1. GENERAL INFORMATION 1-1
1.1 INTRODUCTION 1-1
1.2 PACKAGE DESCRIPTION 1-2
1.2.1 Packaging 1-2
1.2.2 Contents 1-9
1.2.3 Special Requirements for Plutonium 1-27
1.2.4 Operational Features 1-27
1.3 APPENDIX 1-29
Appendix 1.3.1 Package Certification Drawing 1-31
Appendix 1.3.2 SPC JS-YMN3-801580-A002, *ES-3100 Drum Assembly* 1-39
Appendix 1.3.3 SPC JS-YMN3-801580-A001, ES-3100 Containment Vessel 1-71
Appendix 1.3.4 Equipment Specification JS-YMN3-801580-A003, Manufacturing Process Specification for Casting Kaolite 1600™ into the ES-3100 Shipping Package 1-111
Appendix 1.3.5 Equipment Specification SPC JS-YMN3-801580-A005, *Casting Catalog No. 277-4 Neutron Absorber for the ES-3100 Shipping Package* 1-131
Appendix 1.3.6 Package Category Determination 1-161
Appendix 1.3.7 ES-3100 Design Drawings 1-165
Appendix 1.3.8 Pyrophoricity of Uranium Metal 1-213
Appendix 1.3.9 Equipment Specification SPC M801580-0002, *ES-3100 Ethylene Propylene Diene Monomer (EPDM) Containment Vessel O-rings* 1-233
Appendix 1.3.10 SPC M801580-0004, *ES-3100 Heavy Can Spacer Assemblies* 1-263
Appendix 1.3.11 SPC M801794-0003, *Packcrete Preliminary Lot Qualification* 1-289
Appendix 1.3.12 SPC M801580-0003, *ES-3100 Packcrete Final Lot Qualification and Production Processing* 1-341
Appendix 1.3.13 Chapter 1 References 1-369
2. STRUCTURAL EVALUATION 2-1
2.1 DESCRIPTION OF STRUCTURAL DESIGN 2-2
2.1.1 Discussion 2-2
2.1.2 Design Criteria 2-6
2.1.3 Weights and Centers of Gravity 2-13
2.1.4 Identification of Codes and Standards for Package Design 2-13
2.2 MATERIALS 2-17
2.2.1 Material Properties and Specifications 2-17
2.2.2 Chemical, Galvanic, or Other Reactions 2-17
2.2.3 Effects of Radiation on Materials 2-28

2.3 FABRICATION AND EXAMINATION 2-28
2.3.1 Fabrication 2-28
2.3.2 Examination 2-30
2.4 GENERAL REQUIREMENTS FOR ALL PACKAGES 2-33
2.4.1 Minimum Package Size—10 CFR 71.43(a) 2-33
2.4.2 Tamper-Indicating Feature—10 CFR 71.43(b) 2-33
2.4.3 Positive Closure—10 CFR 71.43(c) 2-34
2.5 LIFTING AND TIE-DOWN STANDARDS FOR ALL PACKAGES 2-34
2.5.1 Lifting Devices 2-34
2.5.2 Tie-Down Devices 2-34
2.6 NORMAL CONDITIONS OF TRANSPORT 2-35
2.6.1 Heat 2-39
2.6.2 Cold 2-42
2.6.3 Reduced External Pressure 2-47
2.6.4 Increased External Pressure 2-47
2.6.5 Vibration 2-48
2.6.6 Water Spray 2-50
2.6.7 Free Drop 2-51
2.6.8 Corner Drop 2-52
2.6.9 Compression 2-52
2.6.10 Penetration 2-54
2.7 HYPOTHETICAL ACCIDENT CONDITIONS 2-55
2.7.1 Free Drop 2-59
2.7.2 Crush 2-69
2.7.3 Puncture 2-76
2.7.4 Thermal 2-81
2.7.5 Immersion—Fissile Material 2-86
2.7.6 Immersion—All Packages 2-86
2.7.7 Deep Water Immersion Test (for Type B Packages Containing More than 10^5 A_2) 2-86
2.7.8 Summary of Damage 2-87
2.8 ACCIDENT CONDITIONS FOR AIR TRANSPORT OF PLUTONIUM 2-101
2.9 ACCIDENT CONDITIONS FOR FISSILE MATERIAL PACKAGES FOR AIR TRANSPORT 2-101
2.10 SPECIAL FORM 2-101
2.11 FUEL RODS 2-101
2.12 APPENDIX 2-102
Appendix 2.12.1 Chapter 2 References 2-104
3. THERMAL EVALUATION 3-1
3.1 DESCRIPTION OF THERMAL DESIGN 3-1
3.1.1 Design Features 3-2
3.1.2 Content's Decay Heat 3-3
3.1.3 Summary Tables of Temperatures 3-4
3.1.4 Summary Tables of Maximum Pressures 3-7
3.2 MATERIAL PROPERTIES AND COMPONENT SPECIFICATIONS 3-10
3.2.1 Material Properties 3-10
3.2.2 Component Specifications 3-10

3.3 THERMAL EVALUATION UNDER NORMAL CONDITIONS OF TRANSPORT 3-16
3.3.1 Heat and Cold 3-17
3.3.2 Maximum Normal Operating Pressure 3-29
3.3.3 Maximum Thermal Stresses.....3-30
3.4 THERMAL EVALUATION UNDER HYPOTHETICAL ACCIDENT CONDITIONS 3-31
3.4.1 Initial Conditions 3-31
3.4.2 Fire Test Conditions.....3-32
3.4.3 Maximum Temperatures and Pressure.....3-35
3.4.4 Maximum Thermal Stresses.....3-52
3.4.5 Accident Conditions for Fissile Material Packages for Air Transport.....3-52
3.5 APPENDIX 3-53
Appendix 3.5.1 Containment Vessel Pressure due to Normal Conditions of Transport for the Proposed Contents.....3-55
Appendix 3.5.2 Containment Vessel Pressure due to Hypothetical Accident Conditions for the Proposed Contents.....3-65
Appendix 3.5.3 Silicone Rubber Thermal Properties from Therm 1.2 Database 3-73
Appendix 3.5.4 Estimates of Hydrogen Buildup in the ES-3100 Package Containing Highly Enriched Uranium 3-75
Appendix 3.5.5 Chapter 3 References 3-89

4. CONTAINMENT 4-1
4.1 DESCRIPTION OF THE CONTAINMENT SYSTEM 4-5
4.1.1 Containment Boundary 4-5
4.1.2 Special Requirements for Plutonium 4-6
4.2 CONTAINMENT UNDER NORMAL CONDITIONS OF TRANSPORT 4-6
4.3 CONTAINMENT UNDER HYPOTHETICAL ACCIDENT CONDITIONS 4-9
4.4 LEAKAGE RATE TESTS FOR TYPE B PACKAGES.....4-11
4.5 APPENDIX 4-13
Appendix 4.5.1 Determination of A_2 for the ES-3100 Package with HEU Contents 4-15
Appendix 4.5.2 Calculation of the ES-3100 CV Regulatory Reference Air Leakage Rates.....4-23
Appendix 4.5.3 Chapter 4 References 4-41

5. SHIELDING EVALUATION 5-1
5.1 DESCRIPTION OF SHIELDING DESIGN 5-1
5.1.1 Design Features.....5-1
5.1.2 Summary Table of Maximum Radiation Levels.....5-2
5.2 SOURCE SPECIFICATION.....5-2
5.2.1 Gamma Source.....5-5
5.2.2 Neutron Source 5-8
5.3 SHIELDING MODEL.....5-9
5.3.1 Configuration of Source and Shielding.....5-10
5.3.2 Material Properties.....5-33
5.4 SHIELDING EVALUATION.....5-35
5.4.1 Methods.....5-35
5.4.2 Input and Output Data.....5-36
5.4.3 Flux-to-Dose-Rate Conversion 5-36
5.4.4 External Radiation Levels.....5-36

5.5 APPENDIX 5-39
Appendix 5.5.1 Origen-S Input Data 5-41
Appendix 5.5.2 MCNP Input Data 5-43
Appendix 5.5.3 Comparative NCT Dose Rates for Kaolite and Packcrete 5-109
Appendix 5.5.4 Chapter 5 References 5-117
6. CRITICALITY EVALUATION 6-1
6.1 DESCRIPTION OF THE CRITICALITY DESIGN 6-1
6.1.1 Design Features 6-1
6.1.2 Codes and Standards 6-2
6.1.3 Summary of the Criticality Evaluation 6-4
6.1.4 Criticality Safety Index 6-41
6.2 PACKAGE CONTENTS 6-42
6.2.1 Fissile Material Contents 6-42
6.2.2 Convenience Cans, Teflon and Polyethylene Bottles, and 277-4 Canned Spacers 6-44
6.2.3 Packing Materials 6-45
6.2.4 Package Content Loading Restrictions 6-45
6.3 GENERAL CONSIDERATIONS 6-47
6.3.1 Model Configuration 6-48
6.3.2 Material Properties 6-65
6.3.3 Computer Codes and Cross-Section Libraries 6-78
6.3.4 Demonstration of Maximum Reactivity 6-81
6.4 SINGLE PACKAGE EVALUATION 6-83
6.4.1 Solid HEU Metal of Specified Geometric Shapes 6-83
6.4.2 HEU Broken Metal; Solid HEU Metal with Unspecified Geometric Shape and Characterized as Broken Metal; or Turnings, Fines, or Powder 6-97
6.4.3 HEU Oxide 6-101
6.4.4 UNH Crystals 6-106
6.5 EVALUATION OF PACKAGE ARRAYS UNDER NORMAL CONDITIONS OF TRANSPORT 6-108
6.5.1 Solid HEU Metal of Specified Geometric Shapes 6-108
6.5.2 HEU Broken Metal; Solid HEU Metal of Unspecified Geometric Shape and Characterized as Broken Metal; or Turnings, Fines, or Powder 6-116
6.5.3 HEU Oxide 6-121
6.5.4 UNH Crystals 6-123
6.6 EVALUATION OF PACKAGE ARRAYS UNDER HYPOTHETICAL ACCIDENT CONDITIONS 6-124
6.6.1 Solid HEU Metal of Specified Geometric Shapes 6-124
6.6.2 HEU Broken Metal; Solid HEU Metal of Unspecified Geometric Shape and Characterized as Broken Metal; or Turnings, Fines, or Powder 6-126
6.6.3 HEU Oxide 6-130
6.6.4 UNH Crystals 6-132
6.7 FISSILE MATERIAL PACKAGES FOR AIR TRANSPORT 6-133
6.7.1 Results for HEU Metal (Excluding TRIGA Fuel Elements) 6-133
6.7.2 Results for TRIGA Fuel Elements, Three Pieces per Convenience Can 6-137
6.7.3 Results for HEU Broken Metal, Turnings, Fines, or Powder 6-143
6.7.4 Results for UF_4 Compounds 6-146
6.7.5 Results for UO_2F_2 Compounds 6-148
6.7.6 Results for UC Compounds 6-150

6.7.7 Results for UN Compounds 6-152
6.7.8 Results for U_3Si_2 Compounds at 40% Enriched 6-154
6.7.9 Results for U_3Si_2 Compounds at 60% Enriched 6-156
6.7.10 Results for U_3Si Compounds at 40% Enriched 6-158
6.7.11 Results for U_3Si Compounds at 60% Enriched 6-160
6.7.12 Conclusions 6-162
6.8 BENCHMARK EXPERIMENTS 6-162
6.8.1 Applicability of Benchmark Experiments 6-162
6.8.2 Details of Benchmark Calculations 6-163
6.8.3 Bias Determination 6-163
6.9 APPENDIX 6-165
Appendix 6.9.1 Fissile Content and Packaging Models 6-167
Appendix 6.9.2 HAC Package Model 6-197
Appendix 6.9.3 Package Material Compositions 6-209
Appendix 6.9.4 Qualification of a Neutron-absorber Material for the ES-3100 6-245
Appendix 6.9.5 Miscellaneous Information and Data 6-257
Appendix 6.9.6 Abridged Summary Tables of Criticality Calculation Results 6-261
Appendix 6.9.7 Input Listings of ES-3100 Calculation Models for Select Cases 6-507
Appendix 6.9.8 Criticality Evaluation of Additional Content 6-795
Appendix 6.9.9 Criticality Evaluation for Increasing the Fissile Loading Limit for HEU Oxide 6-859
Appendix 6.9.10 Criticality Evaluation of HEU Oxide Product Content for Air Transportation 6-915
Appendix 6.9.11 Criticality Evaluation of the Removal of Carbon Limits for Oxides; Removal of Cladding Limits; and Uranium Tetrafluoride at a Criticality Safety Index of 2.0 6-1019
Appendix 6.9.12 Chapter 6 References 6-1041

7. PACKAGE OPERATIONS 7-1
7.1 PACKAGE LOADING 7-4
7.1.1 Preparation for Loading 7-4
7.1.2 Loading of Contents 7-8
7.1.3 Preparation for Transport 7-11
7.2 PACKAGE UNLOADING 7-13
7.2.1 Receipt of Package from Carrier 7-14
7.2.2 Removal of Contents 7-15
7.3 PREPARATION OF EMPTY PACKAGE FOR TRANSPORT 7-16
7.4 OTHER OPERATIONS 7-18
7.5 APPENDIX 7-19
Appendix 7.5.1 Records and Reporting Requirements 7-21
Appendix 7.5.2 Example Leak-Test Procedure, Y-12 Product Specification Procedure Y51-01-B2-R-074, *Shipping Container Leak Test* 7-23
Appendix 7.5.3 Chapter 7 References 7-33

8. ACCEPTANCE TESTS AND MAINTENANCE PROGRAM 8-1
8.1 ACCEPTANCE TESTS 8-3
8.1.1 Visual Inspections and Measurements 8-6
8.1.2 Weld Examinations 8-7
8.1.3 Structural and Pressure Tests 8-7
8.1.4 Leakage Tests 8-8

8.1.5 Component and Material Tests 8-8
8.1.6 Shielding Tests 8-9
8.1.7 Thermal Tests 8-9
8.1.8 Miscellaneous Tests 8-9
8.2 MAINTENANCE PROGRAM 8-9
8.2.1 Structural and Pressure Tests 8-10
8.2.2 Leakage Tests 8-10
8.2.3 Component and Material Tests 8-12
8.2.4 Thermal Tests 8-12
8.2.5 Miscellaneous Tests 8-13
8.3 APPENDIX 8-15
Appendix 8.3.1 Example Leak-test Procedure, Y-12 Product Specification Procedure Y51-01-B2-R-140, *He Leak Testing in B2* 8-17
Appendix 8.3.2 Chapter 8 References 8-39
9. QUALITY ASSURANCE 9-1
9.1 INTRODUCTION 9-1
9.2 SCOPE 9-2
9.3 QUALITY ASSURANCE PLAN 9-3
9.3.1 Quality Assurance Organization 9-3
9.3.2 Quality Assurance Program 9-5
9.3.3 Package Design Control 9-11
9.3.4 Procurement Document Control 9-11
9.3.5 Instructions, Procedures, and Drawings 9-12
9.3.6 Document Control 9-13
9.3.7 Control of Purchased Material, Equipment, and Services 9-13
9.3.8 Identification and Control of Materials, Parts, and Components 9-14
9.3.9 Control of Special Processes 9-15
9.3.10 Internal Inspection 9-15
9.3.11 Test Control 9-15
9.3.12 Control of Measuring and Test Equipment 9-16
9.3.13 Handling, Storage, and Shipping Control 9-16
9.3.14 Inspection, Test, and Operating Status 9-17
9.3.15 Nonconforming Materials, Parts, or Components 9-17
9.3.16 Corrective Action 9-18
9.3.17 Quality Assurance Records 9-18
9.3.18 Audits 9-19
9.3.19 Software Quality Assurance 9-20
9.4 APPENDIX 9-21
Appendix 9.4.1 Chapter 9 References 9-23

REVISION LOG

Date	Revision No.	Description	Affected Pages
9/25/09	A	Draft for DOE EM review. All revisions to the previous ES-3100 SAR approved by the NRC (Y/LF-717/R3) are shown in red text. Since the revisions to Appendix 3.5.4 and Sects. 7 and 9 were extensive, these sections are shown in black text. Appendices 5.5.2 and 6.9.8 are new, but they are shown in black text.	All
8/12/10	0	Incorporated responses to comments received from DOE EM, Packaging Certification Program SARP Review Team.	All
11/10/10	0 Page Change 1	Incorporated minor revisions to make SARP consistent with Rev. 2 of the CoC.	Cover, title page, iii, v, xxiii, 1-2, 1-12, 1-14, 1-16, 1-17, 1-22, 2-1, 3-37, 6-598, 7-13
2/10/11	0 Page Change 2	• Clarified description of U-Zr oxide in "HEU oxide" category (designated as UO_2-ZrO_2 throughout the SARP) • Added a physical form of oxide under "HEU Oxide" in Sect. 1.2.2 for pellets • In Table 1.3, – Modified "CSI" and "277-4 can spacer" entries for U-Zr in "Research reactor fuel elements and components" category – Added a new content group called "Oxides of U-Zr" under the "Research reactor fuel elements and components" category • Changed the maximum enrichment of TRIGA fuel to ≤70% • Revised CSI entries for air transport in Table 1.3b • Clarified appropriate DOE marking on the drum in Sect. 7.1.2.2 • Editorial corrections as necessary	Cover, title page, iii, v, xxiii, 1-10 through 1-12, 1-15 through 1-17, 2-1, 2-2, 4-3, 6-4, 6-30, 6-33, 6-35, 6-598, 7-11

Date	Revision No.	Description	Affected Pages
6/21/12	0 Page Change 3	• Change the U-233 concentration limit in oxide contents to 0.006 g/gU from 200 ppm • Add bulk HEU oxide as an authorized content for air transport • Add uranium silicide as an authorized content for ground transport • Add Viton GLT-S as an optional O-ring material in addition to EPDM and extend the basis for periodic maintenance from 1 to 2 years for packagings with Viton GLT-S O-rings and temperature monitoring • Revise the spacer can drawing (Drawing M2E801580A043) to make the "vibration absorbing silicone can pad" optional • Increase the amount of U-235 in U-Al reactor fuel • Make allowance for convenience cans with diameters >4.25 in. along with a void volume limit for gas expansion and offgassing materials in the CV • Remove the requirement to place empty convenience cans on top of the loaded cans • Revise the wording regarding convenience can use to allow for contents that cannot fit into a convenience can to be bagged only (no convenience can) • Add the option of applying an RFID system to the ES-3100 • Editorial corrections as necessary	All
1/10/13	0 Page Change 4	Incorporate responses to Q1 comments. 1. GENERAL INFORMATION

1.1 INTRODUCTION

This safety analysis report for packaging (SARP) presents the results of the safety analysis prepared in support of the Consolidated Nuclear Security, LLC (CNS) request for licensing of the Model ES-3100 package with bulk highly enriched uranium (HEU) contents and issuance of a Type B(U) Fissile Material Certificate of Compliance. This SARP, published in the format specified in the U.S. Nuclear Regulatory Commission (NRC) Regulatory Guide 7.9 and using information provided in UCID-21218 and NRC Regulatory Guide 7.10, demonstrates that the Y-12 National Security Complex (Y-12) ES-3100 package with bulk HEU contents meets the established NRC regulations for packaging, preparation for shipment, and transportation of radioactive materials given in Title 10, Part 71, of the Code of Federal Regulations (CFR) [10 CFR 71] as well as U.S. Department of Transportation (DOT) regulations for packaging and shipment of hazardous materials given in Title 49 CFR.

To protect the health and safety of the public, shipments of radioactive materials are made in packaging that is designed, fabricated, assembled, tested, procured, used, maintained, and repaired in accordance with the provisions cited above. Safety requirements addressed by the regulations that must be met when transporting radioactive materials are containment of radioactive materials, radiation shielding, and assurance of nuclear subcriticality.

A general description and a summary of the evaluation of the packaging are presented in this chapter. Subsequent chapters address structural (Chap. 2) and thermal (Chap. 3) responses to Normal Conditions of Transport (NCT) and Hypothetical Accident Conditions (HAC) and the packaging's ability to contain the radioactive materials (Chap. 4) when subjected to the requirements of 10 CFR 71.71 and 71.73, respectively. A shielding evaluation was prepared to ensure adequate nuclear radiation shielding (Chap. 5). Criticality evaluations that are unique to the contents were prepared to ensure nuclear subcriticality (Chap. 6). Chapters 7 and 8 discuss the operating procedures, the new packaging acceptance tests, and the maintenance program for the planned use and maintenance of the packaging. Chapter 9 describes the packaging quality assurance requirements as demonstrated by the *Packaging and Transportation Quality Assurance Program Plan* (QAP-Y-91-273860-1).

The ES-3100 package was subjected to verification (analysis, similarity comparisons, tests, or a combination of these) for NCT and HAC. Full-scale packages were used for design verification testing (Chaps. 2 and 3). The ES-3100 package with bulk HEU content was verified solely on the ability of the package to meet the requirements of 10 CFR 71. Transport conveyance influence on the package is not required to meet 10 CFR 71 requirements.

The packaging verification activities (Chaps. 2, 3, and 4), using content test masses of between 3.6 and 50.3 kg (8 and 111 lb), show that the packaging meets the containment requirements of 10 CFR 71. The shielding evaluations (Chap. 5) show that the packaging meets the NCT requirements of 10 CFR 71.47, *External Radiation Standards for all Packages*, and the HAC requirements of 10 CFR 71.51, *Additional Requirements for Type B Packages*. Based on the results of the thermal and shielding evaluations, the ES-3100 package with bulk HEU content may be shipped as a nonexclusive use package. The criticality evaluation (Chap. 6) shows that the packaging meets the requirements of 10 CFR 71.55, *General Requirements for Fissile Material Packages*, and 10 CFR 71.59, *Standards for Arrays of Fissile Material Packages*.

1.2 PACKAGE DESCRIPTION

A schematic of the ES-3100 shipping package is shown in Fig. 1.1, and an exploded view of the packaging components is presented in Fig. 1.2. The packaging design drawings (Appendix 1.3.7) provide material lists, dimensions, safety components, welding requirements, and gasket requirements. The maximum nominal gross shipping weight of the ES-3100 package with bulk HEU content is 187.81 kg (414.05 lb). The maximum authorized gross shipping weight of the ES-3100 package is 190.5 kg (420 lb). The certification drawing of the ES-3100 can be found in Appendix 1.3.1. The ES-3100 as specified in this SARP is classified as a Type B(U) fissile material Category I package (see Appendix 1.3.6).

1.2.1 Packaging

The main functions of the packaging are containment, shielding, and nuclear criticality safety. The bulk HEU contents create a maximum decay heat of ~5 W (Sects. 1.2.2.7 and 3.1.2); therefore, the packaging does not require any special design features such as coolant valves or continuous venting to meet the thermal requirements of 10 CFR 71.

1.2.1.1 Drum assembly

The drum assembly consists of a double open-head reinforced stainless-steel 30-gal drum, arched cover that forms the bottom, arched lid, inner liner, and top plug with cast refractory insulation (Kaolite or Packcrete) [Drawing M2E801580A001, Appendix 1.3.7]. The inside diameter of the drum is 46.36 cm (18.25 in.) with an overall height of 110.49 cm (43.5 in.) including the cover and lid (Drawings M2E801580A004 and M2E801580A001, Appendix 1.3.7). The outside diameter of the drum (including the hoops) is 49.2 cm (19.37 in.). The drum and lid are made from 16-gauge [~0.152-cm (0.0598-in.)-thick] Type 304 or 304L stainless steel. A 12-gauge [~0.267-cm (0.105-in.)-thick] stainless-steel arched cover (Drawing M2E801580A005, Appendix 1.3.7) is welded to the double open-head drum to create the bottom of the drum assembly. An inner liner (Drawing M2E801580A003, Appendix 1.3.7) is attached to the drum by an internal flange (angle) that is welded to both the drum and liner. The cavity created by the inner liner for placement of a containment vessel (CV) is a three-tier volume. The uppermost tier accommodates the top plug and has an inside diameter of 37.52 cm (14.77 in.) and is 13.26-cm (5.22-in.) deep (Drawing M2E801580A003, Appendix 1.3.7). The second tier, which accommodates the CV flange, has a 21.84-cm (8.60-in.) inside diameter that is 5.59-cm (2.20-in.) deep (Drawing M2E801580A003, Appendix 1.3.7). The third tier, which accommodates the CV body, has a 15.85-cm (6.24-in.) inside diameter that is 78.31-cm (30.83-in.) deep (Drawing M2E801580A003, Appendix 1.3.7). An additional cavity is created between the second and third tier liners. This cavity runs the full length of the third tier height [78.31 cm (30.83 in.)] and is ~3.00-cm (1.18-in.) thick (Drawing M2E801580A003, Appendix 1.3.7). This cavity is filled with a castable refractory (277-4 special dry mix) for neutron attenuation purposes. Aluminum foil tape is applied over the 277-4 cavity fill and vent holes (four places) located on the drum liner lower shelf (Drawing M2E801580A002, Appendix 1.3.7). The additional cavities between the liner and the drum are filled with an inorganic castable refractory material (Kaolite 1600 or Packcrete), which acts as both an impact-absorbing and thermal-insulating material.

In accordance with NUREG/CR-3854, Part 4.2 for a Category I shipping package, an acceptable specification for drums used in any of the component safety groups is DOT Specification 17C or better. It should be noted that the Specification 17C package is no longer included in the DOT regulations (49 CFR 178). The drum used in the ES-3100 is fabricated in accordance with the dimensional requirements of Military Standard MS27683 and modified as shown on Drawing M2E801580A004 (Appendix 1.3.7). The fabrication requirements for the ES-3100 drum assembly are shown in SPC JS YMN3-801580-A002 (Appendix 1.3.2). Material, fabrication, and quality control criteria are

generally equivalent to those imposed for a DOT Specification 17C drum. Furthermore, the drum of the ES-3100 is part of a performance-based package that has been tested and analyzed to demonstrate its ability to maintain confinement and containment of its contents under both NCT and HAC. By certifying that the outer shell of the drum assembly used in production meets the same specifications as those tested and analyzed, as described in subsequent chapters of this SARP, the outer drum shell used for the ES 3100 is acceptable for a Category 1 shipping package.

As previously discussed, the drum has been modified by the attachment of an inner liner connected to the drum by an internal flange welded to both the drum and the liner. Weld studs are attached to the upper face of the internal flange. The body seams are welded. The following items are conducted in accordance with Sect. IX of the *American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code* (ASME Code, Sect. IX): welding procedures qualification and welders certification to these qualified procedures.

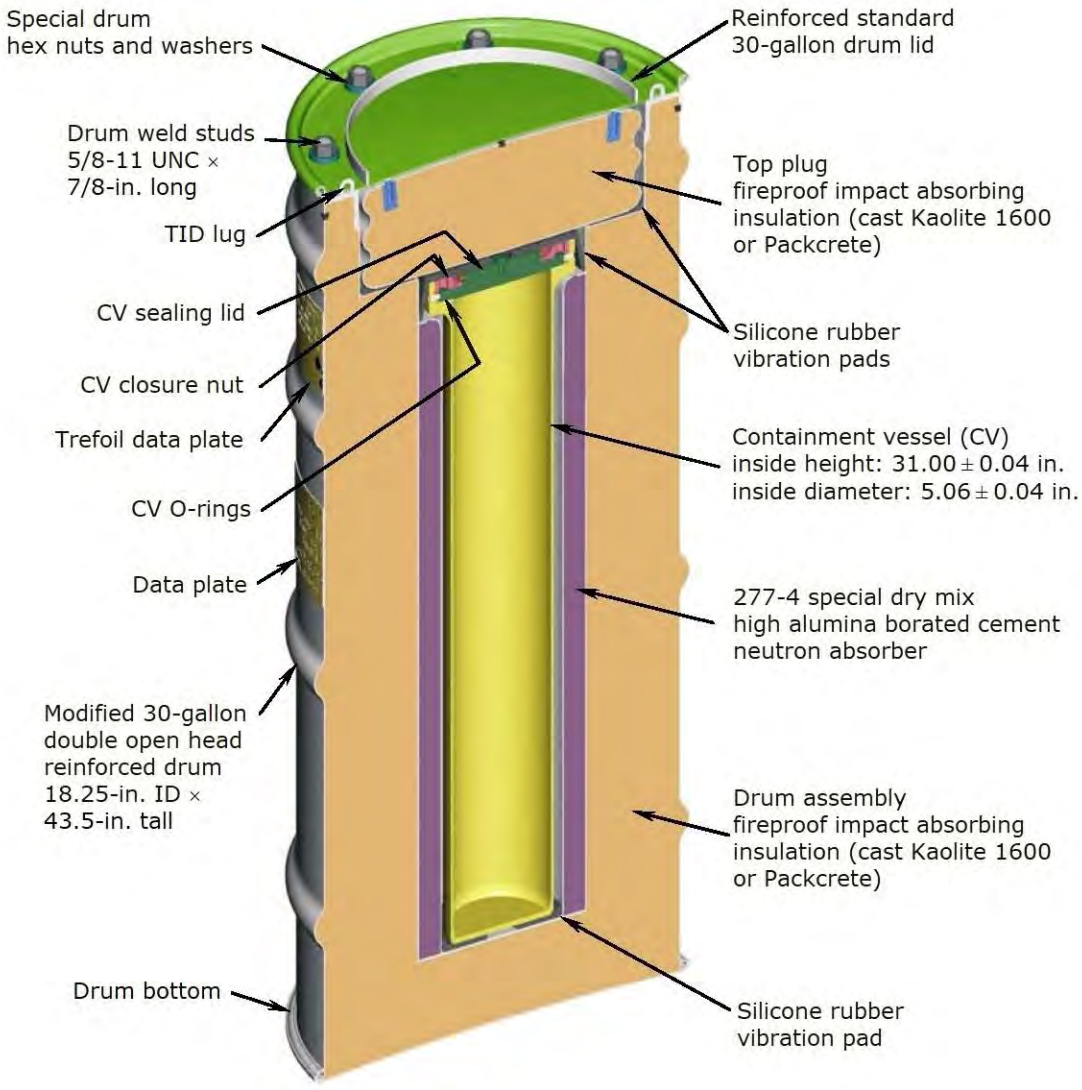

Fig. 1.1. Schematic of the ES-3100 shipping package.

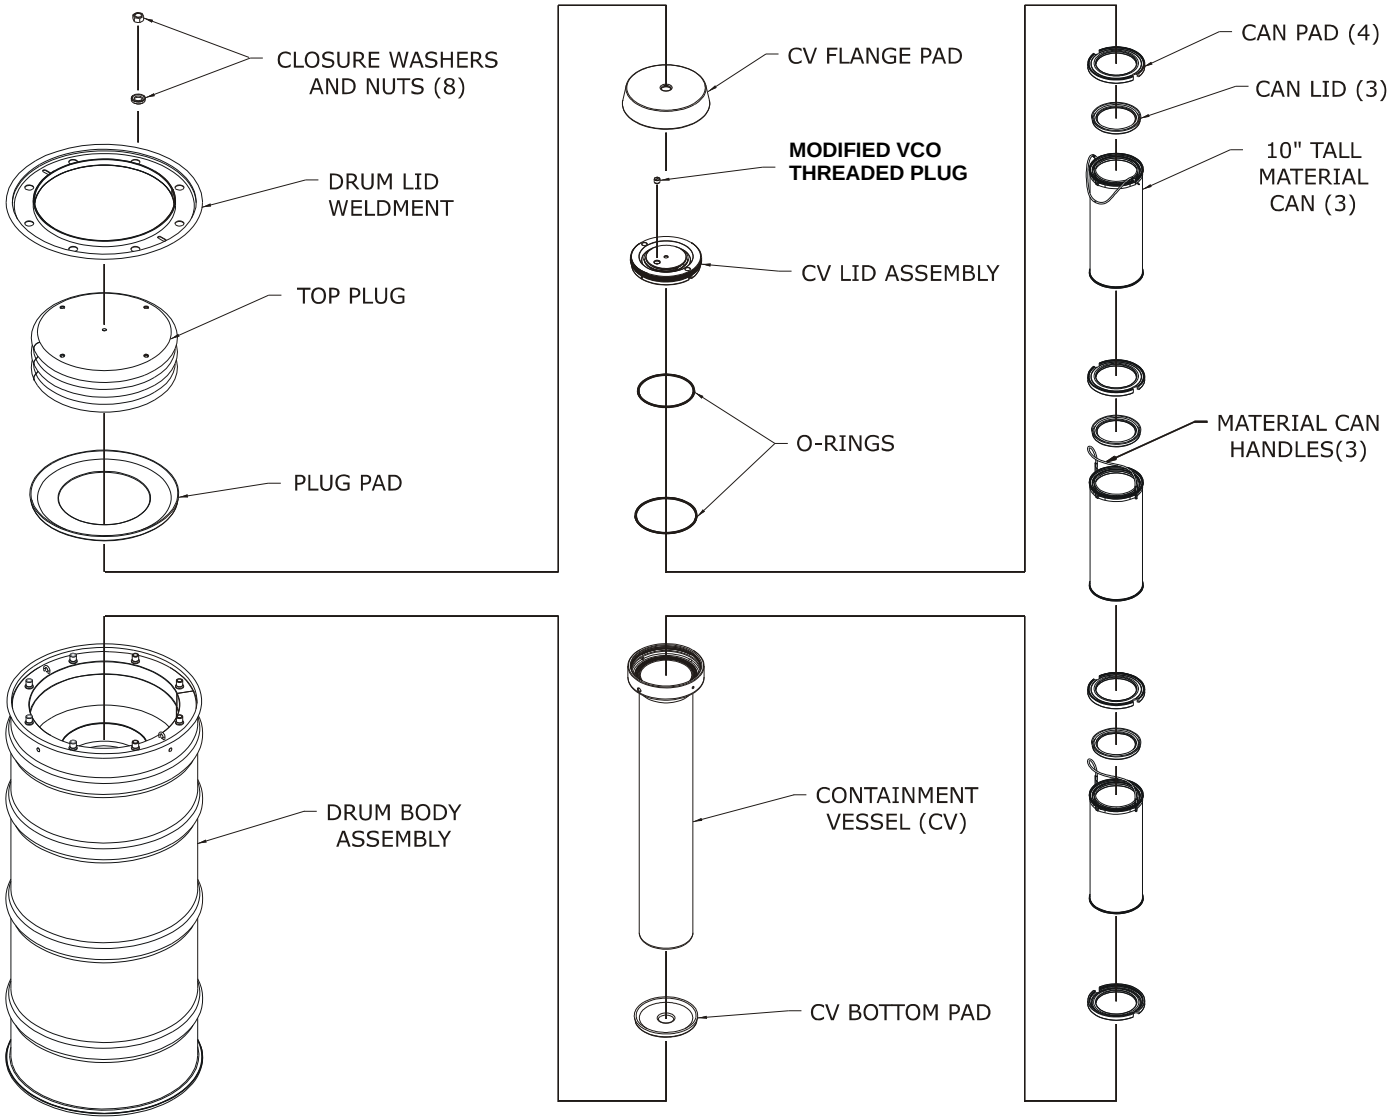

Fig. 1.2. Exploded view of the ES-3100 package with bulk HEU contents.

The drum has four circumferential hoops formed into the body. The drum has four 0.795-cm (0.313-in.)-diam holes equally spaced around the circumference ~3.81 cm (1.50 in.) from the top rim to relieve pressure in the drum in the event of a thermal accident (Drawing M2E801580A002, Appendix 1.3.7). Plastic plugs (Nylon 6/6, Micro Plastic, Inc., Item Number 62MP0312) are placed into these holes from the outside to prevent leakage of water into the drum during NCT and storage. The drum is fabricated with a data plate, trefoil data plate, paint, and two lid TID lugs for use with tamper-indicating devices (TIDs). The two electrochemically etched data plates are affixed to the exterior of the drum body in the locations, and with the methods, indicated on Drawing M2E801580A031 (Appendix 1.3.7). The trefoil data plate (M2E8015803A010-1) provides the owner's return address, container model, container serial number, and the trefoil symbol. The other data plate (M2E801580A010-2) provides the required DOT markings—certificate number, maximum gross weight, and "Type B" designation.

The removable lid is attached to the drum body by a flange with eight silicon bronze, 5/8-11 UNC-2B hex-head nuts [C65100, American Society for Testing and Materials (ASTM) F 467] with stainless-steel washers. These nuts are tightened onto the weld studs (Type 304 or 304L stainless steel, 5/8-11 UNC-2A, ASTM A 493 or F 593) to 40.67 ± 6.78 N·m (30 ± 5 ft-lb) of torque with no sequence specified. A radio-frequency identification (RFID) system may be attached to the ES-3100 package if desired. If an RFID is attached to the package using the drum stud and nut assembly, the normal thread engagement of the external nut shall not be reduced when compared to adjacent stud and nut attachments.

The top plug is 36.5 cm (14.37 in.) in diameter and 13.41 cm (5.28 in.) in height at the center. The skin is made from 16 gauge [~0.152-cm (0.0598-in.)-thick] Type 304 or 304L stainless steel and is filled with Kaolite 1600 or Packcrete.

The drum assembly also contains three silicone rubber pads. The first pad (CV bottom pad) is placed on the bottom of the innermost liner to support the CV bottom during transport. The second pad (CV flange pad) is placed on top of the CV lid during transport. The third pad (plug pad) is placed on the top shelf of the mid-liner to cushion the top plug during transport. The locations of these three pads are shown on Drawing M2E801580A001 (Appendix 1.3.7), and the dimensions of the pads are shown on Drawing M2E801580A009 (Appendix 1.3.7).

The ES-3100 is handled using industry-standard drum handling equipment. When using a forklift, it can be placed on the tines of the forklift from below, or it is designed for a forklift pincher assembly that can be used to grasp the exterior of the drum assembly. Based on analytical results for a similar package (the Model ES-2100), forklift gripping forces of up to 5400 lb can be used with no detrimental effects on the package (DAC-EA-801376-A003).

No tie-down devices are integral to the package, nor can any features be used for these purposes. The ES-3100 package is designed to be shipped using blocking, bracing, and tie-down equipment that meets industry-standard practices to prevent shifting in the conveyance during NCT.

1.2.1.2 Insulation

The void area formed by the drum and the attached inner liner is filled with an inorganic castable refractory material [Kaolite 1600 (made by Thermal Ceramics, Inc.) or Packcrete], which acts as both a thermal insulating and an impact limiting material. The top plug assembly, which is placed between the CV and the drum lid, is also filled with Kaolite 1600 or Packcrete. These materials (Kaolite and Packcrete) are a mixture of cement and vermiculite and have a nominal cured density of ~358.8 kg/m^3 (22.4 lb/ft^3). Additional information regarding the characteristics and properties of Kaolite material is presented in several supporting documents (Kaolite product data sheet, Kaolite material safety data sheet, Y/DW-1661, ORNL-TM-2003/49, Y/DW-1890, Y/DW-1972, Y/LF-565, Moody 2004) and

material properties for Packcrete are specified in RP 802282-0002. Casting takes place while the drum is being vibrated in an inverted orientation to ensure that the castable material penetrates into all areas in the void space formed by the drum and the inner liner and that no considerable voids are formed during this process. The Kaolite or Packcrete material is then baked in a furnace at elevated temperatures [~260°C (500°F)]. The processing of Kaolite 1600 for the ES-3100 is controlled by Equipment Specification JS-YMN3-801580-A003, *Manufacturing Process Specification for Casting Kaolite 1600 into the ES-3100 Shipping Package*, (Appendix 1.3.4), and the processing of Packcrete is controlled by SPC M801794-0003, *Packcrete Preliminary Lot Qualification* (Appendix 1.3.11) and SPC M801580-0003, *ES-3100 Packcrete Final Lot Qualification and Production Processing* (Appendix 1.3.12).

One of the ES-3100 design goals was to build a shipping package entirely of materials that do not char, burn, or thermally decompose when exposed to the temperatures and conditions associated with HAC [800°C (1475°F)]. The Kaolite or Packcrete material is nonflammable and will not undergo chemical decomposition at temperatures below 1260°C (2300°F). When Kaolite or Packcrete is heated to >100°C (212°F), water vapor from free water contained within the casting will form. Pressurization of the drum and top plug is prevented by pressure-relief holes (vent holes) located near the top of the drum and on the top center of the top plug (Sect. 1.2.1.1 and Drawings M2E801580A002 and M2E801580A008, Appendix 1.3.7). The cured Kaolite 1600 or Packcrete material does not decompose, and thus there are no exothermic chemical reactions that could produce superheated offgasses.

Extensive testing of Kaolite 1600 was performed by the Y-12 Development Division to determine the performance of the material for this type of application (Y/DW-1661). Testing showed that Kaolite 1600 has a tremendous ability to absorb shock over a wide range of material densities, curing temperatures and times, and material temperatures. The 10 CFR 71.73 HAC testing documented in Sect. 2.7 demonstrates that Kaolite 1600 is a robust impact limiter and good thermal insulating material for Type B shipping containers. Post HAC drop testing radiographs of a similar package, the ES-2100, showed some minor cracking of the Kaolite structure in some cases. However, subsequent thermal testing of these ES-2100 packages demonstrated that these cracks were inconsequential to the ability of the package to meet regulatory requirements.

Insulation thicknesses within the liner/drum volume adjacent to the side walls of the ES-3100 CV are at least 4.27 cm (1.68 in.), with typical thicknesses of ~12.10 cm (4.77 in.). Below the CV, the minimum thickness of insulation is 10.05 cm (3.96 in.), and the top plug, which is above the CV, includes a 12.55-cm (4.94-in.) thickness of insulation.

1.2.1.3 Shielding

The ES-3100 packaging does not require dedicated shielding materials of specific design to control external radiation levels for the bulk HEU contents. However, the intervening packaging materials of construction (stainless steel of the drum and CV, the Kaolite or Packcrete material, and the 277-4 material) provide some attenuation of the relatively low levels of penetrating radiation emitted by the contents. The amount of shielding modeled for the NCT analysis is represented by the thickness and density of the materials reported in Sects. 1.2.1.1, 1.2.1.2, and 1.2.1.5 and the packaging dimensions (Appendix 1.3.7). HAC physical testing showed that the CV and insulation remain confined within the drum assembly. However, the HAC shielding evaluation conservatively assumes that only the CV remains for shielding purposes (i.e., no shielding credit is taken for the drum and insulation in the HAC analysis).

1.2.1.4 Nuclear criticality safety

The packaging materials of construction in the ES-3100 provide neutron absorption (stainless steel and 277-4) and reflection (stainless steel and insulation). The 277-4 (or Cat 277-4 as it is sometimes referred) material is a noncombustible cast neutron-absorbing material. This material is cast into the innermost liner of the package adjacent to the CV as shown in Fig. 1.1. The material is a high alumina borated concrete composed of aluminum, magnesium, calcium, boron, carbon, silicon, sulfur, sodium, iron, and water. The 277-4 material was manufactured specifically for the ES-3100 package by adding boron carbide to a standard material (Cat No. 277-0) and increasing the boron content from 1.56 wt % to 4.23 wt %. Additional information on the neutron-absorbing characteristics of this material is presented in Appendix 6.9.3. Properties of the 277-4 material are presented in Table 2.17 and several supporting documents (ORNL/TM-2004/290, Y/DW-1987, Y/DZ-2585, COR-NDA-04-93, Y/DV-1914). The cast material has a nominal density of 1681.9 kg/m^3 (105 lb/ft^3). The procedure for mixing this material and casting into the ES-3100 shipping package is documented in SPC JS-YMN3-801580-A005, *Casting Catalog No. 277-4 Neutron Absorber for the ES-3100 Shipping Package* (Appendix 1.3.5). The procedure for mixing and casting 277-4 material into the can spacers is documented in SPC M801580-0004, *ES-3100 Heavy Can Spacer Assemblies* (Appendix 1.3.10).

Although shown by tests up to HAC as not being credible, the criticality analysis considers water leakage into the CV in accordance with 10 CFR 71.55(b). Depending on the content being shipped and the shipping configuration being used, criticality safety index (CSI) values for the ES-3100 package may range from 0 to 3.2 (Sect. 1.2.2).

1.2.1.5 Containment system

A single CV is used in the ES-3100 shipping package for the transport of bulk HEU contents. The ES-3100 containment boundary (consisting of the CV body, lid assembly, and inner O-ring) is shown in Fig. 1.3.

During fabrication, all ES-3100 containment vessels will be inspected and tested to the requirements specified on the design drawings (Appendix 1.3.7) and equipment specification (Appendix 1.3.3). Certification documents received from the vendor with each component acknowledge the use of these drawings and the specification. These certifications are on file with the Y-12 Quality Organization.

The containment boundary of the ES-3100 package is a pressure vessel that is designed, fabricated, examined, and tested in accordance with the ASME Code, Sect. III, Div. 1, Subsection NB. The ES-3100 CV body is constructed of Type 304L stainless steel and may be fabricated by one of two methods. The first method uses a standard 5-in., schedule 40 stainless-steel pipe (ASME SA-312, Type TP304L), a machined flat-head bottom forging (ASME SA-182, Type F304L), and a machined top flange forging (ASME SA-182, Type F304L). Each of these pieces is joined with circumferential welds as shown on Drawing M2E801580A012 (Appendix 1.3.7). The top flange is machined to provide two concentric half-dove-tailed O-ring grooves in the flat face, to provide locations for two 18-8 stainless-steel dowel pins, and to provide the threaded portion for closure using the lid assembly. The second fabrication method for the ES-3100 CV uses flow forming to create the complete body (flat bottom, cylindrical body, and flange) from a single forged billet or bar with final material properties in accordance with ASME SA-182, Type F304L. The top flange area using this fabrication technique is machined identically to that of the welded forging method.

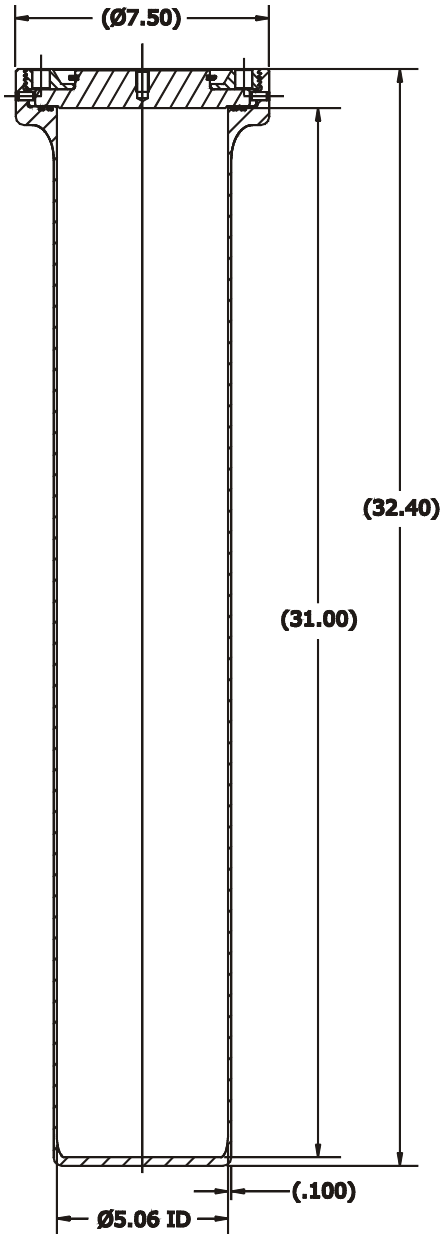

Fig. 1.3. Containment boundary of the ES-3100 shipping package.

The lid assembly, which completes the containment boundary structure, consists of a sealing lid, closure nut, and external retaining ring (Drawing M2E801580A014, Appendix 1.3.7). The CV sealing lid (Drawing M2E801580A015, Appendix 1.3.7) is machined from Type 304 stainless-steel bar with final material properties in accordance with ASME SA-479. The CV closure nut is machined from a Nitronic 60 stainless-steel bar with material properties in accordance with ASME SA-479. These two components are held together using a WSM-400-S02 external retaining ring made from Type 302 stainless steel. The sealing lid is further machined to accept a ⅜-16 swivel hoist ring bolt, to provide a leak-test port between the elastomeric O-rings, and notched along the perimeter to engage two dowel pins. The swivel hoist ring is only intended for use when loading and unloading the CV. The swivel hoist ring will be removed for shipment. The lid assembly and CV body (with O-rings in place) are joined together by torquing the closure nut to 162.70 ± 6.78 N·m (120 ± 5 ft-lb). The sealing lid portion

of the assembly is restrained from rotating during this torquing operation by the two dowel pins installed in the body flange.

The use of a design that includes two O-ring seals permits assembly verification leak testing of the CV by measuring the leak rate from the volume between the inner and outer O-rings. A leak-test port is located between the O-rings in the CV to facilitate a pressure rise or drop leakage test following assembly or 10 CFR 71 compliance testing. This port is sealed during transport using a modified VCO threaded plug. Only the inner O-ring is considered a part of the containment boundary. The O-rings on this CV are ethylene propylene diene monomer (EPDM) fabricated to ASTM D 2000, M3BA712A14B13F17. The equipment specification for the EPDM O-rings is presented in Appendix 1.3.9.

The inner diameter of the CV is 12.852 cm (5.06 in.) and the usable height inside the CV is 78.74 cm (31.0 in.). The wall thickness of the body excluding the flange is 0.254 cm (0.10 in.). The maximum nominal diameter of the CV body is 19.05 cm (7.50 in.). The nominal thickness of the CV flat bottom is 0.635 cm (0.25 in.). The overall height of the CV without the swivel hoist ring is 82.296 cm (32.40 in.). The CV drawing number, drawing revision, and serial number are electroetched onto the side of the CV body, as well as onto the top of the sealing lid and the closure nut (Drawing M2E801580A011, Appendix 1.3.7). No penetrations, connections, or fittings into this sealed container exist.

1.2.2 Contents

The ES-3100 shipping package will be used to ship bulk HEU in the form of oxide [UO_2, UO_3, U_3O_8, U_3O_8-Al, UO_2-Mg, and product oxides (UO_2, UO_3, U_3O_8) mixed with ThO_2, ZrO_2, and Th metal], uranium metal and alloy in the form of solid geometric shapes or broken pieces, uranium compounds, uranyl nitrate crystals (UNX), fuel elements from TRIGA reactors, and research reactor fuel elements or fuel components. Actual loading limits are determined in subsequent chapters of the SARP. The maximum weight of all contents (including convenience cans or bottles, can spacers, bagging and other packing materials) shall not exceed 40.82 kg (90 lb). The maximum concentration of uranium isotopes permitted in the ES-3100 content are listed in Table 1.1. In addition to the uranium isotopes shown in Table 1.1, transuranic isotopes (with the exception of ^{237}Np) may be present in the HEU metal and alloy contents transported by ground at a maximum concentration of 800.0 µg/gU and at a maximum concentration of 40.0 µg/gU in all other contents. Contents to be transported by air are limited to a maximum transuranic concentration of 40.0 µg/gU, and the transportation of plutonium by air (due to the transuranic concentration allowance) shall be in accordance with the requirements in 10 CFR 71.88, which includes restrictions for no more than an A_2 quantity of plutonium in any isotope or form. The concentration of ^{237}Np is limited to 0.0250 g/gU. Unless otherwise specified, the contents described in this section pertain to ground transport only. A discussion of contents of air-transport is included in Sect. 1.2.2.1.

