirements	✓	✓	✓
– Packaging components identified upon receipt and checked for damage	✓	✓	✓
§ 71.117, *Identification and control of materials, parts, and components*			
– Positive identification and traceability of each packaging component	✓		
– Control, identification, and traceability to heat number, part number, or other appropriate means throughout fabrication, installation, and use	✓	✓	
– Identification to end use instructions, procedures, specifications, or drawings	✓	✓	✓
§ 71.119, *Control of special processes*			
– Special processes including welding, heat treating, and nondestructive testing performed with qualified personnel and procedures	✓	✓	
– Special process qualification records	✓	✓	
– Special processes conducted in accordance with specified requirements	✓	✓	✓
§ 71.121, *Internal inspection*			
– Documented inspection to verify conformance with instructions, procedures, drawings, and specifications	✓	✓	
– Process monitoring provided as appropriate to assure quality control	✓	✓	
– Examination, measurements, or tests of material or products processed in accordance with specified requirements	✓	✓	
– Qualified inspectors independent of those performing the activities being inspected	✓	✓	
– Visual examination in accordance with specified requirements	✓	✓	✓
§ 71.123, *Test control*			
– Formal test program implemented using written test procedures	✓	✓	
– Formal test for complex items (first article evaluation)	✓		
– Test results are documented and evaluated	✓	✓	
– Observation and evaluation of supplier acceptance tests in accordance with specified requirements	✓	✓	
– Testing and acceptance criteria in accordance with specified requirements	✓	✓	✓
§ 71.125, *Control of measuring and test equipment*			
– Formal calibration program to ensure that tools, gauges, instruments, and other measuring and testing devices are controlled, calibrated, and adjusted	✓	✓	

Table 9.1. Typical level of quality assurance effort by graded quality category

10 CFR 71, Subpart H, level of quality assurance effort	Graded quality category		
	A	B	C
§ 71.127, *Handling, storage, and shipping control*			
– Written procedures for handling, storing, shipping, cleaning, and preservation of packaging components to prevent damage or deterioration	✓	✓	
– Routine handling activities			✓
§ 71.129, *Inspection, test, and operating status*			
– Status or condition of individual packaging components is identified	✓	✓	
– Stamps, tags, labels, or other suitable means indicate the status or condition	✓	✓	✓
§ 71.131, *Nonconforming materials, parts, or components*			
– Written procedures to identify, document, segregate, disposition, notify affected organizations, and to prevent inadvertent use or installation	✓	✓	✓
– Nonconforming conditions must be documented and closed in accordance with written procedures	✓	✓	✓
– Records of disposal (i.e., reject or scrap) required	✓	✓	
§ 71.133, *Corrective action*			
– Written procedures to identify and correct conditions adverse to quality	✓	✓	✓
– Cause and corrective action documented	✓	✓	
– Significant conditions adverse to quality reported	✓	✓	✓
§ 71.135, *Quality assurance records*			
– Records of reviews, inspections, tests, audits, surveillances, and material analyses	✓	✓	
– Records of design, fabrication, acceptance testing, and maintenance retained for the life of the packaging plus 3 years	✓	✓	
– Records of each shipment of radioactive materials for 3 years after the shipment	✓	✓	✓
– Qualification records of personnel, procedures, and equipment in accordance with specified requirements	✓	✓	✓
– Procurement records and nonconformance reports	✓	✓	✓
– Records managed by written program	✓	✓	✓
§ 71.137, *Audits*			
– All auditors are qualified	✓		
– Lead auditor is qualified	✓	✓	
– Written plan of periodic audits	✓	✓	✓
– Implementation by written procedures or checklists	✓	✓	✓