Table 1.1. Uranium concentration limits

Uranium isotope	Limit
^{232}U	0.040 µg/gU
^{233}U	0.006 g/gU
^{234}U	0.02 g/gU
^{235}U	1.00 g/gU
^{236}U	0.40 g/gU
^{238}U	1.00 g/gU

HEU Metal and Alloy

HEU metal and alloy (alloys of uranium with aluminum, molybdenum, thorium, zirconium, stainless steel, titanium, tungsten, niobium, silicon, or vanadium) may be in the form of solid geometric shapes. Solid shapes may include the following:

1. cylinders having a diameter no larger than 4.25 in. (maximum of one cylinder per convenience can);
2. square bars having a cross section no larger than 2.29 in. × 2.29 in. (maximum of one bar per convenience can); and
3. slugs having dimensions of 1.5-in. diam × 2-in. tall (maximum of 10 per convenience can).

HEU bulk metal and alloy contents not covered by the geometric shapes category specified above will be in the broken metal category, and will be so limited.

Alloys of uranium may include aluminum, molybdenum, thorium, zirconium, stainless steel, titanium, tungsten, niobium, silicon, or vanadium. Uranium-aluminum alloys are typically 70 to 95% aluminum. Uranium-molybdenum alloys are typically 1 to 12% molybdenum. Uranium/molybdenum alloys may be plated with, clad with, or contain traces of aluminum, gold, stainless steel, nickel and/or chromium. Other uranium alloys may contain up to 50% of the non-uranium constituents.

HEU bulk metal and alloy contents in the broken metal category may be of unspecified geometric form. HEU bulk metal and alloy in this category may also be of a specific shape where one or more of the characteristic dimensions vary from piece to piece (i.e., the height, width, length, radius).

For pyrophoric considerations, HEU metal and alloy must meet the following restrictions (Appendix 1.3.8):

1. Uranium metal and alloy (broken) pieces must have a surface-area-to-mass ratio of not greater than 1 cm^2/g or must not pass through a 3/8-in. (9.5-mm) mesh sieve (or equivalent size-grading method).
2. Particles and small shapes which do not pass the size restriction tests in #1, and powders, foils, turnings, and wires, are not permitted unless they are in a sealed, inerted container. Material meeting this criteria will be in the HEU metal or alloy turnings, fines, or powder category, and will be so limited.

Note: A "sealed, inerted container" is a container with an inert atmosphere that is leaktight as defined in ANSI N14.5-1997.

HEU in the form of oxide with residual metallic particles is referred to as clinkers and screenings. This material results from metal casting operations where uranium metal is melted in a graphite crucible. After the metal is poured into casting molds, the crucibles are cleaned of residual material. The residual are bits of scrap metal and oxide debris. This residual material is passed through a sieve, where finer oxide passes through the sieve and is considered to be skull oxide. The material that does not pass through the sieve is considered to be clinkers and screenings. This material is predominantly oxide but often will have small particles of metal. Clinkers and screenings from metal casting operations will be loaded in accordance with the HEU metal or alloy turnings, fines, and powders mass loading limits in a sealed container under an inert cover gas. Clinkers and screenings shipments must be completed within 12 months after sealing the CV.

Metal and alloy may be shipped in tin-plated carbon-steel, stainless-steel, aluminum, or nickel-alloy convenience cans; Teflon convenience bottles; or Teflon bottles inside metal convenience cans. Solid form HEU contents (i.e., spheres, cylinders, bars, slugs) that will not fit in a convenience can may be bagged with no convenience can required around the content. The HEU metal and alloy

content may be wrapped or bagged, and the convenience cans may also be wrapped to further reduce the possibility of radioactive contamination of the packaging.

HEU Oxide

The HEU oxide content in the ES-3100 package includes UO_2, UO_3, U_3O_8, U_3O_8-Al, UO_2-Mg, and product oxides (UO_2, UO_3, U_3O_8) mixed with ThO_2, ZrO_2 and Th metal. Maximum overall uranium isotopic concentrations are presented in Table 1.2. The physical form of all contents is dense, loose powder (which may contain clumps) or pellets. Moisture content in oxide is limited to 3 wt % water (Sect. 1.2.2.8, *Loading restrictions*, Item 8 also applies). Theoretical densities of UO_2, U_3O_8, and UO_3 are 10.96, 8.30, and 7.29 g/cm^3, respectively. Allowable oxide bulk densities are 0.5 to 6.54 g/cm^3. Oxide may be shipped in tin-plated carbon-steel, stainless-steel, or nickel-alloy convenience cans; polyethylene or Teflon convenience bottles; or glass (UO_2-Mg oxide only), polyethylene, or Teflon bottles inside metal convenience cans.

Table 1.2. Bounding uranium isotopic concentrations in oxide

Isotope	Bounding limit
^{232}U	40 ppb
^{233}U	0.6 wt %
^{234}U	2.0 wt %
^{235}U	100.0 wt %
^{236}U	40.0 wt %

Uranium oxide shipments must be completed within 12 months after sealing the CV in order to prevent the buildup of hydrogen gas beyond 5 mol %. The time period begins when the CV is sealed. Hydrogen generation calculations are provided in Appendix 3.5.4.

Research Reactor Fuel Elements and Components

Research reactor fuel elements or fuel components composed of clad U-Zr, U-Al, U_3O_8-Al, UO_2, oxides of U-Zr, UO_2-Mg, or U_3Si_2-Al will be shipped in the ES-3100 package. The fuel elements consist of multiple fuel components in the form of plates, rods, and tubes clad in aluminum, stainless steel, or zircalloy and held together as a single unit by other inert structural components. The fuel components are individual plates, rods, or tubes removed from fuel elements. The uranium in these fuel elements and components is enriched to 10 to 93.5 wt % ^{235}U.

The U-Al fuel in the research reactor fuel elements and components is an alloy of uranium and aluminum (U-Al) or in the form of $UA1_x$-Al (alloy in an aluminum matrix). The U-A1 fuel contains ~8 to 30 wt % uranium. The U_3O_8-Al fuel is in the form of a U_3O_8 compound contained in an aluminum metal matrix. The U_3O_8-Al contains ~8 to 40 wt % U_3O_8. The UO_2 fuel is a ceramic compound. The UO_2-Mg fuel is a ceramic UO_2 compound contained in a magnesium metal matrix. The UO_2-Mg fuel contains ~88 wt % UO_2.

The research reactor fuel elements and components will be bundled together and placed inside a modified convenience can [a 17.5-in.–tall can (two 8.75-in.–tall cans brazed together) or a 30-in.–tall can (three 10-in.–tall cans brazed together)] or protected on each end with an open-ended convenience can constructed of stainless steel, tin-plated carbon steel, or nickel alloy (see Fig. 1.4).

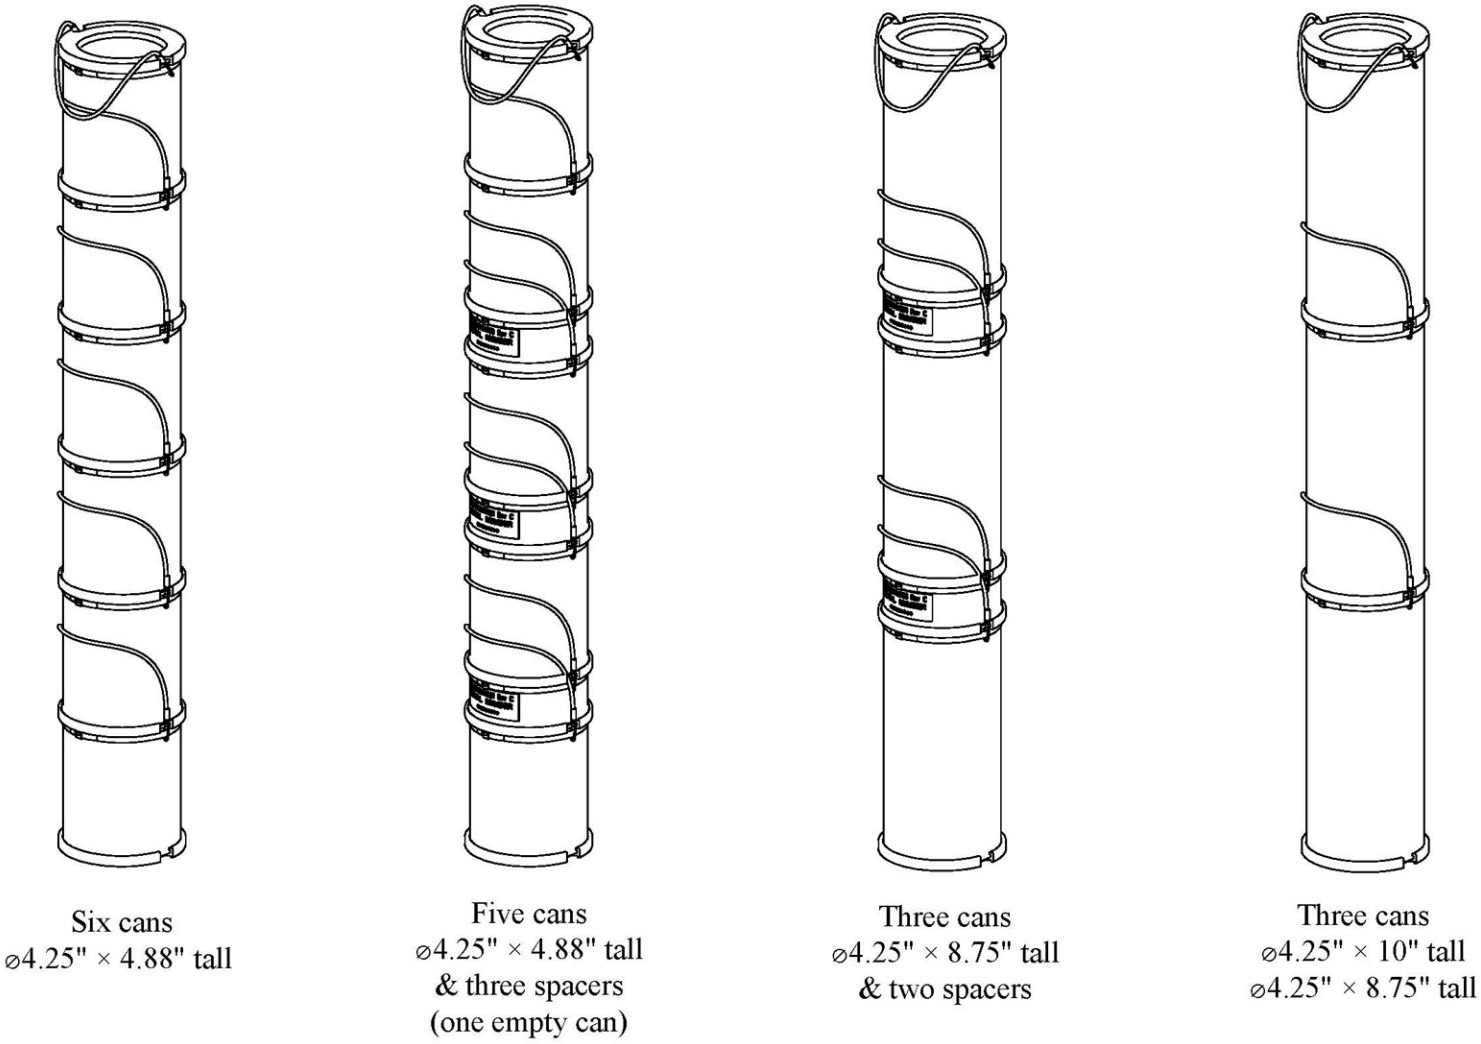

Fig. 1.4. Typical shipping configurations inside the ES-3100 containment vessel.

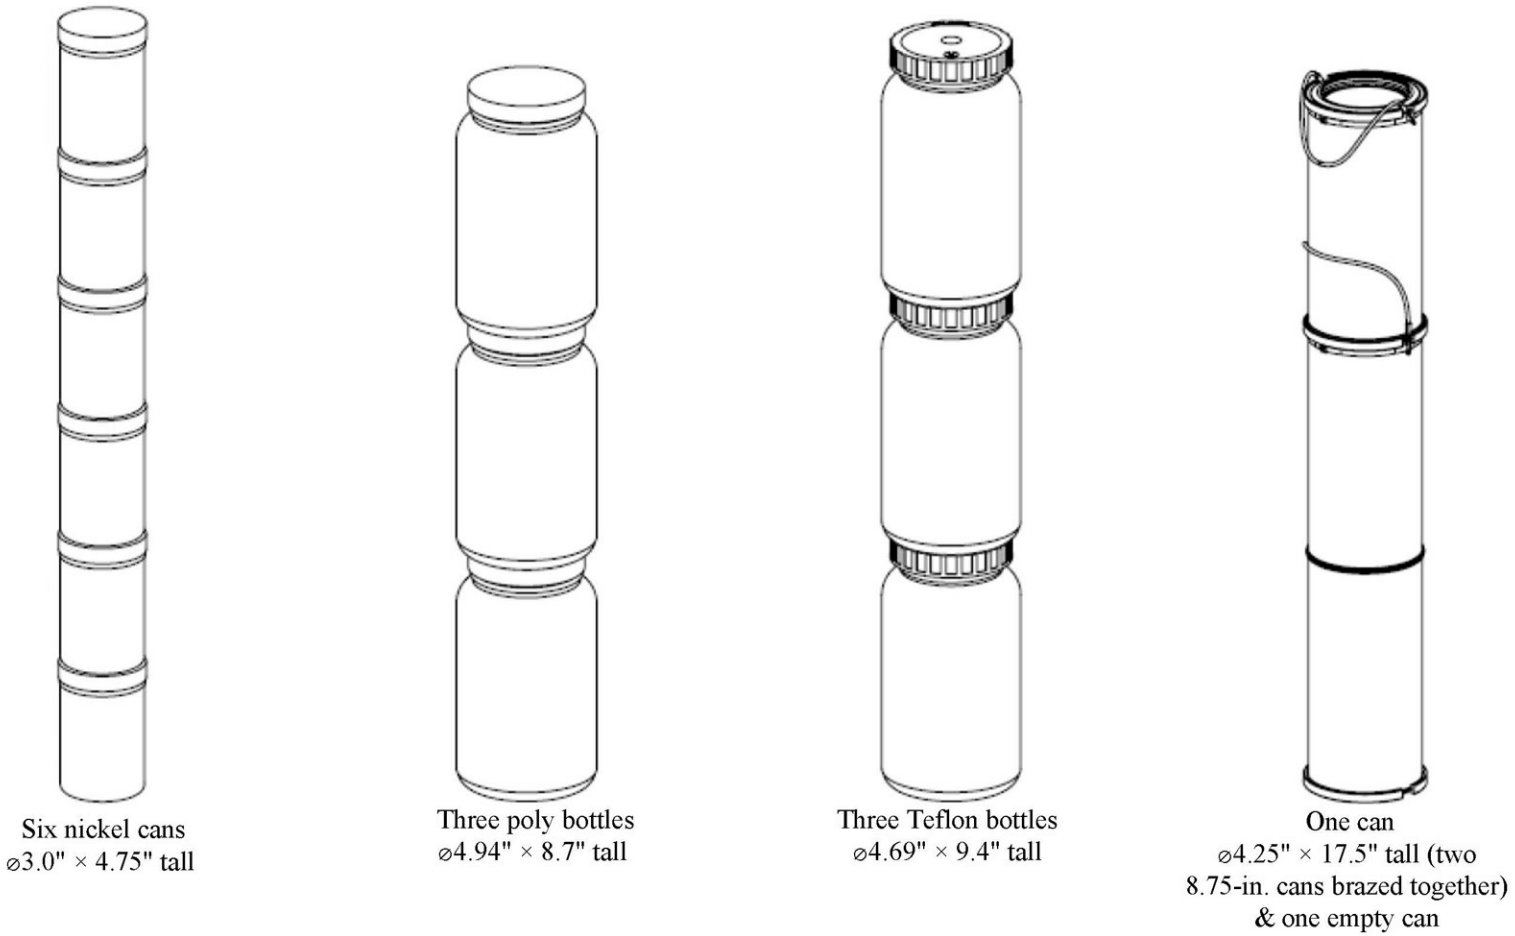

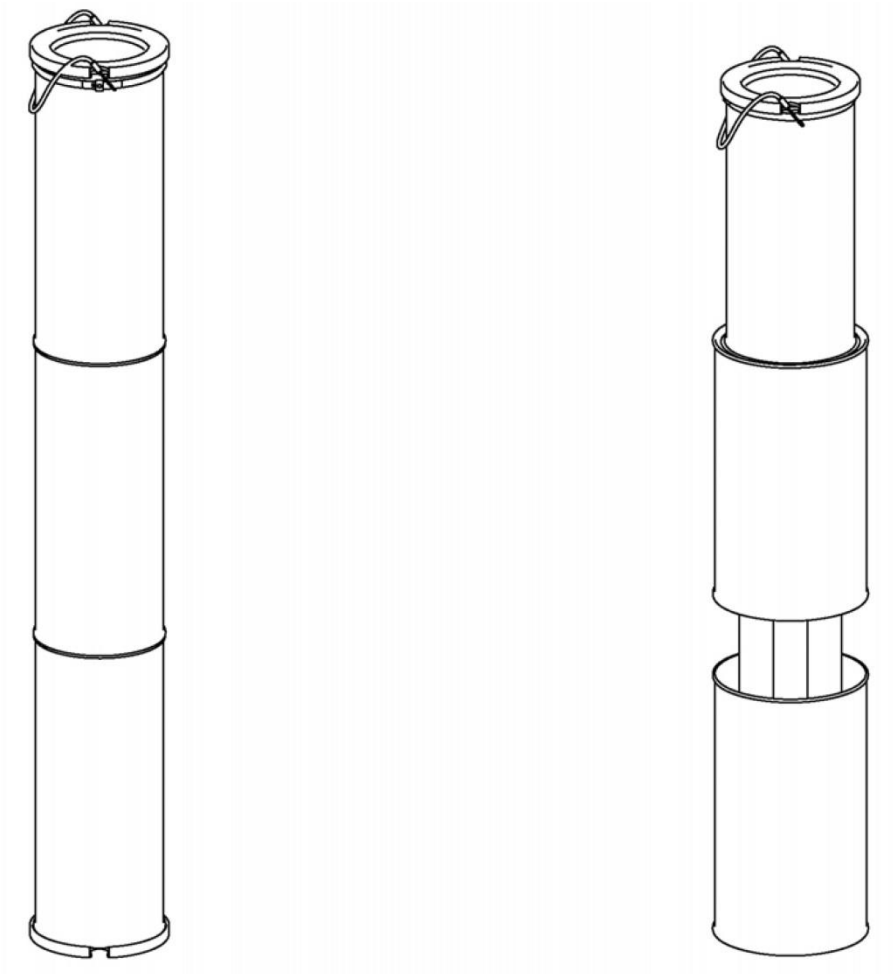

Fig. 1.4. Typical shipping configurations inside the ES-3100 containment vessel (cont.).

One can
⌀4.25" × 30" tall
(three 10-in. cans brazed together)

Two cans open ended
⌀≤5" × ≤10" tall
(one empty can or stainless steel scrubbers on top)

Fig. 1.4. Typical shipping configurations inside the ES-3100 containment vessel (cont.).

Intact TRIGA reactor elements and fuel pellets will also be shipped in the ES-3100. The fuel shall be unirradiated. The TRIGA fuel shall be in the form of uranium zirconium hydride ($UZrH_x$), where $x \leq 1.6$. Fuel from three types of TRIGA fuel elements are allowed: TRIGA Standard Fuel Elements, Instrumented TRIGA Standard Fuel Elements, and TRIGA Fuel Follower Control Rods. These fuel elements have three fuel pellets (or sections) per element. The TRIGA Standard Fuel Elements and Instrumented TRIGA Standard Fuel Elements have fissile loadings of 45.33-g ^{235}U per pellet (136-g ^{235}U per element) and the dimensions are 5 in. in length and 1.44 in. in diameter. The TRIGA Fuel Follower Control Rods have a fissile loading of 37.66-g ^{235}U per pellet (113-g ^{235}U per element) and the dimensions are 5 in. in length and 1.31 in. in diameter.

TRIGA fuel may be shipped as crimped fuel elements or as $UZrH_x$ fuel pellets (if disassembled), both of which shall be packed into convenience cans prior to shipment. Convenience cans of 4.25-in. diam by various lengths shall be used. Fuel pellets loaded into convenience cans shall be up to 5 in. in length (full-length) and no more than three full-length pellets shall be loaded into a convenience can. Crimped fuel rods are clad fuel pellets and can be up to 15 in. in length (full length of the fuel section from one fuel element). Cladding material is stainless steel or aluminum. Only the fuel section of the TRIGA fuel element is allowed to be shipped; however, there may be residual cladding up to ½ in. in length at either end of the crimped fuel rod. Up to three 15-in.-long crimped fuel elements shall be loaded into a single convenience can for shipping. Maximum loading of bare fuel pellets and crimped fuel elements shall be 3 fuel element equivalence per ES-3100 CV. TRIGA fuel with enrichments up to 70% has been evaluated. For TRIGA Standard Fuel Elements and Instrumented TRIGA Standard Fuel Elements, the maximum allowable loading is 408-g ^{235}U per package, and for TRIGA Fuel Follower Control Rods, the maximum allowable loading is 339-g ^{235}U per package. No spacer cans are required.

Fuel elements or pins from the Systems for Nuclear Auxiliary Power (SNAP) reactor will also be shipped in the ES-3100 package. The SNAP reactor fuel pins are composed of $UZrH_x$ ($x \leq 2$) with Hastelloy N cladding. The fuel pins are ~1.25 in. in diameter and ~12.45 in. long. The SNAP reactor fuel pins are enriched to 93 wt % ^{235}U. The SNAP reactor fuel pins will be packed in appropriate length convenience cans or bundled together and protected on each end with an open-ended can. Up to three fuel elements may be packed into any one convenience can or any one bundle. Up to two loaded convenience cans or two bundles may be shipped in the ES-3100.

Uranium Compounds

Several compounds of uranium, including uranium tetrafluoride, uranyl fluoride, uranium carbide, uranium nitride, and uranium silicide, will be shipped in the ES-3100 package. The physical form of these uranium compounds is solid crystalline, granular, or powder. The uranium compounds contain no moisture.

Uranium tetrafluoride (UF_4), often called green-salt because of its characteristic color, is generally an intermediate in the conversion of UF_6 to either uranium oxide (U_3O_8 or UO_2) or uranium metal. UF_4 is a solid composed of agglomerating particles with a texture similar to baking soda. It is non-volatile and non-hygroscopic, but only slightly soluble in water. After exposure to water, UF_4 slowly dissolves and undergoes hydrolysis, forming several possible uranium compounds and hydrogen fluoride (HF). The density of solid UF_4 is 6.7 g/cm^3.

Uranyl fluoride (UO_2F_2) is an intermediate in the conversion of uranium hexafluoride (UF_6) to a uranium oxide or metal form and is a direct product of the reaction of UF_6 with moisture in the air. It is very soluble in water. Uranyl fluoride is hygroscopic and changes in color from brilliant orange to yellow after reacting with water. Uranyl fluoride is reported to be stable in air to 300°C, above which slow decomposition to U_3O_8 occurs. When heated to decomposition, UO_2F_2 emits toxic fluoride fumes. The density of UO_2F_2 is 6.37 g/cm^3.

Uranium carbide is a hard refractive ceramic material. It comes in several stoichiometries such as uranium monocarbide (UC), uranium sesquicarbide (U_2C_3), and uranium dicarbide (UC_2). Like uranium dioxide and some other uranium compounds, uranium carbide can be used as a nuclear fuel for nuclear reactors, usually in the form of pellets or tablets. Uranium carbide is a dull, dark charcoal-gray or flat black colored powder. The densities of UC, U_2C_3, and UC_2 are 13.63, 12.7, and 11.3 g/cm^3, respectively. Loadings for U_2C_3 and UC_2 fall under the general category of UC.

Uranium nitride (UN) and uranium sesquinitride (U_2N_3) are ceramic compounds used as nuclear fuel in nuclear test reactors whose properties are similar to uranium dioxide or uranium carbide. They can be synthesized by the reaction of nitrogen with uranium at 700 K. Uranium nitride is also formed as a product of uranium combustion in air. The densities of solid UN and U_2N_3 are 14.32 and 11.24 g/cm^3, respectively. Loadings for U_2N_3 fall under the general category of UN.

Uranium-silicon compounds (U_3Si_2 and U_3Si) are produced by melting together uranium metal and high purity silicon. The silicon content of U_3Si_2 is ~7.5 wt % and of U_3Si is ~3.9 wt %. Except for minor impurities, the balance of the uranium silicide (U_3Si_2 and U_3Si) is uranium. The composition of the uranium in uranium silicide is as follows: ranging from 19.7 to 60 wt % ^{235}U, 0.5 maximum wt % ^{234}U, 1.0 maximum wt % ^{236}U, and the balance wt % ^{238}U. The bulk density range of uranium silicide powder is 5–7 g/cm^3. Uranium silicide particles may also be dispersed in aluminum (U_3Si_2-Al and U_3Si-Al).

Other uranium compounds consist primarily of finished tristructural-isotropic (TRISO) micro fuel particles; however, also included are pure/impure scrap materials generated during various stages of the manufacturing process. These materials have a ^{235}U assay ≤93.17% and are typically in a solid crystalline or granular form. A finished TRISO fuel particle consists of a kernel composed of UO_X (or sometimes UC or UCO) coated with four exterior layers of three isotropic materials. The four layers are a porous buffer layer made of carbon, followed by a dense inner layer of pyrolytic carbon (PyC), followed by a ceramic layer of SiC to retain fission products at elevated temperatures and to give the TRISO particle more structural integrity, followed by a dense outer layer of PyC.

Uranium compounds may be shipped in tin-plated carbon-steel, stainless-steel, or nickel-alloy convenience cans.

Uranyl Nitrate Crystals

Uranyl nitrate crystals are formed by dissolving uranium metal or any of the uranium oxides in nitric acid and the UNX crystalline precipitates are acquired through a variety of extraction, filtration, and purification processes. The UNX crystals are soluble in water, forming a weak solution of nitric acid. Uranyl nitrate hexahydrate (UNH) has a chemical formula of $UO_2(NO_3)_2 \cdot 6H_2O$. This most reactive form is used as the bounding composition for uranyl nitrate crystals in the criticality evaluation. Therefore, for UNX contents, X must be less than or equal to 6. The theoretical density of UNH crystals is 2.79 g/cm^3; however, the working densities will be less.

The user of the ES-3100 for UNX shipments will be required to use non-metallic containers only (Teflon bottles) as the convenience container.

Shipments of UNX crystals must be completed within the times shown in Table 1.3a in order to prevent the buildup of hydrogen gas beyond 5 mol %. The time period begins when the CV is sealed. Hydrogen generation calculations are provided in Appendix 3.5.4.

1.2.2.1 Radioactive/fissile constituents

For the ES-3100 package with bulk HEU content, the maximum number of A_2s is 4752.8 (at 70 years) and the maximum activity is 0.72554 TBq (at 10 years) [Table 4.4].

Ground Transport

Fissile material loading limits for ground transport of the various contents of the ES-3100, as determined by criticality analyses, structural analyses, or hydrogen gas generation evaluations, are presented in Tables 1.3 and 1.3a.

Air Transport

Contents for air transport of the ES-3100 package are HEU in the form of metal/alloy, research reactor fuel elements and components, and HEU oxide [UO_2, UO_3, U_3O_8, U_3O_8-Al, UO_2-Mg, and product oxides (UO_2, UO_3, U_3O_8) mixed with ThO_2, ZrO_2, and Th metal]. Fissile material mass loading limits for these contents, as determined by the criticality analyses, are presented in Table 1.3b for air transport.

1.2.2.2 Chemical and physical form

The fissile material contents are in solid (HEU metal or alloy, uranium compounds, or research reactor fuel elements and components), crystalline (UNX), or powder (HEU oxide) form. Some moisture (up to 3 wt %) may be present in the HEU oxide material, thereby making the oxide content clump together.

As presented for shipment, the UNX crystals exist as crystalline solids; however, the melting point for uranyl nitrate hexahydrate, trihydrate, and dihydrate is reported as ~60°C, 113°C, and 184°C, respectively (Marshall 1951). Heating of uranyl nitrate hexahydrate crystals up to 200°C results in a stepwise release of water molecules of crystallization (Dash 1999 and Kozlova 2007), which in a closed system results in the partial dissolution of the crystals. During transport of UNH crystals, crystalline solids and a saturated solution of uranyl nitrate will coexist at a temperature above ~60°C (MCW-1424). Given that the NCT maximum CV gas temperature with insolation is ~90°C (194°F) and the HAC maximum predicted gas temperature inside the CV at the location near the Teflon bottles is 167.78°C (334°F), the uranyl nitrate dihydrate and lower hydrates will remain in a solid phase during transportation. However, the trihydrate and higher hydrate crystals will release water molecules of crystallization upon heating above their melting point, thus converting them into a lower hydrate species, which require a successively higher temperature to release additional water molecules. The melting point for hexahydrate (~60°C) will be exceeded during NCT and HAC; and the melting point for trihydrate (~113°C) crystals will be exceeded during HAC. Upon cooling, the uranyl nitrate hydrate melt will recrystallize to a solid form.

1.2.2.3 Reflectors, absorbers, and moderators

The reflectors, absorbers, and moderators present in the ES-3100 package are those associated with the materials of construction. For example, the thermal insulation acts as a neutron reflector to the contents of a single package and as a neutron moderator in an array of packages. The degree of neutron moderation is a function of the hydrogen content in the Kaolite 1600 or Packcrete and 277-4 materials. The stainless-steel materials of the CV and the drum also act as neutron reflectors to the contents of a single package but act as neutron absorbers in an array of packages. The nuclear properties of the materials of construction and of the contents are important and have been taken into account in the criticality safety evaluation (Chap. 6). In addition to the materials of construction in the ES-3100 shipping package mentioned above, the 277-4 material has been specifically added to the ES-3100 package for the purpose of enhancing the neutron absorption characteristics for safety purposes (see Chap. 6 for additional discussion of the neutron-absorbing characteristics of this material).

1.2.2.4 Shipping configurations

Authorized content convenience containers for the ES-3100 are cans constructed of stainless steel, tin-plated carbon steel, aluminum, or nickel-alloy (Series 200, passivated), and polyethylene and Teflon convenience bottles. Modified convenience cans are constructed by brazing two 8.75-in.–tall cans together to create a 17.5-in.–tall can or by brazing three 10-in.–tall cans together to create a 30-in.–tall can. Research reactor fuel elements and fuel components may also be bundled together and protected on each end with open-ended convenience cans having an outer diameter ≤5 in. Solid form HEU contents (i.e., spheres, cylinders, bars, slugs) that will not fit in a convenience can may be bagged only with no convenience can required around the content. Enriched uranium oxide in the form of UO_2-Mg will be packed inside glass bottles, which are placed inside sealed, inerted metal convenience cans. These convenience containers are used to hold the HEU contents for shipment in the ES-3100 package and to assure that the inside of the CV does not become contaminated with HEU under NCT. Convenience containers used in the ES-3100 package must have an outer diameter less than or equal to 12.7 cm (5 in.). The height can vary up to the full internal height of the CV or 78.74 cm (31 in.). Some contents require the use of can spacers (see Table 1.3). These can spacers are thin-walled stainless-steel cans (Drawing M2E801580A043, Appendix 1.3.7) filled with 277-4 material (SPC M801580-0004, Appendix 1.3.10). Each convenience can and spacer may be equipped with a stainless-steel band and nylon-coated wire to facilitate loading and unloading operations. Silicone rubber pads may also be used between convenience cans to dampen vibration and minimize contact between metal components. Any combination of convenience containers will be allowed in a single package, as long as the total height of the stack-up (including spacers, if required) does not exceed the inside working height of the CV [78.74 cm (31 in.)]. If can spacers are required, no more than one-third of the total HEU content mass limit shown in Table 1.3 may be placed between any two spacers.

Typical configurations of authorized ES-3100 convenience containers are shown in Fig. 1.4. The shipping configurations shown in Fig. 1.4 utilize convenience cans having ≤5.0-in. diam and various heights [such as 4.75 in., 4.88 in., 8.75 in., 10 in., 17.5 in. (two 8.75-in. cans brazed together), and 30 in. (three 10-in. cans brazed together)], 4.94-in.-diam by 8.7-in.-tall polyethylene bottles, and 4.69-in.-diam by 9.4-in.-tall Teflon bottles. Although any combination of the convenience cans that will fit inside the internal volume of the CV may be used, content forms shall not be mixed in a single package (i.e., HEU oxides may not be packed with HEU metal). Empty cans and/or stainless-steel scrubbers may be used to fill the void space at the top of the CV. If empty cans are shipped, a minimum 0.32-cm (0.125-in.)-diam hole must be placed through the lid to prevent over-pressurization of the can in the event of a thermal accident. These empty cans may be placed above or below the loaded cans. In configurations not requiring can spacers for criticality control, can spacers may be shipped for convenience if placed on top of loaded cans in the CV. The HEU contents may be bagged or wrapped in polyethylene, nylon or Teflon, and the convenience containers may also be wrapped in polyethylene, nylon, or Teflon to further reduce the possibility of contamination. If metal cans or polyethylene bottles are used as convenience containers, the total amount of offgassing material (including polyethylene bottles; polyethylene, nylon, or Teflon bagging; and lifting slings) is limited to 500 g per package. If Teflon bottles are used as convenience containers, the total amount of offgassing material (including Teflon bottles, polyethylene, nylon, of Teflon bagging, and lifting slings) is limited to 1490 g per package (limit established by assuming three 330-g Teflon bottles and 500-g polyethylene bagging). If closed convenience cans with an outer diameter greater than 4.25 in. are used, at least 43 $in.^3$ of free or void volume must exist inside the CV to allow for gas expansion and offgassing of material at temperatures associated with NCT or HAC. In accordance with Sect. 6.2.4, Item 7, the amount of hydrogenous packing material inside the CV shall not exceed an equivalent mass of 500 g polyethylene. In some shipping configurations, silicone rubber pads will be placed between the convenience cans to reduce vibration.

1.2.2.5 Maximum normal operating pressure

As defined in 10 CFR 71.4, the maximum normal operating pressure is the maximum gauge pressure that would develop in the containment system in one year under an ambient temperature of 38°C (100°F) in still air, with appropriate insolation in the absence of venting, external cooling by an ancillary system, or operational controls during transport. Under these conditions, the maximum normal operating pressure in the ES-3100 CV would be 107.39 kPa (15.576 psig). In comparison, the design internal pressure of the CV is 1378.95 kPa (200 psig). The design internal pressure is a conservatively assumed value that was assigned for the purpose of the ASME Code calculations in DAC-M900000-0002.

1.2.2.6 Maximum and minimum weight

The maximum allowable gross shipping weight for the ES-3100 package is 190.5 kg (420 lb). The largest nominal gross shipping weight of the ES-3100 package with HEU content is 187.81 kg (414.05 lb) [Table 2.8]. The total weight of the tested ES-3100 units ranged from 157.4 to 204.6 kg (347 to 451 lb) [Table 2.9].

The weight of HEU contents in the ES-3100 shipping package is limited to 35.2 kg (77.60 lb). This limit has been established as a bounding case for the maximum structural, thermal, and containment limit for the package. There is no minimum content weight requirement. Actual mass restrictions for the various contents based on the various analyses presented in the SARP are listed in Tables 1.3, 1.3a, and 1.3b. The maximum allowable payload weight of any configuration, including packing components (convenience cans and bottles; polyethylene, nylon, or Teflon bags; silicone pads; can spacers; etc.), is 40.82 kg (90 lb). ES-3100 shipping package weights are discussed in greater detail in Chap. 2 and are broken down into individual component weights in Tables 2.8 and 2.9.

The payload weight (including convenience cans, silicone rubber pads, can spacers, and the HEU mockup) used in the ES-3100 package tests ranged from a minimum of 3.6 kg (8 lb) to a maximum of 50.3 kg (111 lb).

1.2.2.7 Maximum decay heat

As shown in Sect. 3.1.2, the conservatively calculated maximum heat generation rate of the contents is ~5 W. The ES-3100 package was designed for a maximum heat load of 20 W. Thermal analyses with Kaolite have been performed assuming heat sources of 5, 10, 15, 20, 25 and 30 W in the ES-3100 CV (DAC-PKG-801940-A001) and updated thermal analyses of the ES-3100 with Packcrete were performed with content heat loads of 0 and 5 W (DAC M801940-0002).

[a] With the exception of the UNX crystals (Sect. 1.2.2.2), which are loaded in crystalline solid form, HEU in solution form is not permitted for shipment in the ES-3100.

[b] All limits are expressed in kg ^{235}U unless otherwise indicated.

[c] Mass loadings cannot be rounded up.

[d] 277-4 can spacers as described on Drawing M2E801580A043 (Appendix 1.3.7).

[e] HEU bulk metal and alloy not covered by these specific geometric shapes must be put into the broken metal category. Geometries of solid shapes are as follows:
- Cylinder A is larger than 3.24-in. diam but no larger than 4.25-in. diam: maximum of 1 cylinder per can.
- Cylinder B is no larger than 3.24-in. diam: maximum of 1 cylinder per can.
- Cylinder C is a uranium-molybdenum alloy with ≤ 95 wt % uranium and ≤ 93.5% ^{235}U enrichment; the cylinder length is ≤ 3.30 in. with an inner diam of ≥ 1.50 in., an outer diam of ≤ 4.35 in., and a maximum mass of 13.5 kg: maximum of 1 cylinder per CV.
- Cylinder D is a uranium-molybdenum alloy with ≤ 95 wt % uranium and ≤ 93.5% ^{235}U enrichment; the cylinder length is ≤ 5.80 in. with an inner diam of ≥ 1.35 in., an outer diam of ≤ 3.86 in., and a maximum mass of 16.5 kg: maximum of 1 cylinder per CV.
- Square bars are no larger than 2.29 in. × 2.29 in. (cross section): maximum of 1 bar per can.
- Slugs are a maximum of 1.5-in. diam × 2.0-in. tall: a maximum of 10 per convenience can where the actual number permitted is restricted by the stated loading limit.

[f] Maximum planned content weight is 35.20 kg. Maximum analyzed for criticality safety is 36.0 kg.

[g] Samples and small quantities (≤ 50 g) of HEU metal or alloy turnings, fines, or powders may be shipped under the parent form mass limits (e.g., broken metal, reactor fuel, etc.).

[h] Seal time must be 12 months or less. Seal time is the length of time after the ES-3100 containment vessel is sealed that the shipment must be complete.

[i] Allowable HEU oxide bulk densities are 0.5–6.54 g/cm^3 and the total mass of oxide in all cases is limited to 15.13 kg. Moisture content in oxide is limited to 3 wt % water.

[j] UO_2-Mg will be shipped in a glass bottle inside a metal convenience can under an inert cover gas.

[k] For SNAP $UZrH_x$, $x \leq 2$. For TRIGA $UZrH_x$, $x \leq 1.6$. Carbon coating for reactor fuel is not controlled (Sect. 6.9.8.3.1).

[l] Evaluation limit based on specific fuel type as opposed to a maximum calculated limit for $UZrH_x$.

[m] Oxides of U-Zr are UO_2-Zr and UO_2-ZrO_2.

[n] No control on the amount of aluminum.

Table 1.3a. Uranyl nitrate crystal content loading limits for ground transport

Product [a, b]	Seal time [c] (months)	CSI	Loading limit [d, e] (kg UNX)	U content [f] (wt %)
UNX, $0 < X \leq 3$	2	0.4	11.90	$52 < U \leq 61$
	4	0.4	6.70	$52 < U \leq 61$
UNX, $X > 3$	2	0.4	9.17	$46 < U \leq 52$
	4	0.0	4.75	$46 < U \leq 52$

[a] UNX is uranyl nitrate hydrate $[UO_2(NO_3)_2 \cdot XH_2O]$ where $0 < X \leq 6$.
[b] Must be shipped in Teflon bottles.
[c] Seal time—length of time after the ES-3100 containment vessel is sealed that the shipment must be complete. Seal times listed in this table are much lower than the calculated values shown in Table 3.5.4.1 in Appendix 3.5.4 and have been reduced for additional conservatism.
[d] Total mass of UNX crystals. Spacers are not required for this content type.
[e] Loading limits for uranyl nitrate crystals are based on hydrogen generation calculations presented in Appendix 3.5.4.
[f] Enrichment up to 100%.

1.5 g/cm³ ≤ bulk density < 2.0 g/cm³			0.83
1.0 g/cm³ ≤ bulk density < 1.5 g/cm³			0.70

Table 1.3b. Authorized content and fissile mass loading limits for air transport [a, b, c]

Content description	Enrichment	CSI	^{235}U (kg)
Product oxides (UO_2, UO_3, U_3O_8) mixed with Th metal	≤100%	— [d]	
5.0 g/cm^3 ≤ bulk density ≤ 6.54 g/cm^3			7.57
4.0 g/cm^3 ≤ bulk density < 5.0 g/cm^3			6.02
3.0 g/cm^3 ≤ bulk density < 4.0 g/cm^3			4.66
2.0 g/cm^3 ≤ bulk density < 3.0 g/cm^3			2.55
1.5 g/cm^3 ≤ bulk density < 2.0 g/cm^3			1.71
1.0 g/cm^3 ≤ bulk density < 1.5 g/cm^3			1.18
Uranium compounds [l]			
UF_4	≤100%	— [d]	24.0 kg UF_4 18.13 kg ^{235}U
UO_2F_2	≤100%	— [d]	3.0 kg UO_2F_2 2.06 kg ^{235}U
UC	≤100%	— [d]	2.0 kg UC 1.81 kg ^{235}U
UN	≤100%	— [d]	2.0 kg UN 1.88 kg ^{235}U
U_3Si_2	≥19.7%, <40%	— [d]	8.5 kg U_3Si_2 3.15 kg ^{235}U
	≥40%, ≤60%	— [d]	6.5 kg U_3Si_2 3.61 kg ^{235}U
U_3Si	≥19.7%, <40%	— [d]	8.5 kg U_3Si 3.27 kg ^{235}U
	≥40%, ≤60%	— [d]	6.5 kg U_3Si 3.75 kg ^{235}U

[a] All limits are expressed in kg ^{235}U unless otherwise indicated.
[b] Mass loadings cannot be rounded up.
[c] The loading limit for mixed-mode transportation is taken as the most restrictive limit for either ground or air mode of transportation (Table 1.3 or 1.3b).
[d] CSI and spacer use are governed by ground transport mode.
[e] If the mass of metal or alloy turnings, fines, or powders is ≤ 50 g, then it may be shipped as the parent form (e.g., broken metal, reactor fuel, etc.).
[f] For SNAP $UZrH_x$, x ≤ 2. For TRIGA $UZrH_x$, x ≤ 1.6.
[g] Oxides of U-Zr are UO_2-Zr and UO_2-ZrO_2.
[h] Seal time must be 12 months or less. Seal time is the length of time after the ES-3100 containment vessel is sealed that the shipment must be complete.
[i] Allowable uranium oxide bulk densities are 1.0–6.54 g/cm^3. Moisture content in oxide is limited to 3 wt % water.
[j] UO_2-Mg will be shipped in a glass bottle inside a metal convenience can under an inert cover gas.
[k] Carbon coating for reactor fuel is not controlled (Sect. 6.9.8.3.1).
[l] Allowable uranium compound bulk densities are 2.0–6.54 g/cm^3.

1.2.2.8 Loading restrictions

Loading restrictions based upon the results of the criticality safety calculations presented in Sect. 6.2.4 and additional limitations on packing materials outlined in Chap. 3 are as follows:

(1) HEU fissile material to be shipped in the ES-3100 package must be placed in stainless-steel, tin-plated carbon-steel, aluminum, or nickel alloy convenience cans, polyethylene bottles, or Teflon bottles. Solid form HEU contents (i.e., spheres, cylinders, bars, slugs) that will not fit in a convenience can may be bagged only with no convenience can required around the content. For contents that are bagged only, stainless-steel metal scrubbers may be placed on the top and bottom of this assembly inside the CV. For these bagged contents, the void volume requirement stated in Loading Restriction 8 must still be satisfied. Enriched uranium oxide in the form of UO_2-Mg will be shipped in glass bottles inside a metal convenience can. Convenience containers used in the ES-3100 package must have an outer diameter less than or equal to 12.7 cm (5 in.). The height can vary up to the full internal height of the CV or 78.74 cm (31 in.). Any closure on the convenience can is allowed.

(2) Any combination of convenience cans is allowed in a single package, as long as the total height (including silicone rubber pads and can spacers, if required) does not exceed the inside working height of the CV (~31 in.).

(3) In situations where empty convenience cans are shipped in the package, they may be placed either above or below the loaded cans, and a minimum 0.32-cm (0.125-in.)-diam hole must be placed through the lid to prevent over pressurization of the can.

(4) The concentration of uranium isotopes in the content is limited as shown in Table 1.1; concentration limits for uranium oxide are shown in Table 1.2. In addition to the uranium isotopes shown in Table 1.1, transuranic isotopes (with the exception of ^{237}Np) may be present in the HEU metal and alloy contents transported by ground at a maximum concentration of 800.0 μg/gU and at a maximum concentration of 40.0 μg/gU in all other contents. Contents to be transported by air are limited to a maximum transuranic concentration of 40.0 μg/gU, and the transportation of plutonium by air (due to the transuranic concentration allowance) shall be in accordance with the requirements in 10 CFR 71.88, which includes restrictions for no more than an A_2 quantity of plutonium in any isotope or form. The concentration of ^{237}Np is limited to 0.0250 g/gU.

(5) For pyrophoric considerations, HEU metal or alloy pieces must have a specific area not greater than 1 cm^2/g or must not pass through a 3/8-in. (9.5-mm) mesh sieve (or equivalent size-grading method). Incidental small pieces that do not pass the size restriction tests, and powders, foils, turnings, and wires, may only be shipped if they are in a sealed, inerted container. Glass bottles containing enriched uranium oxide in the form of UO_2-Mg must be placed in a sealed, inerted container.

(6) The content shall not exceed "per package" fissile material mass loading limits specified in Tables 1.3, 1.3a, and 1.3b. Where can spacers are required for a "per package" mass loading, the quantity of fissile material located in any vacancy between or adjacent to can spacers shall not exceed one-third of the mass loading limit in Tables 1.3. A spacer must be positioned between each convenience can, or in the case of shipping only one convenience can, the spacer must be positioned on top of the single convenience can.

(7) The package content is defined as the HEU fissile material, the convenience cans and can spacers, and the associated packing materials (plastic bags, pads, tape, etc.) inside the ES-3100 CV.

(8) If metal cans are used as convenience containers, the amount of polyethylene bagging and lifting slings is limited to 500 g per package. If Teflon bottles are used as convenience containers, the total amount of offgassing material (including Teflon bottles; polyethylene, nylon, or Teflon bagging; and lifting slings) is limited to 1490 g per package. If metal cans or polyethylene bottles are used as convenience containers, the total amount of offgassing material (including polyethylene bottles; polyethylene, nylon, or Teflon bagging; and lifting slings) is limited to 500 g per package (see Sect. 6.2.4, Item 7). If closed convenience cans with an outer diameter greater than 4.25 in. are used, at least 43 $in.^3$ of free or void volume must exist inside the CV to allow for gas expansion and offgassing of material at temperatures associated with NCT or HAC. These mass limits do not include moisture in oxide. Moisture is accounted for in criticality safety calculations (Sect. 6.1.2).

(9) The amount of hydrogenous packing material inside the CV shall not exceed an equivalent mass of 500 g polyethylene (Sect. 6.2.4, Item 7).

(10) Shipments of UNX crystals must be completed in the time period noted in Table 1.3a. Shipments of uranium oxide must be completed in 12 months. This time period begins when the CV is sealed.

(11) The mass of any unidentified constituents in content to be shipped in the ES-3100 must be counted against the fissile mass loading limit. Content must not contain unevaluated moderating materials.

(12) Allowable HEU oxide bulk densities are 0.5–6.54 g/cm^3 for ground transport and 1.0–6.54 g/cm^3 for air transport.

(13) As noted in Table 1.3, Note e, ground transport of solid HEU metal or alloy of specified geometric shapes is limited to one item per convenience container, with the exception of slugs, which are limited to a maximum of 10 per convenience container. Cylinders C and D are limited to one cylinder per CV.

(14) For air transport, the total free water permitted in the ES-3100 packaging is limited to 12 lb (5,443 g).

(15) Clinkers and screenings will be loaded in accordance with the HEU metal or alloy turnings, fines, and powders mass loading limits in a sealed container under an inert cover gas. Clinkers and screenings shipments must be completed within 12 months after sealing the CV.

1.2.3 Special Requirements for Plutonium

The contents to be shipped in the ES-3100 have only trace amounts of transuranic isotopes [<0.74 TBq (20 Ci)]. Therefore, the requirements in 10 CFR 71.63 are not applicable.

1.2.4 Operational Features

The ES-3100 package is a Type B(U) fissile material package designed in accordance with DOT and NRC regulations. These regulations require that the package be operated without undue risk to the public, even in the event of a severe accident, and that the dose rate and nonfixed radioactive contamination on the external surface of the package conform with 49 CFR 173.441 and 173.443, respectively. These requirements are translated into the designs for the containment, shielding, and nuclear criticality safety of the contents when subjected to NCT and HAC. Designs for containment, shielding, and nuclear subcriticality safety are supported by operational procedures for loading, unloading, and maintenance to ensure that those design features are used and maintained in a manner commensurate with their intended function. Drop tests, crush tests, puncture tests, thermal tests, and water immersion tests (Sects. 2.6 and 2.7) show that the drum assembly maintains the insulation and the CV in their intended configurations when subjected to NCT and HAC.

Design features that provide shielding, containment, and nuclear criticality control perform these functions in a passive manner. No valves, connections, gauges, active coolants, or operationally pressurized parts are integral to the ES-3100 package.