Table 9.2. Quality category for ES-3100 packaging components

ES-3100 component	Quality category
ES-3100 drum assembly (Drawing M2E801580A001, Appendix 1.3.7)	
Drum, inner liner, lid, and top plug weldments	B
Weld studs	B
Hex nuts	B
Washers	C
TID lugs, data plate, and trefoil data plate	C
Kaolite or Packcrete insulation	B
277-4 neutron-absorbing material	A
Silicone rubber pads (CV bottom pad, CV flange pad, and plug pad)	C
Aluminum foil duct tape	C
Nylon plug	C
Paint	C
RFID monitoring system tag	NITS [a]
ES-3100 containment vessel assembly (Drawing M2E801580A011, Appendix 1.3.7)	
Body [b]	A
Lid assembly	
Sealing lid and closure nut	A
Round bar and weld filler material	B
External retaining ring	C
Inner O-ring	A
Outer O-ring	C
Super-O-Lube	C
Modified VCO threaded plug with O-ring	C
Krytox grease, grade 240 AC	C
Hoist ring	C
ES-3100 packing materials (Sect. 1.2.2.4)	
Convenience cans	C
Convenience bottles	C
Silicone rubber pad [c] (can pad)	C
Heavy can spacer assembly [d]	
Can body and end cover	B
277-4 neutron-absorbing material	A
Lanyard, band clamp, and labels	C
Metal scrubbers	C
Polyethylene, nylon, or Teflon bag	C

[a] An optional radio-frequency identification (RFID) monitoring system tag (categorized as not important to safety) may be secured to the drum assembly. The QA requirements for the design, procurement, operation, and maintenance of the RFID monitoring system tag and support programs are presented in ANL/DIS-09-5.
[b] Component including any weld filler material.
[c] Drawing M2E801580A024, Appendix 1.3.7.
[d] Drawing M2E801580A043, Appendix 1.3.7.

9.3.3 Package Design Control

PTE is responsible for the ES-3100 package design and any design changes in accordance with approved design control procedures. The ES-3100 packaging certification drawing (Appendix 1.3.1) specifies those details of the package design that affect its evaluation under 10 CFR 71. The packaging design drawings (Appendix 1.3.7) and the equipment specifications (Appendices 1.3.2–1.3.5 and 1.3.9–1.3.12) provide detailed fabrication and acceptance criteria for the packaging components.

PTE performs or coordinates the preparation of design calculations and analyses, which are incorporated into or referenced in the certification documentation (i.e., SARP). As applicable, design inputs are collected from safety guides, regulatory requirements, national codes and standards, and customer performance requirements. In accordance with Sect. 3 of QAPP, PTE is also responsible for the design process, including design verification activities. Design output documents include drawings; system requirements; equipment specifications; data sheets; thermal, structural, criticality, and shielding analyses; and the safety grading worksheet.

Any changes to design inputs or final designs shall be justified and subjected to design control measures commensurate with those applied to the original design. Changes shall be approved by the same groups or organizations that reviewed and approved the original design documents. A change to Category A and B components (Sect. 9.3.2 and Tables 9.1 and 9.2) that affects a design feature, requirement, or specification shown on the ES-3100 certification drawing (Appendix 1.3.1) or condition of approval in the Certificate of Compliance shall be submitted to DOE Headquarters Certifying Official for review and approval, and the change shall not be implemented until the DOE Headquarters Certifying Official has provided approval of the change in writing. A change to Category C or NITS components may be approved by PTE (the design authority and SARP owner). Approved design changes must also be incorporated by revising procurement specifications and documents, manufacturer drawings, and operational procedures that are affected by the design change. At a minimum, design control measures will be applied to the following: criticality physics, radiation shielding, structural, thermal, containment, and accident analyses; compatibility of materials; accessibility for in-service inspection, maintenance, and repair; features to facilitate decontamination; and delineation of acceptance criteria for inspections and testing.

Design verification for the package design and design changes is performed in accordance with approved procedures. Qualified personnel, other than those who performed the original design work, check and verify design output documents and the supporting calculations and analyses using standard engineering practices identified in approved procedures. The package design is reviewed by a qualified design review team, and the results are documented. The design engineer and review team approve the drawings, specifications, and data sheets. These specific interfaces are discussed in approved design control procedures, which also implement peer reviews as quality control checks.

9.3.4 Procurement Document Control

In accordance with Sect. 4 of the QAPP, the Y-12 procurement process is implemented in accordance with documented management controls and approved procedures to ensure that adequate quality controls are incorporated in the procurement documents for packaging material, equipment, and services, whether purchased by Y-12 or its suppliers. Controls are implemented to ensure that procurements are planned and applicable technical and quality requirements are included or referenced in the procurement documents, that procurement documents are reviewed, and that changes are subject to the same degree of control used in preparation of the original documents. These controls also ensure that the items, materials, or services required for safety systems have been assigned a quality category. This procurement process, which is based on NQA-1 requirements, ensures that those items and/or services

provided by approved suppliers meet the 10 CFR 71, Subpart H requirements. Using a graded approach, the QA organization executes the procurement process by performing vendor qualification reviews, assessments, and first article evaluations (FAEs), as required, ensuring that:

- requirements are accurately, completely, and clearly communicated to the supplier;
- suppliers comply with regulatory qualification requirements;
- suppliers fabricate according to the design documentation; and
- the requested documentation is provided.

Applicable QA requirements are flowed down and verified through reviews, assessments, audits, and inspections of suppliers and sub-tier suppliers, as required, to ensure that they are capable of and continue to meet the specified technical and quality requirements. Packaging components identified as either Category A or B must be purchased from qualified vendors or through commercial grade dedication in accordance with established procedures. Approved design changes must also be incorporated by revising procurement specifications and documents, manufacturer drawings, and operational procedures that are affected by the design change.

Controls are implemented to ensure that procurements are planned and applicable technical and quality requirements are included or referenced in the procurement documents, that procurement documents are reviewed, and that changes are subject to the same degree of control used in preparation of the original documents. These controls also ensure that the items, materials, or services have been assigned a quality category (Sect. 9.3.2).

9.3.5 Instructions, Procedures, and Drawings

Y-12 organizations responsible for specific packaging-related operations and activities prepare the procedures, instructions, checklists, and/or similar documents for their particular packaging activities. These documents provide quantitative or qualitative acceptance criteria to ensure that the activities have been performed satisfactorily and that they meet the packaging requirements. In accordance with Sect. 5 of the QAPP, the packaging activities that are important to safety are accomplished and controlled in accordance with written and approved instructions, procedures, drawings, and other documents that identify the quality requirements for each item, service, or activity, and should include the methods for complying with applicable sections in 10 CFR 71, Subpart H. Packaging activities will be described to a level of detail commensurate with the complexity of the operation and the need to ensure consistent and acceptable results.

Y-12 organizations that fabricate, test, or maintain packagings or that pack, unpack, or maintain packages are defined as packaging users. Users are responsible for preparing and controlling procedures and instructions that implement packaging requirements. These activities are coordinated with QA personnel to verify that all inspections, hold points, and work activities have been performed satisfactorily. The instructions, procedures, and drawings used to carry out work activities also contain acceptance criteria to demonstrate activities that are important to safety have been completed as required. Procedures that concern packaging activities (i.e., packing, unpacking, maintenance) must be reviewed and concurred by the PTE Manager or designee.

9.3.6 Document Control

In accordance with Sect. 6 of the QAPP, Y-12 has an established document control system to ensure that documents within the scope of the Packaging and Transportation QA Program, including changes thereto, are prepared, reviewed for adequacy and completeness, and approved for release. Documents necessary to accomplish and/or verify packaging-related activities are identified and controlled to ensure that only current, accurate, approved documents are used. Implementation of this document control system ensures that:

- changes to documents (other than minor "non-intent" changes) are reviewed and approved by the same organizations that performed the original review and approval;
- approved documents are available at work locations when operations, which are essential to the effective functioning of the quality system, are performed; and
- recipients are notified when documents are superseded so they can be promptly removed from all points of issue or use, and originals are maintained for establishing history and maintaining traceability.

9.3.7 Control of Purchased Material, Equipment, and Services

In accordance with Sect. 7 of the QAPP, Y-12 has an established system for planning and executing packaging-related procurements to ensure that purchased material, equipment, and services whether purchased directly or through contractors and subcontractors, conform to the packaging procurement documents. Purchased items and services are controlled to ensure conformance to specified requirements. Depending on the quality level required, control measures for purchased items and services are performed relative to the level of importance, complexity, and quantity of the item or service being procured and the supplier quality performance. In addition, Y-12 has a suspect and counterfeit item (S/CI) program to prevent and control the hazards posed by the use of S/CIs, which can lead to unexpected equipment failures and undue risks to the DOE/NNSA mission, the environment, and personnel. Procurement documents contain provisions to ensure that suppliers are aware of any S/CI issues.

Procurement planning helps ensure that the appropriate QA requirements are identified in procurement documents. Y-12 evaluates the supplier capability to provide items or services in accordance with the requirements of the procurement documents. The supplier evaluation process includes one or more of the following, as appropriate:

- historical performance review,
- commercial grade survey
- third-party audit/survey review, or
- supplier QA program audit.