CONTAINMENT VESSEL SEALING LID ASSEMBLY

SECTION F-F

WELD NOTES:

1. ALL WELDS ON THE CONTAINMENT VESSELS SHALL BE DONE EITHER BY THE GTAW OR GMAW PROCESS, MANUAL OR AUTOMATIC, AT THE DISCRETION OF THE SELLER UNLESS SPECIFICALLY CALLED OUT ON THE DRAWINGS. BACKING RINGS, EVEN IF REMOVED AFTER THE WELD HAS BEEN MADE, SHALL NOT BE USED. AS PREVIOUSLY STATED, WELD SYMBOLS ARE PROVIDED ON THE DRAWING INDICATING FOR EACH WELD THE TYPE OF WELD AND DIMENSIONS OF THE WELD.
2. EXCEPT AS LIMITED BY THIS SPECIFICATION, THE APPLICABLE REQUIREMENTS OF NB-4300 AND NB-4400 SHALL APPLY TO THE CONTAINMENT VESSEL.
3. PRIOR TO WELDING, ALL WELD PREPARATION AREAS AND THE SURFACES WITHIN ONE INCH OF THE WELD AREA SHALL BE EXAMINED VISUALLY AND WITH LIQUID PENETRANT. THE ACCEPTANCE CRITERIA FOR THESE EXAMINATIONS ARE THOSE STATED IN NB-5130 (A) THROUGH NB-5130 (D). THE RESULTS OF THESE SURFACE EXAMINATIONS SHALL BE REPORTED TO THE COMPANY TOGETHER WITH THE WELD EXAMINATION REPORTS, SEE SECTION 3.4 OF THIS SPECIFICATION.
4. WELDERS PERFORMING TWO OR MORE WELDS IN ONE DAY THAT ARE REJECTED BASED UPON WELDER TECHNIQUE SHALL BE SUBJECT TO BE RE-QUALIFIED TO THE APPROPRIATE WELDING PROCEDURES, SEE SECTION IX, PARAGRAPH QW-320 OF THE ASME CODE.
5. THE APPLICABLE REQUIREMENTS IN PARAGRAPHS NB-5110, NB-5120, NB-5210, NB-5220, NB-5260, AND NB-5300 SHALL APPLY TO THE CONTAINMENT VESSELS. THE PLUG WELD SHOWN ON DRAWING M2E801580A015 SHALL BE EXAMINED VISUALLY AND WITH PENETRANT. THE APPLICABLE REQUIREMENTS IN PARAGRAPHS NB-5110, AND NB-5350 SHALL APPLY TO THE PLUG WELD. NOTE THAT THE REFERENCE TO THE INSPECTOR IN NB-5112, FOR THE PURPOSES OF THIS SPECIFICATION IS EITHER THE COMPANY'S INSPECTOR OR A SUBCONTRACTOR DESIGNATED BY THE COMPANY.
6. MATERIALS USED IN THE PENETRANT EXAMINATION OF WELDS AND IN THE FINAL SURFACE EXAMINATION OF FINISHED COMPONENTS (SEE SECTION 3.7) SHALL BE SPECIFICALLY RECOMMENDED BY THEIR SUPPLIERS FOR USE WITH AUSTENITIC STAINLESS STEELS, AND COPIES OF THE CERTIFICATION OF CONTAMINANT CONTENT OF MATERIALS USED (SEE SECTION V, ARTICLE 6, T-641) SHALL BE SUPPLIED TO THE COMPANY WITH THE EXAMINATION REPORTS.
7. REPAIR WELDING SHALL MEET THE APPLICABLE REQUIREMENTS OF NB-2500.
8. CERTIFIED WRITTEN WELD EXAMINATION REPORTS TOGETHER WITH THE CORRESPONDING MATERIAL SURFACE EXAMINATION REPORTS, AND WELD MAP SHALL BE SUBMITTED TO THE COMPANY AS STATED IN THE PROCUREMENT SPECIFICATION FOR THE ES-3100 CONTAINMENT VESSEL. WELD EXAMINATION REPORTS FOR ALL WELD AND SURFACE EXAMINATION SHALL INCLUDE: THE CONTAINMENT VESSEL SERIAL NUMBER, A WELD MAP SHOWING THE LOCATION OF THE WELD AND EXAMINATION AREA, THE WELDER'S NAME, THE EXAMINER S NAME, THE TIME AND DATE OF THE WELD EXAMINATION, THE EXAMINATION PROCEDURE(S) NUMBER USED, THE WPS NUMBER, THE HEAT NUMBERS OF THE MATERIALS JOINED, THE HEAT NUMBER OF THE WELD FILLER, AND EXAMINER S REMARKS. THE EXAMINER S REMARKS SHALL INCLUDE THE RESULTS OF THE EXAMINATION AND ACCEPTANCE, OR REJECTION OF THE WELD BASED ON THE STATED CRITERIA. ONE SET OF RADIOGRAPHS SHALL BE PROVIDED TO THE COMPANY WITH RADIOGRAPHIC EXAMINATION REPORTS. IF THE WELD OR SURFACE IS REJECTED, A DESCRIPTION OF THE DEFECT AND SKETCH SHOWING THE LOCATION SHALL BE PROVIDED.
9. IF A WELD IS REJECTED, THE AREA SHALL BE WELD REPAIRED BY THE SELLER AND RE-EXAMINED. AFTER TWO UNSUCCESSFUL REPAIR ATTEMPTS, THE COMPANY SHALL BE NOTIFIED FOR APPROVAL TO PERFORM MORE REPAIR ATTEMPTS. THE COMPANY MAY, AT ITS OPTION, CHOOSE TO REJECT FURTHER REPAIR EFFORTS AND REQUIRE THAT A REPLACEMENT PART BE FABRICATED.

1.0 SCOPE

This specification, the Company's drawings, referenced codes, standards, and the documents referenced herein provide the requirements for the procurement of materials and components, fabrication, inspection, examination, assembly, documentation, and testing of a ES-3100 Drum Body Assembly.

The Drum Assembly will be manufactured in accordance with the applicable requirements stated in the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (B&PVC), hereinafter referred to as the ASME Code, Section III, Division 1, Sub-section NB for Class 1 Components as described on the Company's drawings and in this specification. The reference to the Inspector in any of the ASME Codes shall in this particular case be that person designated by the Company.

If conflicting requirements appear in these documents, the Supplier shall immediately notify the Company Subcontract Technical Representative (STR) for resolution.

The Supplier shall not deviate from the requirements of this specification without prior written consent from the Company. Requests for changes or deviations shall be submitted on form UCN-13816B, Request for Waiver or Deviation (RFWD), and the latest RFWD form may be requested from the Subcontract Administrator (SA) or STR.

1.1 General Description of the Item

The Drum Assembly is a confinement barrier capable of aiding in maintaining the content quality during and after designated accident scenarios.

1.2 Background

The ES-3100 Shipping Package is a general-purpose fissile material container accommodates many forms of highly enriched uranium (HEU) and other special nuclear materials in bulk quantities for ground and air transport.

2.0 REFERENCES

2.1 Definitions

Company – The Company, as used in this specification, is the buyer of the Supplier's final product (i.e., Y-12 National Security Complex)

Deviation - A specific written authorization, granted by the Company **prior to the manufacture** of an item, to depart from a subcontract requirement for a specific piece or pieces of equipment or a specified period of time.

First Article - Product that is submitted to the Company for evaluation prior to the Supplier being released to manufacture the remaining quantities in the subcontract. This product must be representative of production items by virtue of having been produced and inspected using the same facilities, testing, processes, and type of personnel planned for use in production.

First Article Evaluation (FAE) – An evaluation by the Company of the first unit(s) manufactured and the facilities, tooling, processes, etc. concerned with the manufacture and inspection.

Hold Point - A hold point is defined as the designated point(s) in the fabrication where the Supplier will stop and hold further production. The Company contact will be provided production data and will decide if it will be necessary to visit the manufacturing facility or if the supplied data will be sufficient.

Manufacturing Plan – A written, step-by-step, process plan for the equipment to be fabricated. The plan includes material control, major fabrication steps, hold points, all in-process inspections, welding, welding inspection/examination, dimensional inspections, testing, and shipping.

Non-conformance - A deficiency in characteristic, documentation, or procedure that renders an item to be in non-compliance with specified requirements.

Offeror - The Organization or person(s) submitting an offer to the Company to provide the product(s) described.

Request for Waiver or Deviation (RFWD) - A formal request by the Supplier for a waiver or deviation to the equipment specification, drawing, or PO using the Company form, which can be provided by the SA or STR. The form must be approved by the Company in writing before the Supplier being granted authorization to proceed.

Supplier - Any individual or organization that furnishes items or services in accordance with a purchase order. Also an all-inclusive term used in place of the following: vendor, seller, subcontractor, dealer, fabricator, consultant, manufacturer, distributor, and their sub-tier levels.

Subcontract Administrator - The person(s) designated in the subcontract as having authority to act officially for the Company.

Subcontract Technical Representative (STR) – The Subcontract Technical Representative, as used in this specification, is the person designated by the Subcontract Administrator as having the authority to represent the Company in technical matters.

Traveler - A written, step-by-step, process document used for the control of components/equipment to be fabricated. The traveler includes material identification, all fabrication steps, hold points, all in-process inspections, welding, welding inspection/examination, dimensional inspections, testing, and preparation for shipping.

Waiver - A specific written authorization, granted by the Company, to accept a configuration item or other designated items which, during production or after having been submitted for inspection, are found to depart from specified requirements, but are considered suitable for use as is or after rework by an approved method.

Witness Point - The Witness point is similar to the hold point except the manufacturing, testing or inspection is halted until the Company representative(s) can visit the manufacturing facility and witness the designated operations.

2.2 Codes/Standards/Orders/Regulations

Drum Assemblies shall be fabricated, inspected, and tested according to the design drawings and the applicable documents referenced herein.

- American Society of Mechanical Engineers, Boiler and Pressure Vessel Code, Section III, Division 1, 2019.

- American Society of Mechanical Engineers, Boiler and Pressure Vessel Code, Section II, Parts A and C, 2019.

- American Society of Mechanical Engineers, Boiler and Pressure Vessel Code, Section V, 2001 2019.

- American Society of Mechanical Engineers, Boiler and Pressure Vessel Code, Section IX, 2019.

- American Society for Nondestructive Testing, No. SNT-TC-1A, Recommended Practice for Nondestructive Testing Personnel Qualification and Certification, 2016.

- American Society for Testing Materials, ASTM A 380-17, Standard Practice for Cleaning, Descaling, and Passivation of Stainless Steel Parts, Equipment and Systems.

- Military Standard, MS27683, Drum, Metal-Shipping and Storage 16 to 80 Gallons.

All references to the ASME Code in this document are to the ASME Boiler and Pressure Vessel Code, 2019 Edition.

DS 801580-0001	ES-3100 Shipping Container Modified Hex Nut

3.0 ITEM REQUIREMENTS

The Supplier shall be responsible for supplying all materials, services, facilities, and equipment to meet the requirements of this specification and Company drawings unless otherwise noted.

3.1 Performance Requirements

3.1.1 Boiler and Pressure Vessel Code Compliance

3.1.1.1 The drum assembly shall be manufactured in accordance with those paragraphs of the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code, Section VIII, Division 1 that are specified in this document. A certificate of compliance to the code shall be supplied to the Company.

3.1.1.2 The drum assemblies are not pressure vessels and are not to be hydrostatically tested, nor are they to be stamped.

3.1.1.3 The Supplier shall hold a Certificate of Authorization from the ASME that authorizes it to manufacture and inspect pressure vessels in accordance with Section VIII or Section III of the ASME Code. If the Supplier does not have a certificate of authorization for Section VIII or III, the Supplier shall provide data with its offer that demonstrates its ability to meet the requirements in Subsections NB and NCA as referenced in this specification.

3.2 Design Requirements

3.2.1 Materials and Material Examinations

3.2.1.1 Material requirements are specified on Company drawings, in this specification, and in the documents referenced in this specification.

3.2.2 Certified Material Test Reports (CMTR's)

3.2.2.1 Except for the weld studs, documented Certified Material Test Reports (CMTR's) shall be provided to the Company for all materials used in weldments for the fabrication of the drum assembly, including weld filler metal.

3.2.2.2 CMTR's shall be traceable to heat numbers and shall demonstrate compliance with the applicable SA or SFA material specifications.

3.2.2.3 For materials not used in weldments, Certificates of Conformance (CoC's) shall be provided to the Company certifying that the materials provided comply with the requirements stated on the Company's drawings and specifications as referenced in Section 3.2.5.

3.2.2.4 Materials shall be traceable to each drum assembly's serial number.

3.2.2.5 Supplier shall transfer heat numbers and serial numbers to base materials used in weldments to maintain control of materials to ensure this traceability.

3.2.2.6 Results of these examinations shall be included with the CMTR's provided to the Company.

3.2.2.7 Weld filler metal used in the fabrication and repair of the drum assemblies shall be procured to comply with ASME BPVC Section III, Rules for Construction of Nuclear Facility Components -

Sub-section NCA General Requirements for Division 1 and Division 2- Article NCA-3800 and shall comply with the SFA specifications of Section II; Part C of the ASME Code.

3.2.2.8 Weld filler metal shall be traceable to heat numbers and CMTR's shall be furnished to the Company for each heat of weld filler metal used.

3.2.2.9 Results of the delta ferrite determination shall be included with the CMTR for the weld filler metal (see NB-2433) and shall be a minimum of 5 FN.

3.2.2.10 Weld examiner shall be able to determine the heat number of the weld filler used in each weld on each drum body assembly.

3.2.3 Hold points and Witness points

Hold points and Witness points will be required as noted below.

- For the FAE units, QA Witness Points will be the Dimensional Inspection.
- QA witness points and hold points will be determined based on the submitted manufacturing schedule and in accordance with a normal sampling plan based on the total PO quantity in accordance with Y17-69-316 Chapter 6, attachment 6-C. For the Production Units, QA Witness Points shall include at a minimum the Dimensional Inspection. Other processes may be selected.

3.2.4 First Article Evaluation (FAE)

The Company shall conduct an FAE in two (2) phases in accordance with this specification.

3.2.4.1 In Phase I the Company will conduct a review of the Supplier's process control forms and manufacturing procedures. The Supplier shall furnish an electronic copy of all procedures, travelers, data entry forms, processing records, and related data used by the Supplier to define and/or control those aspects of the manufacturing, testing, and inspection operations that influence the quality of the product being produced prior to fabrication, in accordance with schedule dates described in the subcontract.

3.2.4.2 Phase II of the FAE shall consist of audits and such examinations, inspections and testing oversight as deemed appropriate by the Company at the Supplier's site. The results of these audits and examinations will be evaluated to determine final acceptance of the FAE parts and release to produce production quantities.

3.2.4.3 The Supplier shall not proceed to manufacture parts beyond the initial First Article quantity until a successful FAE has been completed and written notification to proceed has been received from the Company's subcontract administrator.

The criteria established for the performance of the FAE, and subsequent production, shall also apply to the Supplier's subcontractors and sub-tier subcontractors as deemed appropriate by the Company. A listing of any such subcontractors and their involvement shall be submitted to the Company. The Company reserves the right to provide oversight of these proposed Subcontractors if deemed necessary. Signed approval of the proposed Subcontractors shall be received by the Supplier from the Company STR prior to proceeding with fabrication.

3.2.4.4 Once the Company has approved an FAE, any subsequent process changes by the Supplier to manufacturing and acceptance procedures, facilities, type of personnel, testing, etc., which could conceivably impact product quality, shall require the Supplier to notify the STR of the proposed changes. The STR shall then determine if a new First Article Evaluation is warranted.

3.2.5 Certificates of Conformances (CoCs)

CoCs for procured items shall meet the following requirements:

a. The CoC shall identify the purchased item by the purchase order number.

b. The CoC shall identify the specific procurement requirements met by the purchased item, such as codes, standards, and other specifications. This may be accomplished by including a list of the specific requirements or by providing a copy of the purchase order and the procurement specifications or drawings, together with a suitable CoC.

c. The CoC shall identify any approved changes, waivers, or deviations applicable to the item.

d. The CoC shall identify any procurement requirements that have not been met, together with an explanation and the means for resolving the request for waiver or deviation.

e. The CoC shall be signed or otherwise authenticated by a person who is responsible for this quality assurance function and whose function and position are described in the quality assurance program of the Supplier.

f. The Supplier's certification system, including the procedures to be followed in filling out a CoC and the administrative procedures for review and approval of the certificates, shall be described in their quality assurance program.

3.3 Fabrication and Assembly Requirements

The Supplier shall prepare a written, step-by-step, controlled manufacturing plan for all work to be performed. This plan shall include at a minimum:

a. Materials to be procured
b. Suppliers to be used
c. Quality Program used to buy or manufacture each subassembly
d. Major fabrication steps (sequence of operations)
e. Equipment to be utilized
f. All in-process checks
g. All welding
h. All weld inspection/examination including Non-Destructive examination and testing
i. Dimensional inspection.

3.4 Requirements

3.4.1 Welding and Weld Repair (If Required)

3.4.1.1 All welds on the drum assemblies shall be done either by the GTAW, GMAW, or PAW process, manual or automatic, at the discretion of the Supplier unless specified otherwise on the drawings.

3.4.1.2 Weld symbols are provided on the Company's drawings indicating for each weld the type of weld and dimensions of weld.

3.4.1.3 Butt welds in rolled sheet, pipe and angle joints shall be full penetration butt welds.

3.4.1.4 Markings on the weldment materials shall not be removed until after all weld examination is complete.

3.4.1.5 Welding shall be done in accordance with welding procedure specifications that are written and performance qualified in accordance with the ASME Code, Section IX.

3.4.1.6 Welders shall be performance qualified to weld using these procedures, and their qualifications documented in accordance with the ASME Code, Section IX.

3.4.1.7 Welding fabrication requirements stated in the ASME Code, Section VIII, Division 1, paragraphs UW-26 through UW-48 shall be met.

3.4.1.8 Welders performing two or more welds in one day that are rejected based upon welder technique shall be re-qualified to the appropriate welding procedures. Reference Section IX, and paragraph QW-320 of the ASME Code.

3.4.1.9 If a weld is rejected, the area may be reworked by the Supplier and re-examined. After two unsuccessful repair attempts, the Company shall be notified for approval to perform more repair attempts. The Company may, at its option, choose to reject further repair efforts and require that a replacement part be fabricated.

3.4.1.10 Prior written approval of the Company shall be obtained for any weld repair on base materials, and the weld repair areas shall be noted in a Request for Waiver or Deviation (RFWD) Form accompanied by a sketch and the CMTR for the material to be weld repaired. Note that depending on the specific defect in a specific material, the Company may or may not approve the weld repair, even if it is permitted by the material specification.

3.4.1.11 The Supplier shall submit welding information as Appraisal Data in accordance with Attachment A.

a. Job Specific Welding Procedure Specifications (WPS)

b. Job Specific Welding Procedure Qualification Record for each WPS submitted (unless WPS is prequalified (PQR).

c. Job Specific Welder Performance Qualification (WPQ) records, including evidence of process usage updates

d. Job Specific Visual examination and Nondestructive examination procedures

e. Job Specific Certification records of examination personnel

f. Job Specific Post Weld Heat Treatment (PWHT) procedures with appropriate procedure demonstrations (as required) and Supplier's acceptance documentation

g. Provide a list of all welded assemblies not fabricated in accordance with Supplier's welding program. Include any welded assemblies to be purchased as commercial-off-the-shelf

3.4.1.12 The Supplier shall submit welding information as Approval Data in accordance with Attachment A.

a. Welding procedure specifications (WPS)

b. Procedure Qualification Records (PQR) for each WPS submitted (unless WPS is prequalified)

c. Welder Performance Qualification (WPQ) records, including evidence of process usage updates.

d. Roster of all welders to be used to perform work with continuity/expiration dates identified for each process the welder is qualified

e. Updated records (Roster) as required throughout the contract duration, to demonstrate welders submitted have maintained their qualifications

f. NDE-Visual examination and nondestructive examination procedures, VT, MT, PT, RT, UT (as applicable)

g. NDE-Certification records of examination personnel

h. NDE-Procedure for Qualification and Certification of Nondestructive Testing Personnel

i. NDE-Current eye examination record (Annual) for examination personnel

j. Certified Material Test Report (CMTR) for weld filler materials (as required) for each Heat/Lot to be used

k. Weld filler material control procedure

l. Welding fabrication drawings for all welded components

m. Weld examination records, weld maps, radiographs, and PWHT chart recordings

3.4.1.13 Nonconforming Welds

Completed welds that have been inspected and accepted but are later found not to be in compliance shall be documented and submitted to the Company on a nonconformance report in accordance with Supplier's nonconformance procedure. The Supplier's nonconformance procedure shall include language to address welding nonconformances that occur due to both procedural and hardware deficiencies. If a repair by welding is required, the Supplier shall complete a repair procedure that includes the WPS with specific instructions for repair. Additional supporting documents, as required, to make the repairs shall be submitted to the Company. Company approval of the repair procedure shall be obtained before commencing the repairs. Every nonconformance report (NCR) dispositioned "Use-As-Is" or "Repair" requires written concurrence from the Company accepting the disposition and technical justification before continuing work associated with the Nonconformance. A disposition of Rework does not require Company approval. A submittal of the Supplier's nonconformance procedure shall be submitted to the Company in accordance with the Submittal checklist, Attachment A.

3.4.1.14 Weld Filler Material Requirements

a. Weld Filler Material (WFM) shall be selected that matches the base metal as close as possible for mechanical and corrosion resistant properties and be listed on the Welding Procedure Specification (WPS).

b. WFM shall be specified as manufactured in accordance with recognized ASME standards where possible. Use matching WFM or material recommended by the base metal supplier when there is no existing WFM with an assigned AWS classification.

c. Purchase weld electrodes/filler materials with a CMTR as identified in Section 3.6.1.15 below. Submit a Certified Material Test Report (CMTR) for WFM to be used. The reporting requirements are specified in the "Test Requirements for CMTRs" table(s) below for the listed WFM. The CMTR shall provide traceability to the Supplier's purchase order for each heat/lot received. For WFM without an SFA classification, provide the same level of testing, product marking, and packaging, etc. that is required for WFM with a SFA Classification. Use the Supplier's standard designation in lieu of the SFA classification to mark each piece of WFM and the shipping package.

d. All WFM shall meet the requirements of ASME BPVC Section II Part C, *Specification for Welding Rods, Electrodes, and Filler Metals*, except as noted.

3.4.1.15 Weld Filler material Procurement Requirements

a. Weld Filler Material (WFM) and fluxes shall be purchased from manufacturers or suppliers with established Quality System Programs that meet the requirements of ASME BPVC Section III, Rules for Construction of Nuclear Facility Components – Sub-section NCA General Requirements for Division 1 and Division 2- Article NCA-3800 Metallic Material Organization Quality System Program and are active NCA 3800 Quality System Certificate (QSC) holders. The manufacturer or supplier that holds the certificate shall be evaluated by the Supplier and be currently listed on their Quality Approved Suppliers List (QASL).

b. The procurement requirements for WFM apply to all WFM utilized by Supplier organizations that procure their own welding materials. The Supplier at their discretion may elect to procure and use materials to stricter standards. The sections below list the level of Certification for the most commonly used WFM classifications for various applications. Other classification WFM are permitted with the prior approval of the Company. All WFM shall be procured in accordance with material designation (SFA) ASME BPVC Section II SFA 5.01, Procurement Guidelines for Consumables - Welding and Allied Processes - Flux and Gas Shielded Electrical Welding Processes. The level of certification and testing required for these alternate materials shall be the same as required for the similar components described below.

3.4.1.15.1 Weld Filler Material for Stainless Steel Base Materials

Shall comply with ASME BPVC Section II SFA 5.9, Specification for Bare Stainless Steel Welding Electrodes and Rods:

a. Use classification ER308L filler materials for welding 304 or 304L stainless steel base materials. When CMTRs are required, the reports shall also record a minimum delta ferrite of 5 ferrite number and test method.

b. The maximum acceptable carbon content for all "L" grade (low carbon) weld filler material is 0.03%. Heat analysis of weld deposit shall be performed to determine the chemical composition of the material.

3.4.1.15.2 Test Requirements for CMTRs

ASME SPECIFICATION	ASME SFA 5.01 TEST REQUIREMENTS					
	Lot Class	Level of Test	Chemical Analysis	Tensile	Soundness	Impact
5.9 Bare Stainless Steel Welding Electrodes and Rods	S3 or S4	I	Rod/Wire	No	No	No

3.4.2 Weld and Surface Examination (If Required)

Personnel Certification Requirements for Weld Examinations

a. Personnel performing nondestructive examination other than visual shall be currently certified per the employer's written practice in accordance with SNT-TC-1A. Only individuals certified as NDT Level II or III may perform nondestructive examinations in accordance with this specification.

b. Personnel performing visual examination of welds shall be currently certified either as an AWS CWI or as a visual testing Level II or III per the employer's written practice in accordance with SNT-TC-1A. (Note: Eye exams shall be performed on an annual basis and comply with Jaeger 1 visual acuity.)

c. The Level III, in the methods certified, shall conduct the examination of Level II personnel for those same methods.

3.4.2.1 NDE Weld examination procedures shall meet the requirements of the ASME Code, Section V.

3.4.2.2 Certified weld examination reports shall be submitted in accordance with Attachment A for all weld examinations and shall include:

a. Drum assembly serial number
b. A weld map showing the location of the weld
c. Welder's ID
d. Examiner's name
e. The time and date of the weld examination
f. Examination procedure used
g. Welding procedure specification (WPS) number for each weld
h. Heat numbers of the materials joined
i. Heat number of the weld filler
j. Examiner's remarks

3.4.2.3 The examiner's remarks shall include the results of the examination, and acceptance or rejection of the weld based on the stated criteria, and shall include a description and sketch showing the location of any defects.

3.4.2.4 The acceptance criteria for joint fit-up and alignment, and for visual examination of welds are given in the ASME Code, Section VIII, Division 1, paragraphs UW-31 through UW-36. In addition, any visible defects such as lack of fusion, lack of penetration, linear or crack like defects, and visible porosity, are unacceptable.

3.4.3 Cleaning and Passivation

3.4.3.1 After final machining and examination of all welds except the attachment welds for the drum body final closure weld of the drum lid weldment, and prior to filling with Packcrete and Catalog No. 277-4 (see SPC M801580-0003 and SPC JS-YMN3-801580-A005), clean and passivate all stainless steel surfaces of the drum assembly in accordance with ASTM A 380. A certified record of completion of this cleaning step shall be submitted to the Company in accordance with Attachment A.

3.4.3.2 On drawing M2E801580A002 verify that the drum bottom or Packcrete fill hole diameter, where the drum flat cover is assembled and welded to the drum body is round or circular to a tolerance of ±0.03 in. before filling with Packcrete. If not adjust and rework the drum body until it is round or circular to a tolerance of ±0.03 in.

3.4.3.3 After weld examination, cleaning, and passivation for the drum body and drum lid weldment, follow SPC M801580-0003 to fill with Packcrete.

3.4.3.4 After the closure weld on the top plug weldment and the attachment weld on the drum body bottom are examined, clean and locally passivate the weld areas and heat affected zone areas. A certified record of completion of this cleaning step shall be submitted to the Company in accordance with Attachment A.

3.4.3.5 Cleaning procedures for the stainless steel, including weld areas, shall be submitted to the Company for approval, prior to the start of fabrication, in accordance with Attachment A.

3.4.3.6 Finished components awaiting assembly and final drum assemblies shall be free of dirt, debris, foreign objects, cutting fluids, metal chips, grinding residue, and other foreign substances.

3.4.3.7 The Supplier shall clean, cover, and protect parts and subassemblies from becoming dirty while in storage, and to the extent practicable, in the shop environment while performing work.

3.4.3.8 Only non-chloride bearing chemicals shall be used for cleaning (such as trisodium phosphate detergent or acetone).

3.4.3.9 A list of cleaning chemicals to be used shall be submitted for approval in accordance with Attachment A. Safety Data Sheets (SDS) of all cleaning chemicals shall be provided to the Company before use.

3.4.3.10 Water used in cleaning shall have a maximum chlorine content of 4 parts per million tested monthly.

3.4.3.11 Certified cleaning and passivation procedure and report shall be submitted in accordance with Attachment A.

3.5 Government-Furnished Equipment

3.5.1 Modified Hex Nut

Modified Hex Nuts per DS 801580-0001 shall be supplied by the Company

3.6 Final Examination of Finished Surfaces

3.6.1 All accessible welds of the drum assembly (drawing M2E801580A001, M2E801580A002, and M2E801580A004), the drum body liner (drawing M2E801580A003), the drum lid (drawing M2E801580A006), and the top plug (drawing M2E801580A008) shall be examined with liquid penetrant in accordance with NB-2546 (see Section 3.4 for additional requirements for the materials used in liquid the penetrant examination).

3.6.2 The procedure for final surface examination including sample test reports shall be submitted to the Company for approval in accordance with Section 4.1.1 and Attachment A.

3.6.3 The results of the final surface examinations shall be documented in a certified examination report and provided to the Company in accordance with Section 4.1.1 and Attachment A.

3.6.4 If a defect is found, the component shall be tagged and segregated to prevent inadvertent use, and the Company shall be notified in writing using the RFWD in accordance with Section 3.12 and Attachment A, for disposition.

3.6.5 Defective areas may be weld repaired by the Supplier only if specifically permitted by the Company in writing, and the area re-examined. The Company may, at its option, choose to reject repair efforts and require that a replacement part be fabricated.

3.7 Dimensional Inspection

3.7.1 The Supplier shall submit inspection procedures for Company approval in accordance with Attachment A.

3.7.2 Dimensional requirements specified on the Company's drawings require inspection procedure that shall include:

a. A listing of features to be inspected
b. Identification of inspection equipment to be used inspect each dimension or tolerance
c. Sample data sheets with adequate data recording space to record inspection results
d. Adequate information to ensure traceability of inspection data to specific serial numbered drum assemblies

3.7.3 The Supplier shall be responsible for determining stock sizes so that the finished machined components meet the dimensions and tolerances specified on the attached drawings.

3.7.4 Prior to performing final inspection, the Supplier shall perform all deburring and cleaning operations required to ensure that drum assembly is free of all fabrication and handling defects and that no foreign materials are present on the drum assembly surfaces or features.

3.7.5 Inspection, Measuring and Test Equipment shall be calibrated and certified by an organization with ISO 17025 accreditation, or Company approved equal, and traceable to the National Institute of Standards. Documentation shall be submitted in accordance with the attachment A, Submittal Checklist.

3.7.6 Where inspection or test equipment yields quantitative readings, actual measurements and deviation from nominal readings shall be recorded.

3.7.7 The Supplier's inspection shall include, as a minimum, the following:

a. All dimensions and tolerances on Company drawings which are marked with a diamond symbol containing an "I" or "S". These dimensions and tolerances require 100% inspection and documentation. Quantitative documentation of these features shall be provided to the Company for each drum assembly.
b. Edge breaks.
c. Surface finish.
d. Cleanliness as specified in Section 3.4.3.
e. Part identification as specified by the drawings.

3.7.8 Certified inspection report(s) shall be prepared and submitted to the Company in accordance with Attachment A.

3.7.9 Straightening, flattening, and forming of the weldment by mechanical means after welding may be required to ensure proper assembly and fit. The surfaces of areas of the weldment that have been worked shall be examined visually and with liquid penetrant to ensure that no cracks are present and that the weldment has not been degraded. Adjacent welds to these areas shall also be visually and liquid penetrant examined. The acceptance criteria are that no cracks are found in the weldment. The areas worked and the visual inspections performed shall be noted on an inspection report. This metal working and examination shall be performed prior to the installation of Packcrete or Catalog No. 277-4.

3.7.10 All equipment and instruments (Measuring and Testing Equipment (M&TE)) used in the conduct inspections shall bear a calibration sticker that shows the equipment to be within its calibration period. Calibrations must be performed by a laboratory that meets ISO 17025:2005. All calibration sources shall be traceable to the National Institute of Standards and Technology (NIST). All certification documentation shall be submitted to the Company in accordance with Attachment A.

3.8 Schedule (Specify to be submitted for approval)

The Supplier shall prepare a proposed schedule for the fabrication of the ES-3100 Drum Assemblies specified herein. This proposed schedule shall be submitted with the offer in accordance with Attachment A.

The Company will conduct oversight activities. Hold/witness points will be identified by the Company in the Supplier's schedule after it is submitted to the Company for review.

3.9 Deliverables (Including Submittals)

The deliverables for this specification include, but is not limited to:

a. Completed and assembled ES-3100 Drum Assemblies
b. All Requests for Waiver/Deviations shall be closed
c. All submittal documentation in accordance with Attachment A, with applicable documentation in data packages specific to each ES-3100 Drum Assembly identified by its serial number.

The documentation required with the proposal (WP) as indicated in the "Submittal Checklist," Attachment A, shall be submitted to the Company in the quantities listed with the Supplier's offer. Submittals shall be e-mailed to the Company SA and the STR.

The Company will review the submittals that are required prior to fabrication as indicated in the "Submittal Checklist," Attachment A, and respond as shown in the "Instructions to Supplier for Preparation of Submittals," Item h.

The Company shall review the submittals required per Attachment A. Shipping shall not commence without documented permission from the Company.

3.10 Packaging, Handling, Shipping, and Storage Requirements

3.10.1 A packing plan for shipment of Drum Assemblies shall be sent to the Company for approval in accordance with Attachment A.

3.10.2 The packing plan shall include a sketch of the packaging to be used to transport the Drum Assemblies, a list of the documentation that will be included, and a description of the method of transportation.

3.10.3 The drum surfaces must be protected during shipment.

3.10.4 The Supplier shall not ship Drum Assemblies with unapproved RFWD's

3.11 Marking and Identification Requirements

3.11.1 Each drum assembly shall be marked as specified on Company's drawings.

3.11.2 Permanent serial numbers for each drum assembly shall be assigned by the Company and identified in the Purchase Order.

3.12 Requests for Waiver or Deviation

3.12.1 After award, if a waiver or deviation from the specified requirements is desired, then the Supplier shall submit to the Company a Request for Waiver or Deviation form: UCN-13816B. The Company will provide this form upon request.

3.12.2 Use the UCN-13816B form to request permission to change or deviate from the specified requirements; obtain Company approval before proceeding with any changes.

3.12.3 Email the completed form to the Subcontract Technical Representative (STR).

3.12.4 Use the form to report any of the following conditions:

a. A request for deviation from the contract requirements

b. Anytime a requirement contained within the original specification or a contract modification approved by the Company is violated

c. There is nonconformance that cannot be corrected unless an item or process is modified, reworked, or repaired to an equivalent functional condition

d. A request for Company approved substitutions shall be submitted using the RFWD form for Company approval prior to implementation. Adequate information shall be provided with the request so that the Company can determine if the item is equivalent.

3.13 Documentation Retention

3.13.1 Documentation of all inspection and test results shall be maintained by the Supplier for three years after delivery to the Company.

3.13.2 The Company shall be given access to this data upon request.

3.14 Use of Subcontractors

The Supplier shall ensure that all its suppliers and subcontractors comply with the requirements of this specification (including quality assurance requirements). Supplier and subcontractor procedures, approved by the Supplier, shall be included in the procedures submitted to the Company for review and approval.

3.15 Witness of Documentation and Processes

3.15.1 The Company shall be given access to all documentation and shall be allowed to witness any of the processes associated with this specification during the performance of the contract.

3.15.2 The Company shall be informed prior to the start of any testing activities and an agreed upon schedule shall be established. The Company reserves the right to witness any testing activities performed.

3.16 Nonconformance Control

3.16.1 Nonconforming products shall be documented using the Supplier's designated form as required in their QA Plan, and a copy sent to the Company representative.

3.16.2 Deviations or waivers shall be controlled using, Request for Waiver or Deviation, and sent to the Company for approval.

3.17 Approved Procedures

a. Manufacturing, examination, and testing processes shall be controlled by procedure and performed by qualified personnel.

b. Procedures shall incorporate a mechanism to identify process step completion.

c. Procedures shall be submitted to the Company for approval in accordance with Attachment A.

4.0 QUALITY ASSURANCE REQUIREMENTS

4.1 Final Acceptance Method

4.1.1 Final acceptance will be based on the results of the following:

a. Certified Data Package

b. Dimensional inspection reports of each ES-3100 drum assembly in accordance with Section 3.7

c. Any testing witnessed by the Company

d. Submittals listed on Attachment A

e. After all testing, a liquid penetrant report in accordance with NB-2546

4.2 Inspection/Testing Requirements

4.2.1 NDE Examiner Qualifications

4.2.1.1 Qualifications of the personnel performing material or weld examination shall be those provided in NB-5500.

4.2.1.2 Qualification records shall be submitted for approval with the examination procedures in accordance with Attachment A.

4.3 Quality Requirements

The Supplier shall perform all work under a Quality Assurance (QA) Program that complies fully with both 10 CFR 71 Subpart H and NQA-1. If requirements are unclear, or full compliance with both Subpart H and NQA-1 is uncertain, the Supplier shall contact the Company for resolution.

Components (including Packcrete raw materials) are Nuclear Safety Related items. If the Supplier purchases Nuclear Safety Related materials or services from a source that does not have an NQA-1 compliant QA Program, they shall be dedicated in accordance with Commercial Grade Dedication Plans approved by the Company.

For special processes including, but not limited to, flow-forming, heat treating, welding, and NDE, the Supplier shall provide control over activities affecting the quality of the materials and components as necessary to assure conformance to the approved design.

The Supplier shall have implemented and maintain a quality system in accordance with ASME NQA-1 Quality Assurance (QA) Program that meets the requirements of NQA-1 2008, 1a-2009, 1b-2011 Part 1, Section 1-18. A copy of the Supplier's QA Program Manual shall be submitted with the bid in accordance with Attachment A for review and approval. The Supplier shall comply and conduct all work in accordance with their Quality Assurance program and this Equipment Specification.

An uncontrolled copy of the Supplier's controlled QA Program and all applicable subtier suppliers' quality assurance program manuals shall be submitted as Offer Appraisal Data in accordance with Attachment A.

The Supplier shall provide an Excel transmittal or similar file to document the transmission and status of data files. This file shall be updated after each transmission or status change and shall at least identify data by; name, date of transmission, file size, and status (i.e. for review or approval). This file shall be included with the submitted data.

4.3.1 Suspect/Counterfeit Items

The Supplier's QA Program shall implement DOE O 414.1D Attachment 3, with respect to Suspect Counterfeit Items.

Contract terms and conditions that establish the plant's expectations with respect to the Supplier's role in preventing the introduction of Suspect /Counterfeit Items S/CI.

The Supplier's requirements for preventing S/CI from being introduced into the Company's supply chain are referenced in the General Terms and Conditions of the Request for Solicitation and/or Purchase Order.

The Supplier shall use components supplied or assemblies of components from Original Equipment Manufacturer (OEM) or authorized distributors.

4.4 Acceptance Criteria

4.4.1 Approval Data

Approval Data will be reviewed and must be approved by the Company before the Supplier proceeds with the applicable production activity. The Supplier shall schedule at least 4 weeks for Company

review of submittals. A list of the required Approval Data can be found in Attachment A to this specification.

4.4.2 Certified Data

a. A list of the required Certified Data can be found in Attachment A of this specification.
b. An electronic .pdf version of the Certified Data Package shall be provided prior to or with the shipment.
c. The Certificate of Conformance shall be signed by the Supplier and identify the applicable serial number of the containment vessel included in the shipment, one Certificate of Conformance for each Main Assembly (M2E801580A031).
d. The Certificate of Conformance shall attest that the Drum Assembly conforms to the requirements of this specification and Company drawings and approved RFWD's.
e. The assembly drawing number (M2E801580A001) associated with each Drum Assembly shall be recorded on the Certificate of Conformance.
f. The Certified Data package for each Drum Assembly shall be complete, legible, indexed.
g. The Certificate of Conformance shall list the approved RFWD's if applicable.

4.5 Personnel Qualifications/Certifications

4.5.1 Training and Qualification of Personnel

a. The Supplier shall provide for the training and qualification of personnel to ensure their competence in the use of process procedures and specifications.
b. Records of personnel qualifications shall be made available to the Company upon request.

Attachment B: Instruction to Supplier for Preparation of Submittals

Note 1 --All correspondence shall be addressed to the Technical Representative identified by the Company. The Supplier shall forward submittals via transmittal letter to the Company at the address specified in the contract.

Note 2 -- The submittal must have adequate detail so that full compliance with the requirements may be determined. For example, a simple off-the-shelf item to be used in an assembly may only need a Supplier's cut-sheet to show compliance, but a factory acceptance test (FAT) developed and submitted by the Supplier must have each test step detailed with acceptance criteria consistent with the requirements.

a. Review submittal before transmitting to the Company to verify conformance with requirements of the contract documents (e.g., field measurements, field construction criteria, or Supplier's catalog numbers).
b. Coordinate submittals with the work requirements and the contract documents.
c. Organize Submittals
   - Do not use highlight marker or color coding on submittals.
   - The minimum resolution used for scanning submittals shall be 300 dpi x 300 dpi.
   - For submittals containing color information important to the record, a 24-bit color setting should be used.
   - Submittals are to be legible and in the format specified on the submittal checklist.
   - Pen and ink changes are to be made in non-erasable ink, legible, dated and initialed.
   - Mark specific options provided for the work, and cross out options not provided.
   - Each submittal shall be sent as a single pdf file unless otherwise specified.
d. Label submittals with the applicable item number, reference, and requirement description as summarized in the Submittal Checklist. Unlabeled submittals will be returned to the Supplier without review.
e. Include with submittals a transmittal letter that identifies individual documents by specification section.
   - Transmittal for submittals shall be numbered using the purchase order number followed by a 4-digit sequential number. (Example: 430001111-0001).
   - Embedded comments or questions that are not included on the transmittal may not be addressed/resolved by the Company.
f. Direction will be given at the time of award to either upload submittals to a company provided URL address or send by email to a company provided email address.
g. If using a company provided URL to upload submittals, notify the Company via email when submittals have been placed.
h. After review of a submittal, the Company will assemble comments and provide a status on the documents. An example of this submittal status stamp is shown below.

DOCUMENT REVIEW STATUS		
1	☐ Work may proceed.	
2	☐ Revise & resubmit. Work may proceed subject to incorporation of changes indicated.	
3	☐ Revise & resubmit. Work may not proceed.	
4	☐ Review not required. Work may proceed.	
Permission to proceed does not constitute acceptance or approval of design details, calculations, analysis, test methods developed or selected by the supplier and does not relieve supplier from full compliance with contractual obligations.		
REVIEWED BY:	Print Name/Signature :	Date:

i. If a submittal is being resubmitted, then reference the applicable item number, reference, and requirement description and identify it as a resubmittal.
j. Company response will only be returned to the Supplier for those submittals with a Submittal Purpose of "For Action, "unless it is determined that a submittal transmitted "For Information" is not acceptable.
k. AFTER written approval is obtained, THEN proceed with work requiring approved submittals.
l. When approval submittals are required, work done before Company approval is at the Supplier's risk.
m. Maintain a copy of the company-approved submittal and status page on file.

1.0 SCOPE

This specification, equipment specification SPC-M801580-0002, *ES-3100 Ethylene Propylene Diene Monomer {EPDM) Containment Vessel 0-rings,* the Company's drawing, and the referenced codes and standards in Sect. 2.2 of this specification state the requirements for the procurement of materials and components, fabrication, inspection, examination, assembly, and testing of the containment vessel (CV) for the ES-3100 shipping package.

The CV will be manufactured in accordance with the applicable requirements stated in the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (B&PVC), hereinafter referred to as the ASME Code, Section III, Division 1, Sub-section NB for Class 1 Components as described on the Company's drawings and in this specification. The CV will not require an N stamp. However, if the Supplier does not have a certificate of authorization from the ASME to apply the N stamp, the Supplier shall be familiar with, and capable of meeting those requirements in Section III, Division 1, Subsections NB and NCA of the ASME Code that are referenced in this specification. The reference to the Inspector in any of the ASME Codes shall in this particular case be that person designated by the Company.

If conflicting requirements appear in these documents, the Supplier shall immediately notify the Company for resolution.

Any deviation from the requirements specified is not allowed without the Company's written approval of a written request for waiver or deviation.

1.1 General Description of the Item

The CV is a leak tight metal vessel capable of maintaining content quality during and after designated accident scenarios.

2.0 REFERENCES

2.1 Definitions

Company – The Company, as used in this specification, is the buyer of the Supplier's final product (i.e., Y-12 National Security Complex)

Deviation - A specific written authorization, granted by the Company **prior to the manufacture** of an item, to depart from a subcontract requirement for a specific piece or pieces of equipment or a specified period of time.

First Article - Product that is submitted to Y-12 for evaluation prior to the Supplier being released to manufacture the remaining quantities in the subcontract. This product must be representative of production items by virtue of having been produced and inspected using the same facilities, testing, processes, and type of personnel planned for use in production.

First Article Evaluation (FAE) – An evaluation by Y-12 of the first unit(s) manufactured and the facilities, tooling, processes, etc. concerned with the manufacture and inspection.

Hold Point - A hold point is defined as the designated point(s) in the fabrication where the Supplier will stop and hold further production. The Y-12 contact will be provided production data and will decide if it will be necessary to visit the manufacturing facility or if the supplied data will be sufficient.

Manufacturing Plan – A written, step-by-step, process plan for the equipment to be fabricated. The plan includes material control, major fabrication steps, hold points, all in-process inspections, welding, welding inspection/examination, dimensional inspections, testing, and shipping.

Non-conformance - A deficiency in characteristic, documentation, or procedure that renders an item to be in non-compliance with specified requirements.

Offeror - The Organization or person(s) submitting an offer to the Company to provide the product(s) described.

Request for Waiver or Deviation (RFWD) - A formal request by the Supplier for a waiver or deviation to the equipment specification, drawing, or PO using the Company form, which can be provided by the SA or STR. The form must be approved by the Company in writing before the Supplier being granted authorization to proceed.

Supplier - Any individual or organization that furnishes items or services in accordance with a purchase order. Also an all-inclusive term used in place of the following: vendor, seller, subcontractor, dealer, fabricator, consultant, manufacturer, distributor, and their sub-tier levels.

Subcontract Administrator - The person(s) designated in the subcontract as having authority to act officially for the Company.

Subcontract Technical Representative (STR) – The Subcontract Technical Representative, as used in this specification, is the person designated by the Subcontract Administrator as having the authority to represent the Company in technical matters.

Traveler - A written, step-by-step, process document used for the control of components/equipment to be fabricated. The traveler includes material identification, all fabrication steps, hold points, all in-process inspections, welding, welding inspection/examination, dimensional inspections, testing, and preparation for shipping.

Waiver - A specific written authorization, granted by the Company, to accept a configuration item or other designated items which, during production or after having been submitted for inspection, are found to depart from specified requirements, but are considered suitable for use as is or after rework by an approved method.

Witness Point - The Witness point is similar to the hold point except the manufacturing, testing or inspection is halted until the Y-12 representative(s) can visit the manufacturing facility and witness the designated operations.

2.2 Codes/Standards/Orders/Regulations

CVs shall be fabricated, inspected, and tested according to the design drawings and the applicable documents referenced herein.

- American National Standards Institute, ANSI N14.5-1997, American National Standard for Radioactive Materials – Leakage Tests on Packages for Shipment.

- American Society of Mechanical Engineers, Boiler and Pressure Vessel Code, Section III, Division 1 - Subsections NB and NCA, Class 1 Components, 2019.

- American Society of Mechanical Engineers, Boiler and Pressure Vessel Code, Section II, Parts A and C, 2019.

- American Society of Mechanical Engineers, Boiler and Pressure Vessel Code, Section V, 2019.

- American Society of Mechanical Engineers, Boiler and Pressure Vessel Code, Section IX, 2019.

- American Society for Nondestructive Testing, No. SNT-TC-1A, Recommended Practice for Nondestructive Testing Personnel Qualification and Certification, 2016.

- American Society for Testing Materials, ASTM A 380-17, Standard Practice for Cleaning, Descaling, and Passivation of Stainless Steel Parts, Equipment and Systems.

- Society for Protective Coatings, SSPC SP 5/NACE No. 1, White Metal Blast Cleaning, 2006.

- Title 10, Code of Federal Regulations, Section 71, Subpart H, Latest date.

All references to the ASME Code in this document are to the ASME Boiler and Pressure Vessel Code, 2019 Edition.

3.0 ITEM REQUIREMENTS

The Supplier shall be responsible for supplying all materials, services, facilities, and equipment to meet the requirements of this specification and Company drawings unless otherwise noted.

3.1 Performance Requirements

3.1.1 Boiler and Pressure Vessel Code Compliance

3.1.1.1 The term ASME Code in this specification refers to the ASME B&PVC. A paragraph referenced as NB-XXXX or NCA-XXXX, where XXXX is a specific paragraph number, is that paragraph in Section III, Subsection NB or Subsection NCA, respectively, of the ASME Code. If a given paragraph is referenced as a requirement, all subparagraphs under the stated paragraph shall also be requirements. For example, if NB-2430 is referenced as a requirement, not only do the applicable

requirements of NB-2430 apply, but also those of NB-2431, NB-2431.1, NB-2431.1(a), NB-2432, etc.

3.1.1.2 The CV shall be manufactured in accordance with the applicable requirements stated in the ASME B&PVC, Section III, Division 1, Sub-section NB for Class 1 Components as specified on the Company's drawings and in this specification. A certificate of compliance to the code shall be supplied to the Company.

3.1.1.3 The Supplier shall hold a Certificate of Authorization from the ASME that authorizes it to manufacture and inspect pressure vessels in accordance with Section VIII or Section III of the ASME Code. If the Supplier does not have a certificate of authorization for Section III, the Supplier shall provide data with its offer that demonstrates its ability to meet the requirements in Subsections NB and NCA as referenced in this specification.

3.1.1.4 The Supplier is not required to Code stamp the CV. However, the Supplier and an Authorized Nuclear Inspector (ANI) shall fulfill their duties per the Code as though the CV will be Code stamped and both shall sign the Certificate Holder's Data Report, Attachment D.

3.1.1.5 The ANI is not required to verify the design calculations.

3.2 Design Requirements

3.2.1 Materials and Material Examinations

3.2.1.1 Material requirements are specified on Company drawings, in this specification, and in the documents referenced in this specification.

3.2.1.2 The *Containment Vessel Body Assembly* (drawing M2E801580A012), *Containment Vessel Sealing Lid* (drawing M2E801580A015), and the Closure Nut (drawing M2E801580A016) shall be considered pressure retaining materials as defined in paragraph NB-2110 and therefore shall meet the applicable requirements of NB-2120.

3.2.1.3 There are two CV assemblies shown on Drawing M2E801580A012, Parts M2E801580A012-1 and M2E801580A012-4. The CV assembly(s) to be fabricated will be specified in the Company's purchase order. Note that Part M2E801580A012-4 is fabricated by welding a forged bottom, and forged top flange to a cylindrical shell machined from seamless pipe as shown on the drawing.