The Y-12 Supplier Quality organization maintains the Y-12 Quality Approved Supplier List (QASL) and reviews the supplier QA plans to ensure that the appropriate 10 CFR 71, Subpart H elements are properly included and addressed. Procurement of Category A and B packaging components may only be done through suppliers who have been evaluated and placed on the QASL or through commercial grade dedication.

The Y-12 supplier evaluation teams, which typically include representatives from Quality and Procurement, may be supplemented with subject matter experts (i.e., packaging engineers) who are knowledgeable of the technical details and the required manufacturing processes. Suppliers are selected based on their evaluated and documented capabilities to provide items and services. The procurement documents provide for access to facilities and records for inspection or audit and require that records be

forwarded when required for review and approval. These provisions are extended as appropriate through procurement documents to subtier suppliers.

Supplier performance is monitored and reviewed at intervals based on the complexity and technical requirements of the product supplied and the quality performance of the supplier. Records are established and maintained to identify the continuing acceptability of each supplier. FAEs and associated manufacturing hold/witness points are specified in procurement documents for Category A and B items or when they are needed to evaluate the performance of each supplier. When an FAE is specified, the Y-12 FAE team performs an in-depth evaluation of the first article at the supplier facility, and the evaluation is completed before release for production. Upon successful completion and acceptance of the FAE, the supplier is released to initiate the manufacture of production quantities. Any subsequent process change to manufacturing and acceptance procedures, facilities, type of personnel, or testing could conceivably affect product quality and requires the notification of proposed changes to Y-12.

In accordance with Sect. 7.6 of the QAPP, procurement documents will include provisions for: (1) supplier reporting of nonconformances that do not meet specified requirements and (2) obtaining Y-12 approval of the nonconformance report (NCR) disposition. Noncompliances to the procurement specifications, drawings, statement of work, or any other procurement document must be documented and dispositioned using the request for waiver or deviation (RFWD) process before the item can be accepted and released for shipment to Y-12. The procurement documents specify the test/inspection requirements, the acceptance criteria for safety-related items, suitable environmental conditions, and the identity of all documents to be submitted as records for information, review, or approval by the purchaser. When PTE requires the supplier to maintain specific records, the retention times and disposition requirements are prescribed in the purchase order. These documents generally include:

- documentation that identifies material or equipment and the specific procurement requirements (e.g., codes, standard, and specifications met by the items);
- documentation that identifies any procurement requirements that have not been met along with copies of applicable NCRs and RFWDs;
- documentation that the supplier material and equipment meet the applicable procurement requirements prior to installation or use; and
- any other documentation required by the procurement documents.

9.3.8 Identification and Control of Materials, Parts, and Components

In accordance with Sect. 8 of the QAPP, Y-12 packaging and related components, including unique tooling and fixtures, are identified and controlled to ensure their proper fabrication, assembly, use, and status. The identification of items shall be maintained to ensure appropriate traceability. Applicable design documents or implementing procedures specify the traceability requirements. Approved management controls establish and implement the processes to control consumables and items with limited service or shelf life and to prevent the use of incorrect or defective items.

Packagings and packaging components are identified either directly on the item or by tags, markings on envelopes container the part, or other means of documentation directly traceable to the item. Materials designated for destructive testing or special evaluations are controlled to prevent their inadvertent use. Limited life materials or components such as O-rings are identified and controlled to preclude use of expired items and to provide for recall if necessary, “QA accepted” tags must either be attached to the packaging components or to lots of components. These tags are attached after the Y-12 Quality organization completes a successful audit of the supplier certification data and other associated certification documents.

9.3.9 Control of Special Processes

Processes to be controlled as special processes are those where: (1) the results are highly dependent on the control of the process; (2) the results are highly dependent on the skill of the operator; and (3) the quality of the results cannot be readily determined by inspection or test of the item or component. ES-3100 packaging-related special processes comprise, but are not limited to, the following:

- mixing, casting, and curing of thermal insulation and neutron-absorbing materials;
- flow forming;
- welding;
- heat treating of materials;
- and conducting nondestructive examinations (e.g., radiographic, leak testing, liquid penetrant methods).

In accordance with Sect. 9 of the QAPP, Y-12 prepares specifications and requirements that direct the performance of special processes for packagings at offsite locations (i.e., supplier facilities) as well as onsite locations. These measures ensure that special processes are controlled and accomplished with qualified personnel and procedures in accordance with applicable specification, criteria, codes, standards, and other specified requirements.

9.3.10 Internal Inspection

A program for inspection of activities affecting the quality of packaging has been established and implemented. Multiple organizations within Y-12 have the responsibility for conducting inspections within the scope of the overall QA Program and shall provide documented management controls for such actions (E-SD-0002, Sect. 10). Inspections shall be conducted on packaging-related activities, or items affecting quality and/or nuclear safety to verify conformance with applicable codes, standards, regulatory requirements, procedures, and procurement documents or because of specific management requests. Inspection activities shall be documented and controlled by instructions, procedures, specifications, drawings, checklists, travelers, or other appropriate means.

Inspection activities are planned and performed using approved procedures, instructions, and checklists to verify conformance of an item or activity to specified requirements. In accordance with Sect. 10 of the QAPP, these documents will include methods for inspection, acceptance and rejection criteria, and identification of those responsible for performing the inspection. Inspections for acceptance shall be performed by qualified personnel other than those who performed or directly supervised the work being inspected, and those individuals shall not report directly to the supervisor immediately responsible for performance of the work. Personnel who perform nondestructive examinations such as radiographic, liquid penetrant, leak testing, and visual inspection to verify conformance to the specified requirements shall be qualified in accordance with documented management controls. Minimum certification requirements are shown on the ES-3100 certification drawing (Drawing M2E801580A037, Appendix 1.3.1).

9.3.11 Test Control

Y-12 defines requirements and acceptance criteria in conjunction with appropriate quality measures used to verify that packages meet design requirements, directs testing used to verify that the design meets regulatory requirements, and performs some acceptance and maintenance testing onsite. Testing used to verify production of packages is provided in specifications and data sheets produced in accordance with approved procedures. These management control documents ensure that testing and changes to testing are done per design intent, that all necessary testing is completed, and that the results of testing are reviewed to determine acceptability.

PTE has established a test program in accordance with Sect. 11 of the QAPP, which ensures required testing demonstrates that the packaging components will perform satisfactorily in service/use. Before the start of testing-related activities, qualified personnel will ensure that the testing organization has implemented a QA program that is compliant with the appropriate elements of 10 CFR 71, Subpart H. This testing is performed in accordance with written and approved test procedures that incorporate the necessary requirements and acceptance limits contained in the package design documents and federal regulations and ensure that qualification testing of prototype packages is performed under the most adverse design conditions. The packaging and certain components are subject to initial and verification testing in accordance with written test procedures. Test records and test results documentation are maintained by the organization responsible for the tests, and copies are sent to PTE.

9.3.12 Control of Measuring and Test Equipment

As described in Sect. 12 of the QAPP, the Y-12 Standards and Calibration Program, which is administered by the Y-12 Oak Ridge Metrology Center, ensures measuring and test equipment (M&TE) is calibrated and controlled. This control process ensures that tools, gauges, and other instruments used for packaging-related inspections, tests, and measurement activities are of the proper range, type, accuracy, and precision and that they are handled, stored, and maintained within specified calibration limits. The Oak Ridge Metrology Center has the responsibility for:

- maintaining primary standards,
- calibrating and maintaining secondary standards,
- calibrating and maintaining working standards,
- calibrating product acceptance test equipment and process applications equipment, and
- providing oversight and approval of the calibration program.

Calibration of M&TE is required whenever the equipment is used to determine conformance or acceptance to customer or regulatory compliance or whenever the measurement is required to meet safety, health, environmental, or quality parameters. Y-12 calibration organizations supporting packaging and transportation activities (e.g., Analytical Chemistry; Industrial Hygiene; Oak Ridge Metrology Center; Radiological Control) are responsible for maintaining measurement standards and calibrating M&TE by trained personnel and approved procedures or work instructions.

Records shall be established and maintained to indicate calibration status and the capability of M&TE to satisfactorily perform its intended function. Calibration reports and certificates reporting the results of calibrations shall include the information and data necessary for interpretation of the calibration results and verification of conformance to applicable requirements. Calibration records shall be controlled and stored to establish traceability to approved national or international standards.