The flow formed or machined CV body option, Part M2E801580A012-1, shall be flow formed or machined from a single forged billet or bar. Special requirements for the flow formed option are given as follows:

a. The flow formed, heat treated, and finished machined CV body, Part M2E801580A012-1, shall meet the chemical composition requirements of ASME SA-182 for Grade F304L for a forged component as well as the requirements listed below. After final forming, parts shall be solution annealed and quenched per the requirements of ASME SA-182 for Grade F304L. In addition, the requirements of NB-2180 shall also apply. A certified heat treatment Procedure shall be submitted to the Company for approval. A certified heat treatment report shall be provided to the Company for approval stating for each furnace charge the following information: the serial numbers of the CV bodies heat treated in the furnace charge, the time and date of the heat

treating, the person responsible for the heat treating, the time-temperature profile of the furnace and representative parts of the furnace charge, the quench medium, and all other pertinent details of the heat treating. Such a heat treating report is required for all heat treating, both in process annealing and final heat treatment.

b. It shall be demonstrated that the flow formed, heat-treated CV bodies, Part M2E801580A012-1, meet the mechanical property requirements of ASME SA-182 for Grade F304L by mechanical testing of coupons. The test coupons are to be machined from the same heats of materials used to form the CV bodies, and shall have the same or greater amount of cold work (plastic strain) as the CVs will have as a result of the forming process. The mechanical tensile testing of coupons shall be done in accordance with ASME SA-370: A minimum of six test coupons shall be tested for each final heat treatment furnace charge. The first set of three test coupons, chosen at random, shall be tested without being heat treated. The second set of three of more test coupons shall be heat treated together with the CV bodies, and then tested. The heating rates and maximum temperatures of the test coupons shall be representative of the entire furnace charge. Test coupons are not required to be heat treated with intermediate processing annealing steps, but are required in the final heat treatment furnace charge.

c. The results of all the testing of the sample coupons shall be documented, certified and reported to the Company. The mechanical properties test report shall contain the following information: a description of the furnace charge in which the test coupons are to represent; the times and dates of the heat treating and the testing; the person responsible for the testing; a statement that these coupons are prior to or after heat treatment; a description of the testing including a sketch of the tensile test specimen; the make, model, serial number, and current calibration data of the testing machine(s) used in the testing; reference to the written testing procedure used; the resulting measure yield strength, ultimate strength, % elongation and % reduction in area; and any pertinent remarks.

d. It is permissible to deviate from the liquid quench requirements stated in SA-182 provided that the cooling rates of the alternate quench are such that the heat treated material is not susceptible to intergranular corrosion due to chromium carbide precipitation. This is to be demonstrated by testing according to Practice E of ASTM A262, and meeting the stated acceptance criteria. This shall be accomplished by obtaining test coupons from each furnace batch that represent the slowest cooling rates of the batch, or by following a heat treating procedure that has been qualified to ensure that the heat treated batch will not be sensitive to intergranular corrosion. In any case, the requirements of NB-2180 shall apply.

e. The heat treating procedure must be qualified by measuring the annealing temperatures, soak times and cooling rates of the furnace batch, and then testing heat treated specimens that represent the lowest annealing temperatures, soak times and cooling rates for that furnace batch for sensitivity to intergranular corrosion using Practice E of ASTM A262. For subsequent annealing operations, the temperatures, soak times, and cooling rates of subsequent furnace batches must be measured and compared to the qualified procedure. Other factors, such as variations of the size and arrangement of the furnace batch that can affect part temperatures and part cooling rates, and the calibration of the furnace temperature sensors must be assessed in the procedure qualification to ensure that minimum temperatures and cooling rates of production heat treating batches can be properly compared to those of the qualified procedure. Such a procedure should be requalified for each individual furnace used, and for significantly different furnace batch sizes. The procedure shall be requalified annually, or if it has not been used for a period of at least three months.

3.2.2 Certified Material Test Reports (CMTR's)

3.2.2.1 CMTR's shall be provided to the Company for the materials used to fabricate these components in accordance with ASME Section III, Subsection NCA, NCA-3860. The Supplier shall provide the Company with certified material test reports, certified material examination reports and certificates of compliance for the materials stated above as required by this specification.

3.2.2.2 Material suppliers shall meet the requirements of NCA-3800.

3.2.2.3 Materials must be identified by material type, applicable specification, and revision number and be traceable to their lot or batch numbers. Traceability records shall be available for review by the Company's representative.

3.2.2.4 Materials shall be traceable to each CV's serial number.

3.2.2.5 Supplier shall maintain control of materials to ensure this traceability.

3.2.2.6 Materials shall be supplied with Certificates of Compliance in accordance with NCA-3862(g) and (h).

3.2.2.7 Materials shall be examined in accordance with the applicable paragraphs of NB-2500, and shall meet the stated acceptance criteria.

3.2.2.8 Results of these examinations shall be included with the CMTR's provided to the Company.

3.2.2.9 Weld filler metal used in the fabrication and repair of the CVs shall meet the applicable requirements of ASME BPVC Section III, Rules for Construction of Nuclear Facility Components - Subsection NCA General Requirements for Division 1 and Division 2- Article NCA-3800 and shall comply with the SFA specifications of Section II; Part C of the ASME Code.

3.2.2.10 Weld filler metal shall be traceable to heat numbers and CMTR's shall be furnished to the Company for each heat of weld filler metal used.

3.2.2.11 Results of the delta ferrite determination shall be included with the CMTR for the weld filler metal (see NB-2433) and shall be a minimum of 5 FN.

3.2.2.12 Weld examiner shall be able to determine the heat number of the weld filler used in each weld on each CV.

3.2.3 Hold points and Witness points

Hold points and Witness points will be required as noted below.

- For ALL units, QA Witness Points will be the Load Test, Sealing Test, Hydrostatic Test, Helium Leak Test, Air Leak Test and Dimensional Inspection including surface finishes.

3.2.4 First Article Evaluation (FAE)

The Company shall conduct an FAE in two (2) phases in accordance with this specification.

3.2.4.1 In Phase I the Company will conduct a review of the Supplier's process control forms and manufacturing procedures. The Supplier shall furnish an electronic copy of all procedures, travelers, data entry forms, processing records, and related data used by the Supplier to define and/or control those aspects of the manufacturing, testing, and inspection operations that influence the quality of the product being produced prior to fabrication, in accordance with schedule dates described in the subcontract.

3.2.4.2 Phase II of the FAE shall consist of audits and such examinations, inspections and testing oversight as deemed appropriate by the Company at the Supplier's site. The results of these audits and examinations will be evaluated to determine final acceptance of the FAE parts and release to produce production quantities.

3.2.4.3 The Supplier shall not proceed to manufacture parts beyond the initial First Article quantity until a successful FAE has been completed and written notification to proceed has been received from the Company's subcontract administrator.

The criteria established for the performance of the FAE, and subsequent production, shall also apply to the Supplier's subcontractors and sub-tier subcontractors as deemed appropriate by the Company. A listing of any such subcontractors and their involvement shall be submitted to the Company. The Company reserves the right to provide oversight of these proposed Subcontractors if deemed necessary. Signed approval of the proposed Subcontractors shall be received by the Supplier from the Y-12 STR prior to proceeding with fabrication.

3.2.4.4 Once Y-12 has approved an FAE, any subsequent process changes by the Supplier to manufacturing and acceptance procedures, facilities, type of personnel, testing, etc., which could conceivably impact product quality, shall require the Supplier to notify Y-12 of the proposed changes. Y-12 shall then determine if a new First Article Evaluation is warranted.

3.2.5 Certificates of Conformances (CoCs)

CoCs for procured items shall meet the following requirements:

a. The CoC shall identify the purchased item by the purchase order number.

b. The CoC shall identify the specific procurement requirements met by the purchased item, such as codes, standards, and other specifications. This may be accomplished by including a list of the specific requirements or by providing a copy of the purchase order and the procurement specifications or drawings, together with a suitable CoC.

c. The CoC shall identify any approved changes, waivers, or deviations applicable to the item.

d. The CoC shall identify any procurement requirements that have not been met, together with an explanation and the means for resolving the request for waiver or deviation.

e. The CoC shall be signed or otherwise authenticated by a person who is responsible for this quality assurance function and whose function and position are described in the quality assurance program of the Supplier.

f. The Supplier's certification system, including the procedures to be followed in filling out a CoC and the administrative procedures for review and approval of the certificates, shall be described in their quality assurance program.

3.3 Fabrication and Assembly Requirements

The Supplier shall prepare a written, step-by-step, controlled manufacturing plan for all work to be performed. This plan shall include at a minimum:

a. Materials to be procured
b. Suppliers to be used
c. Quality Program used to buy or manufacture each subassembly
d. Major fabrication steps (sequence of operations)
e. Equipment to be utilized
f. All in-process checks
g. All welding
h. All weld inspection/examination including Non-Destructive examination and testing.
i. Dimensional inspection.

3.4 Requirements

3.4.1 Welding and Weld Repair (If Required)

3.4.1.1 All welds on the CVs shall be done either by the GTAW or GMAW process, manual or automatic, at the discretion of the Supplier unless specified otherwise on the drawings.

3.4.1.2 Backing rings, even if removed after the weld has been made, shall not be used. Except as limited by this specification, the applicable requirements of NB-4300 and NB-4400 shall apply to the CV.

3.4.1.3 Prior to welding, all weld preparation areas and the accessible surfaces within one inch of the weld area shall be examined visually and with liquid penetrant. The acceptance criteria for these examinations are provided in NB-5130 (a) through NB-5130 (d). Note: All open, rounded or elongated indications to the surface of the weld metal or adjacent base metal detected by NDE (VT PT) are unacceptable.

3.4.1.4 The results of these surface examinations shall be reported to the Company together with the weld examination reports in accordance with Attachment A.

3.4.1.5 Prior written approval of the Company shall be obtained for any weld repair of base materials. Base material weld repair is only acceptable with Company approval.

3.4.1.6 Repair welding shall meet the applicable requirements of NB-2500. Based on the specific defect, the Company may or may not approve the weld repair, even if it is permitted by the material specification or by paragraph NB-2500.

3.4.1.7 Base material weld repair areas shall be both surface and volumetrically examined. Volumetric examination may be performed by radiography or other method specified by a welding examination procedure approved by the Company prior to welding repair.

3.4.1.8 Repair areas shall be noted in a sketch supplied with the CMTR for the material that was weld repaired and the documented results of the weld examination shall be provided to the Company as Certified Data.

3.4.1.9 Welders performing two or more welds in one day that are rejected based upon welder technique shall be re-qualified to the appropriate welding procedures (see Section IX paragraph QW-320 of the ASME Code).

3.4.1.10 The Supplier shall submit welding information as Appraisal Data in accordance with Attachment A.

a. Job Specific Welding Procedure Specifications (WPS).
b. Job Specific Welding Procedure Qualification Records (PQR).
c. Job Specific Welder Performance Qualification (WPQ) records including evidence of process usage updates.
d. Job Specific Visual examination and Nondestructive examination procedures.
e. Job Specific Certification records of examination personnel.
f. Job Specific Post Weld Heat Treatment (PWHT) procedures with appropriate procedure demonstrations (as required) and Supplier's acceptance documentation. Components that have received PWHT and are to be welded shall be qualified with PWHT WPSs.
g. Provide a list of all welded assemblies not fabricated in accordance with Supplier's welding program. Include any welded assemblies to be purchased commercial-off-the-shelf.

3.4.1.11 The Supplier shall submit welding information as Approval Data in accordance with Attachment A.

a. WPS for all commodities to be welded. Provide drawing, sketch, list of components, etc., where WPS is to be applied.
b. Weld Procedure Qualification Records (PQR) for each WPS submitted (unless WPS is prequalified.
c. Welder Performance Qualification (WPQ) records, including evidence of continuous process usage updates.
d. Roster of all welders to be used to perform work with continuity/expiration dates identified for each process the welder qualified.
e. Updated records (Roster) as required throughout the contract duration, to demonstrate welders submitted have maintained their qualifications.
f. NDE- Visual examination and Nondestructive Examination Procedures, VT, MT, PT, RT, UT (as applicable).

g. NDE- Certification Records of examination personnel.

h. NDE-Procedure for Qualification and Certification of Nondestructive Testing Personnel.

i. NDE-Current eye examination record (Annual) for examination personnel.

j. Certified Material Test Report (CMTR) for weld filler materials (as required) for each Heat/Lot to be used.

k. Weld filler material control procedure.

l. Welding fabrication drawings for all welded components.

m. Weld examination records, weld maps, radiographs, and PWHT chart recordings.

3.4.1.12 Nonconforming Welds

Completed welds that have been inspected and accepted but are later found not to be in compliance shall be documented and submitted to the Company on a nonconformance report in accordance with Supplier's nonconformance procedure. The Supplier's nonconformance procedure shall include language to address welding nonconformances that occur due to both procedural and hardware deficiencies. If a repair by welding is required, the Supplier shall complete a repair procedure that includes the WPS with specific instructions for repair. Additional supporting documents, as required, to make the repairs shall be submitted to the Company. Company approval of the repair procedure shall be obtained before commencing the repairs. Every nonconformance report (NCR) dispositioned "Use-As-Is" or "Repair" requires written concurrence from the Company accepting the disposition and technical justification before continuing work associated with the Nonconformance. A disposition of Rework does not require Company approval. A submittal of the Supplier's nonconformance procedure shall be submitted to the Company in accordance with the Submittal checklist, Attachment A.

3.4.1.13 Weld Filler Material Requirements

a. Weld Filler Material (WFM) shall be selected that matches the base metal as close as possible for mechanical and corrosion resistant properties and be listed on the Welding Procedure Specification (WPS).

b. WFM shall be specified as manufactured in accordance with recognized ASME standards where possible. Use matching WFM or material recommended by the base metal manufacturer when there is no existing WFM with an assigned AWS classification.

c. Purchase weld electrodes/filler materials with a Certified Material Test Report (CMTR) as identified in Section 3.6.1.14 below. Submit a Certified Material Test Report (CMTR) for WFM to be used. The reporting requirements are specified in the "Test Requirements for CMTRs" table(s) below for the listed WFM. The CMTR shall provide traceability to the Supplier's purchase order for each heat/lot received. For WFM without an SFA classification, provide the same level of testing, product marking, and packaging, etc. that is required for WFM with a SFA Classification. Use the Supplier's standard designation in lieu of the SFA classification to mark each piece of WFM and the shipping package.

d. All WFM shall meet the requirements of ASME BPVC Section II Part C, *Specification for Welding Rods, Electrodes, and Filler Metals*, except as noted.

3.4.1.14 Weld Filler material Procurement Requirements

a. Weld Filler Material (WFM) and fluxes shall be purchased from manufacturers or suppliers with established Quality System Programs that meet the requirements of ASME BPVC Section III, Rules for Construction of Nuclear Facility Components - Subsection NCA General Requirements for Division 1 and Division 2- Article NCA-3800 Metallic Material Organization Quality System Program and are active NCA 3800 Quality System Certificate (QSC) holders. The manufacturer or supplier that holds the certificate shall be evaluated by the Supplier and be currently listed on their Quality Approved Suppliers List (QASL).

b. The procurement requirements for WFM apply to all WFM utilized by Supplier organizations that procure their own welding materials. The Supplier at their discretion may elect to procure and use materials to stricter standards. The sections below list the level of Certification for the most commonly used WFM classifications for various applications. Other classification WFM are permitted with the prior approval of the Company. All WFM shall be procured in accordance with material designation (SFA) ASME BPVC Section II SFA 5.01, Procurement Guidelines for Consumables - Welding and Allied Processes - Flux and Gas Shielded Electrical Welding Processes. The level of certification and testing required for these alternate materials shall be the same as required for the similar components described below.

3.4.1.14.1 Weld Filler Material for Stainless Steel Base Materials

Shall comply with ASME BPVC Section II SFA 5.9, *Specification for Bare Stainless Steel Welding Electrodes and Rods*:

a. Use classification ER308L filler materials for welding 304 or 304L stainless steel base materials. When CMTRs are required, the reports shall also record a minimum delta ferrite of 5 ferrite number and test method.

b. The maximum acceptable carbon content for all "L" grade (low carbon) weld filler material is 0.03%. Heat analysis of weld deposit shall be performed to determine the chemical composition of the material.

3.4.1.14.2 Test Requirements for CMTRs

ASME SPECIFICATION	ASME SFA 5.01 TEST REQUIREMENTS					
	Lot Class	Level of Test	Chemical Analysis	Tensile	Soundness	Impact
5.9 Bare Stainless Steel Welding Electrodes and Rods	S3 or S4	I	Rod/Wire	No	No	No

3.4.2 Weld and Surface Examination (If Required)

Personnel Certification Requirements for Weld Examinations

a. Personnel performing nondestructive examination other than visual shall be currently certified per the employer's written practice in accordance with SNT-TC-1A. Only individuals certified as NDT Level II or III may perform nondestructive examinations in accordance with this specification.

b. Personnel performing visual examination of welds shall be currently certified either as an AWS CWI or as a visual testing Level II or III per the employer's written practice in accordance with

SNT-TC-1A. (Note: Eye exams shall be performed on an annual basis and comply with Jaeger 1 visual acuity.)

c. The Level III, in the methods certified, shall conduct the examination of Level II personnel for those same methods.

3.4.2.1 Weld examination procedures shall meet the requirements of the ASME Code, Section V.

3.4.2.2 The applicable requirements in paragraphs NB-5110, NB-5120, NB-5210, NB-5220, NB-5260, and NB-5300 shall apply to the CVs. Note: All open, rounded or elongated indications to the surface of the weld metal or adjacent base metal detected by NDE (VT PT) are unacceptable.

3.4.2.3 The V-groove welds on part M2E801580A012 shall be liquid penetrant and radiographically examined if the welded option is used. Note: All open, rounded or elongated indications to the surface of the weld metal or adjacent base metal detected by NDE (VT PT) are unacceptable.

3.4.2.4 The applicable requirements in paragraphs NB-5110, and NB-5350 shall apply to the plug weld and V-groove welds. Note: All open, rounded or elongated indications to the surface of the weld metal or adjacent base metal detected by NDE (VT PT) are unacceptable.

3.4.2.5 Materials used in the liquid penetrant examination of welds and in the final surface examination of finished components shall be specifically recommended by the manufacturer for use with austenitic stainless steels.

3.4.2.6 Copies of the certification of contaminant content of materials used for liquid penetrant examination (see Section V, Article 6, T-641) shall be supplied to the Company with the examination reports.

3.4.2.7 Certified weld examination reports, together with the corresponding material surface examination reports shall be submitted to the Company in accordance with Attachment A. Examination reports shall include lot number and expiration date of liquid penetrant, developer, and cleaner used.

3.4.2.8 Certified weld examination reports shall be submitted in accordance with Attachment A for all weld and surface examination shall include:

a. The CV serial number
b. A weld map showing the location of the weld and examination area
c. The welder's ID
d. The examiner's name
e. The time and date of the weld examination
f. Identification of the examination procedure(s) used
g. WPS number for each weld
h. Heat numbers of the materials joined
i. The heat number of the weld filler
j. Examiner's remarks

3.4.2.9 Examiner's remarks on weld examination reports and surface examination reports shall include the results of the examination and acceptance or rejection based on the stated criteria and shall include a description and sketch showing the location of defect(s).

3.4.2.10 One set of radiographs shall be provided to the Company with radiographic examination reports.

3.4.2.11 If a weld is rejected, the area may be weld repaired by the Supplier and re-examined. After two unsuccessful repair attempts, the Company shall be notified for approval prior to performing more repair attempts. The Company may, at its option, choose to reject further repair efforts and require that a replacement part be fabricated.

3.4.2.12 Implement, at any and all sub-tier levels during production, the workmanship provisions of ASME Section III, Division 1 as appropriate for the applicable material and not modified by the acceptance criteria presented in this document.

3.4.2.13 Notify the Company through the bid or proposal if a sub-tier will perform welding or non-destructive examination (NDE) services. The sub-tier(s) must be identified with the bid or proposal and submit the applicable documentation specified by the governing code(s) for welding and/or NDE for the sub-tier supplier(s) with the bid and for approval.

3.4.2.14 Notify the Company if, after the award of a subcontract, the Supplier determines the need for welding and/or NDE services from a sub-tier(s). The sub-tier(s) must be identified and submit the applicable documentation specified by the governing code(s) for welding and/or NDE for the sub-tier supplier(s) with the proposed change and for approval.

3.4.2.15 The Company may conduct welding inspection and oversight activities. Hold/witness points will be identified by the Company in the Supplier's manufacturing schedule after it is submitted to the Company for review.

3.4.3 Cleaning, Passivation, and Bead Blasting

3.4.3.1 Cleaning, passivation, and bead blasting procedures for the stainless steel, including weld areas, shall be submitted to the Company for approval in accordance with Attachment A.

3.4.3.2 After final machining and all examination of welds and surfaces, the Supplier shall clean and passivate all stainless steel surfaces of the CV in accordance with ASTM A380.

3.4.3.3 After passivating is complete, the Supplier shall bead blast all exterior surfaces in accordance with SSPC-SP 5/NACE No. 1, White Metal Blast Cleaning, with the exception of sealing or threaded surfaces.

3.4.3.4 Finished components awaiting assembly and final assemblies shall be free of dirt, debris, foreign objects, cutting fluids, metal chips, grinding residue, liquid penetrant and developer, and other foreign substances. The Company shall perform a final inspection of the CV vessel prior to installation with the drum. The Company shall apply an Empty label to the CV assembly prior to installation in the drum.

3.4.3.5 The Supplier shall clean, cover, and protect parts and subassemblies from becoming dirty while in storage, and to the extent practicable, in the shop environment while in work.

3.4.3.6 Only non-chloride bearing chemicals shall be used for cleaning (such as trisodium phosphate detergent or acetone).

3.4.3.7 A list of cleaning chemicals to be used shall be submitted for approval in accordance with Attachment A. Safety Data Sheets (SDS) of all cleaning chemicals shall be provided to the Company before use.

3.4.3.8 Water used in cleaning shall have a maximum chlorine content of 4 parts per million tested monthly.

3.4.3.9 Certified cleaning, passivation, and bead blasting procedures and reports shall be documented per ASTM A380 and submitted in accordance with Attachment A.

3.5 Government-Furnished Equipment

3.5.1 Silicone Rubber Parts

Silicone Rubber Parts per DS 801580-0002 and drawing M2E801580A024 shall be supplied by the Company.

3.5.2 O-ring(s) (Inner & Outer)

O-ring(s) per SPC M801580-0002 and drawing M2E801580A013 shall be supplied by the Company.

3.6 Hydrostatic Testing

3.6.1 A hydrostatic test procedure including sample test report forms shall be prepared by the Supplier and submitted to the Company for approval prior to testing in accordance with Attachment A.

3.6.2 After all machining is complete, assembled CVs shall be hydrostatically tested by the Supplier in accordance with the applicable sections of NB-6000.

3.6.3 The test shall be conducted with a test pressure of 158 psig +/- 5 psig at ambient temperature (60°F to 90°F).

3.6.4 The test medium shall be water with a maximum chlorine content of 4 parts per million tested monthly.

3.6.5 The Supplier shall provide suitable fittings to perform the hydrostatic testing.

3.6.6 Measuring devices used in performance of hydrostatic testing shall be certified and certified calibration reports shall be made available upon request to the Company. Applicable test equipment calibration shall be traceable to NIST.

3.7 Leak Testing

3.7.1 Leak test procedure(s) (written by a leak testing ASNT NDT Level III) including sample test report forms shall be prepared to perform this testing and shall be submitted to the Company for approval in accordance with Section 4.1 and Attachment A.

3.7.2 Leak test equipment shall be calibrated and certified calibration reports shall be made available upon request to the Company. Applicable test equipment calibration shall be traceable to NIST.

3.7.3 Two leak tests shall be performed on the CV after hydrostatic testing.

3.7.4 Prior to conducting any leak test, the CV and O-ring cavities must be thoroughly dried.

3.7.5 The leak testing shall be performed in accordance with the applicable sections of ANSI N14.5-1997.

3.7.6 The leak test procedure(s) and leak testing report shall comply with the applicable requirements of Section V of the ASME Code.

3.7.7 The leak testing for the first leak test shall have the sensitivity to detect a leak less than or equal to 5×10^{-8} ref-cm^3/sec of air, or 1×10^{-7} cm^3/sec helium and shall use the leak test fixture shown on the Company's drawing T2E801827A009.

3.7.8 The first leak test of the CV body and lid shall be performed with the CV assembled as shown on drawing T2E801827A009, (Part T2E801827A009-1, *Containment Vessel Body Leak Test Assembly*). Note that the outer O-ring in the CV body is not to be installed for this test. The leak testing acceptance criteria is as follows: the assembly shall not have an integrated leak rate greater than 1×10^{-7} ref-cm^3/sec of air or 2×10^{-7} cm^3/sec helium.

3.7.9 The second leak test is to be performed with the CV assembled as shown on Drawing M2E801580A011. The leak testing acceptance criteria is that the assembly shall not have an air leak rate greater than 1×10^{-4} ref-cm^3 /sec and the sensitivity of the leak testing procedure shall be less than or equal to 5×10^{-5} ref-cm^3 /sec.

3.7.10 If a leak is found the Company shall be notified in writing using the RFWD form, see Section 3.14.

3.7.11 A leak may be weld repaired by Supplier only if specifically permitted by the Company in writing, and the leak test repeated. The Company may, at its option, choose to reject repair efforts, and require that a replacement part be fabricated.

3.7.12 Certified leak test reports that describe the leak testing process and results shall be provided to the Company in accordance with Section 4.1 and Attachment A.

3.7.13 The leak test reports shall include the following data:

a. CV serial number
b. identification of all standard leaks, gauges, transducers and electronic readouts
c. CV serial number
d. date on which these instruments were certified
e. identification of the leak detector
f. date on which the leak detector was last certified
g. date of the leak test
h. time of the start and end of the test
i. recorded pressures and leak rates at the start and end of the test
j. name of the person conducting the test
k. qualifications of the person conducting the test
l. location of areas where the CV was repaired, if applicable
m. any pertinent remarks

3.8 Final Examination of Finished Surfaces

3.8.1 After all finish machining, load testing, leak testing, and hydrostatic testing, all accessible surfaces of the CV body assembly (drawing M2E801580A012), the CV sealing lid (drawing M2E801580A015), and the CV closure nut (drawing M2E801580A016) shall be examined with liquid penetrant in accordance with NB-2546 (see Section 3.4 for additional requirements for the materials used in the liquid penetrant examination).

3.8.2 The procedure for final surface examination including sample test reports shall be submitted to the Company for approval in accordance with Section 4.1 and Attachment A.

3.8.3 The results of the final surface examinations shall be documented in a certified examination report and provided to the Company in accordance with Section 4.1 and Attachment A.

3.8.4 If a defect is found, the component shall be tagged and segregated to prevent inadvertent use, and the Company shall be notified in writing using the RFWD in accordance with Section 3.14 and Attachment A, for disposition.

3.8.5 Defective areas may be weld repaired by the Supplier only if specifically permitted by the Company in writing, and the area re-examined. The Company may, at its option, choose to reject repair efforts and require that a replacement part be fabricated.

3.9 Dimensional Inspection

3.9.1 Dimensional requirements specified on the Company's drawings require inspection procedure that shall include:

a. A listing of features to be inspected
b. Identification of inspection equipment to be used inspect each dimension or tolerance
c. Sample data sheets with adequate data recording space to record inspection results
d. Adequate information to ensure traceability of inspection data to specific serial numbered CVs.

3.9.2 The Supplier shall submit inspection procedures for Company approval in accordance with Attachment A.

3.9.3 The Supplier shall be responsible for determining stock sizes so that the finished machined components meet the dimensions and tolerances specified on the attached drawings.

3.9.4 Prior to performing final inspection, the Supplier shall perform all deburring and cleaning operations required to ensure that CVs are free of all fabrication and handling defects and that no foreign materials are present on the vessel surfaces or features (i.e., scratches, dents, nicks, gouges, tool marks, etc.), that are greater than good workmanship standards.

3.9.5 The forming, fitting, and alignment requirements stated in paragraph NB-4200 shall be met in the fabrication of each CV unless more stringent requirements are specified on the Company's drawings.

3.9.6 The roundness of cylinders, profile of formed head surfaces, and misalignment or offsets in weld joints shall be included in the dimensional inspection reports for each Containment Vessel and shall satisfy the requirements paragraph NB-4200 unless more stringent requirements are specified on the Company's drawings.

3.9.7 The Supplier shall not perform a final inspection of the vessel until all machining and process operations have been completed. Sufficient re-inspection after testing operations are complete may be required to ensure the containers meet the applicable specifications.

3.9.8 Inspection, Measuring and Test Equipment shall be calibrated and certified by an organization with ISO 17025 accreditation, or Y-12 approved equal, and traceable to the National Institute of Standards. Documentation shall be submitted in accordance with the attachment A, Submittal Checklist.

3.9.9 Where inspection or test equipment yields quantitative readings, actual measurements and deviation from nominal readings shall be recorded.

3.9.10 The Supplier's inspection shall include, as a minimum, the following:

a. All dimensions and tolerances on Company drawings including a diamond <I> or <S> shall require 100% inspection, documentation, and shall be submitted per Attachment A.

b. Edge breaks.

c. Surface finish.

d. Cleanliness as specified in Section 3.4.3.

e. Part identification as specified by the drawings.

f. Diameter dimensions that show compliance with the requirements of paragraph NB-4200.

3.9.11 Certified inspection report(s) shall be prepared and submitted to the Company in accordance with Attachment A.

3.9.12 Straightening, flattening, and forming of the weldment by mechanical means after welding may be required to ensure proper assembly and fit. The surfaces of areas of the weldment that have been worked shall be visually examined to ensure that no cracks are present and that the weldment has not been degraded. Adjacent welds to these areas shall also be visually examined. The acceptance criteria are that no cracks are found in the weldment. The areas worked and the visual inspections performed shall be noted on an inspection report.

3.9.13 The Company shall require verification of Diamond <I> or Diamond <S> dimensions in accordance with a normal sampling plan based on the total PO quantity in accordance with Y17-69-316 Chapter 6, attachment 6-C.

3.9.14 All equipment and instruments (Measuring and Testing Equipment (M&TE)) used in the conduct inspections shall bear a calibration sticker that shows the equipment to be within its calibration period. Calibrations must be performed by a laboratory that meets ISO 17025:2005. All calibration sources shall be traceable to the National Institute of Standards and Technology (NIST). All certification documentation shall be submitted to the Company in accordance with Attachment A.

3.10 Schedule (Specify to be submitted for approval)

The Supplier shall prepare a proposed schedule for the fabrication of the ES-3100 CV assembly specified herein. This proposed schedule shall be submitted with the offer in accordance with Attachment A.

The Company will conduct oversight activities. Hold/witness points will be identified by the Company in the Supplier's schedule after it is submitted to the Company for review.

3.11 Deliverables (Including Submittals)

The deliverables for this specification includes, but is not limited to:

a. Completed and assembled ES-3100 CV assembly

b. All Requests for Waiver/Deviations shall be closed.

c. All submittal documentation in accordance with Attachment A, with applicable documentation in data packages specific to each ES-3100 CV assembly identified by its serial number.

The documentation required with the proposal (WP) as indicated in the "Submittal Checklist," Attachment A, shall be submitted to the Company in the quantities listed with the Supplier's offer. Submittals shall be e-mailed to the Company SA and the STR.

The Company will review the submittals that are required prior to fabrication as indicated in the "Submittal Checklist," Attachment A, and respond as shown in the "Instructions to Supplier for Preparation of Submittals," Item h.

The Company shall review the submittals required per Attachment A. Shipping shall not commence without documented permission from the Company.

3.11.1 Material certifications and/or any supporting test data as specified above cannot be waived. Failure to supply the required data shall be cause for rejection of the entire shipment lot.

3.11.2 Certification data shall be provided to the Company as soon as possible after completion of the vessels.

3.12 Packaging, Handling, Shipping, and Storage Requirements

The CVs are part of the ES-3100 Shipping Container and will be shipped with the ES-3100 Drum Assembly package. See specification JS-YMN3-801580-A001 for requirements. A packing plan for shipment of the ES-3100 Drum Assembly package shall be sent to the Company for approval in accordance with Attachment A.

3.12.1 The CV sealing surfaces must be protected during shipment.

3.12.2 The Supplier shall not ship CVs with unapproved RFWD's

3.13 Marking and Identification Requirements

3.13.1 The assembled CVs shall be marked as specified on Company's drawings.

3.13.2 Permanent serial numbers for each CV shall be assigned by the Company and identified in the Purchase Order.

3.14 Requests for Waiver or Deviation

3.14.1 After award, if a waiver or deviation from the specified requirements is desired, then the Supplier shall submit to the Company a Request for Waiver or Deviation form: UCN-13816B. The Company will provide this form upon request.

3.14.2 Use the UCN-13816B form to request permission to change or deviate from the specified requirements; obtain Company approval before proceeding with any changes.

3.14.3 Email the completed form to the STR.

3.14.4 Use the form to report any of the following conditions:

a. A request for deviation from the contract requirements.

b. Anytime a requirement contained within the original specification or a contract modification approved by the Company is violated.

c. There is nonconformance that cannot be corrected unless an item or process is modified, reworked, or repaired to an equivalent functional condition.

d. A request for Company approved substitutions shall be submitted using the RFWD form for Company approval prior to implementation. Adequate information shall be provided with the request so that the Company can determine if the item is equivalent.

3.15 Documentation Retention

3.15.1 Documentation of all inspection and test results shall be maintained by the Supplier for three years after delivery to the Company.

3.15.2 The Company shall be given access to this data upon request.

3.16 Use of Subcontractors

The Supplier shall ensure that all its suppliers and subcontractors comply with the requirements of this specification (including quality assurance requirements). Supplier and subcontractor procedures, approved by the Supplier, shall be included in the procedures submitted to the Company for review and approval.

3.17 Witness of Documentation and Processes

3.17.1 The Company shall be given access to all documentation and shall be allowed to witness any of the processes associated with this specification during the performance of the contract.

3.17.2 The Company shall be informed prior to the start of any testing activities and an agreed upon schedule shall be established. The Company reserves the right to witness any testing activities performed.

3.18 Nonconformance Control

3.18.1 Nonconforming products shall be documented using the Supplier's designated form as required in their QA Plan, and a copy sent to the Company representative.

3.18.2 Deviations or waivers shall be controlled using, Request for Waiver or Deviation, and sent to the Company for approval.

3.19 Approved Procedures

a. Manufacturing, examination, and testing processes shall be controlled by procedure and performed by qualified personnel.
b. Procedures shall incorporate a mechanism to identify process step completion.
c. Procedures shall be submitted to the Company for approval in accordance with Attachment A.

4.0 QUALITY ASSURANCE REQUIREMENTS

4.1 Final Acceptance Method

4.1.1 Final Acceptance will be based on the results of the following:

a. Certified Data Package
b. Hydrostatic test of each ES-3100 CV in accordance with Section 3.6
c. Load test of each ES-3100 CV per drawing M2E801580A011 and in accordance with an approved load test report
d. Sealing test of each ES-3100 CV per drawing M2EM801580A014 and in accordance with an approved sealing test report
e. Helium leak test of each ES-3100 CV in accordance with Section 3.7
f. Air leak test of each ES-3100 CV in accordance with Section 3.4.10
g. Dimensional inspection reports of each ES-3100 CV in accordance with Section 3.9
h. Submittals listed on Attachment A
i. After all testing, a liquid penetrant report in accordance with NB-2564

4.2 Inspection/Testing Requirements

4.2.1 NDE Examiner Qualifications

4.2.1.1 Qualifications of the personnel performing material or weld examination shall be those provided in NB-5500.

4.2.1.2 Qualification records shall be submitted for approval with the examination procedures in accordance with Attachment A.

4.2.1.3 Certified hydrostatic test reports for each CV shall contain the following data:

a. Serial number of the CV
b. Time and date of the test
c. Name of person who performed the hydrostatic testing
d. Hydrostatic test procedure number
e. Name, serial number and calibration date of all gages and transducers
f. Sketch areas showing any leakage or any areas where surface defects where observed after hydrostatic testing.

Certified hydrostatic test reports shall be submitted to the Company in accordance with Section 4.1 and Attachment A.

4.3 Quality Requirements

The Supplier shall perform all work under a QA Program that complies fully with both 10 CFR 71 Subpart H and NQA-1. If requirements are unclear, or full compliance with both Subpart H and NQA-1 is uncertain, the Supplier shall contact the Company for resolution.

If the Supplier purchases Nuclear Safety Related materials or services from a source that does not have an NQA-1 compliant QA Program, they shall be dedicated in accordance with Commercial Grade Dedication Plans approved by the Company. Otherwise, use suppliers already approved on the Company Quality Assurance Suppliers List. Contact the STR for approved suppliers.

For special processes including, but not limited to, flow-forming, heat treating, welding, and NDE, the Supplier shall provide control over activities affecting the quality of the materials and components as necessary to assure conformance to the approved design.

The Supplier shall have implemented and maintain a quality system in accordance with ASME NQA-1 Quality Assurance (QA) Program that meets the requirements of NQA-1 2008, 1a-2009, 1b-2011 Part 1, Section 1-18. A copy of the Supplier's QA Program Manual shall be submitted with the bid in accordance with Attachment A for review and approval. The Supplier shall comply and conduct all work in accordance with their Quality Assurance program and this Equipment Specification.

An uncontrolled copy of the Supplier's controlled QA Program and all applicable subtier suppliers' quality assurance program manuals shall be submitted as Offer Appraisal Data in accordance with Attachment A.

The Supplier shall provide an Excel transmittal or similar file to document the transmission and status of data files. This file shall be updated after each transmission or status change and shall at least identify data by; name, date of transmission, file size, and status (i.e. for review or approval). This file shall be included with the submitted data.

4.3.1 Suspect/Counterfeit Items

The Supplier's QA Program shall implement DOE O 414.1D Attachment 3, with respect to Suspect Counterfeit Items.

Contract terms and conditions that establish the plant's expectations with respect to the Supplier's role in preventing the introduction of S/CI.

The Supplier's requirements for preventing Suspect /Counterfeit Items (S/CI) from being introduced into the Company's supply chain are referenced in the General Terms and Conditions of the Request for Solicitation and/or Purchase Order.

The Supplier shall use components supplied or assemblies of components from OEM or authorized distributors.

4.4 Acceptance Criteria

4.4.1 Approval Data

Approval Data will be reviewed and must be approved by the Company before the Supplier proceeds with the applicable production activity. The Supplier shall schedule at least 4 weeks for Company

review of submittals. A list of the required Approval Data can be found in Attachment A to this specification.

4.4.2 Certified Data

a. A list of the required Certified Data can be found in Attachment A of this specification.
b. An electronic .pdf version of the Certified Data Package shall be provided prior to or with the shipment.
c. The Certificate of Conformance shall be signed by the Supplier and identify the applicable serial number of the CV included in the shipment, one Certificate of Conformance for each Drum Assembly (M2E801580A001).
d. The Certificate of Conformance shall attest that the CV assembly conforms to the requirements of this specification and Company drawings and approved RFWD's.
e. The CV assembly drawing number (M2E801580A011) associated with each Drum Sub-Assembly shall be recorded on the Certificate of Conformance.
f. The Certified Data package for each CV assembly shall be complete, legible, indexed and added to the final drum assembly (M2E801580A001).
g. The Certificate of Conformance shall list the approved RFWD's if applicable.

4.5 Personnel Qualifications/Certifications

The Supplier shall provide for the training and qualification of personnel to ensure their competence in the use of process procedures and specifications.

4.5.1 Records of personnel qualifications shall be made available to the Company upon request.

Attachment B: Instruction to Supplier for Preparation of Submittals

Note 1 -- All correspondence shall be addressed to the Technical Representative identified by the Company. The Supplier shall forward submittals via transmittal letter to the Company at the address specified in the contract.

Note 2 -- The submittal must have adequate detail so that full compliance with the requirements may be determined. For example, a simple off the-shelf item to be used in an assembly may only need a supplier's cut-sheet to show compliance, but a factory acceptance test (FAT) developed and submitted by the Supplier must have each test step detailed with acceptance criteria consistent with the requirements.

a. Review submittal before transmitting to the Company to verify conformance with requirements of the contract documents (e.g., field measurements, field construction criteria, or Supplier's catalog numbers).
b. Coordinate submittals with the work requirements and the contract documents.
c. Organize Submittals
   - Do not use highlight marker or color coding on submittals.
   - The minimum resolution used for scanning submittals shall be 300 dpi x 300 dpi.
   - For submittals containing color information important to the record, a 24-bit color setting should be used.
   - Submittals are to be legible and in the format specified on the submittal checklist.
   - Pen and ink changes are to be made in non-erasable ink, legible, dated and initialed.
   - Mark specific options provided for the work, and cross out options not provided.
   - Each submittal shall be sent as a single pdf file unless otherwise specified.
d. Label submittals with the applicable item number, reference, and requirement description as summarized in the Submittal Checklist. Unlabeled submittals will be returned to the Supplier without review.
e. Include with submittals a transmittal letter that identifies individual documents by specification section.
   - Transmittal for submittals shall be numbered using the purchase order number followed by a 4-digit sequential number. (Example: 430001111-0001).
   - Embedded comments or questions that are not included on the transmittal may not be addressed/resolved by the Company.
f. Direction will be given at the time of award to either upload submittals to a company provided URL address or send by email to a company provided email address.
g. If using a company provided URL to upload submittals, notify the Company via email when submittals have been placed.
h. After review of a submittal, the Company will assemble comments and provide a status on the documents. An example of this submittal status stamp is shown below.

DOCUMENT REVIEW STATUS		
1	☐ Work may proceed.	
2	☐ Revise & resubmit. Work may proceed subject to incorporation of changes indicated.	
3	☐ Revise & resubmit. Work may not proceed.	
4	☐ Review not required. Work may proceed.	
Permission to proceed does not constitute acceptance or approval of design details, calculations, analysis, test methods developed or selected by the supplier and does not relieve supplier from full compliance with contractual obligations.		
REVIEWED BY:	Print Name/Signature :	Date:

i. If a submittal is being resubmitted, then reference the applicable item number, reference, and requirement description and identify it as a resubmittal.
j. Company response will only be returned to the Supplier for those submittals with a Submittal Purpose of "For Action, "unless it is determined that a submittal transmitted "For Information" is not acceptable.
k. AFTER written approval is obtained, THEN proceed with work requiring approved submittals.
l. When approval submittals are required, work done before Company approval is at the Supplier's risk.
m. Maintain a copy of the company-approved submittal and status page on file.

Attachment D: Requirements for Authorized Nuclear Inspector (ANI)

1.0 REQUIREMENTS

If requirements are unclear, or conflicts exist between applicable documents on this work, the Supplier shall contact the Company STR for resolution. If multiple interpretations are possible, the Supplier shall contact the STR for clarification based on the Company's intent. All work associated with this attachment is important to nuclear safety.

1.1 The Supplier shall subcontract for and oversee this work in accordance with its Nuclear QA Manual approved by the Company for this subcontract, for a nuclear safety related item.

1.2 Both the Supplier and the ANI shall perform their duties per the ASME Code as though the CVs will be Code stamped and both shall sign the Certificate Holder's Report of Inspection provided at the end of this attachment.

1.3 Each inspection by the ANI shall be documented and included with the Supplier's certification records for the item being inspected.

1.4 Supplier approval Data Documents and Certification Data Documents like procedures, inspection reports, test reports, etc. associated with ASME Code work shall be stamped and/or signed and dated by the ANI, indicating his review and approval.

1.5 ANI inspection results, reports, and other quality records associated with the ANI's work shall be submitted to the Company along with other quality records required in this specification.

1.6 The ANI shall not inspect 100% of the CVs but shall inspect based on EPRI recommendations for a NORMAL sampling plan (EPRI Guideline for Sampling, document number TR-017218-R1, dated January 1999). The ANI's sampling plan or approach shall be approved by the Company in advance of the work, to ensure. As a minimum, each manufacturing batch of items being worked shall be sampled. A manufacturing batch is defined as a segment of the overall quality to be manufactured that is being worked as a batch with no breaks or interruptions that would affect the quality of the work. Manufacturing batches must be identified by the Supplier and approved by the Company in advance so Company resources can make plans to oversee and participate with the work the Company deems appropriate.

2.0 DOCUMENTATION REQUIREMENTS

2.1 Submittals for Company approval prior to initiating work

2.1.1 Copy of a valid commission issued by the National Board of Boiler and Pressure Vessel Inspectors for the ANI (Approval Data)

2.1.2 Approval Data Documents for ASME Code work with stamp or signature showing ANI review and approval (Approval Data)

2.1.3 Sampling Plan for ANI inspections (Approval Data)

2.2 Submittals following the work for Company acceptance

2.3 ANI inspection results, reports, and other quality records associated with the ANI's work (Certification Data)

2.4 Certification Data Documents for ASME Code work with stamp or signature showing ANI review and approval (Certification Data)

3.0 ACCEPTANCE OF WORK

Final acceptance of this work will be based on the Company's acceptance of the applicable Advance Data documents and Certification Data documents submitted to the Company for approval as required in this attachment.

Certificate Holder's Report of Inspection
Subcontract Number TBD

Item name: _____ Item drawing number: _____
Item serial number: _____

Certificate Holder – Supplier
The Supplier certifies that the subject item was manufactured in accordance with the ASME Boiler and Pressure Vessel Code requirements specified in Equipment Specification _____, Revision _____, and all Owner approved Deviations and Waivers.

Certificate of Authorization Number: _____Expiration date: _____
Authorized Representative name and title (printed):
_____
Authorized Representative signature and date:
_____

Authorized Nuclear Inspector
Holding a valid commission issued by the National Board of Boiler and Pressure Vessel Inspectors, the following ANI has inspected the subject item during the manufacturing process and certifies that it has been manufactured in accordance with the ASME Boiler and Pressure Vessel Code requirements specified in Equipment Specification _____, Revision _____, and all Owner approved Deviations and Waivers.
ANI Commission number and expiration date: _____
ANI Name (printed): _____
ANI signature and date: _____
By signing this certificate, the Inspector makes any warranty, expressed or implied, concerning the subject item. Furthermore, neither shall be liable in any manner for any personal injury or property damage or a loss of any kind arising from or connected with this inspection.

REVISIONS/ENGINEERING AND PLANT APPROVALS

REV. NO.	DESCRIPTION OF REVISION
A	Issue for procurement
B	Removed the reference to the Prototype Procurement Specification document number OO-PP-1210. Change the equipment reference in Section 3.1.3(c) from a "large mortar mixer or plaster mixer with moving vanes or a smooth wall cement mixer with the fixed vanes removed" to "Whiteman Multiquip's WM700S-H8 plaster/mortar mixer, refereed to as WM700". In Section 3.2 changed the method and time that the water and dry mix were added into the mixer based upon the mixer qualification in Section 3.5. Added Section 3.5, added attachments E and F to determine the proper mixing time and the Mixer Qualification Castings. In section 3.3.1 and 3.3.3 added misting procedure. Section 3.3.2(b) added a circular concave of .32±.10 to the Kaolite before it is baked to match drawing M2E801580A002. Section 3.3.4(b) add a circular convex scrape of .09±.06 to the Kaolite before it is baked to match drawing M2E801580A008. Updated the attachments with general revisions. Section 3.4 has been subdivided into 3.4.1 Baking Instruction and 3.4.2 Baking Documentation and added attachment F to this section.
C	Revised patent information in scope. Added recommended "Before Baking" weights for the Body Weldment and Top Plug Weldment based upon a more refined Kaolite 1600™ product code GI80ACCUMD0027 that is produced to the lower side and a smaller range of the manufactures normal tolerance band. This Kaolite 1600™ product code requires using 1.65 times the dry weight for the water weight (instead of 1.5) and generates an acceptable wet mix density of 56.2+/− 5.8 lb/ft^3. This additional water requires between 36 to 46 hours of bake time at 500°F.

1 Scope

This manufacturing process specification describes the quality assurance and technical requirements that shall be met when weighing, mixing, pouring, vibrating, curing, and baking the Kaolite 1600™ for the ES-3100 shipping container Body Weldment and Top Plug Assemblies. The product produced by following this manufacturing process is protected under U.S. Patent 6,299,950. The United States Government has rights in this invention pursuant to Contract No. DE-AC05-84OR21400, between the U.S. Department of Energy and BWXT Y-12 L.L.C.

This specification describes the instructions that shall be followed for these activities. The components (Body Weldment and Top Plug Assembly) will be fabricated to the design requirements specified on the engineering drawings for the components.

Reference to the Company in this specification shall mean the package certificate holder and reference to the Seller shall mean the supplier of the fabricated Body Weldment and Top Plug Assemblies.

2 Applicable Documents

The following documents apply when Casting Kaolite 1600™ Into ES-3100 Shipping Containers.

ES-3100 Drawing Numbers
M2E801580A002, Body Weldment
M2E801580A008, Top Plug Weldment,

Procurement Specification for ES-3100 Confinement Boundary Assembly
JS-YMN3-801580-A002 Equipment Specification for the ES-3100 Drum Assembly

3 Kaolite 1600™ Processing Requirements

3.1 General

The Kaolite 1600™ material referenced with in this specification shall be provided by Thermal Ceramics, Incorporated or an authorized distributor. The material certification documentation (Certificate of Conformance) for the Kaolite 1600™ must be provided by the supplier for each manufacturer's lot of material to a product code of GI80ACCUMD0027.

3.1.1 Kaolite 1600™ Receiving and Storage Instructions

a. Damaged packages of Kaolite 1600™ shall be rejected by the Seller upon receipt. Damaged packages are those that are wet, those that are visually determined to have been wet, and packages that have been torn.

b. Packages of Kaolite 1600™ must be stored unopened in a dry location and protected from damage. Opened unused and partial used Kaolite 1600™ packages are to be discarded at the end of the work shift. The term work shift shall be defined by the Seller and approved by the Company before commencing operations.

3.1.2 Cleaning Instructions

a. Use **NO CHLORINE BLEACH** for cleaning. Potable water shall be used and if required some mild soap (tri-sodium phosphate) may be added to the water to clean all processing equipment and manufactured components before casting. Before the start of any mixing/blending operation, the mixer shall be clean from all foreign materials or previous mixing residues from the inner surface of the mixer. The mixer shall be flushed thoroughly with potable water at the completion of the final mixing operation of the work shift to remove residues. Mixing, and casting shall be performed within a temperature range of 70 (± 25) °F.

b. Fabricated assemblies must be cleaned and protected prior to the casting operation to prevent the introduction of foreign materials into the assemblies. The assemblies shall be inspected and wiped clean prior to casting to ensure no visible contaminants are present inside the casting cavity. This inspection shall be documented in the checklist.

3.1.3 Mixing Water and Mixing Equipment Requirements

a. Potable water, that has been filtered through a 20-micron filter and has a chlorine content less than 4 mg/L (4 ppm, 0.0004 percent by mass) for chlorine shall be used for the mixing of Kaolite 1600™. If the potable water is higher then 4 ppm, then use an activated charcoal filter or some other means to reduce the amount of chlorine to at or below 4 ppm. Test the water quality for chlorine weekly during casting operations. Unfiltered potable water may be used for the cleaning of equipment used to process Kaolite 1600™.

b. All weighing operations of assemblies and materials shall be conducted on certified scales with a minimum accuracy of ½ lb.

c. This specification has been developed around the Whiteman Multiquip's WM700S-H8 plaster/mortar mixer, refereed to as WM700. This steel-drum machine mixes 7-cubic feet (193 liters) of material with an 8-horsepower Honda engine running at a slow speed. Other models of plaster/mortar mixers may be used if the speeds and mix times are qualified per section 3.5 and approved by the company.

d. A Heavy Duty Drum Vibrator/Packer(like McMaster-Carr, No. 5809K11, or Company approved equal) shall be used to clamp the Body Weldment, M2E-801580-A002 or Top Plug Weldment, M2E-801580-A008 upside down for vibration casting the Kaolite 1600™ into the welded stainless steel forms.