9.3.13 Handling, Storage, and Shipping Control

In accordance with Sect. 13 of the QAPP, Y-12 has established measures to ensure that the handling, storing, shipping, cleaning, and preservation of materials and equipment to be used in packaging are accomplished in accordance with design requirements to prevent damage or deterioration by environmental conditions such as temperature and humidity, damage, mixing, substitution, or loss. The requirements for handling, storage, shipping, cleaning, packing, segregating, and preserving are specified in procedures, shipping instructions, checklists, or other documents. When necessary, special handling, lifting, storage devices, or equipment and special protective environments (e.g., inert gas or controlled moisture/temperature levels) are specified with appropriate provisions for their verification.

Packaging components shall be stored in weather-protected indoor facilities commensurate with established storage requirements. Stored packagings and components are placed in designated controlled storage areas. Monitoring of items in storage is conducted at appropriate intervals as determined by PTE. Marking and labeling measures shall be established (Sect. 9.3.8) for the handling, storage, packing, and shipping of items as necessary to adequately identify, maintain, and preserve the item. Markings and labels shall indicate the presence of special environments or the need for special controls if necessary.

ES-3100 package operations will be performed in accordance with Chap. 7 and applicable NRC, DOT, and other federal, state, and local regulations to protect the health and safety of the public, workers, and the environment. In accordance with Sect. 13 of the QAPP, operators will ensure (prior to shipment) that (1) packages have been prepared in accordance with approved drawings, procedures, specifications, regulatory requirements, SARP, DOE directives, and certificate; (2) packages have passed applicable inspections and tests; (3) packages are properly identified by physical markings or tags; and (4) shipping papers have been prepared as required and reviewed by qualified personnel to verify completeness and accuracy.

9.3.14 Inspection, Test, and Operating Status

Approved procedures and procurement documents describe the use of markings (i.e., stamps, tags, labels, routing cards, or other suitable means) and the status of inspections, tests, and operating conditions (including maintenance of items) that may be performed on packaging components. Facility operating procedures identify which methods are used and how they are implemented.

The status of inspection and test activities is identified in operating procedures to ensure that (1) required inspections and tests are performed and (2) items that have not passed the required inspections and tests are not inadvertently installed, used, or operated. Independent inspections are implemented at critical acceptance steps that are conducted by the QA organization through the use of certification reports. Y-12 uses a production control system, which schedules an inspection, test, or other activity before the packaging moves to the next activity. The status of each packaging can be determined from the production control system.

9.3.15 Nonconforming Materials, Parts, or Components

Items that do not conform to specified requirements shall be controlled to prevent inadvertent installation, use, or shipment. Controls shall provide for identification, documentation, evaluation, segregation when practical, disposition of nonconforming items, and notification to affected organizations.

In accordance with Sect. 15 of the QAPP, Y-12 employees are responsible for identifying and documenting nonconformances. If a vendor supply issue for packaging components is identified, items that are out of specification may be used as is with a RFWD approved by PTE. Items that cannot be returned to an acceptable condition are appropriately controlled to prevent inadvertent installation or use. Waivers or deviations on quality Category A and B packaging components also require approval by the DOE Certifying Official prior to implementation. After receipt at Y-12, the nonconforming materials, parts or components will be appropriated tagged, segregated when practical, and dispositioned. These nonconformance control activities are necessary to prevent further processing, delivery, installation, or inadvertent use of nonconforming items until affected organizations (including QA) are notified, and the proposed technical disposition, remedial actions, and corrective actions are approved.

9.3.16 Corrective Action

The identification, cause, and corrective actions for conditions adverse to quality are documented and reported in accordance with approved procedures to the appropriated levels of management. If a significant condition is identified, the system ensures that: (1) the root cause of the conditions is determined, (2) a Price-Anderson Amendments Act screening is performed, and (3) corrective action is taken to prevent recurrence.

In accordance with the Sect. 16 of the QAPP, Y-12 approved procedures establish the process to be used for conditions that may be noncompliant with respect to contractual requirements or that are adverse to safety, health, environment, operations, quality, safeguards and security, or mission performance. These issues are managed in accordance with the significance of the issues and the associated risk. For reportable occurrences involving packaging and transportation, the DOE Occurrence Reporting and Processing System is used in accordance with DOE O 232.2A. In addition to the DOE O 232.2A notification and reporting requirements, occurrences will be reported to the DOE Certifying Official upon discovery of the following:

- instance in which there is a significant reduction in the effectiveness (as defined by the certificate holder) of any approved fissile or Type B packaging during use,
- discovery of a defect with safety significance (as determined by the certificate holder) in a Type B or fissile material packaging, after first use (by any shipper), and
- instance in which the conditions of approval in the Certificate of Compliance were not met in making a shipment.