3.2 Mixing of Kaolite 1600™

Mixing shall be performed by operators qualified in accordance with requirements in Section 4.4.

The term batch is defined as a mixture of one bag of Kaolite 1600™ with the appropriate amount of water. The required mix ratio is 1.65 pounds of filtered water per pound of Kaolite 1600™.

The mixing activity shall be recorded on Attachment A, *Kaolite Mixing Control*. Each batch shall be given a mixture control number (MCN) and recorded upon its data Attachment. (A 10-digit control number is recommended consisting of the date and the time format using a 24-hour clock. Example: 1021041515 for October 21, 2004 at 3:15 pm.)

The Kaolite 1600™ mixing shall be performed as follows:

a. Record the weight of the bag of Kaolite 1600™ on the mixing Attachment.

b. The required mix ratio is 1.65 pounds of filtered water per pound of Kaolite 1600™. For a 50 pound bag of Kaolite 1600™, weigh and record 82.5 (± ½) lbs. of filtered water generating an acceptable wet mix density of 56.2±5.8 lb/ft^3.

c. Start the mortar mixer motor and when ready to engage the moving vanes, pour the weighed filtered water, pour all of the 50-pound bag of Kaolite 1600™ over the water. Immediately start the WM700 moving vanes for 3.0 (±0.2) minutes.

3.3 Vibration Casting and Curing of Kaolite 1600™ into Assemblies

3.3.1 Body Weldment Casting Instructions

Casting operations shall be performed by operators and witnesses qualified in accordance with requirements listed in Section 4.4.

Use Attachment B, *Body Weldment Vibration Casting Control,* to record information gathered during this operation.

Complete the casting of the mixture in less than 70 minutes. This timed procedure starts when the first batch is poured into the vibrating component. The casting and vibrating procedure must be completed within 77 minutes from initial pour for each assembly.

Casting operations shall be performed as follows:

a. Weigh the Body Weldment clean and empty. Record the weight.

b. Fill the Body Weldment with potable water that has been filtered through a 20 micron filter and has a chlorine content of ≤ 4 ppm and weigh it. Record the weight.

c. Remove the water from the assembly as much as is practical.

d. Secure the assembly on the vibration table. Set the vibration table dial indicators to approximately 800 lb-force at 450 vibrations per minute (VPM). Assure that the Body Weldment is properly secured to the table and start the vibration table. The Body Weldment must be vibrated continuously throughout the casting operation.

e. The mixture shall then be poured directly into the assembly after mixing through the fill hole provided.

f. Repeat the mixing operation in Section 3.2 and continue pouring until the mixture overflows the fill hole by ½ to ¾ inch.

g. Mist the top surface of the mixture with a bottle water sprayer if necessary to get the mixture into a solution after the pouring is completed. Do not add more than 8 ounces of water.

h. Vibrate the filled assembly for 5 to 7 minutes after the casting is completed.

3.3.2 Body Weldment Curing Instructions

A designated area shall be set aside for curing the assemblies. The temperature of the curing area shall be controlled to 70°F (±25°F) and shall prevent the introduction of foreign materials into the mixture.

Curing operations shall be performed as follows:

a. Remove the Body Weldment from the vibration table and place it in the curing area. Let it rest uncovered for 2½ (±½) hours.

b. Weigh and record the Before Baking weight of the cast assembly. If the weight is outside of 330 to 386 lbs range it is recommended not to cure the casting but to clean out and recast the Kaolite. This Before Baking weight is a recommended process control for the finished baked density. The manufacture may continue with a part outside of this weight range but it has a high chance being rejected for not meeting the finished baked density.

c. After resting, scrape the excess mixture from the fill opening until the Kaolite surface has a circular concave of .32±.10 to match drawing M2E801580A002.

d. Weigh the cast assembly, and photograph the fill opening. Record the weight.

e. Cover the fill opening with plastic sheeting and let the assembly set undisturbed in the curing area for at least 24 hours.

3.3.3 Top Plug Assembly Casting Instructions

Use Attachment C, Top Plug Assembly Vibration Casting Control, to record information gathered during this operation.

Complete the casting of the mixture in less than 70 minutes. This timed procedure starts when the first batch is poured into the vibrating component. The casting and vibrating procedure must be completed within 77 minutes from initial pour for each assembly.

Casting operations shall be performed as follows:

a. Weigh the top plug assembly clean and empty. Record the weight.

b. Fill the top plug assembly with potable water that has been filtered through a 20-micron filter and has a chlorine content of ≤ 4 ppm and weigh it. Record the weight.

c. Remove the water from the assembly as much as practical.

d. Place the assembly on the vibration table. Assure that the assembly is properly secured to the table. Set the vibration table dial indicator to approximately 120 lb-force at 450 vibrations per minute and start the vibration table. The top plug assembly must be vibrated continuously throughout the casting operation.

e. The mixture shall then be poured directly into the assembly after mixing through the fill hole provided.

f. Repeat the mixing operation in Section 3.2 and continue pouring until the mixture overflows the fill hole by ½ to ¾ inch.

g. Mist the top surface of the mixture with a bottle water sprayer if necessary to get the mixture into a solution after the pouring is completed. Do not add more than 4 ounces of water.

h. Vibrate the filled assembly for 5 to 10 minutes after the casting is completed.

3.3.4 Top Plug Assembly Curing Instructions

Curing operations shall be performed as follows:

a. Remove the top plug assembly from the vibration table and place it in the curing area. Let it rest uncovered for 2½ (± ½) hours.

b. Weigh and record the Before Baking weight of the cast assembly. If the weight is outside of 29.2 to 34.2 lbs range it is recommended not to cure the casting but to clean out and recast the Kaolite. This Before Baking weight is a recommended process control for the finished baked density. The manufacture may continue with a part outside of this weight range but it has a high chance being rejected for not meeting the finished baked density.

c. After resting, scrape the excess Kaolite mixture from the fill opening until surfaces are a circular convex shape of .09±.06 before it is baked to match drawing M2E801580A008.

d. Weigh the cast assembly, and photograph the fill opening. Record the weight.

e. Cover the fill opening with plastic sheeting and let the assembly set undisturbed in the curing area for at least 24 hours.

3.4 Baking of Assemblies Cast and Cured with Kaolite 1600™ mixture

3.4.1 Baking Instructions

Several assemblies may be baked together during each furnace heating cycle. Once the furnace heating cycle has started, no additional assemblies may be inserted into the furnace. The furnace and temperature control requirements to perform the baking operation are as follows:

a. The furnace shall be a gas-fired or a forced convection fresh air circulating electric furnace.

b. The furnace heat zone shall be certified to +25°F from the furnace set point temperature at each baking temperature process point.

c. Furnace time and temperature strip charts for each furnace heating cycle shall be provided with each completed Attachment D. Alternatively, an ASCII furnace time and temperature data file may be provided for each completed Attachment D.

3.4.2 Baking Documentation

Use Attachment D, *Furnace and Baking Control*, to record information gathered during this operation. An Attachment D identified by the Baking Control Number (BCN) shall be generated for each set of assemblies subjected to the furnace baking operations. Record the BCN from Attachment D for each assembly baked during this furnace heating cycle utilizing the proper assembly Casting Attachments B, C, and F. Qualified operators as indicated in Section 4.4 shall perform the baking of the cured assemblies. Movement of the cured assemblies before baking shall be minimized. The time and actual furnace exhaust air temperature shall be recorded at least every 15 minutes for baking control during a furnace heating cycle.

The baking furnace heating cycle shall be completed as follows:

a. Place the assemblies into the furnace.

b. Set the initial set point temperature to 200 (±10) °F.

c. Hold the temperature for 4 hours at a 200 (±10) °F steady state.

d. Increase the furnace set point temperature to 275 (±10) °F.

e. Hold the temperature for 1 hour at a 275 (±10) °F steady state.

f. Increase the furnace set point temperature to 350 (±10) °F.

g. Hold the temperature for 1 hour at a 350 (±10) °F steady state.

h. Increase the furnace set point temperature to 425 (±10) °F.

i. Hold the temperature for 1 hour at a 425 (±10) °F steady state.

j. Increase the furnace set point temperature to 500 (±10) °F.

k. Hold the temperature for 41 (±5) hours at a 500 (±10) °F steady state.

l. Remove assemblies and allow cooling in still air until they reach ambient temperature.

m. Weigh the assemblies after the baking process and record the weights upon the appropriate Attachment (Attachment B or C). Calculate the baked density of the cured mixture using the equation at the bottom of Attachment B or C and record.

EXEMPT FROM 10-155

Acceptance criteria:

An acceptable baking process is defined as the process in which the density of the baked mixture in an assembly is within the acceptance range of 22.4 ±3 lb/ft^3 as defined on Attachments B or C. If the density is less than the allowable value, contact the Company for disposition. If the density is greater than the allowable level, then re-bake the assembly using Section 3.4.5.a through k, with the exception of the final hold time which shall be 5 (±0.5) hours. Remove assemblies and allow cooling in still air until they reach ambient temperature. Recalculate and record the density on the appropriate Attachment. If the density still is greater than the allowable level, contact the Company for disposition.

n. Photograph the surface of the baked mixture (digital images are preferred).

o. Following the acceptable baking process, weld the cover plate onto the assemblies in accordance with the appropriate engineering drawing within 24 hours.

p. Weigh the final assembly and record on the appropriate Attachment (Attachment B or C).

3.5 Mixer Qualification for Kaolite 1600™ Casting Placement

The mixer qualification process shall verify that the mixer speed and mix time are properly set to mix the Kaolite 1600™. The end result of the mixer qualification is the as-baked density of 22.4±1 lb/ft^3 in the Baked Mixer Qualification Samples. This baked density can be estimated by monitoring the wet density. The baked density is approximately 41% of the wet density; therefore, the Target Wet Density is 56.2 lb/ft^3 for an average baked density of 22.4±1 lb/ft^3. The longer the Kaolite 1600™ is mixed the denser it becomes. The mixer qualification process shall verify the mix time required at a fixed and repeatable speed. The operators shall use the mixer to determine a repeatable speed to operate the mixer for all of the tests. Record the speed setting and assure that the speed setting is repeatable. The mixer qualification tests are a two step process: first is a Wet Density Mixer Time Vibration Casting test used to determine the range of mix time versus wet density; second is the mixer Baked Density Qualification Sample Vibration Casting. It is recommended that a 4-gallon or larger metal pail be used for the testing like the 4-1/2 gallon Tin-Plated Steel Pail (McMaster-Carr 4243T16 or equivalent), 9" Top Dia, 19-3/8" Height.

3.5.1 Wet Density Mixing Test

Use Attachment E, *Wet Density Mixer Time Vibration Casting*, to record information gathered during this operation.

Prepare the Kaolite 1600™ and water for mixing per section 3.2 except for the mix time. A digital stop watch shall be used to monitor the running mix time. The mix time shall vary per Form F from 1 to 15 minutes in 1 minute intervals. Use a quick release attachment to affix the two metal pails (at least 4 gallon) to the vibration table. Start the mixer and run it for one minute, start the vibration table and pour the Kaolite 1600™ into the two pails after filling let them vibrate for 2 minutes, stop the vibration table, scrape them flush, and remove the pails and weigh them. Record the weight, dump the Kaolite 1600™ back into the mixer and start the mixer for another minute and repeat the process.

Plot the wet mix density of the two pails versus the mix time in an Excel file. An Excel file generated by the Company can be provided for this task upon request. Curve fit the data

using a third order polynomial curve and show the equation. Plot the target density of 56.2 lb/ft^3 on a chart in Excel along with the wet mix density. Where the curves intersect the target density line is the mixer's target mix time. Consult the Company for verification of this data. Use the Company verified mix time for the Mixer Baked Density Qualification Castings in Section 3.5.2.

3.5.2 Mixer Baked Density Qualification Castings

Use Attachment F, *Baked Qualification Density Sample Vibration Casting*, to record information gathered during this operation.

Prepare the Kaolite 1600™ and water for mixing per section 3.2.1 except for the mix time. A digital stop watch shall be used to obtain the Company verified mix time. Start mixer and run it for the Company verified mix time. Start the vibration table and pour the Kaolite 1600™ into the two pails. After filling, let them vibrate for 5 to 7 minutes then stop the vibration table.

Remove the two pails from the vibration table. Place the filled two pails in the curing area, and let them sit uncovered for 2½ (±½) hours. After sitting 2½ (±½) hours, scrape the excess mixture from the fill opening until surfaces are flush. Cover the fill opening with plastic sheeting or a metal lid and let the assembly sit undisturbed in the curing area for at least 24 hours before weighing. Remove the two pails and weigh the cured qualification samples to an accuracy ±1 pounds. Record the as-cured and after-baking weights and follow the baking instructions in section 3.4.

4. Quality Assurance Requirements

4.1 General

4.1.1 The Seller shall have a quality assurance program that meets the applicable requirements of Title 10 CFR Part 71, Subpart H for packaging and transportation of radioactive material. The quality assurance plan shall be in accordance with the requirements identified in the ES-3100 procurement specification. The Seller shall submit an approved quality assurance program plan that describes the quality assurance policies and practices to be implemented in identifying, controlling and verifying quality of the Kaolite 1600™ processes (weighing, mixing, pouring, vibrating, curing, and baking).

4.1.2 The Seller shall submit a Manufacturing Plan as defined in procurement specification, and shall describe how the Seller will comply with the instructions in this specification. If subcontractors are utilized for any of the processing of the Kaolite 1600™, the Seller shall ensure that the requirements of this specification (including quality assurance requirements) are met by all suppliers and subcontractors. The subcontractor's procedures, approved by the Seller, shall be included in the procedures submitted to the Company for review and approval.

4.1.3 The Seller's quality assurance program plan shall include the requirements for the process controls for the operations, operator and witness' qualifications, and verification records. Operator qualification requirements are identified in Section 4.4.

4.1.4 The Seller shall generate the documentation necessary to show compliance with the approved quality assurance program plan. All records shall be identified based on the assembly serial numbers. The Seller shall maintain quality-related documentation in accordance with requirements in the procurement specification. The Company reserves the right to request any

such documentation and to witness all aspects of the fabrication process in accordance with this specification. The Seller shall ensure that the specified manufacturing and inspection records are generated and supplied to the Company as part of the certification package.

4.1.5 The Seller must ensure all operators are aware of and comply with the quality assurance requirements identified in this specification. The Seller must ensure all operators use and follow written procedures for the respective processes. The Seller shall ensure operators and witnesses are aware of the operational requirements for the common industrial equipment (material handling equipment, mixers, vibration tables, ovens/furnace) used for the processes.

4.2 Material and Equipment Certification

4.2.1 Material certification for the Kaolite 1600™ must be provided by the supplier as defined in Section 8.0 of the procurement specification. Bags of Kaolite 1600™ must be identified with the product name and unique lot number. The material certification will be incorporated into the quality assurance records of the certification package.

4.2.3 All weighting, mixing, casting, curing, and baking processes shall be controlled and performed by qualified personnel (see Section 4.4). Written procedures shall be utilized by the operator at each operation and shall identify process hold points where required by the Company.

4.2.4 All process equipment used for mixing, casting, and baking of the Kaolite 1600™ and water mixture must be the model type identified in this specification, and must be in good working condition. Equipment used for measurements must be certified to traceable NIST standards or similar agency. Variation from specified equipment (vibration table, mixer, and furnace) is not allowed without the written approval of the Company before implementation.

4.3 Nonconformance Control

4.3.1 The Seller shall have an approved procedure for the control of nonconformances, waivers, and deviation requests during the execution of this manufacturing specification.

4.3.2 Nonconforming components shall not be used unless it has been determined by analysis or assessment by the Company that the nonconformance does not impact the physical properties of the material.

4.2.3 The disposition of nonconforming components shall be documented. Any nonconforming component shall be clearly identified and all nonconformance reports shall be traceable to the actual component affected. Copies of all approved nonconformance reports, except for scrapped components shall be supplied by the Seller to the Company as part of the certification package.

4.4 Operator and Witness Qualifications

The Kaolite™ 1600 mixing and vibration casting qualification evaluations shall be sequential. Each operator must mix and cast at least one simulated drum. Mixing and casting operations shall be repeated as necessary to achieve fully cast mock drums. The simulated ES-3100 drums cast during qualification activities shall be baked according to procedure.

4.4.1 Kaolite 1600™ Mixing Process Qualifications

Each operator and witness performing Kaolite 1600™ mixing activities must be qualified to perform this activity. This qualification shall be documented. This qualification shall consist of the following:

a. Location and time.

b. Properly identifying a bag of Kaolite 1600™ the bag of material and associated certification data (such as lot numbers)

c. Inspection of the bag for observable damage (such as water damage)

d. Successfully weighing the bag of Kaolite 1600™ on an industrial scale

e. Successfully calculating the required amount of water to be mixed with the Kaolite 1600™ (1.65 pounds of water per pound of Kaolite 1600™)

f. Properly inspecting the mixing equipment for foreign materials (such as oil, grease, free liquids, trash, or evidence of non-Kaolite 1600™ material affixed to the inner surfaces.)

g. Successfully operating the mixing equipment while mixing a complete bag of Kaolite 1600™.

h. Successfully preparing a uniformly mixed batch of Kaolite 1600™. (Uniformly shall be defined as a thoroughly mixed material with no dry material and no free liquids remaining in the mixer.)

4.4.2 Kaolite 1600™ Vibration Casting Process Qualifications

Each operator and witness performing Kaolite 1600™ casting activities must be qualified by successfully performing a casting activity. This qualification shall consist of the following.

a. Properly inspecting the inner surfaces of an empty simulated ES-3100 drum body for residues (oil, grease, free liquids) and waste material. (A simulated ES-3100 drum body shall consist of a 55-gallon carbon steel open-head drum which has a 16-gallon carbon steel drum secured to the bottom center. The 16-gallon drum may be secured by tack welding or suitable fasteners. The lid of the 55-gallon drum must have an opening 15" in diameter through which the Kaolite 1600™ can be poured into the drum.)

b. Properly securing an empty simulated ES-3100 drum body to the vibration table.

c. Properly adjusting the vibration table controls to the specified values for drum assemblies.

d. Successfully transferring the Kaolite 1600™ from the mixer into the drum while the drum is vibrating.

4.4.3 Kaolite 1600™ Baking Process Qualifications

Each operator and witness performing Kaolite 1600™ baking operations shall review the procedure steps for calculating the as-baked density of the Kaolite 1600™ in the assemblies and perform a sample calculation.

[a] Record the water weight and water temperature within 10 minutes from completion of the weighing process.

[b] Recommended Vibration settings are at 450 VPM and twice the total vibrated weight. The total vibrated weight is the finish cast part and fixtures weight, for a setting of approximately 120 pound-force.

[c] A 10-digit Baking Control Number shall be used to define the date and the time of baking using the format with a 24-hour clock (i.e. 1021041515 is used for October 21, 2004 at 3:15 pm.)

[d] Use the above weights to calculate the Density as shown below. If the density is greater than 25.4 lb/ft^3 then proceed with Baking Cycle 1A. If the density is, less then 19.4 lb/ft^3 then contact the Company for disposition.

$$\text{Density} = \frac{(AfterBaking - CleanAndEmpty)}{(WithWater - CleanAndEmpty)} \times 62.3 \text{ lb/ft}^3 \text{ @ } 70°\text{F}$$

[f] Recommend Before Baking weight is to be 29.2 to 34.2 lb range.

1.0 Scope

1.1 This specification describes the requirements for the procurement, preparation, casting, and verification of a neutron absorber material into the ES−3100 shipping package. The neutron absorber material shall be cast into ES−3100 Body Weldment (Figure 1), Neutron Absorber Form (Figures 4 and 5), and 10 oz. double friction style cans (Figures 6 and 7) with tooling, i.e., Neutron Absorber Casting Funnel Assembly (Figure 2), and Body Weldment and Casting Funnel Assembly (Figure 3).

The Company (Y-12 National Security Complex) will provide training and direct oversight for the casting of the 277-4 Neutron Absorber when the Subcontractor does not have prior 277-4 casting experience.

1.2 Definitions

277-0 - Shieldwerx Catalog No. SWX-277-0 or equivalent, Heat Resistant Shielding "Non-Borated" high alumina cement.

277-4 - A mixture of 277-0 and boron carbide (B_4C) powder to form a neutron absorber material.

Companion Sample Cans - The 10 oz. double friction style cans in Figures 6 and 7 used for sampling.

Company – The Company, as used in this specification, is the buyer of the Supplier's final product (i.e., Y-12 National Security Complex)

Dry Batch - A dry mix of batch size of 277-4.

Dry Blend Batch - A thoroughly mixed Dry Batch.

Overcast – Additional cast material required to achieve the fill requirements.

PGNAA Subcontractor – Independent testing firm that performs the Prompt Gamma-ray Neutron Analysis on the companion sample cans for the Company.

Process Procedures - Dry mixing, wet mixing, casting, sampling, and inspection procedures.

Subcontractor - The manufacturer of the ES-3100 Drum Assembly per SPC JS-YMN3-801580-A002.

Vibration Casting – Vibration during casting to remove the air bubbles.

Wet Mix Batch - A wet mix of Dry Blend Batch and water.

2.0 Applicable Documents

2.1 The following documents are a part of this specification. When there is a conflict between the specification and the applicable documents, the Subcontractor shall bring it to the attention of the Company for resolution.

2.2 Standards

ASTM A 380-2017	*Standard Practice for Cleaning, Descaling, and Passivation of Stainless Steel Parts, Equipment and Systems*
ASTM C 750-2018	*Specification for Nuclear-Grade Boron Carbide Powder*
ASTM C 791-2019	*Standard Test Methods for Chemical, Mass Spectrometric, and Spectrochemical Analysis of Nuclear-Grade Boron Carbide*
ASTM C371-2009 (R 2018)	*Standard Test Method for Wire-Cloth Sieve Analysis of Nonplastic Ceramic Powders*
ASTM E105-2016	*Standard Practice for Probability Sampling of Materials*
ASTM E 11-2017	*Standard Specification for Woven Wire Test Sieve Cloth and Test Sieves*
10 CFR 71 Subpart H	*Code of Federal Regulations - Energy - Packaging and Transportation of Radioactive Material - Quality Assurance*

2.3 Company Documents

SPC JS-YMN3-801580-A002	*ES-3100 Drum Assembly*
SPC M801580-0003	*ES-3100 Packcrete Final Lot Qualification and Production Processing*
M2E801580A002	*Body Weldment*
M2E801580A032	*Neutron Absorber Casting Funnel Assembly*
M2E801580A033	*Neutron Absorber Casting Funnel Weldment*
M2E801580A034	*Neutron Absorber Form Assembly*

2.4 Referenced Documents (Not Provided with Request for Proposal)

DAC-PKG-801624-A001	*Mixing Weights And Elemental Composition of 277-4 Neutron Poison used in the ES-3100*

3.0 Requirements

3.1 General Requirements

The Subcontractor shall be responsible for supplying all materials, services, facilities, and equipment to meet the requirements of this specification unless otherwise noted. Items needed to meet the requirements of this specification that are not identified in this specification shall be specified by the Subcontractor and submitted to the Company in accordance with Attachment A.

3.2 Equipment Requirements

3.2.1 Certified Scales

All equipment and instruments (Measuring and Testing Equipment (M&TE)) used in the conduct inspections shall bear a calibration sticker that shows the equipment to be within its calibration period. Calibrations must be performed by a laboratory that meets ISO 17025. All calibration sources shall be traceable to the National Institute of Standards and Technology (NIST). All certification documentation shall be submitted to the Company in accordance with Attachment A.

3.2.2 Dry Blending the 277-0 and B_4C

A small parts tumbler shall be used to dry blend the ingredients. The small parts tumbler shall be a Multi-Barrel Small Parts Tumbler Benchtop Base (McMaster-Carr No. 44235A11) with Multi-Barrel Small Parts Tumbler 8 Gallon Barrel, 15-3/4" Dia X 14-3/4" W (McMaster-Carr No. 44235A24).

3.2.3 Mortar or Plaster Mixer

A mortar or plaster type mixer with moving vanes to shear the wet mix shall be used. The batch volume is approximately 0.5 ft^3 (15 quarts or 3.8 gallons). Therefore, it is recommended that the mixer volume should be 1.5 to 2 times the mix volume or around 0.75 to 1.0 ft^3 (22.5 to 30 quarts, ~6 to 8 gallons). The 277-4 wet mix is thixotropic when mixed and it is recommended that a heavy duty adjustable vibrator mounted to the mixer for both mixing and pouring is used.

3.2.4 Small Plaster Mixer

A drill-powered mortar or plaster mixer and a 5-gallon plastic bucket may be used on small batches of 277-4 instead of the mortar or plaster type mixer. The 5-gallon plastic bucket shall be placed upon the Heavy Duty Drum Vibrator (see Section 3.2.6).

3.2.5 Vibration Powered Funnel Assembly

The Neutron Absorber Casting Funnel Assembly with a vibration- powered funnel (Figures 2 and 3) shall fill both the Body Weldment (Figure 1) and the Neutron Absorber Form (Figure 4). The Casting Funnel Assembly may be modified as required by the Subcontractor to get the wet mix to flow.

3.2.6 Heavy Duty Drum Vibrator

A Heavy Duty Drum Vibrator/Packer shall be used to hold the Body Weldment (Figure 1) or Neutron Absorber Form (Figure 4) for vibration casting the 277-4 into the stainless steel forms.

3.2.7 Bench Vibrator

A bench vibrator shall be used during the mixing of the companion sample cans. The bench vibrator shall be Tabletop Vibration/Mixing Table 10-in. by 7-in. Platform, 10-lb Capacity Continuous Use (McMaster-Carr No. 5714K61.

3.3 277-4 Neutron Absorber

3.3.1 Raw Casting Material Requirements and Inspection

3.3.1.1 277-0

Shieldwerx Catalog No. SWX-277-0 Heat Resistant Shielding "Non-Borated" shall be procured. The manufacturer model or catalog number and expiration date shall be clearly indicated on the container. A Certificate of Conformance shall be provided with each lot or batch. The Certificate of Conformance shall include the lot or batch number and the expiration date. The 277-0 shall be sealed and stored in a dry place.

3.3.1.2 Type 1 Nuclear-Grade Boron Carbide Powder

The $^{nat}B_4C$ Manufacturer shall supply the Supplier with a CoC stating that the $^{nat}B_4C$ is Type 1 Nuclear Grade $^{nat}B_4C$ and 99.90% of the material has passed through a No. 140 sieve per ASTM E 11. The Supplier shall submit Sampling Plans per ASTM E105 for Company approval in accordance with the submittal checklist. The Company will supply test results to the Supplier from samples obtained from the $^{nat}B_4C$ Manufacturer. A test report will be submitted to the Supplier for inclusion into the final data package. The $^{nat}B_4C$ **shall not be shipped** from the $^{nat}B_4C$ Manufacturer **prior to Company approval.** A copy of the CoC shall be submitted with the final data package **in accordance with the submittal checklist.**

3.3.1.3 ^{10}B Content

B_4C powder shall be procured as Type 1 Nuclear-Grade Boron Carbide Powder per ASTM C 750. The ^{10}B content shall be verified to meet the amount as stated in ASTM C 750 by a testing subcontractor, determined by gravimetric analysis of batch samples per ASTM C791.

3.3.1.4 Water

The water shall be potable, filtered through a 20-micron filter and an activated charcoal filter, have a chlorine content of less than 4 ppm, and have a temperature of 65±15°F. Unfiltered potable water may be used for the cleaning of equipment used to cast the neutron absorber system.

3.3.2 Dry Blending Process

3.3.2.1 Dry Batch

A dry batch of 277-4 shall be a mixture of 93.6 wt% 277-0 and 6.4 wt% B_4C. It shall be of sufficient quantity to fill one ES-3100 Body Weldment or Neutron Absorber Form, i.e., approximately 0.55 ft^3 poured volume and 50 lbs. of dry 277-4 weight. The batch size may be adjusted as necessary based on experience for the ES-3100 Body Weldment or Neutron Absorber Form. The tolerance for 277-0 and B_4C weighting shall be the following:

277-4 Dry Batch Size	277-0	B_4C
Equal to or greater than 30 lbs.	±0.2 lbs.	±.01 lbs.
Less than 30 lbs	±.01 lbs.	±.01 lbs.

The data shall be recorded on Form A.

3.3.2.2 Blended Dry Batch

The dry batch of 277-4 shall be thoroughly blended. The data shall be recorded on Form A.

If the blended dry batch is not used immediately, the blended dry batch shall be sealed and stored in a dry place with a Blended Dry Batch control number attached to the container.

The Blended Dry Batch shall not be used if the 277-0 expiration date has expired.

3.3.3 Wet Mixing

The weight of the dry mix and water shall be to the following weight proportions of 100% dry mix and 27±1% water. The 277-4 is thixotropic when mixed. It is recommended to have a heavy duty adjustable vibrator mounted to the mixer for both mixing and pouring. Place the water in the mixer and add the dry mix into the water. Before casting, mix the dry powder and water for at least 3 minutes and less than 60 minutes. Any material in the mixer after 60 minutes shall be discarded. Mix only in a room with a temperature range of 70±25°F.

The data shall be recorded on the appropriate form, i.e., Form B for overcast, Form C for Body Weldment, Form D for Neutron Absorber Form, and Form E for PGNAA Acceptance Standards.

3.3.4 Body Weldment and Neutron Absorber Form Vibration Casting

3.3.4.1 Vibration Casting Requirements for Body Weldment and Neutron Absorber Form

During the vibration casting of the 277-4, record the Body Weldment (Figure 1) casting data on Form C and the Neutron Absorber Form (Figure 5) casting data on Form D. A stainless steel vibration powered funnel (i.e., Neutron Absorber Funnel Assembly shown in Figure 3) fits inside the 2.10-in. wide slotted fill hole shown in Body Weldment and in Neutron Absorber Form.

a. Weigh and record the data on Form C or on Form D.
b. Weigh and record the water weight and temperature data when filled with water to within 0.25 in. of the top metal surface.
c. Remove the water.
d. Secure the part on the drum vibrator.
e. Plug the 6.24 in. diameter cavity to keep the wet mix from falling into the liner bottom.

f. Place the Neutron Absorber Funnel Assembly in the slot and secure in place. If required, additional vibrators may be added.
g. Prepare the Wet Mix per Section 3.3.3.
h. Start the drum vibrator.
i. Scoop the wet mix into the Neutron Absorber Funnel Assembly.
j. Turn on the vibrating funnel and adjust the vibration force until the wet mix flows.
k. About half way through filling the wet mix in either the Body Weldment or Neutron Absorber Form, cast two companion samples for Section 3.3.7. Record the companion sample data on Form F and either Form C or Form D.
l. Continue filling the wet mix until the part will take no more.
m. After filling is complete, vibrate the container for 45±15 seconds to remove air bubbles.

3.3.4.2 Overcast Requirements for Body Weldment and Neutron Absorber Form

A few hours after casting, the 277-4 will settle in the vertical direction and leave a layer of watery fluid on the top of the casting. Remove this fluid and overcast the top between 4 and 24 hours from the first casting. After the overcast has cured for between 4 and 24 hours inspect the depth of casting to the top metal surface and verify that it is within 0.25 in. If not within the 0.25 in., cast additional 277-4 material and perform the following:

a. Remove the water.
b. Secure the Body Weldment or Neutron Absorber Form on the drum vibrator.
c. Plug the 6.24 in. diameter cavity to keep the wet mix from falling into the liner bottom.
d. Record the Overcast Wet Mix Control Number (WMCN) on the appropriate casting data form.
e. Prepare the Wet Mix per Section 3.3.3.
f. Start the drum vibrator.
g. Scoop the wet mix into the Body Weldment or Neutron Absorber Form Assembly until the vent hole is filled.

The final shrinkage of the 277-4 shall be within 0.25 in. of the metal surface as shown in Figures 1 and 5.

3.3.4.3 Curing Requirements Body Weldment and Neutron Absorber Form

Cover the newly cast wet component with plastic or metal for 7 days. Do not store the cast 277-4 castings in temperatures below 35°F for the first 30 days after casting.

After 7 days, remove the plastic or metal cover and dehydrated using either or both vacuum and heat to create an acceptable density and weight. If heat is used, the maximum temperature of the inner liner shall not exceed 250°F.

Record the diamond I measurements shown on Figures 1 and 5 on the appropriate casting data forms. The acceptable cured height measurement shall be less than 0.25 inches. The acceptable cured casting weight shall be between 45.3 and 57.8 lbs. Cured casting weights shall be used to calculate the cured density. If the cured casting density is greater than 120 lb/ft^3, continue the dehydration process. If the cured casting density is less than 100 lb/ft^3, the casting shall be unacceptable, the appropriate form shall be completed, and a copy of the form shall be sent to the Company.

3.3.5 PGNAA Acceptance Standards

The PGNAA Acceptance Standards shall be made with a Company representative witnessing the manufacturing processes of weighing, blending, wet mixing, and casting. The PGNAA Acceptance Standards shall be the 10-oz. double friction style metal cans as shown in Figures 6 and 7. The cured

casting weight for each can shall be measured and the cured casting density recorded on Form E. A cured casting density of 100 to 120 lb/ft^3 and a cured casting weight of 1.16 to 1.56 lbs shall be acceptable. If the cured casting density is outside the acceptable range, a copy of the form shall be sent to the Company.

One can from the middle of the lot on Form E, i.e., a maximum lot of 22 cans, shall be selected and identified as a companion sample can for Loss On Drying (LOD) testing. The remainder of the lot shall be sent to the PGNAA Subcontractor.

3.3.6 Companion Sample Cans

In addition to the companion sample cans selected in Section 3.3.5, two companion sample cans shall be made half way through the casting process for the Body Weldment and the Neutron Absorber Form per Section 3.3.4.1. Companion sample can data shall be recorded on Test Form F.

a. The cured casting density of all companion sample cans shall be calculated per Section 3.3.8.2 and recorded on Form F. If the cured casting density is outside the acceptable range, a copy of the form shall be sent to the Company. A low cured casting density of a companion sample can shall not be a reason to reject the Body Weldment, Neutron Absorber Form, or PGNAA Acceptance Standards casting lot.
b. The odd serial number companion sample cans for the Body Weldment, Neutron Absorber Form, or PGNAA Acceptance Standards casting lot shall be LOD tested to verify the hydrogen content per Section 3.3.8.3.
c. The even serial number companion sample cans for the Body Weldment and the Neutron Absorber Form casting lot shall be PGNAA tested to verify the ^{10}B content per Section 3.3.8.4.

3.3.7 Casting the 10 oz. Double Friction Style Cans

a. Weigh the empty labeled can and lid and record the casting can data on Forms C, D, or E. It is acceptable to weigh ten cans with ten lids for each purchase order of cans and to use the average can and lid weight on each form.
b. Weigh the water and measure the water temperature. Record this data on Form C, D, or E. Fill with water only up to the bottom of the inside rim. The can lid shall be on the scale. It is acceptable to weigh the water weight of the first ten cans with ten lids of the same lot of cans and to use the average water weight for each of the following cans if the measurements are consistent.
c. Remove the water from the cans.
d. Prepare the Wet Mix Batch following Section 3.3.3.
e. Hold the can on the bench vibrator during filling with the 277-4 wet mix. Quickly vibrate and continue to add wet mix to the can lip.
f. Once all of the cans are full of wet mix, return the first can back to the vibrator for at least 3 minute at a high frequency setting. During the 3 minutes of vibration, continue to add 277-4 wet mix until the can stays full. Repeat this process for all the cans in the casting lot.
g. Between 1 to 24 hours after casting, scrape the top of the casting to meet 1.37±0.06 dimension from bottom of can noted on Figure 7.
h. Clean the can rim around the edge per Section 3.4.2.
i. Perform an in-process measurement of the scraped casting height to ensure that the casting height parameters are met shown in Figure 7.
j. Cover the casting by placing the properly labeled can lid on the can for 7 days.
k. Remove the can lid and let the can air dry or use either or both vacuum and heat to create an acceptable density and weight. If heat is used, the maximum temperature of the can shall not exceed 250°F.
l. Measure casting height and weigh the can with lid. Record this data on Forms C, D, or E.

m. Record the final Companion Sample Can casting density, weight, or casting height measurements data on Form F.
n. Plug lid onto double friction style can, as applicable.

3.3.8 Verification

All verification shall be completed after the casting is cured.

3.3.8.1 Cured Casting Density Verification

The density of cured casting in the Body Weldment, Neutron Absorber Form, and PGNAA Acceptance Standards shall be determined by weighing the casting container before casting, while filled with water, after casting, and when cured.

Since the density of water is known, a simple relationship between the weight differences shall determine the cured casting density.

$$Density = \left(\frac{Cured - Empty}{WithWater - Empty} \right) \times 62.3 \text{ lb/ft}^3$$

3.3.8.2 Companion Sample Can Cured Casting Density Verification

The density of cured casting in each companion sample can shall be determined by weighing the can before casting, while filled with water, after casting, and when cured.

Since the density of water is known, a simple relationship between the weight differences shall determine the cured casting density.

$$Density = \left(\frac{Cured - Empty}{WithWater - Empty} \right) \times 62.3 \text{ lb/ft}^3$$

3.3.8.3 Companion Sample LOD Verification

The companion sample cans identified in Section 3.3.6.b shall be LOD tested. The acceptable LOD percent range shall be based upon the companion sample can cured casting density in Section 3.3.8.2. The Acceptable Maximum and Minimum LOD% at Density is in this table developed from data in DAC-PKG-801624-A001 Table 7, 277-4 Composition @ Extreme Densities and LOD% and compared to the average values as manufactured.

Acceptable Maximum and Minimum LOD% at Density		
Density (lb/ft^3)	Maximum LOD%	Minimum LOD%
100	31.80%	28.61%
101	32.47%	28.33%
102	33.12%	28.06%
103	33.77%	27.79%
104	34.40%	27.52%
105	35.03%	27.26%
106	35.64%	27.00%
107	36.25%	26.75%
108	36.84%	26.50%
109	37.42%	26.25%
110	37.99%	26.01%
111	38.56%	25.78%
112	39.11%	25.55%
113	39.65%	25.32%
114	40.18%	25.10%
115	40.70%	24.88%
116	41.21%	24.66%
117	41.71%	24.45%
118	42.20%	24.25%
119	42.68%	24.05%
120	43.15%	23.85%

a. The lid shall have the serial number permanently transferred by vibro etch or other method.
b. The lid shall have a small vent hole in it. It is recommended that a nail be used to punch a hole 0.12±0.06 in. diameter in the metal lid from the inside surface of the lid.
c. Match the can serial numbers and place the lid on the can.
d. The weight of the can shall be recorded on Form F.
e. The cans shall be placed in an oven at 1500±150°F (800°C) for 4 hours.
f. The weight of the can shall be recorded on Form F with the can temperature not below 100°F.
g. Calculate the LOD% using the equation below and record it on Form F. Due to can oxidizing and gaining weight during the heating cycle, a 0.024 lb correction factor is included in the following LOD% calculation.

$$\text{LOD\%} = \left[1 - \frac{(LODWeight - Empty - 0.024lb)}{(Cured\ \&\ Clean - Empty)}\right] \times 100\%$$

h. Verify that the LOD% is within the acceptable range. If water content is outside the acceptable range, a copy of the form shall be sent to the Company.

3.3.8.4 PGNAA Verification

The PGNAA Acceptance Standards in Section 3.3.5 and Companion Sample Cans identified testing in Section 3.3.6.c shall be sent to the PGNAA Subcontractor.

3.4 Cleaning Requirements

3.4.1 Contact with Chlorides or Fluorides

The stainless steel material shall be protected from contact with chlorides in accordance with ASTM A380, paragraph 8.5, during all operations including packaging. The Safety Data Sheet (SDS) for all cleaning solutions or products used on the ES-3100 shall be submitted to the Company in accordance with Attachment A.

3.4.2 Satisfactory Cleanliness

Cleaning procedures for the stainless steel per Section 3.4.3 of equipment specification SPC JS-YMN3-801580-A002 shall be submitted to the Company in accordance with Attachment A. Only non-chloride-bearing chemicals shall be used for cleaning (e.g., trisodium phosphate detergent or acetone). Water used in cleaning shall have a maximum chlorine content of 4 parts per million.

After casting but prior to packaging, stainless steel components of the forms and cans shall be cleaned per the approved cleaning procedures. Satisfactory cleanliness shall be determined by visual inspection as can be observed by a person with normal visual acuity (natural or corrected) and without magnification. Light intensity of at least 100 ft-candles shall be provided on the surface to be inspected.

3.5 Government-Furnished Equipment

None

4.0 Quality Assurance

4.1 Quality Assurance Program

The Seller shall have implemented and maintain a quality system in accordance with ASME NQA-1 2008, 1a-2009, Part 1, Sections 1-18 and/or 10 CFR 71 Subpart H and DOE O 414.1D Attachment 3, with respect to Suspect Counterfeit Items. A copy of the Seller's QA Program Manual shall be submitted with the bid in accordance with Attachment A for review and approval. The Seller shall comply and conduct all work in accordance with their Quality Assurance program and this Equipment Specification. Company will provide the critical characteristics for any items or services to be dedicated.

4.2 ES−3100 Casting Quality Assurance Requirements

4.2.1 ES−3100 Documentation Package

All records shall be identified based on the ES−3100 serial numbers. The ES-3100 Documentation Package shall be provided as Certified Data with each ES-3100 casting. The ES-3100 Documentation Package shall be complete, legible, indexed, and traceable to the material supplied and include the following:

a. Material measuring, dry blending, wet mixing, casting, sampling, and inspection forms, i.e, Forms A through F.
b. A Certificate of Compliance for each lot of the 277-0 Heat Resistant Shielding "Non-Borated" dry mix documentation with the expiration date identified on each container.
c. A Certificate of Compliances for B_4C powder to Type 1 Nuclear-Grade Boron Carbide Powder per ASTM C 750, chemical and elemental analysis per ASTM C 791, and 99.90% of the powder passes through a No. 140 Sieve per ASTM E 11.

d. A Certificate of Compliance signed by an officer of the Subcontractor confirming that the cast neutron absorber in ES−3100 shipping package meets the subcontract requirements.

4.2.2 Batch Processes

Batch processes such as mixing, pouring, curing, sampling, inspection, etc., shall be performed in accordance with detailed written procedures. These procedures shall specifically describe the exact manner in which these processes are to be performed. All records shall be traceable to the ES−3100 Shipping Package, Neutron Absorber Form, PGNAA Acceptance Standards or Companion can serial numbers.

4.2.3 Materials Traceability

A manufacturing lot or batch number shall identify material furnished to make up the neutron absorber system. Materials shall be identified by material type; applicable specification and revision number, and be traceable to their lot numbers. Traceability records shall be available for review by the Company's representative.

4.2.4 Procedures

Preparation, installation, sample collection, and inspection processes shall be controlled and performed by qualified personnel. The procedures must incorporate a mechanism to identify process step completion. Procedures shall be submitted as Approval Data. The approved procedures shall be provided as Certified Data prior to the start of casting.

4.2.5 Training and Qualification of Personnel

The Subcontractor shall provide for the training and qualification of personnel to ensure their competence in the use of process procedures and specifications. Records of personnel qualifications shall be made available to the Company upon request. Note: If the Subcontractor does not have prior experience in casting 277-4 Neutron Absorber, the Company will provide training and direct oversight on the processes.

4.2.6 The Company reserves the right to request any documentation and to witness any of the processes performed in accordance with this specification.

5.0 Preparation for Delivery

After cleaning of stainless steel surfaces per Section 3.4, aluminum foil duct tape shall be applied over the fill and vent holes in the Body Weldment (Figure 1) and the Neutron Absorber Form (Figure 5).

6.0 Manufacturer's Data

6.1 Offer Appraisal Data shall be submitted with the offer. This data shall become part of the subcontract requirements.

6.2 Approval Data will be reviewed and approved by the Company. Subcontractor shall not proceed with the casting activity until Company approval is given for all the Approval Data. The Approval Data shall be transmitted to the Company by the dates agreed to by the Subcontractor and the Company Subcontractor Administrator.

6.3 Certified Data will be used by the Company as the record for the ES-3100 shipping packages. The Certified Data shall be transmitted as noted.

6.4 Requests for Waiver or Deviation

6.4.1 After award, if a waiver or deviation from the specified requirements is desired, then the Supplier shall submit to the Company a Request for Waiver or Deviation form: UCN-13816B. The Company will provide this form upon request.

6.4.2 Use the UCN-13816B form to request permission to change or deviate from the specified requirements; obtain Company approval before proceeding with any changes.

6.4.3 Email the completed form to the STR.

6.4.4 Use the form to report any of the following conditions:

a. A request for deviation from the contract requirements.
b. Anytime a requirement contained within the original specification or a contract modification approved by the Company is violated.
c. There is nonconformance that cannot be corrected unless an item or process is modified, reworked, or repaired to an equivalent functional condition.
d. A request for Company approved substitutions shall be submitted using the RFWD form for Company approval prior to implementation. Adequate information shall be provided with the request so that the Company can determine if the item is equivalent.

FORM A 277-4 Dry Blend Batch Control Rev G Page 1 of 1

Casting Company Name	Certificate of Conformance of the 277-0 dry mix		
Blended Dry Batch Control Number [a]	Record the expiration date of the 277-0 dry mix [b]		
Certificate of Conformance of the B_4C dry mix	277-0 Heat Resistant Shielding Drum ID Number		
Planning	277-4 Weight	Units	Operator
Batch Size		lb	
Operation	Measurement	Units	Operator
277-0 Weight (Target = 277-4 Weight x 93.6 wt%)		lb	
B_4C Weight (Target = 277-4 Weight x 6.4 wt%)		lb	
Dry Blending Time		min.	
Comments			

[a] A 10-digit Blended Dry Batch Control Number shall be used to define the date and the time of mixing the casting batch using the format with a 24-hour clock (i.e. 1021041515 is used for October 21, 2004 at 3:15 pm.)

[b] Record the expiration date of the Blended Dry Batch and confirm that it is still acceptable to be cast following this specification.

EXEMPT FROM IO-155 (8-02)

FORM B 277-4 Wet Mix Control (Overcast or Special Batch) Rev G Page 1 of 1

[a] For the same lot of sample cans, it is acceptable to use an average weight of ten can bodies and ten can lids.

[b] Recommended vibration settings are at 450 VPM and three times the total vibrated weight. The total vibrated weight is the finish cast part and fixtures weight, for a setting of approximately 5 pound-force.

$$Density = \left(\frac{Cured - Empty}{WithWater - Empty} \right) \times 62.3 \text{ lb/ft}^3$$

$$\text{LOD\%} = \left[1 - \frac{(LODWeight - Empty - 0.024)}{(Cured \ \& \ Clean - Empty)} \right] \times 100\%$$

Attachment A: Instructions to Supplier for Preparation of Submittals

Note 1 –All correspondence shall be addressed to the Technical Representative identified by the company. The Supplier shall forward submittals via transmittal letter to the Company at the address specified in the contract.

Note 2 – The submittal must have adequate detail so that full compliance with the requirements may be determined. For example, a simple off-the-shelf item to be used in an assembly may only need a manufacturer's cut-sheet to show compliance, but a factory acceptance test (FAT) developed and submitted by the Seller must have each test step detailed with acceptance criteria consistent with the requirements.

a. Review submittal before transmitting to the Company to verify conformance with requirements of the contract documents (e.g., field measurements, field construction criteria, or manufacturer's catalog numbers).
b. Coordinate submittals with the work requirements and the contract documents.
c. Organize Submittals
   - Do not use highlight marker or color coding on submittals.
   - The minimum resolution used for scanning submittals shall be 300 dpi x 300 dpi.
   - For submittals containing color information important to the record, a 24-bit color setting should be used.
   - Submittals are to be legible and in the format specified on the submittal checklist.
   - Pen and ink changes are to be made in non-erasable ink, legible, dated and initialed.
   - Mark specific options provided for the work, and cross out options not provided.
   - Each submittal shall be sent as a single pdf file unless otherwise specified.
d. Label submittals with the applicable item number, reference, and requirement description as summarized in the Submittal Checklist. Unlabeled submittals will be returned to the Seller without review.
e. Include with submittals a transmittal letter that identifies individual documents by specification section.
   - Transmittal for submittals shall be numbered using the purchase order number followed by a 4-digit sequential number (Example: 430001111-0001).
   - Embedded comments or questions that are not included on the transmittal may not be addressed/resolved by the Company.
f. Direction will be given at the time of award to either upload submittals to a company provided URL address or send by email to a company provided email address.
g. If using a company provided URL to upload submittals, notify the Company via email when submittals have been placed.
h. After review of a submittal, the Company will assemble comments and provide a status on the documents. An example of this submittal status stamp is shown below.

DOCUMENT REVIEW STATUS		
1	☐ Work may proceed.	
2	☐ Revise & resubmit. Work may proceed subject to incorporation of changes indicated.	
3	☐ Revise & resubmit. Work may not proceed.	
4	☐ Review not required. Work may proceed.	
Permission to proceed does not constitute acceptance or approval of design details, calculations, analysis, test methods developed or selected by the supplier and does not relieve supplier from full compliance with contractual obligations.		
REVIEWED BY:	Print Name/Signature :	Date:

i. If a submittal is being resubmitted, then reference the applicable item number, reference, and requirement description and identify it as a resubmittal.
j. Company response will only be returned to the Supplier for those submittals with a Submittal Purpose of "For Action, "unless it is determined that a submittal transmitted "For Information" is not acceptable.
k. AFTER written approval is obtained, THEN proceed with work requiring approved submittals.
l. When approval submittals are required, work done before Company approval is at the Seller's risk.
m. Maintain a copy of the company-approved submittal and status page on file.

Package Category Determination

The ES-3100 with HEU content package has a maximum activity of 0.72554 TBq (19.6092 Ci) at 10 y after initial fabrication; the maximum number of A2s carried is 4752.8 at 70 y after initial fabrication (Table 4.4). Based on the guidance from Nuclear Regulatory Commission Regulatory Guide 7.11, *Fracture Toughness Criteria of Base Material for Ferritic Steel Shipping Cask Containment Vessels with a Maximum Wall Thickness of 4 Inches (0.1 m)*, this package is classified in Table 1.1 of NUREG-1609 as a Category I package.

Appendix 1.3.8
Pyrophoricity of Uranium Metal

Prepared by: Russell W. Schmidt

Appendix 1.3.8
Pyrophoricity of Uranium Metal

I. Introduction

The ES-3100 is a new shipping container designed for safe and efficient transportation of highly enriched uranium in a wide range of material forms. The ES-3100 has been certified for use with a variety of contents, including enriched uranium metal and alloy. However, the current size limitations on uranium contents in the form of broken metal are unnecessarily restrictive. The size limits exist because under certain conditions uranium metal and some uranium alloys are pyrophoric – they have the potential to spontaneously ignite. The size restrictions are intended to eliminate the possibility of spontaneous ignition during transport.

The purpose of this analysis is to evaluate the potential for uranium metal pieces to spontaneously ignite under the conditions expected for shipment in the ES-3100 shipping container, and to identify limits on the uranium metal content that will prevent spontaneous ignition during transport, while still allowing a high degree of flexibility and utility.

It is important to remember that the content limits developed for the ES-3100 must be implemented in the field. Therefore the criteria derived from this evaluation must be simple, robust, and readily applied in all of the facilities using this package.

This evaluation does not include new laboratory tests of uranium metal ignition parameters. Such tests have been performed and well documented in the past. This evaluation draws on the extensive body of existing data and proven storage and transport practice to identify the bounds within which uranium metal and alloys can be safely transported in the ES-3100 shipping container.

II. Proposed Definition of Pyrophoricity

The Certificate of Compliance (CoC), gives the definition of broken metal in Paragraph 5(b)(1)(ii), as follows:

> *For metal or alloy defined as broken metal, mass limits are specified in Table 2. Uranium metal and alloy pieces must have a surface-area-to-mass ratio of not greater than 1 cm²/g or must have a mass not less than 50 g, whichever is most restrictive. Powders, foils, turnings, wires, and incidental small particles are not permitted, unless they are restricted to not more than 1 percent by weight of the content per convenience can, and they are either in a sealed, inerted container or are stabilized to an oxide prior to shipment.*

It is suggested that the definition of broken metal in Paragraph 5(b)(1)(ii) be revised to the following:

> *For metal and alloy defined as broken metal, mass limits are specified in Table 2. Uranium metal and alloy pieces must have a surface-area-to-mass ratio of not greater than 1 cm²/g or must not pass freely through a 3/8-inch (0.0095 m) mesh sieve. Particles and small shapes that do not pass this size restriction, as well as powders, foils, turnings, and wires, are not permitted, unless they are either in a sealed container under an inert cover gas.*

III. Rational for Proposed Changes

The proposed text makes the following changes:

- The 50 g minimum piece size is eliminated.
- A 3/8-in. mesh limit is added.
- The phrase "whichever is most restrictive" is deleted.
- Remove oxidation as a treatment for pyrophoric uranium, in this context.
- The 1% limit on inerted material is eliminated.

The 1-cm^2/g maximum specific surface area limit is the most significant limit in the original text, and that limit is retained unchanged. Specific surface area is the most significant parameter in determining if a given piece of uranium is at risk of spontaneous ignition under a given set of conditions, and therefore it is appropriate that this restriction should control any other restrictions to the package contents. The discussion section below will demonstrate that the 1 cm^2/g maximum allowable specific surface area is adequate to prevent spontaneous ignition in the ES-3100.

The 50-g minimum piece size is overly restrictive and is inconsistent with the 1-cm^2/g upper limit on specific surface area. Smooth uranium metal pieces can have a mass of less than 0.5 g and still have a specific surface area less than 1 cm^2/g (see Example 1). This makes the 50-g limit two orders of magnitude too large. The 50-g limit is nearly an order of magnitude too large even considering metal pieces with the rough surface of broken metal instead of a smooth cast or polished surface.

Example 1.
Consider a smooth uranium metal sphere with a diameter of 0.32 cm (0.126 in.).
The radius of the sphere is 0.16 cm. The density of uranium metal is 19 g/cm^3.

The volume is	$V = (4 / 3) \times Pi \times r^3 = (4 / 3) \times Pi \times (0.16)^3 = 0.01716\ cm^3$
The mass is	$M = Density \times V = 19\ g/cm^3 \times 0.01716\ cm^3 = 0.3260\ g$
The surface area is	$A = 4 \times Pi \times r^2 = 4 \times Pi \times (0.16)^2 = 0.3217\ cm^2$
The specific surface area is	$SA = A / M = 0.3217\ cm^2 / 0.3260\ g = 0.9868\ cm^2/g$

This specific surface area is just within the 1 cm^2/g upper limit.

If instead of a smooth surface the sphere has a rough surface characteristic of broken uranium metal, a larger size is needed to ensure that the 1 cm^2/g limit is maintained. For a roughness factor of three (meaning that the rough surface has an actual surface area that is three times the surface area calculated from the radius), the radius would need to be three times the above example to give the same specific area. In this case:
$r = 3 \times 0.16\ cm = 0.48\ cm$; $V = (4 / 3) \times Pi \times (0.48)^3 = 0.463\ cm^3$;
$M = 19\ g/cm^3 \times 0.463\ cm^3 = 8.802\ g$; $A = 4 \times Pi \times (0.48)^2 \times 3$ (roughness factor) $= 8.686\ cm^2$
And so the specific surface area is $8.686\ cm^2 / 8.802\ g = 0.9868\ cm^2/g$ as above.

Depending on the surface roughness, a sphere with a mass between 0.33 and 8.8 g will meet the 1 cm^2/g specific surface area limit

The 1 cm^2/g specific surface area limit controls the parameter that is most important in terms of preventing spontaneous ignition, but it is not easy to measure or to use in the field. A mass limit (similar to the 50-g limit in the existing certificate, but more consistent with the 1-cm^2/g specific area limit) could be used, but it is very time-consuming to weigh every piece of metal in a package. An approach that is both effective at enforcing the 1-cm^2/g specific surface area limit and quick and easy to use in the field is to separate large pieces from small ones in a sieve. The recommended text stipulates a 3/8-in. mesh sieve to quickly remove small particles (with a large specific surface area) from large particles which have a small specific surface area.

As demonstrated in Example 1, rough-surfaced spheres 3/8 in. (0.95 cm) in diameter meet the 1 cm^2/g specific surface area limit (a smooth-surfaced sphere of this size has a specific surface area of 0.33 cm^2/g). Therefore, a sphere which does not pass freely through the 3/8-in. mesh sieve will meet the 1 cm^2/g specific surface area limit. Other simple shapes such as cubes and rods are also effectively controlled by the 3/8-in. sieve. Foils, turnings, and wires are explicitly forbidden in both the current and proposed text, unless they are packed in an inert atmosphere.

The phrase "whichever is most restrictive" has been deleted from the proposed text since the sieve test has been sized to effectively enforce the 1-cm^2/g specific surface area limit.

The option of converting pyrophoric uranium to an oxide is removed, since metals need to be shipped as metals for maximum usefulness at the receiver site. In addition, if oxides are produced, packing limits for oxides have been explicitly given in the CoC.

The final change in the proposed text is to eliminate the 1% of content weight limit on inerted material. This limit is unnecessary for uranium metal sealed in a container containing an inert atmosphere. If the metal has been sealed in a container containing an inert atmosphere, there is no oxygen available to the metal and therefore no chance of combustion.

Uranium metal packaged for transport in the ES-3100 is first placed inside a convenience can or other container. These cans are then placed into the ES-3100 containment vessel (CV). The convenience cans will displace most of the oxygen from the CV, leaving only enough to react with a few grams of metal. If a sealed container containing an inert atmosphere somehow came open in transport (an unlikely scenario given the very limited amount of movement possible inside a properly loaded CV), this small amount of oxygen is not enough to support spontaneous ignition. The CV has been shown to retain its structural integrity and remain leak tight under hypothetical accident conditions (HAC), so no additional oxygen can enter.

IV. Discussion

In his 1995 review,[1] Terry Totemeier explains pyrophoricity this way: "Pyrophoricity refers to the tendency of certain metals to ignite and burn in a self-sustaining oxidation reaction. The pyrophoric nature of metals is usually defined in terms of an ignition temperature, which is the temperature at which a metal will ignite and burn in a self-sustained fashion for a given set of conditions." ASTM C-1454[2] defines pyrophoric as "capable of igniting spontaneously under temperature, chemical, or physical/mechanical conditions specific to the storage, handling, or transportation environment."

This evaluation will demonstrate that uranium metal with a specific surface area of 1 cm^2/g will not spontaneously ignite under the conditions existing in the ES-3100 during packaging and transport.

The primary factors determining if the conditions for spontaneous ignition exist are specific surface area and temperature. Totemeier explains, "Because oxidation is a surface reaction, the amount of area available for reaction is a critical factor in the determination of the heat generated in oxidation. Specific area is the best parameter to describe the effect of area, as it also accounts for the amount of material not reacting which can serve as a heat sink." Temperature is critical because the amount of heat generated by the reaction is a function of the reaction rate, which is in turn a function of the temperature. Higher temperatures give higher reaction rates.

An additional safety factor in the case of the ES-3100 is the small amount of oxygen available in the sealed inner CV. This serves to limit the total amount of uranium that can oxidize, and therefore prevents any potential heat build-up from reaching the ignition point of uranium metal.

Ignition Temperature and Transport Conditions

In Figs. 4 and 5 of his review, Totemeier plots two separate tests of uranium ignition temperatures as a function of specific surface area. For a specific surface area of 1 cm^2/g these two plots give values of 390°C (663 K)[1] and 340°C (613 K), respectively. Using the lower value and rounding down gives a conservative value of 600 K for the ignition temperature of uranium metal in the ES-3100.

The ES-3100 thermal analysis determined that the temperature at the CV wall would not exceed 190°F (361 K) for normal conditions of transport (NCT) and 255°F (397 K) for HAC. These values, particularly the HAC temperature, are very conservative. The actual results from six separate package tests showed that the CV wall temperature was typically around 210°F (372 K), with the highest recorded value of 241°F (389 K). Note that all of these temperatures are well below the 600 K ignition temperature of the uranium metal contents.

Maximum Temperature from Oxidation – Basic Equations

Uranium metal readily reacts with oxygen to form uranium dioxide (UO_2). This reaction is exothermic. The heat released by the reaction warms the uranium metal, increasing the reaction rate. Under normal conditions for storage and transport, the reaction rate is slow enough that the small amount of heat generated by the reaction is lost to the environment, and a stable steady-state is achieved. If the reaction rate is fast enough, and the metal is relatively well insulated, the temperature of the uranium metal can build, slowly at first but at an increasing rate, until the ignition temperature is reached and the metal ignites and burns.

The task at hand is to evaluate the balance between heat generation and heat loss in the ES-3100 under HAC to verify that a stable steady state is reached, and that the steady-state condition is safely below the ignition point of uranium metal. A recent paper by Epstein, Malinovic, and Plys[3] lays out a useful approach, which will be followed here without the approximations used in their paper.

---

[1] The curve in Totemeier Fig. 4 is discontinuous, with a transition from a lower curve to an upper curve shown at a specific surface area of 6 cm^2/g. At a specific surface area of 1 cm^2/g, the upper curve would give an ignition temperature of 550ºC, while extrapolation of the lower curve gives 390ºC. The original reference from which Totemeier drew Fig. 4 explains that the transition from the lower curve to the upper curve is influenced by many factors, including the metallurgy of the uranium, any alloying metals or impurities, and the oxygen content of the gas involved. Therefore, this analysis uses the lower curve value of 390ºC.

For uranium metal packed in cylindrical cans, the generation of heat throughout the can and the associated transfer of heat to the can wall is mathematically identical to the generation of heat within a wire due to electrical resistance. In their text "Transport Phenomena"[4] Bird, Stewart & Lightfoot develop the desired relation (Equation 9.2-14):

$$Tcenter - Twall = (S \times R^2) / (4 \times Kth) \quad \text{(Equation 1)}$$

where

Tcenter is the temperature at the center of the can (K)
Twall is the temperature at the can wall (K)
S is the heat production per unit volume (W/cm^3)
R is the radius of the can (cm)
Kth is the thermal conductivity of the uranium contents (W/cm K)

The heat production per unit volume is a function of the reaction rate and the heat of reaction. Since the oxidation reaction occurs at the surface of the uranium, the reaction rate is typically stated as a mass reacted per second per unit area. The specific surface area, the uranium metal density, and the packing density are applied to convert the rate per unit uranium surface area to a rate per unit can volume. The result is:

$$S = Rho \times Phi \times SArea \times dHrxn \times RxnRate \quad \text{(Equation 2)}$$

where

Rho is the density of the uranium metal (g/cm^3)
Phi is the packing density of the uranium in the can (cm^3 U/cm^3 can volume)
SArea is the specific surface area of the uranium (cm^2/g)
dHrxn is the heat of reaction (J/g uranium)
RxnRate is the reaction rate [g uranium / ($s \cdot cm^2$)]

The reaction rate of uranium metal with oxygen has been evaluated by many researchers over the years. The general form of the rate equation used is:

$$RxnRate = K0 \times P^n \times e^{(-Te/T)} \quad \text{(Equation 3)}$$

where

K0 is the reaction rate coefficient [g uranium / ($s \cdot cm^2$)]
P is the partial pressure of water vapor (kPa)
n is the exponential coefficient on the partial pressure of water vapor
Te is the activation energy (K)
T is the temperature of the reactants (K)

For the case at hand, the temperature of the reactants is the highest at the can center (Tcenter) and the lowest at the can wall (Twall). The average temperature of the reactants is midway between these two values. For conservatism the reaction rate of the entire contents is evaluated at the maximum temperature, which occurs at the center of the can (Tcenter). This analysis considers heat transfer only through the can walls, and ignores heat transfer through the top and bottom of the can. This is also a conservative assumption.

Equations 1, 2, and 3 are combined to yield:

$$Tcenter - Twall = (R^2 \times Rho \times Phi \times SArea \times dHrxn \times K0 \times P^n \times e^{(-Te/Tcenter)}) / (4 \times Kth) \quad \text{(Equation 4)}$$

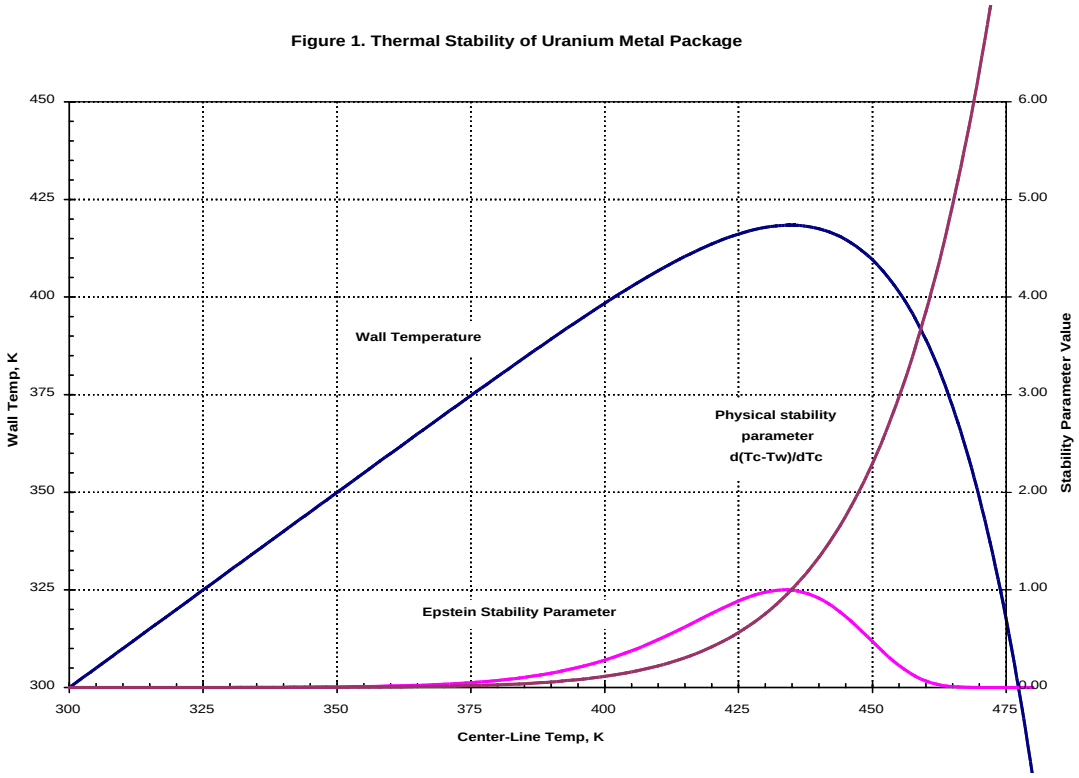
Note that Kth is a property of the can contents (that is, for the bed of uranium metal particles with air in between), and not a property of solid uranium metal. The thermal conductivity of uranium metal is much higher than the thermal conductivity of a bed of uranium metal pieces.

P is the partial pressure of H_2O present in the CV at the center-line temperature. This value is calculated by assuming that the ES-3100 was loaded at ambient conditions of T0 and 100% relative humidity, which yields a water vapor pressure of P0. When the temperature in the CV increases the partial pressure of water vapor increases according to the ideal gas law, which in this case reduces to:

$$P = P0 \times (Tcenter/T0) \quad \text{(Equation 5)}$$

In this evaluation, the maximum possible rate of heat generation due to the oxidation of the uranium metal is also of interest since this heat must be carried away by the package, even at HAC. The maximum rate of heat generation is the heat generated by the oxidation of uranium metal at the highest temperature reached during HAC, assuming the maximum allowable load of uranium metal. This is:

$$Qmax = Mmax \times SArea \times dHrxn \times K0 \times P^n \times e^{(-Te/Tcenter)} \quad \text{(Equation 6)}$$



where

Qmax = the maximum rate of heat generation (W)
Mmax = the maximum uranium metal loading (g)

Evaluation of Thermal Stability

Equation 4 provides the means to evaluate the maximum temperature reached in the uranium metal. It does not by itself validate the stability of the system. This system does present a simple means to evaluate stability – both numerical stability and more importantly physical stability (meaning that the temperature cannot build to spontaneous ignition).

Solving Equation 4 for Twall over a range of Tcenter values and plotting the results produces Fig. 1:

The wall temperature calculated from Equation 4 and plotted here is the temperature needed in order to provide enough heat transfer to maintain the given center-line temperature. The wall temperature initially tracks the center-line temperature – the rate of heat generation is low, so a very small temperature difference is sufficient to remove that heat. As the center-line temperature (and therefore the amount of heat generated) increases, the temperature difference needed to keep the center-line temperature steady at the given value increases exponentially. At some point (~435 K in Fig. 1) the required temperature difference gets so large that the wall temperature would have to decrease in order to maintain a stable center-line temperature. In an actual package there is no cooling mechanism to do this, and once the center-line temperature exceeds this point the amount of heat generated will exceed the ability to carry off that heat, and the center-line temperature will increase until either the reaction runs out of oxygen or the ignition point is reached. The point at which the required wall temperature stops increasing, marks the maximum stable center-line temperature for the package. The required wall temperature stops increasing at the point where the rate of increase in the needed temperature difference [d(Tcenter−Twall)] equals the rate of increase of the center-line temperature (dTcenter). Stated mathematically, when d(Tcenter−Twall)/dTcenter is less than 1 the required Twall increases along with Tcenter, and stability is maintained. When d(Tcenter−Twall)/dTcenter is greater than 1 Twall would have to drop to maintain stability as Tcenter increases. Since this is not possible in a real package, the temperature in the package would steadily increase to either ignition or consumption of all available oxygen. The value of d(Tcenter−Twall)/dTcenter = 1 marks the maximum stable point for a given package.

Equation 4 is

$$Tcenter - Twall = (R^2 \times Rho \times Phi \times SArea \times dHrxn \times K0 \times P^n \times e^{(-Te/Tcenter)}) / (4 \times Kth)$$

Taking the first derivative of this equation with respect to Tcenter yields an equation for the stability parameter derived above:

$$d(Tcenter-Twall)/dTcenter = (Tcenter-Twall) \times Te/Tcenter^2 \quad \text{(Equation 7)}$$

The thermal stability of the system is maintained as long as $(Tcenter-Twall) \times Te/Tcenter^2 \leq 1$. This parameter is equivalent to the stability parameter "B" developed in Epstein et al., without the simplifying assumptions made in that paper. The value of d(Tcenter−Twall)/dTcenter is plotted in Fig. 1, along with the Epstein "B" parameter.

Input Parameters

The key values used to evaluate Equations 4, 5, 6, and 7 are shown in Table 1.

Table 1. Key input parameters

Parameter	Value	Units
R	5.27	cm
Rho	19	g/cm³
Phi	0.26	cm³/cm³
SArea	1	cm²/g
dHrxn	4559	J/g Uranium
K0	76086	gU/(s·cm²)
P0	3.53	kPa
T0	300	K
n	0.3	
Te	11490	K
Kth	0	W/(cm·K)

The sources of these parameters are:

R is the inside radius of a convenience can. The typical can used has an outside diameter of 4.25 in., and an inside diameter of 4.15 in. (10.54 cm).

Rho is the density of uranium metal.

Phi is the packing density of uranium metal when packed into the convenience cans. Operator experience at Y-12 is that a maximum of 5 kg U of broken metal will fit into a 4.25-in. OD by 4.875-in. high can, which has an internal volume of 1000 cm³. This yields a packing density of 0.26 cm³/cm³. The effects of variations on this value are discussed below.

SArea is the specific surface area, which is limited by the package certification to 1 cm²/g.

dHrxn is the heat of reaction, on a uranium basis. This value came from Totemeier, page 17 (1089 cal/gU = 4559 J/gU).

K0, n, and Te are parameters for the reaction rate equation. As noted above, a number of researchers have analyzed the reaction rate of uranium metal with various combinations of oxygen and water vapor. Numerous models have been developed from this data. This analysis used the published model that best fit the conditions present. Many of the published rate models are only valid up to 100 to 130°C. This evaluation requires evaluation beyond 140°C. Many of the models are for either pure oxygen or pure water vapor. McGillivray[5] notes that the reaction rate at a given temperature varies with both the oxygen concentration and the partial pressure of water vapor. The published model that best matches the conditions of this evaluation (reaction in air at temperatures exceeding 140°C, with a small water vapor partial pressure) is the Pearce model (Pearce, <100% RH, in Air, T <192°C) as reported in the Epstein paper.

P0 and T0 are used to calculate P, the partial pressure of H_2O vapor present in the CV at the center-line temperature. This value is calculated by assuming that the ES-3100 was loaded at ambient conditions of T0 = 300 K (80°F) and 100% relative humidity. P0 is therefore the vapor pressure of water at 300 K, which is P0 = 3.53 kPa. When the temperature in the CV increases, the partial pressure of water vapor increases according to equation 5.

Kth is the thermal conductivity of the uranium particle bed. The value here was taken from Epstein et al., page 6. Because of the air-filled void spaces, the bed thermal conductivity is much lower than the uranium metal value of 0.3 W/(cm·K).

Results

The set of equations (4, 5, 6, and 7) was evaluated using a commercial software package named Tk!Solver, which has the advantage of being able to automatically iterate to solutions as needed. This is necessary when solving equation 4 for a fixed wall temperature to determine Tcenter. Attachment 1 shows the rules, input and output for the TK!Solver model for the HAC and NCT cases.

The HAC evaluation gave a maximum CV temperature (Twall) of 255°F (397 K). Evaluating Equations 4–7 for these conditions yields a Tcenter of 398.4 K (257.5°F), with a maximum heat output (assuming a full load of 36 kgU) of 5.9 Watts, and a stability parameter d(Tcenter−Twall)/dTcenter of 0.102, well below the critical value of 1.0.

The 255°F HAC temperature was based on a uranium heat generation of 0.4 W. The 5.9-W maximum heat generated from the oxidation reaction under those conditions would heat the CV wall above that temperature. The thermal analysis evaluated the HAC for heat generation rates of 20 W and 30 W as well as the 0.4-W standard value. Table 3.7 in the thermal analysis shows that for an assumed 20 W heat generation in the uranium metal contents, the peak CV wall temperature is 277°F (409.3 K). Using this value ensures that the heat transfer from the uranium contents to the CV wall and to the rest of the package is conservatively addressed.

For the revised HAC wall temperature of 277°F (409.3 K), Equations 4–7 yield the following results:

Tcenter = 413.3 K (284.4°F) [well below the ignition temperature of 600 K]
MaxQ = 17.0 Watts (below the 20 W assumption)
d(Tcenter−Twall)/dTcenter = 0.272 (well below the critical value of 1.0)

At the NCT wall temperature of 190°F (360.9 K) the results are:

Tcenter = 361.0 K (190.1°F) [well below the ignition temperature of 600 K]
MaxQ = 0.289 Watts (below the 0.4 W assumption)
d(Tcenter−Twall)/dTcenter = 0.006 (well below the critical value of 1.0)

These values clearly show that uranium metal with a specific surface area of no more than 1 cm^2/g will not spontaneously ignite under any anticipated transport conditions.

Variation in Input Packing Density

The density with which uranium metal is packed into the convenience cans limits the surface area available to oxidize. Operator experience at Y-12 is that a maximum of 5 kg U of broken metal will fit into a 4.25-in.-OD by 4.875-in.-high can, which has an internal volume of 1000 cm^3. This yields a packing density of 0.26 cm^3/cm^3.

A search of the literature on packing densities reveals a lot of work on smooth spheres, and very little on anything else. Scott and Kilgour[6] experimented with packing smooth steel spheres in cylinders, and reported a maximum packing density of 0.6366 after extensive vibration to compact the steel spheres as much as possible. The steel balls used in this experiment had a coefficient of friction of 0.2, well below the value for smooth uranium metal of 1.0. Subsequent analysis by Kong and Lannutti[7] considering the effects of friction between particles gives packing fractions in the range of 0.41 to 0.46, with higher friction coefficients producing lower packing fractions.

The broken metal routinely packed at Y-12 consists of large, rough, irregular pieces. The reported packing density of 0.26 for this material is consistent with the literature reviewed, particularly Kong and Lannutti. Therefore, the value of 0.26 was used as the base value in the analyses reported above.

To bound the metal contents of the ES-3100 two additional cases have been analyzed under HAC: rough broken metal at a packing density of 0.46 (the upper end of the range reported by Kong & Lannutti); and smooth cast spheres at a packing density of 0.64 (consistent with Scott & Kilgour).

For rough broken metal at a packing density of 0.46 the maximum center temperature at HAC was 422 K, well below the ignition temperature of 600 K. For smooth cast 3/8” spheres at a packing density of 0.64 the maximum center temperature at HAC was 412 K, well below the ignition temperature of 600 K.

Oxygen Limitation in the Containment Vessel

The analysis above placed no restriction on the amount of oxygen available to react with the uranium metal contents. In reality, the ES-3100 CV has a finite volume, which restricts the amount of oxygen available for reaction.

The CV is a cylinder with inside dimensions of 31.00-in. (78.74-cm) tall and 5.06 in. (12.85 cm) in diameter. This produces a volume of 10,215 cm^3, or 10.215 liters. At ambient conditions of 300 K (80.3°F) and 100% relative humidity, 10.215 liters of humid air contains 2.78 g of oxygen from the air, and another 0.23 grams of oxygen in the H_2O. These 3.01 grams of oxygen can react with 22.40 g of uranium metal. This is 0.06% of the ES-3100’s capacity.

A mass of 22.4 g of U metal when reacted with 3.01 g of oxygen will produce a maximum total heat output of 102 kJ (96.8 BTU), spread out over the time required for the reaction to take place. This total amount of oxygen could sustain the NCT maximum heat output of 0.289 W for 4.1 days, or the HAC peak heat output for 1.7 hours. If somehow released all at once, the 102 kJ would only raise the temperature of 36 kg of uranium by 24.5 K. More realistically, as shown by the calculations above, any reaction will be slow, with enough time for the heat generated to flow to the CV and the rest of the package.

The ES-3100 CV is 15.1 kg of stainless steel, with a heat capacity of 0.515 J/(g·K). The 102 kJ maximum produced by the oxidation reaction could only raise the temperature of the CV (ignoring contents) by 13.1 K. This heat sink, plus the heat sinks offered by the CV contents, ensures that the oxidation reaction will not be able to build to the 600 K ignition temperature required for spontaneous ignition.

In practice there will less than 3 g of oxygen available to react with the uranium metal inside the closed CV. A full load of uranium will, by itself, displace nearly 20% of the air in the CV. The convenience cans, spacer cans, and other packing materials will displace even more air, further reducing the amount of uranium that could possibly react. Also, the uranium metal is packed inside closed convenience cans. These cans limit the oxygen available to react with the contents to the oxygen in the convenience can itself. Finally, part of the available oxygen will react with the uranium before the peak HAC conditions are reached. Figure 22b in Sect. 3 shows that it will take ~4 hours for the CV wall to reach the maximum temperature in the HAC fire. During this four-hour temperature ramp-up 0.9 grams of oxygen would be consumed by reaction with the uranium, leaving only 2.1 grams available to react once the HAC temperature was reached. Even if the uranium surface area was uncontrolled, lack of oxygen would snuff out any increase in the uranium reaction rate before it could reach the ignition point.

Specific Surface Area Implementation via Sieve

As noted above, the 1 cm^2/g specific surface area limit is not easy to measure or to use in the field. A screening method that is simple and easy to use in the field will reduce the potential for packaging mistakes. The recommended approach is to separate large pieces from small ones in a sieve. The recommended text stipulates a 3/8-in. mesh sieve to quickly remove small particles (with a large specific surface area) from large particles which have a small specific surface area.

Example 1 above showed that the minimum size of a metal sphere meeting the 1 cm^2/g specific surface area limit varies with the degree of surface roughness. In Example 1 a smooth sphere 1/8 in. in diameter and a rough sphere 3/8 in. in diameter both had specific surface areas just below the 1 cm^2/g limit. The 3/8-in. mesh is stipulated in the recommended text in order to accommodate both smooth and rough metal.

The actual metal contents of the ES-3100 will include both smooth-surfaced and rough-surfaced metal. The smooth-surfaced items include a variety of cast and machined shapes. The rough-surfaced items are “broken metal” – large castings that have been fractured into smaller pieces. These broken metal pieces will typically have two or three cast surfaces with the remaining 3 or 4 surfaces of fractured metal.

The 3/8-in. mesh recommendation is based on a surface roughness factor of three, meaning that the rough surface has an actual surface area available to react with oxygen that is three times that of a smooth-surface of the same gross dimensions. This roughness factor of three was derived from an evaluation of fracture surfaces for cast uranium metal. Roughness factors ranged from 1.1 to 2.7, with a mean value of 2.0. A roughness factor of three was selected to bound the highest value observed. The

3/8-in. mesh screening is therefore suitable for metal that is fractured on all surfaces. Since as noted above even broken metal will have several smooth faces the 3/8-in. mesh screening should be quite conservative.

As demonstrated above, a rough-surfaced sphere which does not pass freely through the 3/8-in. mesh sieve will meet the 1 cm^2/g specific surface area limit. Other simple shapes such as cubes and rods are also effectively controlled by the 3/8-in. sieve. Foils, turnings, and wires are explicitly forbidden in both the current and proposed text, unless they are packaged in an inert atmosphere. Attachment 2 shows the dimensions of a variety of shapes that have a specific surface area of 1 cm^2/g. All of these items will fall through a 3/8-in. sieve, demonstrating that the sieve will effectively enforce the 1 cm^2/g specific surface area limit.

Most foils and wires will not fall through a sieve of any reasonable size. The current 50 g test would likewise not reliably exclude these materials, which is why foils, turnings, and wires are explicitly forbidden in both the current and proposed text, unless they are packed in an inert atmosphere. Operator training will be required under either the current or the proposed text to ensure that these items are properly packaged.

Operator Training

As part of the transition to using the new shipping container, training materials are being prepared to instruct the field operations personnel on the proper way to use the ES-3100. As noted above, the training for the operators packing uranium metal into the convenience cans for shipment in the ES-3100 will be important in ensuring that potentially pyrophoric materials are properly categorized and inerted as necessary. This training will cover the following points:

- All metal pieces must be evaluated to ensure that their smallest dimension is larger than the 3/8-in. mesh size.
  - Single solid-metal pieces that are clearly larger than the 3/8-in. mesh in every dimension do not require sieving.
  - Items which are obviously unacceptable, such as foils, wires, and turnings, may be removed before the sieving
  - Any item that is not obviously larger than the 3/8-in. mesh in every dimension and which has not been rejected must be sieved.
  - Any item that falls through the sieve must be rejected.
- Operators need to be alert to items which may not fall through the sieve but which are too small:
  - Long, thin shapes such as wires and turnings may not fall through the sieve when shaken. If the wire or turning could be picked up and poked through the mesh it must be rejected, even if it did not fall through unassisted.
  - Wires or turnings may form a tangled ball which will not fall through. The above criterion applies: if the wire or turning could be separated and poked through the mesh it must be rejected.

- No distinction is made between wires and rods – if the item could be picked up and poked through the mesh it must be rejected.
- Foils, thin chips or shards - any item less than 1/8-in. thick – must be rejected.
- Metal showing visible moisture or signs of having been stored in water must be rejected.

- Rejected items must be separated for proper handling:
  - Rejected items can be shipped if packed under an inert cover gas.
  - An acceptable cover gas must be an inert gas or mixture of inert gases with a high-purity (≥99%) and low moisture (≤5 ppm moisture).

V. Conclusion

The evaluations performed show that uranium metal conforming to the 1-cm^2/g limit on specific surface area will not spontaneously ignite under any anticipated transport conditions. Spontaneous ignition is independently prevented by both the 1-cm^2/g limit on the uranium metal and by the limited amount of oxygen available in the sealed ES-3100 CV.

The 3/8-in. sieve specified in the revised text effectively applies the 1-cm^2/g specific surface area limit to broken uranium metal in a manner that is quick and easy to use in the field.

36000	MaxM		gU	Maximum ES-3100 contents
3.01	MaxO		gO	Maximum ES-3100 Oxygen Content
	RRate	6.34E-5	gU/s	Reaction Rate at given Conditions
	ORate	8.52E-6	gO/s	Oxygen Use rate at given conditions
	OTime	98.1015	hr	Oxygen time to run-out
5.27	R		cm	Can radius
1	SArea		cm^2/gU	Specific Surface Area of U particles
	Deriv	.00607		d(Tcenter-Twall)/dTcenter
19	rho		gU/cm^3	Density of uranium
.26	phi			Packing density, U cm^3 / Can cm^3
4559	dHrxn		J/gU	Heat of Reaction
76086	K0		gU/(s*cm^2)	Reaction rate coefficient - Pearce <100%
11490	Te		K	Reaction rate coefficient - Pearce <100%
.3	n			Reaction rate coefficient - Pearce <100%
3.53	P0		kPa	Vapor pressure of water at T0
300	T0		K	Temperature for P0
	P	4.2474	kPa	Vapor Pressure of Water at Tcenter
.004	Kth		W/cm*K	Thermal Conductivity of U particle bed

Attachment 2. Pyrophoric Size Limits on Small Uranium Metal Pieces

Specific Surface Area:	1.0	cm^2/g
Uranium Metal Density:	19.0	g/cm^3
Surface Area Multiplier:	3.0	

The surface area multiplier is the ratio of the actual surface area divided by the simple geometeric surface area.

Spheres - Minimum Safe Diameter

Limiting diameter	0.9474	cm	or	0.3730	in	8.459	grams

Rods - Minimum Safe Diameter

Length	Diameter						
0.9 cm	0.9474	cm	or	0.3730	in	12.688	grams
1.0 cm	0.9231	cm	or	0.3634	in	12.715	grams
1.5 cm	0.8000	cm	or	0.3150	in	14.326	grams
2.0 cm	0.7500	cm	or	0.2953	in	16.788	grams
2.5 cm	0.7229	cm	or	0.2846	in	19.495	grams
Infinite	0.6316	cm	or	0.2487	in		

Cubes - Minimum Safe Side Length

Limiting side length	0.9474	cm	or	0.3730	in	16.155	grams

Square Cross-Section Rods - Minimum Safe Side Length

Length	Side						
0.9 cm	0.9474	cm	or	0.3730	in	16.155	grams
1.0 cm	0.9231	cm	or	0.3634	in	16.189	grams
1.5 cm	0.8000	cm	or	0.3150	in	18.240	grams

REVISIONS

REV. NO.	DESCRIPTION OF REVISION
00	Original issue
01	Made corrections and added procurement-related attachments and O-ring drawing
02	Changed inspection standard and updated requirements and format using SPC-M801794-0005 000 01 as template
03	Updated to incorporate procurement-related waivers and questions. Added inspection lab temperature and humidity report to Sect. 4.1.2.2, Sect. 4.6.1, and submittal checklist (item # 23), added calibration report prior to inspection to Sect. 4.1.2.4, Sect. 4.6.1, and submittal checklist (item # 24), and added serialized tamper-indicating devices (TIDs) to Sect. 3.6.1.1, Sect. 4.6.1 certified data package and submittal checklist (item #25); added control documents and revisions to the Certificate of Conformance (Sect. 4.6) - all per Commercial Grade Survey CGS-225151-17-02.

REFERENCE DOCUMENTS & OTHER INFORMATION

This specification is for procurement of domestic, commercially available items; does not contain scientific, technical, or operational information (STI); and therefore does not require a review by the Information Release Office (IRO).

Recommended Suppliers:

JDS Technologies, Inc.	OR	Rainier Rubber Co.	OR	Other Company Approved Supplier
1299 Airport Road		15660 Nelson Pl		
Oneida, TN 37841		Tukwila, WA 98188

H. AUTHORIZATION

EVALUATOR SIGNATURE	ORGANIZATION	BADGE:	DATE:

Sampling Plan:

Critical characteristics for product identification/marking will be verified in accordance with a normal sampling plan as defined for non-destructive testing in Y17-69-316, *Engineering Procurement Document Manual*, Chapter 6, Attachment 6-C, "Sampling Plan Guidance and Justification," based on the total quantity procured per the purchase order (PO). Based upon Supplier performance and compliance data accumulated from receiving, the sampling plan may be relaxed or tightened accordingly per Table 6.C.1 in Attachment 6-C. This sampling plan is acceptable based on the leak-testing performed on each O-ring after its installation in the containment vessel. As noted in the safety function, these O-rings are used to provide a containment function verified after the O-ring installation by the performance of a pre-shipment leak-test between the inner and outer O-rings. Any issues with a specific O-ring would be identified during this leak testing.

Per the requirements of this specification, the Supplier places a label on each O-ring package, performs dimensional verification and visual configuration inspections on 100% of the O-rings prior to shipment to Y-12. Y-12 personnel will witness these verification activities at the Supplier's facility during the First Article Evaluation (FAE) process if warranted per the EPD. Depending upon Supplier's quality program quality, oversight sampling could be enforced on every order.

For material of composition, one FTIR test will be performed in accordance with Option 1 (destructive testing with production traceability) on a sample size of one for each batch of O-rings as defined in Y17-69-316, Chapter 6, and Attachment 6-C. O-rings and a 6 x 6 in. minimum piece of material are supplied directly to Y-12 from the Supplier with material identified by PO number, batch number, and lot number (if applicable). Based on this lot identification, material composition is verified either on a 6 x 6 in. minimum piece of material from the same batch, which has been cured with the lot or on a specific O-ring. Option 1, according to Attachment 6C, is an acceptable approach based on the rationale provided in the previous paragraphs.

NOTE:

Receipt Inspector will confirm receipt of Supplier Certificate of Conformance (CoC) and Certified Data Package or verify with the Procurement Quality Report (PQR) that O-rings are in accordance with the specification requirements to address

critical characteristics specified in the Commercial Grade Dedication (CGD) Plan **and** for important features specified in the Receiving Inspection Checklist (RIC).

If Method 2 Commercial Grade Survey (CGS) is used for acceptance, critical characteristics 2-3 and the important features will be verified by confirming the CoC meets the requirements of Sect. 4.6 and the Certified Data Package meets the requirements found in Sect. 4.6.1 of this document. Critical characteristic 1 for product identification should be verified per the sampling plan requirements listed above and the results of these inspections documented in the RIC and include the results in the receipt inspection package.

If Method 3 Source Surveillance is used for acceptance, critical characteristics and important features will be verified at the Supplier's facility and documented in the PQR. The Receipt Inspector will verify that the items inspected and documentation of this inspection are traceable to the items shipped and received at Y-12.

After this acceptance, Supplier Quality Engineer (SQE) will green tag (i.e., UCN-4804) the O-rings. O-rings will then be transferred to the user organization for implementation of the Quality Certification and Procurement Instructions (QCPI) requirements and final acceptance as certified O-rings (i.e., UCN-14850). An identification label with product number, MC number, expiration date, and lot number will be added to each O-ring package.

1. SCOPE

This specification and design drawing specify the requirements for O-rings used in Type B shipping packages. Drawing M2E801580A013 (latest revision) specifies the dimensional requirements and refers to this specification for the nondimensional requirements.

If conflicting requirements appear in these documents, the Supplier shall immediately notify the Company for resolution. The Supplier shall not make any assumptions regarding requirements within this specification and shall always contact the Company for clarification.

The Supplier shall not deviate from the requirements of this specification without prior written consent from the Company. Requests for changes or deviations shall be submitted on form UCN-13816B, *Request for Waiver or Deviation (RFWD)*, and the latest RFWD form may be requested from the Subcontract Administrator (SA) or Subcontract Technical Representative (STR).

1.1 General Description of the Item

This specification is applicable to inner and outer containment vessel (CV) O-rings used in fissile hazardous material shipping containers. The O-rings will be used for a static face seal application. The O-ring material shall be ethylene propylene diene monomer (EPDM). The O-ring service temperature range is −40 to 150°C (−40 to 302°F). The O-ring material must properly seal at these extreme temperatures. CV O-rings must comply with strict manufacturing, testing, and quality standards.

1.2 Background

Failure or malfunction of these O-rings will directly result in an unacceptable condition of containment. Proper O-ring sealing is crucial for package containment during storage, shipping, and testing for normal conditions of transport and hypothetical accident conditions. Shipping containers are regulated and certified by the U.S. Nuclear Regulatory Commission, the U.S. Department of Energy, the U.S. Department of Transportation, and the National Nuclear Security Administration.

2. REFERENCES

2.1 Definitions

Batch – A batch of material is defined as a homogeneous mixture of material compound mixed at one time.

Company – The Company (i.e., Y-12 National Security Complex), as referenced in this specification, is the buyer of the Supplier's final product.

First Article – Product that is submitted to the Company for evaluation prior to the Seller being released to manufacture the remaining quantities in the purchase order (PO). This product must be representative of production items by virtue of having been produced and inspected using the same facilities, testing, processes, and type of personnel planned for use in production.

First Article Evaluation (FAE) – An evaluation by the Company of the first article manufactured and the facilities, tooling, and processes, concerned with manufacture, test, and inspection.

Lot – A lot shall be a quantity of product of the same identity, cured in the same production run, and from the same batch.

Manufacturing Plan/Manufacturing Traveler – A written, step-by-step, process plan for the equipment to be fabricated. The plan or traveler includes material control, major fabrication steps, hold points, all in-process inspections, welding, welding inspection/examination, dimensional inspections, testing, and shipping.

Non-conformance - A deficiency in characteristic, documentation, or procedure that renders an item to be in non-compliance with specified requirements.

Offeror - The Organization or person(s) submitting an offer to the Company to provide the product(s) described.

Request for Waiver or Deviation (RFWD) – A formal request by the Supplier for a waiver or deviation to the equipment specification, drawing, or PO using the Company form, which can be provided by the SA or STR. The form must be approved by the Company in writing before the Supplier being granted authorization to proceed.

- **Deviation** – A specific written authorization, granted by the Company prior to the manufacture of an item, to depart from a subcontract requirement for a specific piece or pieces of product, or a specified period of time.
- **Waiver** – A specific written authorization, granted by the Company, to accept a configuration item or other designated items that, during production or after having been submitted for inspection, are rework by an approved method.

Subcontract Administrator (SA) – An individual, generally called the Buyer, who is responsible for the overall subcontract administration and has authority to act officially for the Company. This person may also assign a Subcontract Technical Representative to have authority to represent the Company in technical matters.

Subcontract Technical Representative (STR) – The Subcontract Technical Representative, as used in this specification, is the person designated by the Subcontract Administrator as having the authority to represent the Company in technical matters.

Supplier – The Organization or person(s) entering into a subcontract with the Company to provide the product(s) described in this specification.

Testing Agency (TA) – Supplier may use an approved testing lab with ISO 17025 accreditation for property & chemical testing

2.2 Codes/Standards/Orders/Regulations

The EPDM O-rings shall be fabricated, tested, and inspected according to the design drawing, this specification, and the applicable referenced documents.

- ASME Y14.5, *Dimensioning and Tolerancing*
- ASTM D297, *Standard Test Methods for Rubber Products—Chemical Analysis*
- ASTM D395, *Standard Test Methods for Rubber Property—Compression Set*
- ASTM D412, *Standard Test Methods for Vulcanized Rubber and Thermoplastic Elastomers—Tension*
- ASTM D573, *Standard Test Methods for Rubber—Deterioration in an Air Oven* (high temperature test)
- ASTM D1329, *Standard Test Method for Evaluating Rubber Property—Retraction at Lower Temperatures (TR Test)*
- ASTM D1349, *Standard Practice for Rubber—Standard Conditions for Testing*
- ASTM D2000, *Standard Classification System for Rubber Products in Automotive Applications*

- ASTM D2084, *Standard Test Methods for Rubber Property—Vulcanization Using Oscillating Disc Cure Meter* or equivalent such as ISO 3417, *Rubber—Measurement of Vulcanization Characteristics with the Oscillating Disk Curemeter*
- ASTM D2137, *Standard Test Methods for Rubber Property—Brittleness Point of Flexible Polymers and Coated Fabrics* (low temperature test)
- ASTM D2240, *Standard Test Method for Rubber Property—Durometer Hardness*

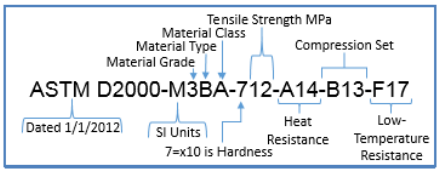
- ASTM D3677, *Standard Test Methods for Rubber—Identification by Infrared Spectrophotometry*
- ISO 3601-3, *Fluid Power Systems — O-rings — Part 3: Quality Acceptance Criteria*
- MIL-DTL-117H, *Bags, Heat-Sealable*
- MIL-PRF-121G, *Barrier Materials, Greaseproof, Waterproof, Flexible, Heat-Sealable*

2.3 Applicable Documents

A Company-provided O-ring drawing will be supplied with the PO.

3. ITEM REQUIREMENTS

3.1 Performance Requirements



See Sect. 3.2

3.2 Design Requirements

O-rings shall meet the requirements specified in ASTM D2000. The "line call-out" or specification for these O-rings shall be as follows: ASTM-D2000-M3BA-712-A14-B13-F17.

NOTE: O-ring application is for a static face seal.

1. Below is a summary of the requirements in this line call-out.

- ASTM D2000 is the required consensus standard.
- M3BA
  - M – prefix letter meaning requirements are in SI units (International System of Units) [Sect. 4.1 in ASTM D2000]
  - 3 – grade number (Sect. 5 in ASTM D2000)
  - B – material type (Sect. 4.3 and Table 1 in ASTM D2000), testing temperature 100°C
  - A – material class based on volume swell in oil (Sect. 4.4 and Table 2 in ASTM D2000), no requirement for these O-rings
- 712
  - 7 – 70 Shore A hardness (Sect. 9.1 in ASTM D2000)
    - Test per ASTM D2240 (Table 5 in ASTM D2000)
  - 12 – 12 MPa tensile strength minimum (Sect. 9.1 in ASTM D2000)

    - Test per ASTM D412 (Table 5 in ASTM D2000)

- A14 (Table 6, BA materials, Grade 3 in ASTM D2000)
  - A – heat resistance (Table 3 in ASTM D2000)
  - 1 – test per ASTM D573 for 70 h (Table 5 in ASTM D2000)
  - 4 – test at 100°C (Table 4 in ASTM D2000)
  - Change in hardness +10 maximum
  - Change in tensile strength −25% maximum
  - Change in ultimate elongation −25% maximum
- B13 (Table 6, BA materials, Grade 3 in ASTM D2000)
  - B – compression set (Table 3 in ASTM D2000)
  - 1 – test per ASTM D395 Method B for 22 h (Table 5 in ASTM D2000)
  - 3 – test at 70°C (Table 4 in ASTM D2000)
  - 25% maximum compression set
- F17 (Table 6, BA materials, Grade 3 in ASTM D2000)
  - F – low temperature resistance (Table 3 in ASTM D2000)
  - 1 – test per ASTM D2137 Method C, Sect. 9.3.3, 3 min (Table 5 in ASTM D2000)
  - 7 – test at −40°C (Table 4 in ASTM D2000)

2. Material shall be EPDM.
3. Color shall be black.
4. Specific gravity/density shall be 1.13–1.19 g/cm^3.
5. Minimum elongation shall be 100%.
6. Normal service temperature range shall be −40 to 150°C (−40 to 302°F).
7. Each O-ring shall be molded as a single piece.
8. O-ring surface imperfection limits shall be in accordance with ISO 3601-3, Sect. 5 and Table 3, “Quality Acceptance Criteria for Grade CS – Critical Service”. A visual inspection report shall be submitted in the Certified Data Package (Sect. 4.6.1) and a visual inspection procedure per the “Submittal Checklist,” Attachment A.
9. O-ring dimensions shall comply with the requirements on the Company drawing (M2E801580A013). A dimensional inspection report shall be submitted in the Certified Data Package (Sect. 4.6.1) and a dimensional inspection procedure per the “Submittal Checklist,” Attachment A.
10. Each lot of O-rings associated with this procurement shall be molded from the same batch of material unless prior Company approval is obtained. A batch of material is defined as a homogeneous mixture of material compound mixed at one time.
11. Each production run (lot) of O-rings shall be cured according to the temperature and time schedule specified in the Supplier’s Company-approved manufacturing plan (Sect. 3.6.2). The Supplier shall provide a copy of the curing time-temperature charts to the Company in the Certified Data Package (Sect. 4.6.1).
12. For each batch of material used to mold O-rings, Supplier shall supply to the Company one molded slab or sheet that is at least 6 x 6 in. and meets the mixing, preparation, and size requirements of ASTM D3182. The sheet shall be identified with the PO, the batch number of the material compound used, and the lot number

(as applicable) that it represents. The sheet shall be provided to the Company with the first shipment of O-rings.

3.3 Service Conditions

See Sect. 3.2.

3.4 Fabrication and Assembly Requirements

N/A

3.5 Installation Requirements

N/A

3.6 Requirements

3.6.1 Property testing

1. Raw material containers shall be secured with four serialized tamper indicating devices (TIDs). Required a) once material is received, b) while specimens are being tested at a third party lab, c) until material is released for production, and d) for excess material between production runs. Time stamped photos that document the security of the raw material shall be submitted in accordance with the submittal checklist, Attachment A.
2. Specimens shall be hardness tested in accordance with ASTM D2240. The acceptance criteria is 70 ± 5 Shore A points. Median values shall be recorded from five determinations taken a minimum of 6.0 mm apart and a minimum of 12.0 mm from any edge. The specimen shall be ≥6.0 mm in thickness and may be composed of plied pieces.
3. Tensile strength test a minimum of three dumbbell specimens and, if needed, up to two spare specimens in accordance with ASTM D412. Specimen size shall be per Die C dimensions with thickness requirement of 2.0 ± 0.2 mm. The length of the specimens shall be die cut parallel with the sheet grain direction. The acceptance criteria is 12 MPa (1740 psi) minimum. The median of three thickness measurements on each specimen shall be used to calculate cross-sectional area. The test speed shall be 500 ± 50 mm/min. Median tensile values shall be recorded from the test specimens.
4. High temperature test a minimum of three specimens and, if needed, up to two spare specimens in accordance with ASTM D573 for 70 h at 100°C. The acceptance criteria are ≤10 max Shore A hardness points, 25% maximum reduction in tensile strength, and 25% maximum reduction in elongation. Final testing shall be performed following ≥16 h cooling period (conditioning time) after removal from the oven. Hardness, tensile, and elongation tests shall be performed as described in Sects. 3.6.1.1, 3.6.1.2, and 3.6.1.7. Median values shall be recorded from the test specimens.
5. Compression set test three specimens in accordance with ASTM D395 Method B for 22 h at 70°C. The acceptance criteria is ≤25% maximum compression set. Final measurements shall be performed following ≥30 min cooling period after removal from the oven and fixture. Button diameter and thickness shall be per ASTM D395, Sect. 5.2.1, Type 1 specimen. Median values expressed as a percentage shall be recorded from the test specimens.
6. Low temperature test five specimens in accordance with ASTM D2137 Method C for 3.0 ± 0.5 min at −40°C. Acceptance criteria is non-brittle after 3 min. Failure is

defined as any crack, fissure, or hole in the test specimens visible to the naked eye, or complete separation into two or more pieces. None of the specimens shall fail this test per Sect. 9.3.3 of ASTM D2137. Die cut specimens with a thickness requirement of 2.0 ± 0.2 mm per Fig. 2 of ASTM D2137. Prior to testing, condition the specimens for ≥16 h. The striker speed shall be ≥1.8 m/s and be maintained for ≥6.0 mm of travel following impact.

7. Low temperature TR-10 test three specimens in accordance with ASTM D1329 performed on representative cured test specimens from the batch of material. Die cut specimens with a thickness requirement of 2.0 ± 0.2 mm per Fig. 2 of ASTM D1329. Following ASTM procedure, stretch specimens 250% or half the ultimate elongation if 250% is unobtainable. While stretched in the specimen rack, soak specimens for a minimum of 10 min at −70 to −73°C. Release stretched specimen with a controlled temperature rise of 1°C per min. First retraction reading shall be recorded at −70°C. Specimen length shall be measured every 2 min until 75% retraction is completed. Median values shall be recorded from the test specimens. A 10% specimen retraction is desired prior to the temperature rising above −40°C. The results of this test are for information only and shall not be used for rejection purposes but are expected to be met.
8. Elongation test a minimum of three dumbbell specimens and up to two spare specimens in accordance with ASTM D412. Specimen size shall be per Die C dimensions with a thickness requirement of 2.0 ± 0.2 mm. The length of the specimens shall be die cut parallel with the sheet grain direction. The acceptance criteria is 100% minimum elongation. The median of three measurements on each specimen shall be used to calculate thickness for cross-sectional area. The test speed shall be 500 ± 50 mm/min. Median values shall be recorded from the test specimens.
9. Composition test in accordance with ASTM D3677 using Fourier transform infrared (FTIR) spectroscopy on two representative cured specimens from each batch. The purpose of this test is to verify that the material is EPDM. The result shall be consistent with that of "known" infrared spectra of EPDM recorded over the 4000 to 666 cm^{-1} region. The results shall be compared to standard reference spectra and by reference to tables of diagnostic absorptions (significant absorption frequencies). Compare and identify the pyrolysis method to the significant absorption frequency graph shown in ASTM D3677, Fig. 16, "EPM Pyrolyzate from a Vulcanizate," and the film method to the significant absorption frequency graph shown in ASTM D3677, Fig. 32, "EPM Film from a Vulcanizate."
10. Density (specific gravity) test in accordance with ASTM D297 on two representative cured specimens from each batch. The acceptance criteria is 1.13–1.19 g/cm^3 using the hydrostatic method. To eliminate air bubbles, dip specimens in alcohol and blot prior to suspending in water.
11. Supplier's procedures for conducting all of these tests shall be provided to the Company in accordance with Sect. 3.9 requirements.
12. Rubber sheets for test specimens shall conform to the mixing, preparation, and size requirements of ASTM D3182. Sheets may be used for all property testing except for the compression set test.
13. Test specimen conditioning and testing shall be conducted at 23 ± 2°C (73.4 ± 3.6°F) and 50 ± 10% relative humidity (RH) per ASTM D1349, Sect. 2.1.2, *standard laboratory atmosphere* requirements. Materials shall be conditioned for no less than 12 h at this controlled atmosphere prior to testing unless specified otherwise.

3.6.2 Manufacturing Requirements

1. The Manufacturer shall be responsible for supplying all materials, services, facilities, and equipment to meet the requirements of this specification and Company drawing unless otherwise noted.
2. The Supplier shall submit manufacturing plans (i.e., routings, written procedures, follow sheets, data forms, and processing records) for FAE and production orders as required to document and control the manufacturing processes to ensure consistency of all operations for Company approval. At a minimum, the plan should include materials to be procured, Suppliers to be used, quality assurance (QA) program used to buy or manufacture product, sequence of operations, equipment to be utilized, and hold point(s) TBD with Company approval. These submittals shall be provided in accordance with the "Submittal Checklist," Attachment A.
3. The Supplier shall prepare and submit to the Company inspection procedures as specified in Sect. 4.1 for review and approval. These procedures shall be submitted in accordance with the "Submittal Checklist," Attachment A.

3.7 Government-Furnished Material, Equipment, Services

N/A

3.8 Schedule

Proposed contract performance schedule (i.e., raw material procurement, fabrication, testing, inspection, delivery) shall be submitted with the proposal. This proposal shall be approved by the company prior to start of fabrication. Hold/witness points shall be included as applicable.

3.9 Deliverables (Including Submittals)

The documentation required with the proposal as indicated in the "Submittal Checklist," Attachment A, shall be submitted to the Company in the quantities listed with the Supplier's offer. Submittals shall be e-mailed to the Company SA and the STR.

Additional documentation listed in "Submittal Checklist," Attachment A, shall be submitted at the times requested.

The Company will review the submittals that are required prior to fabrication as indicated in the "Submittal Checklist," Attachment A, and respond as shown in the "Instructions to Supplier for Preparation of Submittals," Item h.

The Company shall review the submittals required per Attachment A. Shipping shall not commence without documented permission from the Company. Submittals apply to both FAE work and production work.

3.10 Packaging, Handling, Shipping, and Storage Requirements

3.10.1 Packaging Requirements

1. Each O-ring will be thoroughly cleaned after the completion of all processing and prior to inspection and individual packaging. The Supplier will clean the O-rings in accordance with industry standard cleaning procedures for O-rings to ensure that they are free of foreign materials (including dirt, grease, curing compound, etc.) on the surface. After cleaning, O-rings will be handled with clean nitrile gloves. Supplier shall submit a cleaning procedure for Company approval per "Submittal Checklist," Attachment A.

2. O-ring packaging will be accomplished under conditions that will ensure no contamination by dust, oil, grease, and other extraneous matter. Packaging will be carried out in an atmosphere in which RH <65%.
3. Each O-ring shall be packaged in an individual sealed package that provides adequate protection against ultra violet rays.
4. Packaging material shall be a heat-sealable, greaseproof, waterproof, flexible barrier made of laminated paper or film in accordance with MIL-PRF-121G, Type I (medium duty) and identified on each bag. Supplier shall submit Certificate of Conformance (CoC) for packaging material per "Submittal Checklist," Attachment A.
5. Packaging method shall be in accordance with MIL-DTL-117H, Type II (medium duty), Class C (waterproof, greaseproof), Style 1 (opaque) and identified on each bag. Supplier shall submit CoC for packaging material per "Submittal Checklist," Attachment A.
6. Bag sizes shall be 8 × 8 in. unless Company approves otherwise. One source for the Poly Kraft bag sizes shown is Edco Supply.
7. Tape or any other material shall not be used inside the heat-sealed bag. O-rings <10-in. diameter shall not be folded over and shall be packaged per Fig. 1. O-rings >10-in. diameter shall be folded over one time and packaged per Fig. 2. Adequate spacing is required around each O-ring for proper heat-seal closure of bag. O-rings are required to lay flat after storage.

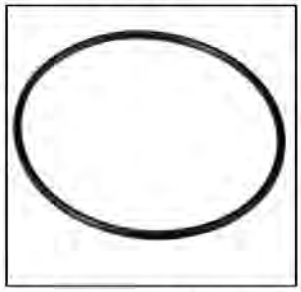


Fig. 1. O-rings <10-in. diameter.

Fig. 2. O-rings >10-in. diameter.

3.10.2 Shipping Requirements

O-rings shall be shipped in containers that will protect the O-rings during shipment and storage. The O-rings shall be protected against exposure to weather or any other normal conditions of transportation and storage. Unless otherwise specified in the Company PO, as a minimum, the box shall be marked with the following information:

- Supplier company name and return ship-to address
- Supplier part number
- Supplier part name
- Company ship-to address
- Company PO
- Date of shipment
- Number of O-rings inside

3.11 Marking and Identification Requirements

Each individual O-ring package shall be marked with the following information:

- MIL-DTL-117H, Type II, Class C, Style 1
- MIL-PRF-121G, Type I
- O-ring Supplier company name
- O-ring PO
- O-ring batch number
- O-ring lot number (if applicable)
- O-ring part number shown on Drawing M2E801580A013 (i.e., M2E801580A013-1 or M2E801580A013-2)
- O-ring compound number
- O-ring size (inside diameter and cross section as stated per Drawing M2E801580A013)
- O-ring cure date, quarter and year (i.e., 4Q15)
- O-ring expiration date, 4 years from cure date (i.e., 4Q19)

3.12 Request for Waiver or Deviation (RFWD)

1. The Supplier must comply with all requirements specified in this specification, the design drawing, and the applicable documents referenced herein unless approved otherwise in writing by the Company.
2. Any requested exceptions, deviations, or proposed changes to the requirements of a procurement specification by the Supplier after award or before acceptance shall be submitted using UCN-13816B, *Request for Waiver or Deviation (RFWD)*.
3. The Supplier shall contact the STR or SA to obtain the latest UCN-13816B, *Request for Waiver or Deviation (RFWD)*, form and submit the RFWD to the STR or SA when a nonconforming condition is identified that includes:
   - requirements in Supplier documents approved by the Company are violated,
   - non-conformances cannot be corrected by continuing the original manufacturing process except by reworking or repairing the item, or
   - the item does not meet original requirements, even though it can be restored to a fully functional condition.
4. The Supplier shall not ship nonconforming O-rings to the Company without a Company-approved RFWD to justify such action.
5. Any nonconforming O-ring approved for shipment shall be documented on the CoC with a reference to the approved RFWD number.
6. Certified Data Packages (Sect. 4.6.1) for the applicable O-rings being shipped shall include all applicable Company-approved RFWDs per Sect. 4.6.

4. QUALITY ASSURANCE REQUIREMENTS

4.1 Final Acceptance Method

1. Final acceptance of a shipment of O-rings will be based on receipt inspection performed by the Company at the Supplier's facility or upon receipt.
2. Any O-ring not meeting the requirements set forth in this document will be cause for rejection of the entire lot.
3. No O-rings shall be shipped with unapproved RFWDs.

4.1.1 General Requirements

The Supplier shall ensure the quality of the O-rings by fully complying with all drawings, requirements, testing, inspections, reports, documentation, and approvals required by this specification.

1. Prior to the start of production, the Supplier shall submit an uncontrolled copy of the QA program that meets 10 CFR 71, Subpart H requirements. This shall include a copy of the cover page with signatures, date, and revision number of their current Quality Manual with the Proposal. The Company reserves the right to evaluate and approve the QA plan of the Supplier. The Company reserves the right to perform oversight activities if there are deficiencies in the Supplier's quality program.
2. The Supplier shall notify the Company a minimum of 14 calendar days prior to the fabrication start date. The Company reserves the right to inspect the fabrication prior to, during, and after completion. Hold/witness points will be identified by the Company in the Supplier's manufacturing schedule after it is submitted to the Company for review.
3. The Supplier shall document the results of each inspection and/or test on quality record forms.
4. Where inspection or test equipment yields quantitative readings, actual measurements or deviation from nominal readings shall be submitted. Test results from the chemical analysis and physical properties test results from the batch shall be provided to the Company per the Certified Data Package (Sect. 4.6.1) requirements and the submittal schedule (Attachment A).
5. The quality requirements shall be applicable and implemented by the Supplier and flowed down to all sub-tier supplier and subcontractors.
6. The Company shall be notified in advance of any subcontracting work and provided a copy of the sub-tier supplier or subcontractor project specific QA plan(s) addressing the quality requirements.
7. The Supplier shall provide an assessment/oversight plan for ensuring implementation of sub-tier supplier QA requirements.
8. For requirements governing suspect/counterfeit items (S/CI), reference the section regarding S/CI in the General Terms and Conditions. The General Terms and Conditions can be found in the request for solicitation.
9. The Supplier shall ensure the packaged O-rings are traceable from the marking on the individual packaging (Sect. 3.11) to the raw material Supplier quality records accepted by the Supplier. The Supplier shall ensure that the Company has full access to all records that validate this traceability, including all lower-tier raw material certifications. The Supplier shall ensure that only raw material meeting the applicable specifications are used in the fabrication of the O-rings.
10. Documentation of all final inspection, traceability, and testing results shall be maintained by the Supplier for a minimum of five (5) years after acceptance by the Company. The Company shall have the option to retrieve and review this data during this period, if and when deemed necessary to ensure compliance with all product requirements.

4.1.2 Dimensional Inspections

1. Cross-sectional width/diameter shall be measured and documented on all of the O-rings. This width/diameter shall be measured with an optical/vision system,

micrometer or other method via a Company-approved procedure. This diameter shall be measured at a minimum of eight locations equally spaced around the O-rings. All eight locations shall meet the width/diameter tolerance specified on the Company drawing.

2. Per ASME Y14.5, all O-ring dimensions are applicable at 20 ± 1.1°C (68 ± 2°F). **Submittal of inspection lab temperature and humidity report are required in accordance with Attachment A.** Recommended recording frequency for the report is every 5 minutes. Affected parts must be re-measured and dimensions updated on the dimensional inspection report if the temperature and humidity report identifies any non-conforming lab conditions. The relative humidity (RH) shall be less than 50%. The Temperature and Humidity gage shall be calibrated and certified by an ISO-17025 accredited organization. **Caution:** If O-rings are verified at the Company, and the Supplier's dimensional lab is not controlled at this level, the Company's measurements may be used to determine dimensional acceptance or rejection.
3. Inside diameter shall be measured and recorded on all of the O-rings. This diameter shall be measured with an optical/vision system, Pi tape or other method via a Company-approved procedure. Diameter shall meet the specified tolerance on the Company drawing.
4. Supplier procedures for dimensional inspection shall be provided to the Company in accordance with Sect. 3.9 requirements. **Submittal of daily dimensional inspection equipment calibration report is required in accordance with Attachment A.** Calibration accuracy of the daily calibration to be 1/5th of the tolerance band (+/-.001") at a minimum. Measuring equipment shall be calibrated and certified by an ISO-17025 accredited organization.
5. Dimensional inspection reports shall be prepared and submitted to the Company for approval in the Certified Data Package according to Sect. 4.6.1.

4.1.3 Visual Inspections

1. All of the O-rings shall be visually inspected per ISO 3601-3, Sect. 5, Grade CS. O-ring surfaces shall be free from foreign material (including dirt, grease, curing compound, etc.) and cracks, ruptures, blisters, or other imperfections that are greater than the limits given in Table 3 of ISO 3601-3 when the unstretched O-ring is viewed under a 2X magnifier with adequate illumination.
2. Supplier's procedure for visual inspection shall be provided to the Company in accordance with Sect. 3.9 requirements.
3. Visual inspection reports shall be prepared and submitted to the Company for approval in the Certified Data Package per Sect. 4.6.1.

4.2 Inspection/Testing Requirements

See Sect. 4.4, "Quality Requirements"

4.3 Surveillance and Audits

See Sect. 4.5 (FAE)

4.4 Quality Requirements

Program/Plan Quality Assurance Requirements

The Supplier's specific QA plan shall, as a minimum, address the requirements listed in this section. The specific QA plan shall be submitted for approval.

4.4.1 Quality Assurance Organization

Responsibilities for the establishment and implementation of the QA program shall be defined. The organizational structure, functional responsibilities, levels of authority, and lines of communications for activities affecting quality shall be documented.

4.4.2 Quality Assurance Program

The QA program shall be based upon requirements of 10 CFR 71, Subpart H. The program shall provide control over activities affecting quality to an extent consistent with their importance. The program shall include monitoring activities against acceptance criteria in a manner sufficient to provide assurance that the activities affecting quality are performed satisfactory and shall be established at the earliest time consistent with the schedule for accomplishing the activities.

The program shall provide for planning and accomplishment of activities affecting quality under suitable controlled conditions. The controlled conditions shall include the use of appropriate equipment, suitable environmental conditions for accomplishing the activity, and assurance that prerequisites for the given activity have been satisfied.

The program shall provide for any special controls, processes, test equipment, tools, and skills to attain the required quality of activities and items and for verification of that quality. The organization shall establish and implement processes to detect and correct quality problems.

The program shall provide for indoctrination and training, and qualification as necessary of personnel performing or managing activities affecting quality to assure that suitable proficiency is achieved and maintained.

Management shall regularly assess the adequacy and effective implementation of the QA program.

4.4.3 Design Control

N/A

4.4.4 Procurement Document Control

Applicable design bases and other requirements necessary to assure adequate quality requirements shall be included or referenced in documents for procurement of items and services.

4.4.5 Instructions, Procedures and Drawings

Activities affecting quality and services shall be prescribed by and performed in accordance with documented instructions, procedures, or drawings that include or reference appropriate quantitative or qualitative acceptance criteria for determining prescribed results have been satisfactorily attained.

4.4.6 Document Control

The preparation, issue, and change of documents that specify quality requirements or prescribe activities affecting quality (i.e., instructions, procedures, and drawings) shall be controlled to assure correct documents are being employed.

Such documents, including changes thereto, shall be reviewed for adequacy and approved for release by authorized personnel.

4.4.7 Control of Purchased Items and Services

The procurement of items and services shall be controlled to ensure conformance with specified requirements.

4.4.8 Identification and Control of Items

Controls shall be established to assure that only correct and accepted items are used or installed. Identification shall be maintained on the items or in documents traceable to the items or in a manner assuring that identification is established and maintained.

4.4.9 Special Processes

N/A

4.4.10 Inspection

Inspections requiring verifying conformance of an item or activity to specified requirements or continued acceptability of items in service shall be planned and executed. Characteristics subject to inspection and inspection methods shall be specified, and inspection results shall be documented.

Inspection for acceptance shall be performed by qualified persons other than those who performed or directly supervised the work being inspected.

4.4.11 Test Control

Tests requiring collecting data for design input to verify conformance of an item or computer program to specified requirements or to demonstrate satisfactory performance for service shall be planned and executed. Characteristics to be tested and test methods to be employed shall be specified. Test results shall be documented, and their conformance with test requirements and acceptance criteria shall be evaluated.

4.4.12 Control of Measuring and Test Equipment

Tools, gages, instruments, and other measuring and test equipment used for activities affecting quality shall be controlled, adjusted, and maintained to required accuracy limits. Measuring and test equipment shall be calibrated and certified by an organization with ISO 17025 accreditation or Company-approved equal and traceable to the National Institute of Standards. Documentation shall be submitted in accordance with the "Submittal Checklist," Attachment A.

4.4.13 Handling, Storage, and Shipping

Handling, storage, cleaning, packaging, shipping, and preservation of items shall be controlled to prevent damage or loss and to minimize deterioration. These activities shall be conducted in accordance with established work and inspection instructions, drawings, specifications, shipment instructions, or other pertinent documents or procedures specified for use in conducting the activity.

4.4.14 Inspection, Test, and Operating Status

The status of inspection and test activities shall be identified either on the item or in documents traceable to the items where it is necessary to assure required inspections and tests are performed and to assure items that have not passed the required inspections and tests are not inadvertently installed, used, or operated.

Status shall be maintained through indicators (i.e., physical location and tags, markings, shop travelers, stamps, inspection records) or other suitable means.

The authority for application and removal of tags, markings, labels, and stamps shall be specified.

4.4.15 Control of Nonconforming Items

Items that do not conform to specified requirements shall be controlled to prevent inadvertent installation or use. Controls shall provide for identification, documentation, evaluation, segregation when practical, and disposition of nonconforming items, and for notification to affected organizations.

4.4.16 Corrective Action

Conditions adverse to quality shall be identified promptly and corrected as soon as practicable. In the case of a significant condition adverse to quality, the cause of the condition shall be determined, and corrective action shall be taken to preclude recurrence. The identification, cause, and corrective action for significant conditions adverse to quality shall be documented and reported to appropriate levels of management. Completion of corrective actions shall be verified.

4.4.17 Quality Assurance Records

QA records shall furnish documentary evidence that items or activities meet specified quality requirements. QA records shall be identified, generated, authenticated, and maintained, and their final disposition specified. Requirements and responsibilities for these activities shall be documented.

4.4.18 Audits

N/A

4.4.19 Software Quality Assurance (SQA)

If applicable, the SQA process shall be established to provide assurance that software will satisfy customer requirements. The process shall apply to acquisition, development, operation, maintenance, and retirement.

4.4.20 Suspect/Counterfeit Items (S/CIs)

For requirements governing Suspect / Counterfeit Items (S/CIs), reference the section regarding Suspect/Counterfeit Items in the General Terms and Conditions. The General Terms and Conditions can be found in the Request for Solicitation. Use components supplied or assemblies of components from OEM or authorized distributors. These items should be treated as nonconforming items.

4.5 Acceptance Criteria

First Article Evaluation (FAE)/Surveillance and Audits

NOTE: Follow-on orders will not require additional FAEs unless warranted by changes at the Supplier.

The primary objective of a FAE is to verify that the O-ring conforms to its requirements and the facilities, tooling, processes, controls, personnel, and acceptance methods, can consistently furnish O-rings of the required quality and quantity. The FAE is conducted in two phases. The first phase is an evaluation at the Supplier's site of all critical manufacturing, inspection, and testing operations and equipment. The second phase is an independent evaluation by the Company of the FAE O-rings received by the Company.

FAE O-rings must be submitted to the Company for evaluation prior to releasing the Supplier to manufacture the remaining quantities in the PO. The O-rings must be representative of production items by virtue of having been produced and inspected using the same facilities, testing, processes, compounds, and type of personnel planned for use in production.

The total number of O-rings to be manufactured for the FAE and production shall be specified in the Company's PO.

1. Supplier shall notify the Company approximately 14 calendar days in advance of initiating fabrication of FAE O-rings.
2. Supplier shall provide the Company a Certified Data Package (Sect. 4.6.1) for the FAE O-rings, same as required for production O-rings.
3. The Supplier shall not proceed to manufacture O-rings beyond the initial FAE quantities until a successful FAE has been completed and notification to proceed has been received from the Company. The Company will notify the Supplier in writing with the results of the FAE. The FAE results will be reported in one of the following three categories:
   - Acceptable: Supplier is released to initiate manufacture of production quantities.
   - Conditionally Acceptable: The Company will specify actions that the Supplier must complete before being released for production quantities.
   - Not Acceptable: The first article units have serious deficiencies, or the ability of the Supplier to consistently furnish product of the required quality and quantity is subject to major uncertainty. The Company will specify the required action.

After the Company has approved an FAE, the Supplier shall notify the Company of <u>any</u> proposed changes to manufacturing and acceptance procedures, facilities, personnel, testing, tooling, and compounds, which could conceivably impact product quality. The Company will determine if a new FAE is warranted.

The Company may periodically perform quality surveys of the Supplier's operations for assurance that the evaluated facilities, procedures, personnel, processes, testing, and tooling, are being used in fulfilling the subcontract.

4.6 Certificate of Conformance (CoC)

A CoC shall be submitted to the Company with each shipment of O-rings.

- The CoC shall identify the purchased material or equipment by the PO number.
- The CoC shall identify the specific procurement requirements met by the purchased material or equipment (i.e., codes, standards, other specifications). This may be accomplished by including a list of the specific requirements or by providing to the Company a copy of the PO and the procurement specifications or drawings, together with a suitable CoC.
- The CoC shall identify any approved changes, waivers, or deviations applicable to the subject material or equipment.
- The CoC shall identify any procurement requirements that have not been met, together with an explanation and the means for resolving the RFWD.
- The CoC shall be signed or otherwise authenticated by a person who is responsible for this QA function and whose function and position are described in the QA program of the Supplier.
- The Supplier's certification system, including the procedures to be followed in filling out a CoC and the administrative procedures for review and approval of the CoCs, shall be described in their QA program.

- The CoC shall state the Commercial Grade Survey (CGS) Survey number: CGS-225151-17-02 and list the following procedures and forms that were evaluated during the CGS and used to produce the O-rings.

Procedure or Form	Revision
QM-101 Cover Sheet for JDS Quality Manual	Rev 02, 12/10/2018
QM-102 JDS Quality Cover Sheet Crosswalk for CNS	Rev 0, 11/20/2017

4.6.1 Certified Data Package Requirements

The following Certified Data Package shall be forwarded to the Company with each shipment of O-rings. One copy shall be forwarded to the SA and STR **before** shipment via PDF files. E-mail is preferred. One copy shall be included with the shipment of O-rings. Failure to supply the required data may be cause for rejection.

- CoC (Sect. 4.6)
- Raw material Supplier CoC that raw material is EPDM and meets specification requirements
- Oscillating disc rheometer (ODR) curve for vulcanization characteristics in accordance with ASTM D2084, ISO 3417, or approved equal for each batch of material, to be supplied for information purposes only
- If used, testing agency CoC that physical and/or chemical testing meets specification requirements
- Curing time-temperature charts, the Supplier shall certify each lot was cured according to the temperature and time parameters specified in the Seller's approved manufacturing plan.
- ASTM D2000 physical properties
  - ASTM D573 high temperature test report (A14)
  - ASTM D395 compression set test report (B13)
  - ASTM D2137 low temperature test report (F17)
  - ASTM D2240 hardness test report (7)
  - ASTM D412 tensile strength test report (12)
- ASTM D412 elongation test report
- ASTM D1329 low temperature TR-10 test report
- ISO 3601-3 Grade CS visual inspection report
- ASTM D3677 FTIR spectroscopy report (**two specimens from each batch**)

- ASTM D297 density test report (**two specimens from each batch**)
- Dimensional inspection report
- 6 x 6 in. batch test slab/sheet (in box with shipment of O-rings only)
- Applicable RFWDs
- Temperature and humidity data recorded in the lab during the dimensional inspection of products manufactured for CNS
- Daily Calibration Report for measuring equipment prior to CNS O-ring dimensional inspection
- Time stamped photos of serialized TIDs that verify each container is securely controlled in accordance with Sect. 3.6.1.

4.7 Factory Acceptance Testing or Inspection

N/A

4.8 Personnel Qualifications/Certification

The Supplier shall provide for the training and qualification of personnel, as necessary, to ensure their competence in the use of process, test and inspection procedures, and specifications.

ATTACHMENT A: SUBMITTAL CHECKLIST

Instructions to Supplier for Preparation of Submittals

Note 1 --All correspondence shall be addressed to the Technical Representative identified by the company. The Supplier shall forward submittals via transmittal letter to the Company at the address specified in the contract.

Note 2 -- The submittal must have adequate detail so that full compliance with the requirements may be determined. For example, a simple off-the-shelf item to be used in an assembly may only need a manufacturer's cut-sheet to show compliance, but a factory acceptance test (FAT) developed and submitted by the Seller must have each test step detailed with acceptance criteria consistent with the requirements.

a. Review submittal before transmitting to the Company to verify conformance with requirements of the contract documents (e.g., field measurements, field construction criteria, or manufacturer's catalog numbers).
b. Coordinate submittals with the work requirements and the contract documents.
c. Organize Submittals
   - Do not use highlight marker or color coding on submittals.
   - The minimum resolution used for scanning submittals shall be 300 dpi x 300 dpi.
   - For submittals containing color information important to the record, a 24-bit color setting should be used.
   - Submittals are to be legible and in the format specified on the submittal checklist.
   - Pen and ink changes are to be made in non-erasable ink, legible, dated and initialed.
   - Mark specific options provided for the work, and cross out options not provided.
   - Each submittal shall be sent as a single pdf file unless otherwise specified.
d. Label submittals with the applicable item number, reference, and requirement description as summarized in the Submittal Checklist. Unlabeled submittals will be returned to the Seller without review.
e. Include with submittals a transmittal letter that identifies individual documents by specification section.
   - Transmittal for submittals shall be numbered using the purchase order number followed by a 4-digit sequential number. (Example: 430001111-0001).
   - Embedded comments or questions that are not included on the transmittal may not be addressed/resolved by the Company.
f. Direction will be given at the time of award to either upload submittals to a company provided URL address or send by email to a company provided email address.
g. If using a company provided URL to upload submittals, notify the Company via email when submittals have been placed.
h. After review of a submittal, the Company will assemble comments and provide a status on the documents. An example of this submittal status stamp is shown below.

DOCUMENT REVIEW STATUS		
1	☐ Work may proceed.	
2	☐ Revise & resubmit. Work may proceed subject to incorporation of changes indicated.	
3	☐ Revise & resubmit. Work may not proceed.	
4	☐ Review not required. Work may proceed.	
Permission to proceed does not constitute acceptance or approval of design details, calculations, analysis, test methods developed or selected by the supplier and does not relieve supplier from full compliance with contractual obligations.		
REVIEWED BY:	Print Name/Signature :	Date:

i. If a submittal is being resubmitted, then reference the applicable item number, reference, and requirement description and identify it as a resubmittal.
j. Company response will only be returned to the Supplier for those submittals with a Submittal Purpose of "For Action," unless it is determined that a submittal transmitted "For Information" is not acceptable.
k. AFTER written approval is obtained, THEN proceed with work requiring approved submittals.
l. When approval submittals are required, work done before Company approval is at the Seller's risk.
m. Maintain a copy of the company-approved submittal and status page on file.

1 Scope

This specification describes the requirements for the procurement, preparation, casting, and verification of a neutron absorber material into the ES-3100 Heavy Can Spacer Assemblies. The neutron absorber material shall be cast into the ES-3100 Heavy Can Spacer Assembly (Figure 1), and 10 oz. double friction can (Figure 4).

The Company (Y-12 National Security Complex) will provide training and direct oversight for the casting of the 277-4 Neutron Absorber when the Supplier does not have prior 277-4 casting experience.

1.1 Definitions

277-0 - Shieldwerx Catalog No. SWX-277-0 or equivalent, Heat Resistant Shielding "Non-Borated" high alumina cement.

277-4 - A mixture of 277-0 and boron carbide (B4C) powder to form a neutron absorber material.

Companion Sample Cans - The 10 oz. double friction style cans in Figure 4 used for sampling.

Company – The Company, as used in this specification, is the buyer of the Supplier's final product (i.e., Y-12 National Security Complex)

Dry Batch - A dry mix of batch size of 277-4.

Dry Blend Batch - A thoroughly mixed Dry Batch.

Heavy Can Spacer Assembly - The 10 oz. crimp style can in Figure 1.

Overcast – Additional cast material required to achieve the fill requirements.

PGNAA Subcontractor – Independent testing firm that performs the Prompt Gamma Neutron Activation Analysis on the companion sample cans for the Company.

Process Procedures - Dry mixing, wet mixing, casting, sampling, and inspection procedures.

Supplier - The manufacturer of the ES-3100 Heavy Can Spacer Assemblies.

Wet Mix Batch - A wet mix of Dry Blend Batch and water.

2 Applicable Documents

The following documents are a part of this specification. When there is a conflict between the specification and the applicable documents, the Supplier shall bring it to the attention of the Company for resolution.

2.1 Standards

ASME NQA-1 2008	*Quality Assurance Requirements for Nuclear Facility Applications*
ASME NQA-1A-2009	*NQA-1 Addendum*
ASTM A 380-2017	*Standard Practice for Cleaning, Descaling, and Passivation of Stainless Steel Parts, Equipment and Systems*
ASTM C 750-2018	*Specification for Nuclear-Grade Boron Carbide Powder*
ASTM C 791-2019	*Standard Test Methods for Chemical, Mass Spectrometric, and Spectrochemical Analysis of Nuclear-Grade Boron Carbide*
ASTM C371-2009 (R 2018)	*Standard Test Method for Wire-Cloth Sieve Analysis of Nonplastic Ceramic Powders*
ASTM E105-2016	*Standard Practice for Probability Sampling of Materials*
ASTM E 11-2017	*Standard Specification for Woven Wire Test Sieve Cloth and Test Sieves*
10 CFR 71 Subpart H	*Code of Federal Regulations - Energy - Packaging and Transportation of Radioactive Material - Quality Assurance*
DOE O 414.1D	*Quality Assurance - DOE Directives*
ISO/IEC 17025	*General Requirements for the Competence of Testing and Calibration Laboratories*

2.2 Company Documents

M2E801580A043	*Heavy Can Spacer Assembly (SST)*
M2E801580A026	*Heavy Can Spacer Assembly*

2.3 Referenced Documents (Not Provided with Request for Proposal)

DAC-PKG-801624-A001	*Mixing Weights And Elemental Composition of 277-4 Neutron Poison used in the ES-3100*

3 Requirements

3.1 General Requirements

The Supplier shall be responsible for supplying all materials, services, facilities, and equipment to meet the requirements of this specification unless otherwise noted. Items needed to meet the requirements of this specification that are not identified in this specification shall be specified by the Supplier and submitted to the Company in accordance with Attachment A.

3.2 Equipment Requirements

3.2.1 Certified Scales

All equipment and instruments (Measuring and Testing Equipment (M&TE)) used in the conduct inspections shall bear a calibration sticker that shows the equipment to be within its calibration period. Calibrations must be performed by a laboratory that meets ISO 17025. All calibration sources shall be traceable to the National Institute of Standards and Technology (NIST). All certification documentation shall be submitted to the Company in accordance with Attachment A.

3.2.2 Dry Blending the 277-0 and B_4C

A small parts tumbler shall be used to dry blend the ingredients. The small parts tumbler shall be a Multi-Barrel Small Parts Tumbler Benchtop Base (McMaster-Carr No. 44235A11) with Multi-Barrel Small Parts Tumbler 8 Gallon Barrel, 15-3/4" Dia X 14-3/4" W (McMaster-Carr No. 44235A24).

3.2.3 Mortar or Plaster Mixer

A mortar or plaster type mixer with moving vanes to shear the wet mix shall be used. The batch volume is approximately 0.5 ft^3 (15 quarts or 3.8 gallons). Therefore, it is recommended that the mixer volume should be 1.5 to 2 times the mix volume or around 0.75 to 1.0 ft^3 (22.5 to 30 quarts, ~6 to 8 gallons). The 277-4 wet mix is thixotropic when mixed and it is recommended that a heavy duty adjustable vibrator mounted to the mixer for both mixing and pouring is used.

3.2.4 Small Plaster Mixer

A drill-powered mortar or plaster mixer and a 5-gallon plastic bucket may be used on small batches of 277-4 instead of the mortar or plaster type mixer.

3.2.5 Bench Vibrator

A bench vibrator shall be used during the mixing of the companion sample cans and Heavy Spacer Can Assemblies. The bench vibrator shall be Tabletop Vibration/Mixing Table 10-in. by 7-in. Platform, 10-lb Capacity Continuous Use (McMaster-Carr No. 5714K61).

3.3 277-4 Neutron Absorber

3.3.1 Raw Casting Material Requirements and Inspection

3.3.1.1 277-0

Shieldwerx Catalog No. SWX-277-0 Heat Resistant Shielding "Non-Borated" shall be procured. The manufacturer model or catalog number and expiration date shall be clearly indicated on the container. A Certificate of Conformance shall be provided with each lot or batch. The Certificate of Conformance shall include the lot or batch number and the expiration date package **in accordance with the submittal checklist, Attachment A**. The 277-0 shall be sealed and stored in a dry place.

3.3.1.2 Type 1 Nuclear-Grade Boron Carbide Powder

The $^{nat}B_4C$ Manufacturer shall supply the Supplier with a CoC stating that the $^{nat}B_4C$ is Type 1 Nuclear Grade $^{nat}B_4C$ and 99.90% of the material has passed through a No. 140 sieve per ASTM E 11. The Supplier shall submit Sampling Plans per ASTM E105 for Company approval in accordance with the submittal checklist, Attachment A. The Company will supply test results to the Supplier from samples obtained from the $^{nat}B_4C$ Manufacturer. A test report will be submitted to the Supplier for inclusion into the final data package. The $^{nat}B_4C$ **shall not be shipped** from the $^{nat}B_4C$ Manufacturer **prior to Company approval.** A copy of the CoC shall be submitted with the final data package **in accordance with the submittal checklist, Attachment A.**

3.3.1.3 ^{10}B Content

B_4C powder shall be procured as Type 1 Nuclear-Grade Boron Carbide Powder per ASTM C 750. The ^{10}B content shall be verified to meet the amount as stated in ASTM C 750 by a testing subcontractor, determined by testing of batch samples per ASTM C791.

3.3.1.4 Water

The water shall be potable, filtered through a 20-micron filter and an activated charcoal filter, have a chlorine content of less than 4 ppm, and have a temperature of 65 ± 15°F. Unfiltered potable water may be used for the cleaning of equipment used to cast the neutron absorber system.

3.3.2 Dry Blending Process

3.3.2.1 Dry Batch

A dry batch of 277-4 shall be a mixture of 93.6 wt% 277-0 and 6.4 wt% B_4C. The tolerance for 277-0 and B_4C weighting shall be the following:

277-4 Dry Batch Size	277-0	B_4C
Equal to or greater than 30 lbs.	±0.2 lbs.	±.01 lbs.
Less than 30 lbs	±.01 lbs.	±.01 lbs.

The data shall be recorded on Form A.

3.3.2.2 Blended Dry Batch

The dry batch of 277-4 shall be thoroughly blended. The data shall be recorded on Form A.

If the blended dry batch is not used immediately, the blended dry batch shall be sealed and stored in a dry place with a Blended Dry Batch control number attached to the container.

The Blended Dry Batch shall not be used if the 277-0 expiration date has expired.

3.3.3 Wet Mixing

The weight of the dry mix and water shall be to the following weight proportions of 100% dry mix and 27 ± 1% water. The 277-4 is thixotropic when mixed. It is recommended to have a heavy duty adjustable vibrator mounted to the mixer for both mixing and pouring. Place the water in the mixer and add the dry mix into the water. Before casting, mix the dry powder and water for at least 3 minutes and less than 60 minutes. Any material in the mixer after 60 minutes shall be discarded. Mix only in a room with a temperature range of 70 ± 25°F.

The data shall be recorded on the appropriate form, i.e., Form C for ES-3100 Heavy Can Spacer Assembly/PGNAA Acceptance Standards.

3.3.4 Heavy Can Spacer Assembly

The Heavy Can Spacer Assembly shown in Figure 1 shall be the 10-oz. crimp style stainless steel can as shown in Figures 2 and 3. The cured casting weight for each can shall be measured and the cured casting density recorded on Form C. A cured cast density of 100 to 120 lb/ft^3 and a cured weight range of 1.16 to 1.56 lbs shall be acceptable. If the cured casting density is outside the acceptable range, a copy of the form shall be sent to the Company in accordance with Attachment A.

Two cans from the middle of the lot on Form C, i.e., a maximum lot of 22 cans, shall be selected and identified as companion sample cans. Cans that are not from the middle of the lot on Form C may be selected with Company approval.

3.3.5 PGNAA Acceptance Standards

The PGNAA Acceptance Standards shall be made with a Company representative witnessing the manufacturing processes of weighing, blending, wet mixing, and casting. The PGNAA Acceptance Standards shall be the 10-oz. double friction style metal cans as shown in Figures 4 and 5. The cured casting weight for each can shall be measured and the cured casting density recorded on Form C. A cured casting density of 100 to 120 lb/ft^3 and a cured casting weight of 1.16 to 1.56 lbs shall be acceptable. If the cured casting density is outside the acceptable range, a copy of the form shall be sent to the Company in accordance with Attachment A.

One can from the middle of the lot on Form C, i.e., a maximum lot of 22 cans, shall be selected and identified as a companion sample can for Loss On Drying (LOD) testing. The remainder of the lot shall be sent to the PGNAA Subcontractor.

3.3.6 Companion Sample Cans

Companion sample can data shall be recorded on Form D.

a. The cured casting density of all companion sample cans shall be calculated per Section 3.3.8.2 and recorded on Form D. If the cured casting density is outside the acceptable range, a copy of the form shall be sent to the Company in accordance with Attachment A. The cured casting density of a companion sample outside the acceptable range can shall not be a reason to reject the Heavy Can Spacer Assembly casting lot or PGNAA Acceptance Standards casting lot.

b. The odd serial number companion sample cans for the Heavy Can Spacer Assembly casting lot or PGNAA Acceptance Standards casting lot shall be LOD tested to verify the hydrogen content per Section 3.3.8.3.
c. The even serial number companion sample cans for the Heavy Can Spacer Assembly casting lot shall be PGNAA tested to verify the ^{10}B content per Section 3.3.8.4.

3.3.7 Casting the 10 oz. Double Friction Metal Cans or 10 oz. Crimp Style Cans

a. Weigh the empty labeled can and lid and record the casting can data on Form C. It is acceptable to weigh ten cans with ten lids for each purchase order of cans and to use the average can and lid weight on each form.
b. Weigh the water and measure the water temperature. Record this data on Form C. Fill with water only up to the bottom of the inside rim. The can lid shall be on the scale. It is acceptable to weigh the water weight of the first ten cans with ten lids of the same lot of cans and to use the average water weight for each of the following cans if the measurements are consistent.
c. Remove the water from the cans.
d. Prepare the Wet Mix Batch following Section 3.3.3.
e. Hold the can on the bench vibrator during filling with the 277-4 wet mix. Quickly vibrate and continue to add wet mix to the can lip.
f. Once all of the cans are full of wet mix, return the first can back to the vibrator for at least 3 minutes at a high frequency setting. During the 3 minutes of vibration, continue to add 277-4 wet mix until the can stays full. Repeat this process for all the cans in the casting lot.
g. Between 1 to 24 hours after casting, scrape the top of the casting to meet 1.37 ± 0.06 dimension from bottom of can noted on Figures 3 or 5.
h. Clean the can rim around the edge per Section 3.4.2.
i. Perform an in-process measurement of the scraped casting height to ensure that the casting height parameters are met shown in Figures 3 or 5.
j. Cover the casting by placing the properly labeled can lid on the can for 7 days.
k. Remove the can lid and let the can air dry or use either or both vacuum and heat to create an acceptable density and weight. If heat is used, the maximum temperature of the can shall not exceed 250°F.
l. Measure casting height and weigh the can with lid. Record this data on Form C.
m. Record the final Companion Sample Can casting density, weight, or casting height measurements data on Form D.
n. Crimp lid onto crimp style can or plug lid onto double friction style can, as applicable.

3.3.8 Verification

All verification shall be completed after the casting is cured.

3.3.8.1 Cured Casting Density Verification

The density of cured casting in the Heavy Can Spacer Assembly and PGNAA Acceptance Standards shall be determined by weighing the casting container before casting, while filled with water, after casting, and when cured. Since the density of water is known, a simple relationship between the weight differences shall determine the cured casting density.

$$Density = \left(\frac{Cured - Empty}{WithWater - Empty} \right) \times 62.3 \quad lb/ft^3$$

3.3.8.2 Companion Sample Can Cured Casting Density Verification

The density of cured casting in each companion sample can shall be determined by weighing the can before casting, while filled with water, after casting, and when cured.

Since the density of water is known, a simple relationship between the weight differences shall determine the cured casting density.

$$Density = \left(\frac{Cured - Empty}{WithWater - Empty} \right) \times 62.3 \quad lb/ft^3$$

3.3.8.3 Companion Sample LOD Verification

The companion sample cans identified in Section 3.3.6.b shall be LOD tested. The acceptable LOD percent range shall be based upon the companion sample can cured casting density in Section 3.3.8.2. The Acceptable Maximum and Minimum LOD% at Density is in this table developed from data in DAC-PKG-801624-A001 Table 7, 277-4 Composition @ Extreme Densities and LOD% and compared to the average values as manufactured.

Acceptable Maximum and Minimum LOD% at Density		
Density (lb/ft^3)	Maximum LOD%	Minimum LOD%
100	31.80%	28.61%
101	32.47%	28.33%
102	33.12%	28.06%
103	33.77%	27.79%
104	34.40%	27.52%
105	35.03%	27.26%
106	35.64%	27.00%
107	36.25%	26.75%
108	36.84%	26.50%
109	37.42%	26.25%
110	37.99%	26.01%
111	38.56%	25.78%
112	39.11%	25.55%
113	39.65%	25.32%
114	40.18%	25.10%
115	40.70%	24.88%
116	41.21%	24.66%
117	41.71%	24.45%
118	42.20%	24.25%
119	42.68%	24.05%
120	43.15%	23.85%

a. The lid shall have the serial number permanently transferred by vibro etch or other method.

b. The lid shall have a small vent hole in it. It is recommended that a nail be used to punch a hole 0.12 ± 0.06 in. diameter in the metal lid from the inside surface of the lid.

c. Match the can serial numbers and place the lid on the can.

d. The weight of the can shall be recorded on Form D.

e. The cans shall be placed in an oven at 1500 ± 150°F (800°C) for 4 hours.

f. The weight of the can shall be recorded on Form D with the can temperature not below 100°F.

g. Calculate the LOD% using the equation below and record it on Form D. Due to can oxidizing and gaining weight during the heating cycle, a 0.024 lb correction factor is included in the following LOD% calculation.

$$\text{LOD\%} = \left[1 - \frac{(LOD Weight - Empty - 0.024 lb)}{(Cured \,\&\, Clean - Empty)}\right] \times 100\%$$

h. Verify that the LOD% is within the acceptable range. If water content is outside the acceptable range, a copy of the form shall be submitted to the Company in accordance with Attachment A.

3.3.8.4 PGNAA Verification

The PGNAA Acceptance Standards in Section 3.3.5 and Companion Sample Cans identified in Section 3.3.6.c shall be sent to the PGNAA Subcontractor.

3.4 Cleaning Requirements

3.4.1 Contact with Chlorides or Fluorides

The stainless steel material shall be protected from contact with chlorides in accordance with ASTM A380, paragraph 8.5, during all operations including packaging. The Safety Data Sheet (SDS) for all cleaning solutions or products used on the ES-3100 Heavy Can Spacer Assemblies shall be submitted to the Company in accordance with Attachment A.

3.4.2 Satisfactory Cleanliness

Cleaning procedures for the stainless steel shall be submitted to the Company in accordance with Attachment A. Only non-chloride-bearing chemicals shall be used for cleaning (e.g., trisodium phosphate detergent or acetone). Water used in cleaning shall have a maximum chlorine content of 4 parts per million.

After casting but prior to packaging, stainless steel cans shall be cleaned per the approved cleaning procedures. Satisfactory cleanliness shall be determined by visual inspection as can be observed by a person with normal visual acuity (natural or corrected) and without magnification. Light intensity of at least 100 ft-candles shall be provided on the surface to be inspected.

3.5 Schedule

The Supplier shall prepare a proposed schedule for the fabrication of the ES-3100 Heavy Can Spacer Assemblies specified herein. This proposed schedule shall be submitted with the offer in accordance with Attachment A.

The Company will conduct oversight activities. Hold/witness points will be identified by the Company in the Supplier's schedule after it is submitted to the Company for review.

3.6 Deliverables

The deliverables for this specification includes, but is not limited to:

a. Completed and assembled ES-3100 Heavy Can Spacer Assemblies.

b. All Requests for Waiver/Deviations (RFWDs) shall be closed.

c. All submittal documentation in accordance with Attachment A, with applicable documentation in data packages specific to each ES-3100 Heavy Can Spacer Assembly serial numbers.

The documentation required with the proposal (WP) as indicated in the "Submittal Checklist," Attachment A, shall be submitted to the Company in the quantities listed with the Supplier's offer. Submittals shall be e-mailed to the Company Subcontract Administrator (SA) and the Subcontract Technical Representative (STR).

The Company will review the submittals that are required prior to fabrication as indicated in the "Submittal Checklist," Attachment A, and respond as shown in the "Instructions to Supplier for Preparation of Submittals," Attachment B, Item h.

The Company shall review the submittals required per Attachment A. Shipping shall not commence without documented permission from the Company.

3.7 Packaging, Handling, Shipping, and Storage Requirements

3.7.1 A packing plan for shipment of ES-3100 Heavy Can Spacer Assemblies shall be sent to the Company for approval in accordance with Attachment A.

3.7.2 The ES-3100 Heavy Can Spacer Assembly surfaces must be protected during shipment.

3.7.3 The Supplier shall not ship ES-3100 Heavy Can Spacer Assemblies with unapproved RFWD's.

3.8 Marking and Identification Requirements

3.8.1 The ES-3100 Heavy Can Spacer Assemblies shall be marked as specified on the Company's drawing M2E801580A043.

3.8.2 Permanent serial numbers for each ES-3100 Heavy Can Spacer Assembly shall be assigned by the Company and identified in the Purchase Order.

3.9 Requests for Waiver or Deviation

3.9.1 After award, if a waiver or deviation from the specified requirements is desired, then the Supplier shall submit to the Company a Request for Waiver or Deviation form: UCN-13816B. The Company will provide this form upon request.

3.9.2 Use the UCN-13816B form to request permission to change or deviate from the specified requirements; obtain Company approval before proceeding with any changes.

3.9.3 Email the completed form to the STR.

3.9.4 Use the form to report any of the following conditions:

a. A request for deviation from the contract requirements.

b. Anytime a requirement contained within the original specification or a contract modification approved by the Company is violated.

c. There is nonconformance that cannot be corrected unless an item or process is modified, reworked, or repaired to an equivalent functional condition.

d. A request for Company approved substitutions shall be submitted using the RFWD form for Company approval prior to implementation. Adequate information shall be provided with the request so that the Company can determine if the item is equivalent.

4 Quality Assurance

4.1 Quality Assurance Program

The Supplier shall have implemented and maintain a quality system in accordance with ASME NQA-1 2008, 1a-2009, Part 1, Sections 1-18 (excluding requirement 3), and 10 CFR 71 Subpart H and DOE O 414.1D Attachment 3, with respect to Suspect Counterfeit Items. A copy of the Supplier's QA Program Manual shall be submitted with the bid in accordance with Attachment A for review and approval. The Supplier shall comply and conduct all work in accordance with their Quality Assurance program and this Equipment Specification. Company will provide the critical characteristics for any items or services to be dedicated.

4.2 ES−3100 Casting Quality Assurance Requirements

4.2.1 ES−3100 Heavy Can Spacer Assembly Documentation Package

All records shall be identified based on the ES−3100 Heavy Can Spacer Assembly serial numbers. The Documentation Package shall be provided in accordance with Attachment A with each ES-3100 Heavy Can Spacer Assembly casting lot. The Documentation Package shall be complete, legible, indexed, and traceable to the material supplied and include the following:

a. Material measuring, dry blending, wet mixing, casting, sampling, and inspection forms, i.e, Forms A through D.

b. A Certificate of Compliance for each lot of the 277-0 Heat Resistant Shielding "Non-Borated" dry mix documentation with the expiration date identified on each container.

c. Certificate of Compliances for B_4C powder to Type 1 Nuclear-Grade Boron Carbide Powder per ASTM C 750, chemical and elemental analysis per ASTM C 791, and 99.90% of the powder passes through a No. 140 Sieve per ASTM E 11.

d. A Certificate of Compliance signed by an officer of the Supplier confirming that the cast neutron absorber in the ES−3100 Heavy Can Spacer Assemblies meets the subcontract requirements.

4.2.2 Batch Processes

Batch processes such as mixing, pouring, curing, sampling, inspection, etc., shall be performed in accordance with detailed written procedures. These procedures shall specifically describe the exact manner in which these processes are to be performed. All records shall be traceable to the PGNAA Acceptance Standards or Companion can serial numbers.

4.2.3 Materials Traceability

A manufacturing lot or batch number shall identify material furnished to make up the neutron absorber system. Materials shall be identified by material type; applicable specification and revision number, and be traceable to their lot numbers. Traceability records shall be available for review by the Company's SA or STR.

4.2.4 Procedures

Preparation, installation, sample collection, and inspection processes shall be controlled and performed by qualified personnel. The procedures must incorporate a mechanism to identify process step completion. Procedures shall be submitted prior to fabrication in accordance with Attachment A.

4.2.5 Training and Qualification of Personnel

The Supplier shall provide for the training and qualification of personnel to ensure their competence in the use of process procedures and specifications. Records of personnel qualifications shall be made available to the Company upon request in accordance with Attachment A. Note: If the Supplier does not have prior experience in casting 277-4 Neutron Absorber, the Company will provide training and direct oversight on the processes.

4.2.6 The Company reserves the right to request any documentation and to witness any of the processes performed in accordance with this specification.

FORM A 277-4 Dry Blend Batch Control

Casting Company Name	Certificate of Conformance of the 277-0 dry mix		
Blended Dry Batch Control Number [a]	Record the expiration date of the 277-0 dry mix [b]		
Certificate of Conformance of the B_4C dry mix	277-0 Heat Resistant Shielding Drum ID Number		
Planning	277-4 Weight	Units	Operator
Batch Size		lb	
Operation	Measurement	Units	Operator
277-0 Weight (Target = 277-4 Weight x 93.6 wt%)		lb	
B_4C Weight (Target = 277-4 Weight x 6.4 wt%)		lb	
Dry Blending Time		min.	
Comments			

[a] A 10-digit Blended Dry Batch Control Number shall be used to define the date and the time of mixing the casting batch using the format with a 24-hour clock (i.e. 1021041515 is used for October 21, 2004 at 3:15 pm.)

[b] Record the expiration date of the Blended Dry Batch and confirm that it is still acceptable to be cast following this specification.

EXEMPT FROM IO-155 (8-02)

FORM B 277-4 Wet Mix Control (Overcast or Special Batch)

Casting Company Name		Blended Dry Batch Control Number		
Wet Mix Control Number (WMCN) [a]		Record the expiration date of the Dry Blend Batch		
Water Temperature °F	Air Temperature °F	Measurement	Units	Operator
277-4 Weight			lb	
Water Weight (Target = 277-4 Weight × 27±1 wt%)			lb	
Mix Time			min.	
Mix Finish Time			min.	
Comments				

[a] A 10-digit Wet Mix Control Number (WMCN) shall be used to define the date and the time of mixing the casting batch using the format with a 24-hour clock (i.e. 1021041515 is used for October 21, 2004 at 3:15 pm.)

FORM C ES-3100 Heavy Can Spacer Assembly Lot Casting Control

Casting Company Name			Can Lot Serial Number [a]				
Average 10 Can and Lid **Empty** Weight		Temperature of Water Weight (°F)		Average 10 Can and Lid **Water** Weight			
Wet Mix Control		Blended Dry Batch Control No.		Dry Blend Batch Expiration Date			
(Target Water = 277-4 Weight × 27±1 wt%)		277-4 Weight	lb	Water Weight	lb		
		Air Temperature	°F	Water Temperature	°F		
		Mix Time		Mix Finish Time			
Wet Mix Control Number (Overcast), if required							
Can Serial #	After Casting Weight (lb)	Cured Weight (lb)	Pass or Fail Cured Weight [b]	Cured Height (in)	Pass or Fail Cured Height [b]	Cured Density (lb/ft³)	Pass or Fail Cured Density [c]
Companion Samples [d]		−1			−2		
Operator		Comments					

[a] A 10-digit Can Lot Serial Number shall be used to define the date and the time of setup using the format with a 24-hour clock (i.e., 1021041515 is used for October 21, 2004 at 3:15 pm).

[b] Acceptable weight is 1.16 to 1.56 lbs and height 1.37 ± 0.06 as shown in Figure 3.

[c] Use this equation for the; $Density = \left(\frac{Cured - Empty}{WithWater - Empty} \right) \times 62.3$ lb/ft³. Acceptable 100 to 120(lb/ft³).

[d] Use Form D for Companion Samples.

FORM D ES-3100 Companion Sample Casting Control

Casting Company Name		Ave. 10 Can and Lid Empty Weight [a]			Ave. 10 Can and Lid Water Wgt. [a]		Temp. of Water Weight (°F)
Serial Numbers		Can Measurement Weights ±0.01 (lb)			For Record Only	Loss On Drying (Odd Serial Numbered Cans)	
Can Lot#	Companion Sample Can [a]	After Casting Weight	Cured Weight	LOD Weight	Cured Density (lb/ft³)	Calculated LOD%	Pass Or Fail per Sec. 3.3.8.3
Complied by					Comments		

[a] For the same lot of sample cans, it is acceptable to use an average weight of ten can bodies and ten can lids.
[b] Recommended vibration settings are at 450 VPM and three times the total vibrated weight. The total vibrated weight is the finish cast part and fixtures weight, for a setting of approximately 5 pound-force.

$$Density = \left(\frac{Cured - Empty}{WithWater - Empty} \right) \times 62.3 \text{ lb/ft}^3$$

$$\text{LOD\%} = \left[1 - \frac{(LODWeight - Empty - 0.024)}{(Cured\ \&\ Clean - Empty)} \right] \times 100\%$$

Attachment B: Instructions to Supplier for Preparation of Submittals

Note 1 --All correspondence shall be addressed to the Technical Representative identified by the company. The Supplier shall forward submittals via transmittal letter to the Company at the address specified in the contract.

Note 2 -- The submittal must have adequate detail so that full compliance with the requirements may be determined. For example, a simple off-the-shelf item to be used in an assembly may only need a manufacturer's cut-sheet to show compliance, but a factory acceptance test (FAT) developed and submitted by the Supplier must have each test step detailed with acceptance criteria consistent with the requirements.

a. Review submittal before transmitting to the Company to verify conformance with requirements of the contract documents (e.g., field measurements, field construction criteria, or manufacturer's catalog numbers).
b. Coordinate submittals with the work requirements and the contract documents.
c. Organize Submittals
   - Do not use highlight marker or color coding on submittals.
   - The minimum resolution used for scanning submittals shall be 300 dpi x 300 dpi.
   - For submittals containing color information important to the record, a 24-bit color setting should be used.
   - Submittals are to be legible and in the format specified on the submittal checklist.
   - Pen and ink changes are to be made in non-erasable ink, legible, dated and initialed.
   - Mark specific options provided for the work, and cross out options not provided.
   - Each submittal shall be sent as a single pdf file unless otherwise specified.
d. Label submittals with the applicable item number, reference, and requirement description as summarized in the Submittal Checklist. Unlabeled submittals will be returned to the Supplier without review.
e. Include with submittals a transmittal letter that identifies individual documents by specification section.
   - Transmittal for submittals shall be numbered using the purchase order number followed by a 4-digit sequential number. (Example: 430001111-0001).
   - Embedded comments or questions that are not included on the transmittal may not be addressed/resolved by the Company.
f. Direction will be given at the time of award to either upload submittals to a company provided URL address or send by email to a company provided email address.
g. If using a company provided URL to upload submittals, notify the Company via email when submittals have been placed.
h. After review of a submittal, the Company will assemble comments and provide a status on the documents. An example of this submittal status stamp is shown below.

DOCUMENT REVIEW STATUS		
1	☐ Work may proceed.	
2	☐ Revise & resubmit. Work may proceed subject to incorporation of changes indicated.	
3	☐ Revise & resubmit. Work may not proceed.	
4	☐ Review not required. Work may proceed.	
Permission to proceed does not constitute acceptance or approval of design details, calculations, analysis, test methods developed or selected by the supplier and does not relieve supplier from full compliance with contractual obligations.		
REVIEWED BY:	Print Name/Signature:	Date:

i. If a submittal is being resubmitted, then reference the applicable item number, reference, and requirement description and identify it as a resubmittal.
j. Company response will only be returned to the Supplier for those submittals with a Submittal Purpose of "For Action, "unless it is determined that a submittal transmitted "For Information" is not acceptable.
k. AFTER written approval is obtained, THEN proceed with work requiring approved submittals.
l. When approval submittals are required, work done before Company approval is at the Supplier's risk.
m. Maintain a copy of the company-approved submittal and status page on file.

1. SCOPE

This specification describes the quality assurance and technical requirements for Packcrete raw materials and preliminary lot qualification (PLQ). It includes procuring, inspection and accepting raw materials; weighing, mixing, casting, vibrating, curing, and baking Packcrete in a 30-gallon and other sizes of containers. For successful completion of the PLQ, samples shall pass verification tests. Once verification tests are complete and affirmed by the Company [Y-12 National Security Complex, Consolidated Nuclear Security, LLC (CNS)], the Seller is approved (but not yet qualified) to start the Packcrete casting process into a specific shipping package (SSP). Separate equipment specifications will specify the qualification requirements for each SSP.

If conflicting requirements appear in this specification and an SSP equipment specification (SSPES), the SSPES shall supersede this equipment specification. If additional conflicting requirements appear in this document, the Seller shall immediately notify the Company for resolution. Waivers and deviations from these requirements are not allowed without the Company's written approval on UCN-13816B, *Request for Waiver or Deviation (RFWD)*, [Attachment B]. The subcontract technical representative (STR) will provide an electronic copy of the RFWD form upon request.

The product produced from this specification is protected under U.S. Patent 6,299,950 B1. The U.S. Government has rights in this product pursuant to Contract No. DE-NA0001942 between the U.S. Department of Energy and CNS.

1.1 GENERAL DESCRIPTION OF THE ITEM

Packcrete is a fireproof, lightweight cast refractory. It is comprised of water, Airalon 3000 (air entraining agent), Portland cement, and vermiculite. Fig. 1 shows a sample section without magnification of Packcrete with a centimeter scale.

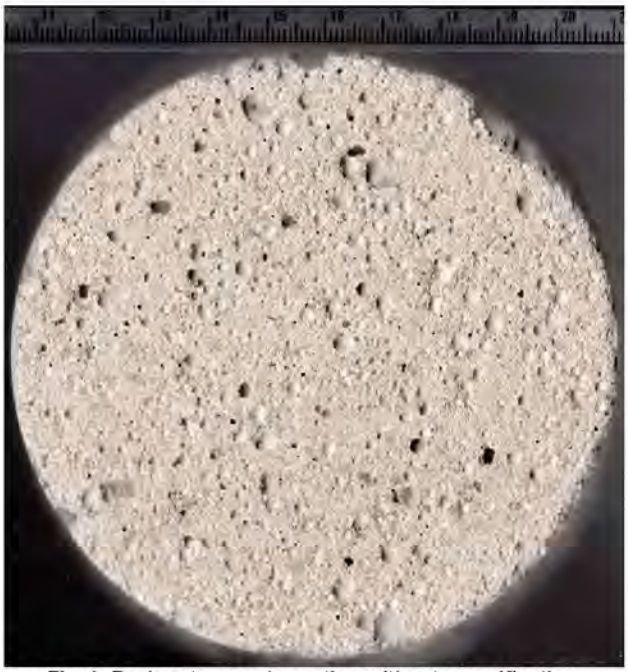

Fig. 1. Packcrete sample section without magnification.

1.2 BACKGROUND

Packcrete is a non-commercially available mixture that was developed as an insulation material for Type-B radioactive material shipping packages. Mixtures of Packcrete must comply with strict manufacturing standards, outlined in this specification.

2. REFERENCES

2.1 DEFINITIONS

4.5-gal pail – A metal container that is at least 4.5 gal and is >18-in. deep. The McMaster-Carr tin-plated steel pail and lid (Part 4243T16) with 4¾-gal capacity and 9-in. top outer diameter is acceptable.

Acceptable Raw Materials – Upon the purchase of new lots of raw materials they must pass Sect 5.4 testing before use in preliminary lot qualification. (Before production use, the raw materials must also pass final lot qualification testing for each simulated specific shipping package and unique casting volume and weight before production approval.)

Baking Control Number (BCN) – B alpha prefix control number that defines the date and the time when baking is started and recorded on Forms C through F (Attachment E).

Baked density – The calculated density of the Packcrete after baking using the following equation.

$$\text{Baked density} = \frac{(AfterBaking - CleanAndEmpty)}{\text{Volume}} \text{ lb/ft}^3 \quad \text{[see equation names below]}$$

Baking Qualification Control Number-Vol (BQCN-Vol) – BQ alpha prefix control number with a volume in cubic feet suffix used to document the date and time the baking process qualification is started and the volume of Packcrete casting used. The BQCN-Vol shall be recorded on each production baking form if used (Form F, Attachment E) to define the appropriate baking process qualification settings.

Certificate of Conformance (COC) – A declaration from a Seller/Supplier stating that the referenced product/material meets all requirements, standards, and/or specifications, but it is not a summary of test results. At minimum, the COC should include the following information:

Certification on Seller/Supplier's letterhead
Manufacturer's name
Purchase order number
Lot number (if available)
Quantity
Purchased material or equipment
Certification system followed
Appropriate Seller/Supplier signature
Seller/Supplier name
Manufacturing location
Part/item number
Date codes
Seller/Supplier contact information
Procurement requirements met/not met
Means of verification

Certified material test report (CMTR) – A document attesting that the materials are in accordance with specified requirements, including the actual results of all required chemical analyses, tests, and examinations from a third party testing facility.

Company – The Company, as used in this specification, is the Y-12 National Security Complex.

Control Number (CN) – 10-digit control number is used with an alpha prefix to document the date and time that process was started using a 24-h format (i.e., B1021081515 is used for starting baking on October 21, 2008, at 3:15 p.m.).

Deviation – A specific written authorization initiated by the supplier and granted by the Company prior to the manufacture of an item to depart from a subcontract requirement.

Equation names – Equation names are used to calculate the wet and baked densities on the casting forms. The following definition of terms clearly states how this data is to be used.

Name	Equation Name	Definitions
After baking cycle	AfterBaking	The baked Packcrete and metal container's weight after it has finished the baking cycles.
Before baking	BeforeBaking	The weight of the metal container with cured Packcrete scraped to the finished casting level before baking.
Clean and empty	CleanAndEmpty	The weight of the metal container that is dry, clean, and empty.
Wet after casting	WetCast	The weight of the scraped and cleaned actual wet cast Packcrete in the container after the vibration process has stopped.
Filled with water	WithWater	The weight of the metal container filled with water to the level of the finished casting.

Final lot qualification (FLQ) – Is required for new lots of raw materials before production castings may start. FLQ shall generate acceptable material property testing results using sample pipes and samples cut from a simulated specific shipping package lid and body casting following written procedures approved by the Company as described in Sect. 9.

Material test report (MTR) – A document attesting that the materials are in accordance with specified requirements, including the actual results of all required chemical analyses, tests, and examinations from the Seller.

Mix Control Number (MCN) – M alpha prefix control number for starting the mixing process.

Nonconformance – A deficiency in characteristic, documentation, or procedure that renders an item to be in noncompliance with specified requirements.

Operator (on casting forms) – A qualified individual, other than the witness, who is responsible for recording the casting measurement, or an individual other than the witness who made a density calculation using the recorded measurements. Multiple operators are acceptable on the forms.

Preliminary lot qualification (PLQ) – Is required before production castings and after raw materials passes the Sect 5.4 testing. It is accomplished using a 30-gallon drum to gain experience in casting and testing process control. The same 30-gallon drum tests may be acceptable to use during production to obtain verification material properties if there is a correlation made between the 30-gallon drum test results of the simulated specific shipping package PQ casting material properties test results.

Process qualification (PQ) – An individual process procedure following this or a SSPES used to verify that the mixing, vibration casting, curing, baking for a unique container size and weight that generates acceptable material properties. Qualified processes may vary process equipment, vibration force, and baking time. For a PQ of a SSP a SSSP lid and body casting must pass FLQ. The vibration force and baking time of each process may vary the most. For PQ of the sample pipes Forms A, B, E, and F are needed and a different vibration table. For PQ of the SSSP lid or body requires Forms A, B, and F and form(s) in the SSPES.

Sample Pipes – Successful dynamic testing results is required following Sect. 9.2 for LQ. A 4NPS Schedule 40 carbon steel pipe, 6.5 ± 0.02-in. long with no sharp edges, used for compression testing Packcrete samples. The inside of the pipe must be smoothed to a maximum surface roughness of 125 microfinish. The Packcrete casting in the pipe is finished to a depth of 0.3 ± 0.09-in. and 4.5 ± 0.09 in. from the fill hole, for a cast height of 4.2 in. Each finished end shall be finished flat to within 0.02. A large flat bottom drill bit and a small drill press works well to finish the cured casting flat.

Setup Approval Control Number (SACN) – SA alpha prefix control number to document the date and the time that the setup approval is started. The SACN shall be recorded on each mixing form (Form B, Attachment E) to define the appropriate Packcrete mixing process and casting materials amounts. A particular setup of hardware, settings, mixing times, and vibration speeds for mixing and casting Packcrete defined on Form A with casting records and submitted to the Company for approval. The sample pipes and SSSP may each have a unique SACN

to follow the PQ testing for approval. The Company approval SACN date gives the Seller authorization to cast record parts following the SACN. Due to changes in the mixing or vibration hardware, the Seller may have more than one SACN for the same lot of materials.

Seller – The organization or person(s) entering into a subcontract with the Company to provide the product(s) described.

Specific shipping package (SSP) – The final placement of Packcrete will be following the SSPES. This PLQ specification must be completed before and as part of the SSPES. Since the references, drawings, size, and weight of the shipping package or container are defined by the SSPES. Final acceptance of the Packcrete material properties shall be when the SSSP is cut and tested following Sect. 9 of this specification.

Simulated specific shipping package (SSSP) – Is defined in the SSPES and will have a body and lid that reasonably match the volume and weight of the SSP body and lid. The SSSP is used to verify the Seller's operating procedures produce parts that are acceptable to the SSPES.

Subcontract administrator – A Company person, called the buyer, who is responsible for overall subcontract administration.

Subcontract technical representative (STR) – A Company person responsible for managing, monitoring, and ensuring compliance with technical requirements of a subcontract.

Supplier – The organization or person(s) entering into a subcontract with the Seller to provide the product(s) described.

Technical representative (TR) – A Company person who identifies technical and quality requirements necessary to support development of a procurement specification.

Third party – An independent test organization, person, or company that tests products and materials in accordance with the contract requirements. The organization cannot be affiliated with the producer or the user of the item being tested. These independent testing facilities are sometimes called third party testing facilities. The third party test agency shall be certified to ANSI/ISO/IEC 17025 or be evaluated and accepted to meet the Seller's Company-approved quality assurance program, as applicable.

Volume – The calculated casting volume in cubic feet using the equations below.

For a metal container filled to Packcrete casting level.

$$\text{Volume} = \frac{(WithWater - CleanAndEmpty)}{62.3}\ \text{ft}^3 \text{ @ } 70^\circ\text{F}$$

For pipes or cylinders the internal diameter (ID) and the baked internal height (BIH) in inches.

$$\text{Volume} = \frac{ID^2 \times BIH}{2200.16}\ \text{ft}^3$$

Waiver – A specific written authorization initiated by the supplier and granted by the Company to accept a configuration item or other designated items that, during production or inspection, are found to depart from specified requirements but are considered suitable for use as is or after rework by an approved method.

Wet density – The calculated density of Packcrete after the container is filled and scraped, but not cured, using the equation below.

$$\text{Wet density} = \frac{(WetCast - CleanAndEmpty)}{\text{Volume}}\ \text{lb/ft}^3$$

Witness (on mixing and casting forms) – A qualified individual other than the operator trained in mixing and casting Packcrete who has verified that the data is accurately recorded. If a density is to be calculated, then the witness is an individual other than the operator who independently checked and verified the density calculation. Multiple witnesses are acceptable on the forms.

2.4 APPLICABLE DOCUMENTS FOR CNS Y-12'S USE ONLY

The following documents apply when casting Packcrete.

RP-802282-0002	*Packcrete Material Properties*
Y/DW-2345	*Impact Properties of Packcrete Material at −40°F and 100°F*

3. ITEM REQUIREMENTS

Packcrete must be cast into a steel container specified in this equipment specification. The manufacturing controls are based on a finished baked density of 22.4 ± 3 lb/ft^3 that controls the proper thermal and impact properties. The serial numbers for the casting shall be on the casting and recorded on proper casting forms.

3.1 PERFORMANCE REQUIREMENTS

The Seller has no responsibilities for performance of Packcrete beyond the measured density of 22.4 ± 3 lb/ft^3 when the requirements of this specification are satisfied.

3.2 DESIGN REQUIREMENTS

NA

3.3 SERVICE CONDITIONS

NA

3.4 FABRICATION AND ASSEMBLY REQUIREMENTS

See production processing in Sect. 7.7

3.5 INSTALLATION REQUIREMENTS

NA

3.6 REQUIREMENTS

NA

3.7 GOVERNMENT-FURNISHED MATERIAL, EQUIPMENT, SERVICES

NA

3.8 SCHEDULE

A manufacturing plan with written, step-by-step process plans shall be submitted to the Company for approval and used by the Seller to comply with requirements in this specification. At a minimum, the plan shall include:

- material control and materials to be procured,
- subtiers to be used, and control thereof,
- quality plan used to procure materials and manufacture Packcrete,
- major fabrication steps and sequence of operations,
- hold points to be determined for Company involvement,
- all in-process inspection/examination, and
- dimensional inspections and testing.

3.9 DELIVERABLES AND SUBMITTALS DOCUMENTS

There are two types of submittals associated with this specification: (1) Approval Data documents and (2) certification data documents. The submittal schedule, submittal format, number of copies, and submittal purpose are shown in Attachment A. All records shall be traceable to the casting and identified by serial numbers. The Seller shall maintain quality-related documentation in accordance with requirements in the purchase order and this specification. The Company reserves the right to request any such documentation and to witness all aspects of the manufacturing process in accordance with this specification.

3.9.1 Approval Data Documents

Approval Data documents are identified in Attachment A. Approval Data documents include written procedures and personnel qualifications which must be approved by the Company prior to conducting the work defined in Sect. 7.

With each submittal transmitted to the Company, the Seller will include an updated submittal checklist using an Excel spreadsheet. The checklist shall identify all of the documents to be submitted and the status of each. All submitted documents shall be identified with document title, document number, revision level, computer filename, and submission date. The reply date of and disposition by the Company shall be included in the Excel spreadsheet for documents already submitted and dispositioned by the Company.

The Seller shall generate documentation in compliance with the Company-approved quality assurance plan (QAP). All records shall be identified based on the component serial numbers traceable to the casting serial number. The Company reserves the right to request any additional documentation used in fabrication or raw material qualification.

Procedures shall be submitted to the Company for approval prior to use in accordance with Attachment A and shall identify all mixing and vibrating equipment models and settings required to complete the casting process. Approvals of submittals must be received from the Company prior to implementing any activities involving these procedures. Submittal version control must be exercised to ensure correct and approved versions are used. All fabrication activities used to make Packcrete must be described in approved written procedures.

3.9.2 Certification Data Documents

Certification data documents are identified in Attachment A, and document measurements, testing, and calculations created during the performance of the work described in Sect. 7 as documented in Attachment E forms.

Certification data documents include raw material test reports (MTRs) in accordance with the requirements of Sect. 5.4.

The Seller shall provide a certification data package that connects all specified processing data collected to the particular casting.

3.10 Packaging, Handling, Shipping, and Storage Requirements

See Sect. 5.2 for storage requirements for raw materials.

3.11 Marking and Identification Requirements

Packcrete as a material is not marked in any way. For production the procurement and processing records (forms) for Packcrete raw materials and procedures used shall be tracked by the manufacturing SSP serial numbers for the drum lid and body.

3.12 Requests for Waiver or Deviation

Any requested exceptions, deviations, or proposed changes to the requirements of this specification by the Seller after award and before acceptance shall be submitted using UCN-13816B. This form is included as Attachment B. The Seller shall request an electronic copy of the form with instructions from the STR or subcontract administrator.

4. Quality Assurance Requirements

The Seller shall perform this work under a Company-approved quality assurance program that meets the applicable requirements of 10 CFR Part 71, Subpart H, for packaging and transportation of radioactive materials.

The Seller shall submit a QAP for the scope of this work that describes the quality assurance policies and practices to be implemented in identifying, controlling, and verifying the quality of Packcrete processes (weighing, mixing, pouring, vibrating, curing, and baking). The Seller's QAP shall ensure full compliance with

all requirements, tests, inspections, reports, documentation, and approvals contained within this specification. The Seller's QAP shall include the requirements for the process controls for the operations, the qualifications of the operator(s) and witness(es), and verification records.

4.1 FINAL ACCEPTANCE TEST METHOD

The final acceptance test method includes verification that 100% of the castings contain Packcrete with a finished baked density of 22.4 ± 3 lb/ft^3 and the process used to achieve that density followed the prescribed steps included in Sect. 7.

Final acceptance will be based on compliance with the Approval Data documents as verified through surveillance activities by the Company, compliance with the technical requirements in this specification as verified through surveillance activities by the Company, and final review and acceptance of the certification data package documents that apply to Packcrete.

4.2 INSPECTION/TESTING REQUIREMENTS

See Sect. 7 for additional information.

4.3 SURVEILLANCE AND AUDITS

The Company shall reserve the right to evaluate the Seller's QAP and subtiers to ensure compliance with this specification at the Company's discretion. The Company shall be allowed to witness any of the processes associated with this specification during the performance of the contract.

4.3.1 Quality Hold Points

4.3.1.1 Raw Material Lots Must Be Qualified

Before any materials are used in LQ castings, the MTRs shall show that the materials meet the testing requirements and acceptance criteria specified in Sect. 5.4. The MTR number and the water weight shall be documented on Forms A and B (Attachment E).

Raw materials shall not be used until the Company has reviewed the MTRs and provided documented approval to use the materials.

4.3.1.2 Components Must Pass Geometric Inspection Requirements

NA

4.3.1.3 Company Approval Setup for Lot Qualified Raw Materials

Each change to the approved setup on Form A must be documented on a new Form A and reapproved by the Company. These changes may include hardware, mixing amounts, mixing rotation speed, mixing times, vibration speed setting (Sect. 7.3.1.5), and vibration time.

Modifications to the vermiculite dry weight percent shall require LQ testing and written Company approval. Changing from one lot of raw materials to another shall require LQ testing and written Company approval. Approval requires positive testing results of LQ testing defined in Sect. 9. Several months of lead time will be needed to perform these tests and for the results to be evaluated by the Company.

Changes to a Form A shall not be implemented for production castings until the Company has approved the changes. This approval process requires PLQ testing results. The Company may witness implementation of the changes through PQ and review third-party qualification testing results/reports, and then provide its documented approval to proceed via second signatures on the Form As.

4.3.2 Quality Observations

The Company reserves the right to perform quality observations of the Packcrete casting process at any time. Observations will include, but not be limited to, LQs, first article evaluation casting, and initial production casting.

4.4 QUALITY REQUIREMENTS

NA

4.5 ACCEPTANCE CRITERIA

The acceptance criteria for fabrication and assembly requirements are based on the baked density of 22.4 ± 3 lb/ft^3, and evidence that Packcrete was cast in compliance with this specification.

4.6 PERSONNEL QUALIFICATIONS/CERTIFICATIONS

Personnel qualified and trained as operators and witnesses shall be able to follow and perform written instructions and procedures and accurately record operations involving weighing, mixing, casting, vibrating, curing, and baking processes.

4.7 TRAINING AND QUALIFICATION OF PERSONNEL

The Seller shall provide the Company (1) a plan for qualifying and training personnel and (2) documented evidence that personnel have been qualified and trained in accordance with the Seller's procedures approved by the Company to ensure their competence in the use of process procedures and specifications. The Seller must ensure all operators use and follow written procedures for the respective processes. Submit the training plans for Company approval.

4.7.1 Operator and Witness Training and Qualifications

Each operator and witness who performs Packcrete processing activities shall be trained and qualified. This requires the operator and witness to (1) have read the operating procedures and (2) have experience making the measurements, filling out the forms, and successfully performing the activity. Operator and witness qualifications shall be documented and submitted to the Company for approval with the casting forms as evidence that personnel have been qualified and trained.

4.7.1.1 Packcrete mixing and vibration casting training shall consist of successfully completing mixing and casting activities described in Sects. 7.2 and 7.3.

4.7.1.2 Packcrete curing and baking process training shall consist of successfully completing curing and baking activities described in Sect. 7.4.

4.8 DOCUMENTATION RETENTION

Documentation of all inspection and test results shall be maintained by the Seller for 3 years after acceptance by the Company. The Company shall have access to this documentation to ensure compliance with all requirements.

The Seller shall not destroy quality records without notifying the Company in advance to confirm that the Company does not have a need for the records.

4.9 NONCONFORMANCE CONTROL

The Seller shall have an approved procedure for the control of non-conformances, waivers, and deviation requests during the execution of this specification. A nonconforming component shall not be used unless it has been specifically approved by the Company (see Sect. 3.12). The disposition of a nonconforming component shall be documented. Any nonconforming component shall be clearly identified, and each nonconformance report shall be traceable to the actual component affected. A copy of each approved nonconformance report for a component shall be provided to the Company as a part of the certification data package.

5. PACKCRETE RAW MATERIAL REQUIREMENTS

This section defines the requirements for Packcrete raw material procurement, receiving, storage, sampling, testing, and acceptance.

5.1 PROCURING PACKCRETE RAW MATERIALS

The Seller shall procure the Packcrete raw materials (i.e., vermiculite, Portland cement, and Airalon 3000) in accordance with the requirements in Sect. 5.4.

5.2 Receiving and Material Storage Instructions

Packcrete raw materials procured per this specification shall be marked and received with a traceable Certificate of Conformance (COC).

5.2.1 Damaged Packages

The Seller shall not accept and/or use damaged packages of Packcrete raw materials. Damaged packages are those that are visually determined to be wet, have been wet, have been torn open, or are leaking.

5.2.2 Storage of Raw Materials

Packcrete raw materials shall be stored in a dry location and protected from damage and moisture with an air temperature range of 70 ± 20°F and compliant with the manufacturers recommended practices.

5.3 Sample Plan for Third Party Testing

Packcrete raw materials must be purchased in accordance with Sect. 5.4. The plan will require each lot of sampled material to be tested by an independent third party. A sample plan must be created by the Seller to determine the definition of appropriate lot and sample size(s) in order to achieve reasonable assurance that the sample size chosen provides an adequate representation of the purchased item(s) quality. The sample plan shall comply with guidelines as directed by the Company. The lot size is defined in Sect. 5.4.

5.4 Material Procurement and Acceptance Criteria

Packcrete raw MTRs shall be provided with the COCs. The Seller shall also provide a CMTR from a qualified third party testing laboratory in accordance with the requirements in this section.

Note 1: One lot of Airalon 3000 is comprised of a single 55-gal drum that is (1) marked with a manufacturer's lot number and (2) noted in the manufacturer's COC.

Note 2: One lot of Portland cement is comprised of bags received against the same purchase order that have a date code (1) noted in the COC and (2) within the time period noted on the MTR provided with the manufacturer's COC.

Note 3: One lot of vermiculite is comprised of bags received against the same purchase order that have the same manufacturer's lot number noted in the manufacturer's COC.

5.4.1 Vermiculite Acceptance Criteria

The raw material manufacturer shall provide a COC package that includes the following, as a minimum: (1) the Buyer's purchase order number; (2) the date(s) of manufacture; (3) a statement that the material complies with ASTM C516; (4) a signature by the supplier's official or quality manager; and (5) a Certificate of Analysis in accordance with ASTM C516 for bulk density and grading. The COC shall also include the lot numbers in the order and the number of bags for each lot number.

All bags in the order shall come from a single manufacturing run in order to ensure consistency from bag to bag in terms of chemical composition, bulk density, and particle size distribution.

The manufacturer shall mark each bag as being vermiculite, Type 1, Grade 3, per ASTM C516 requirements. The manufacturer shall also mark each bag with (1) the lot number, (2) the manufacturing line identifier, and (3) a date code showing when the material was manufactured and bagged.

The manufacturer shall maintain quality records that connect the lot number, manufacturing line identifier, or date codes to the raw materials, manufacturing processes, operating procedures, and other manufacturing specifics associated with the manufacturing run.

Bagged vermiculite shall be stored in an area where vibrations from adjacent equipment and handling or movement are minimized, and be stored and transported in a manner that protects the bags and materials from exposure to water.

Bulk density and grading shall be independently tested by a third party testing laboratory in accordance with ASTM C516 (Type 1, Grade 3 Fine).

When tested in accordance with Sect. 9.1.1 of ASTM C516 and ASTM C520, third party testing must show each sample has a bulk density between 6.4 and 8 lb/ft3. When tested in accordance with Sect. 9.1.2 of ASTM C516 and ASTM C136, all samples must have a particle size distribution that complies with Table 1

Table 1. Particle size distribution acceptance criteria

U.S. Sieve No.	Weight % passing through the sieve
8	90 to 100
16	40 to 82
30	0 to 35
50	0 to 20
100	0 to 10
200	0 to 2

If all samples do not pass the bulk density and particle size distribution acceptance criteria, the lot shall be rejected by the Seller and the Company should be notified.

5.4.2 Portland cement Acceptance Criteria

The manufacturer shall provide a COC package for each purchase order that includes the following, as a minimum: (1) the Buyer's purchase order number; (2) the date(s) of manufacture; (3) a statement that the material complies with ASTM C150; (4) a signature by the supplier's official or quality manager; (5) an MTR in accordance with ASTM C150; and (6) a statement that all bags in the order were bagged during the time period stated in the MTR. The COC package shall also include the lot number in the order and the numbers of bags in each lot number.

The manufacturer shall mark each bag as being Portland cement, Type III, per ASTM C150 requirements. The manufacturer shall also mark each bag with a date code showing the week and year the material was bagged. All bags in the order/lot shall have a date code that is within the valid time period stated in the MTR.

The manufacturer shall maintain quality records that connect the lot number or date codes to the raw materials, manufacturing processes, operating procedures, and other manufacturing specifics associated with the manufacturing run.

The packaging practices of the manufacturer are acceptable unless stated otherwise in the Buyer's purchase order. Material shall be stored and transported in a manner that protects the bags and materials from exposure to water.

A CMTR shall be provided from a third party independent testing laboratory showing that all samples comply with ASTM C150, Table 1, Type III standard chemistry requirements when tested in accordance with the test methods specified in ASTM C114, Table 1.

If all samples do not pass the acceptance criteria, the lot shall be rejected by the Seller, and the Company should be notified.

5.4.3 Airalon 3000 Acceptance Criteria

The manufacturer shall provide a COC package with each purchase order that must include the following as a minimum: (1) the Buyer's purchase order number; (2) the date(s) of manufacture; (3) a statement attesting to the fact that the material complies in concentration, composition, and performance to ASTM C260 requirements; (4) a statement providing the chloride content of the material; and (5) a signature by the supplier's official or quality manager. The COC package shall also include the lot number, the date codes, and the number of containers in the order for each date code.

The manufacturer shall mark each container as being Airalon 3000 per ASTM C260 requirements. The manufacturer shall also mark each container with (1) the lot number and (2) a date code showing when the material was manufactured and containerized.

The manufacturer shall maintain quality records that connect the lot number or date codes to the raw materials, manufacturing processes, operating procedures, and other manufacturing specifics associated with the manufacturing run.

A CMTR shall be provided from a third party independent testing laboratory that shows that each 55-gal drum of Airalon 3000 complies with the acceptance criteria in Table 2.

Table 2. Airalon 3000 55-gal drum acceptance criteria

Reference	Test	Original lot	Acceptance criteria*
ASTM C494, C260, or C233	Infrared analysis**	Attachment C	Essentially similar to Attachment C
ASTM C494, C260, or C233	Specific gravity	1.01 S.G	0.91 to 1.13 S.G.
ASTM C260 or C233	pH	10.25 pH	9.15 to 11.48 pH
ASTM C260 or C233	Residue (solids)	3.15 wt %	2.82 to 3.52 wt %

*The acceptance criteria are based on the measurements of the original lot and a 12% range.
**ASTM C260 for air-entraining admixtures does not require infrared analysis. Therefore, the infrared analysis for chemical composition testing is determined by ASTM C494 using the oven-dried residue as determined by ASTM C260/C233.

If the sample does not pass the acceptance criteria, the Airalon 3000 55-gal drum shall be rejected, and the Company shall be notified.

5.5 Mixing Water

Water that has been filtered through at least a 20-micron filter and has a chlorine content that is <4 mg/L (4 ppm, 0.0004% by mass) shall be used for the mixing of Packcrete. Record the manufacturer, model number, and serial number of the water filter showing that it is at least a 20 micron filter on Form B (Attachment E). The water temperature shall be between 50 and 80°F. Form B in Attachment E shall be used to document and record the water temperature and that the chlorine requirements are met each day before mixing starts.

6. Facility and Process Equipment Requirements

A written plan shall be submitted to the Company for approval that defines the cleaning process, including cleaning solutions used, equipment, and work and storage environments.

6.1 Cleaning Instructions

NO CHLORINE PRODUCTS (sodium hypochlorite) shall be used in the cleaning materials. Potable water shall be used and, if required, some mild soap (tri-sodium phosphate) may be included to clean all processing equipment and manufactured drum bodies and lids before casting. Chlorine is known by many names on the ingredient list (e.g., sodium hypochlorite, hypochlorite, chloramine, bleach, hydrochloric acid, trihalomethanes, and generic disinfection by-products). Not all cleaning products list their ingredients, therefore, only cleaning materials that disclose all ingredients shall be used.

If the mixer sits for >15 min between mixer batches, the mixer shall be flushed thoroughly with potable water before reuse. Before the start of mixing operations described in Sect. 7, the mixer shall be clear of foreign materials or loose previous mixing residues from the inner surface of the mixer.

Manufactured drum bodies and lids that have passed geometric inspection must be cleaned and protected prior to the casting operation to prevent the introduction of foreign materials into the assemblies. The assemblies shall be inspected and wiped clean prior to casting to ensure no visible contaminants are present inside the casting cavity.

6.2 Equipment Requirements

All process equipment used for mixing, casting, and baking of the Packcrete shall be (1) identified in the Seller's operating procedures with the operational tolerances and (2) in good working condition.

6.2.1 Scales Requirements
Scales used for weight measurements shall be calibrated and traceable to National Institute of Standards and Technology. All weighing operations of assemblies and materials shall be conducted on digital certified scales with a minimum accuracy of 0.5 lb.

6.2.2 Plaster or Mortar Mixers
The Multiquip's Whiteman WM70S-H8 (8-hp Honda engine) and the Whiteman WM70PE (1.5-hp electric motor) mixers with a 7 ft^3 capacity have been used previously for Packcrete mixing. The WM70PE machine mixes 7 ft^3 of material running at a slow rotation speed with the mixer vanes measuring between 19-27 rpm. The motor speed controller was set to a value of 28–38 rpm. Other models of plaster/mortar mixers may be used if the rotation speed and mix times are qualified in accordance with the requirements in Sect. 7 and approved by the Company. The maximum batch size that mixes well in the WM70PE mixer is approximately 2.7 ft^3 using 22.5 lb of vermiculite. The electric motor bogs down with larger loads. The Whiteman WM90PE (3-hp electric motor) mixer with a 9 ft^3 capacity is recommended to mix larger volumes. Blastcrete Equipment Co. has the D3522MP (mixer pump) that can mix batches up to 5 ft^3 and dump them into a hopper and start mixing another batch. The hopper feeds a peristaltic pump that pumps the material to the end of the 2" diameter hose. No labor is required to move the mixed Packcrete using the mixer pump. Other mixers models may be used by the Seller if qualified in accordance with the requirements in Sect. 7 and approved by the Company.

6.2.3 Low Profile Platform Vibrator
The VIBCO Low Profile Platform Vibrator (24-in. wide × 36-in. long) with the SCR-1000 adjustable eccentric vibrator, or a Company-approved equal, must be selected based upon the maximum estimated wet cast weight (EWCW). The vibration force and duration must be controllable for the container size and weight in accordance with the requirements in Sect. 7.3.1.6. Other models may be used by the Seller if qualified in accordance with the requirements in Sect. 7 and approved by the Company. Verify that the Low Profile Platform Vibrator selected has the capacity to generate the forces required in Sect. 7.3.1.6 and to cast the specific Type-B shipping package. If other vibration equipment is used for a SSP, Sect. 6.2.3 and 7.3.1.6 must document all changes in the SSP casting using the PLQ equipment specification.

6.2.4 Table Vibrator
A standard table vibrator from VIBCO with at least a 6- by 12-in. table top and an electric motor vibrator producing up to 100 lb of force should be used. This vibrator is required to vibrate small 4.5-gal or sample pipes cast during production when the table in 6.2.3 will be loaded with the shipping package.

6.2.5 Time Clocks
The Company recommends the use of two different types of time clocks. The first is a digital 24-h clock with the date that identifies the processes. The start time and date shall become a part of the unique identifier [e.g., alpha prefix (B, BQ, M, P, or SA) plus a 10-digit number for the start date and time of the process using a 24-h format (1021131415 is used for October 21, 2013, at 2:15 p.m.)] for the qualification, mixing, and baking processes.

The second type of time clock is a magnetic digital timer that measures both the mixer and vibration cycle times. One timer should be used to measure each operation. The magnet lets the operators connect it to the mixer housing or other steel support.

6.2.6 Furnace with Temperature Recorded and Controller
The furnace shall be a vented gas-fired or a forced convection fresh air circulating electric furnace with the heat zone verified with thermocouples to 500 ± 25°F at the baking location of the containers in the furnace.

6.3 WORK ENVIRONMENTS

The temperature and humidity of the material storage, casting, and curing environments can have a major impact on casting densities. Variations in mixing air, water, and curing temperatures can also influence the baked density. The Company requires controlled work and material storage environments.

6.3.1 Mixing and Casting
Mixing and casting operations shall be performed out of direct sunlight and rain with an air temperature of 70 ± 20°F.

6.3.2 Mixing and Casting Water
Mixing and casting operations shall be performed with water that complies with the requirements in Sect. 5.5.

6.3.3 Curing Storage
Curing storage shall be in an environment with an air temperature of 70 ± 20°F with the containers covered with plastic.

6.3.4 Portland Cement and Vermiculite Storage
Bags of Portland cement and vermiculite that have been opened for more than one work shift shall be discarded unless they are stored in a waterproof container in a dry location.

7. PACKCRETE PRELIMINARY LOT QUALIFICATION

Packcrete PLQ requires using documented and approved equipment, equipment settings, operating procedures, containers, and raw materials that have passed third party inspections in Sect. 5.4. Packcrete properties are influenced by the raw materials (Sect. 5), equipment (Sect. 6), and process controls. The Packcrete PLQ is shown in Fig. 2.

This section provides the PLQ requirements for establishing a mix setup for casting the 4.5-gal pail, 30-gal drum, SSSP, and SSP. Section 7.5 establishes a process setup and adjusts the mixing and casting process if required to obtain the required wet and baked densities. Once the process setup is established, the Seller may cast a set of PLQ castings in a 30-gal drum and a set of six sample pipes. When the densities are acceptable, the 30-gal drum and sample pipes are sent for additional testing that is performed as defined in Sect. 9.

The PLQ options 1 and or 2 and sub-options are selected by the Seller based upon the Packcrete casting experience they have with the PLQ and SSP equipment specifications. It is recommended that new Sellers start with option 1 until they are confident to move to option 2. Before a Seller will be approved to cast a SSP by the Company confirmation samples must be cast and tested from a simulated specific shipping package (SSSP).

Once the PLQ setup is Company approved, the Seller shall follow Form A to produce a Form B (Attachment E) for each Packcrete batch and next follow the shipping package specific casting specification and cast a simulated shipping package. For FLQ the SSPES will reference this equipment specification for many mixing, casting, curing, baking, and testing operations. The difference between PLQ and FLQ is that the samples for testing come from a 30-gal drum or a SSSP. Depending upon the casting results and where the forms are used, the casting forms in Attachment E could be for approval as part of a certification data package.

7.1 PROCESSING SETUP REQUIREMENTS

The Packcrete processing setup requirements ensure that the Seller is following Company approved procedures, using acceptable raw materials, and that fabricated hardware has passed all inspections. Each casting's serial number shall be traceable to the lots of materials used in the mixing process. All changes shall be documented in the Seller's procedures and approved by the Company. Final lot qualification (FLQ) will occur in the SSPES. FLQs are possible using the six cast pipes and samples cut and tested from the SSSP. Tested samples must pass the testing requirements described in Sect. 9. Additional production sample set testing is defined in Sect. 8.2.

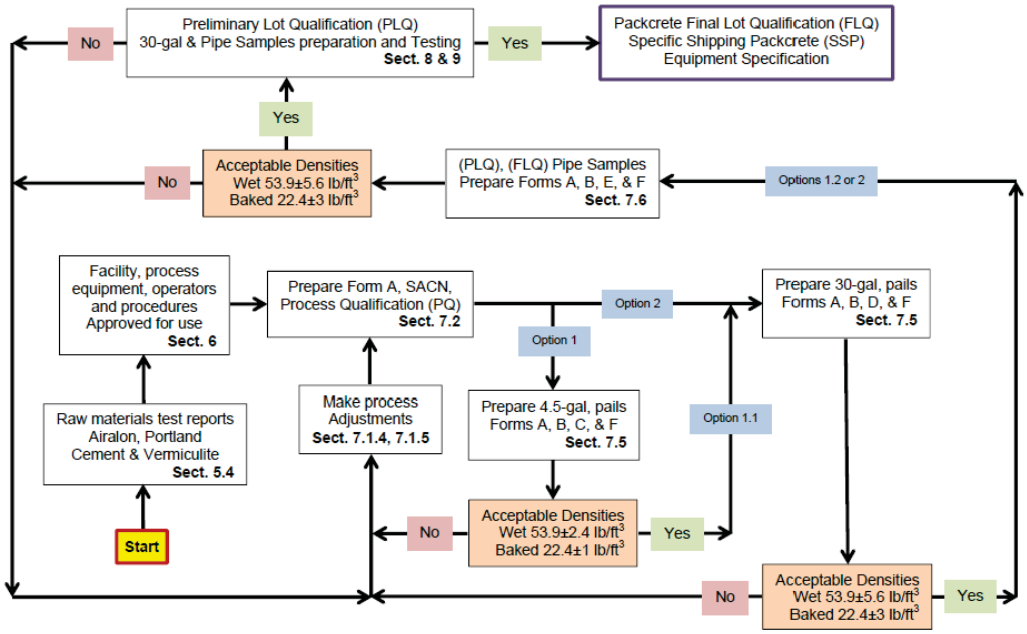

Fig. 2. Packcrete preliminary lot qualification.

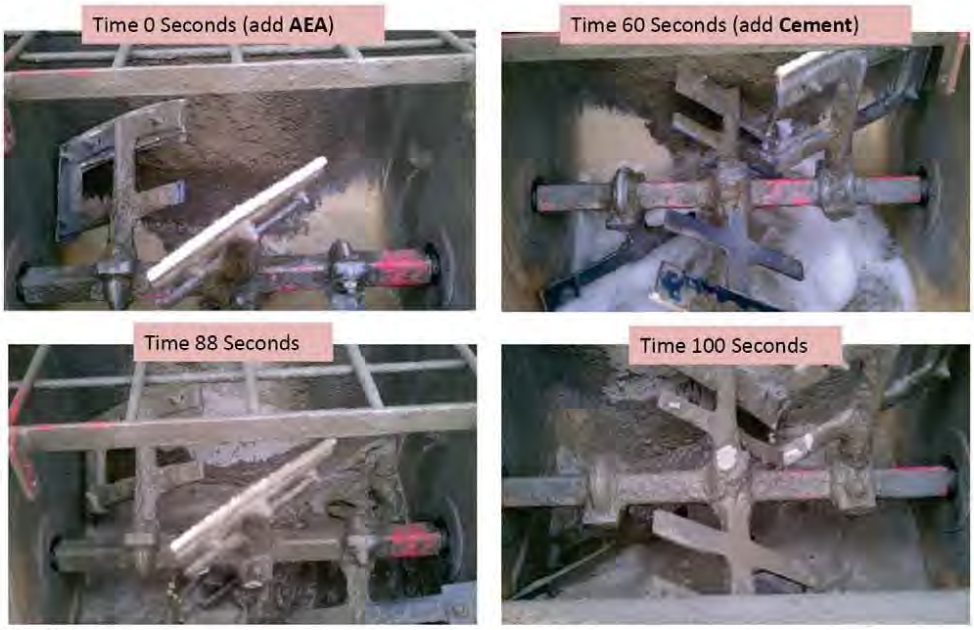
7.1.1 Setup Verification
It is recommended that new casting setups begin by using the nominal setup and casting the 4.5-gal pails documented on Form A (Attachment E) and identified by the SACN. Mixers and vibration tables must be qualified following this specification using the proper adjustments of rpm (frequency) (Sect. 7.3.1.5), and force settings based on the wet cast weight estimate (Sect. 7.3.1.6). Once confident in the SACN, the Seller may apply the manufacturing process to the 30-gal drum to gain more casting experience.

7.1.2 Preliminary Lot Qualifications (PLQs)
Following a SACN, and casting the 30-gal drum requires Forms A, B, D, E, and F for PLQ castings per Sect. 7.5. The Seller is responsible for the PLQ baked Packcrete to have a density of 22.4 ± 3 lb/ft^3 and has the option to adjust the mixing recipe amounts in accordance with Sect. 7.1.4 or 7.1.5 and requalify the mixing, casting, vibration, curing, and baking processes to bring the baked density to the nominal values. Process changes made to processing times, adjustments to process equipment settings, or dry weight percent within a lot of raw materials require a new Form A to be approved by the Company.



7.1.3 Final