9.3.17 Quality Assurance Records

The Y-12 records management process is established in accordance with approved procedures (QAPP, Sect. 17) and implemented to ensure that sufficient records are specified, prepared, completed, reviewed, approved, and maintained to accurately reflect completed work. A QA record is a completed document that furnishes evidence of the quality of items and/or activities affecting quality. Records are identified, generated, reviewed, approved, collected, and indexed for both accountability and retrievability; are protected in storage for required retention limits; and have a specified final disposition. The records may be originals, copies of authenticated records (if needed to be stored by different organizations), or electronic media. These records are generated by many Y-12 organizations, including suppliers. QA records generated for or by PTE provide evidence of packaging quality. Examples of the types of QA record documents are listed in Table 9.3; specific records associated with operations are listed in Appendix 7.5.1.

Records are to be legible, complete, retrievable, and protected from damage, deterioration, and loss. In accordance with 10 CFR 71.91(a), records of each shipment of radioactive material are maintained for 3 years after the shipment, and quality records are maintained for 3 years beyond the life of the packaging (i.e., following decommissioning of the packaging) as required by 10 CFR 71.91(d). Records to be generated, supplied, or maintained are specified in applicable documents, such as design specifications, procurement documents, test procedures, and operational procedures. Site-level and departmental procedures provide for the retention, protection, preservation, traceability, accountability, and retrievability of records in the Y-12 document and record management systems.

Table 9.3. Typical quality assurance records

System requirements documents	SARPs
Design drawings	Work requests
Data sheets	Manufacturing and assembly procedures
Design criteria documents	Personnel qualification records
Graded approach results	Operating and maintenance procedures
Equipment specifications	Vendor certification evidence
Design review documentation	Product Information and Control Summary
Design change documentation	Preshipment leak-test records
Test plans and procedures	Offsite fissile material container inspection forms
Test reports	NCRs and log sheets
Quality assurance/control manuals	Corrective action reports
Procurement specifications	Quality Certification and Procurement Instructions
Material specifications	Certification data verification work requests
Manufacturing specifications	Certification procedures
Vendor QA program evaluation results	Self-appraisal reports
Audit reports	Surveillance reports
Weld radiographs	Liquid penetrant reports
Prototype data certification	Dimensional inspection results
Packing follow sheets	Maintenance follow sheets
Calibration procedures	Equipment calibration records

9.3.18 Audits

In accordance with Sect. 18 of the QAPP, a comprehensive system of planned and scheduled audits are conducted using written procedures to: (1) verify compliance with the requirements of packaging-related processes; (2) determine the effectiveness of the program; and (3) focus on improving items and processes. Audit personnel are provided with reasonable and timely access to facilities, documents, and appropriate personnel in the audited organizations. Audits are performed in accordance with procedures, and audit teams use prepared checklists to guide the audit process. Audit results are documented in formal reports that are transmitted to the responsible audited organization management as well as the auditing organization management.

Audit teams include both individuals trained in assessment and subject matter experts who are knowledgeable in the area being audited. Audits are led by a qualified lead auditor and conducted by qualified personnel who are (1) technically knowledgeable/experienced in the functional area being audited, (2) independent with no direct responsibilities in the functional area being audited, and (3) granted organizational freedom and authority to perform an effective audit. Lead auditors are certified by management and have qualifications that are outlined in accordance with approved procedures.

The results of each audit report are reviewed, and the managers who are assigned responsibility for an issue shall ensure that corrective actions addressing the cause are planned, implemented, and tracked to closure. For corrective actions to be considered complete, the audit team lead shall verify that (1) the audited organization provides a timely response to the audit report, (2) the response is adequate and complete, and (3) the corrective actions have been implemented. Areas of improvement that are not findings but may warrant strengthening are also considered as potential quality improvements.

9.3.19 Software Quality Assurance

Y-12 uses software in the design and analysis of packages. In addition, software is used to track packaging activities, file occurrences, maintain records, and provide communications. Y-12 has developed and implemented computer software programs, including configuration controls, which will improve safety, increase the reliability of packaging operations and data, and support the achievement of programmatic missions. Software controls include verification, validation, and configuration management. Software is used in accordance with the responsibilities and requirements for developing, procuring, implementing, maintaining, and applying computer software as described in Sect. 19 of the QAPP.
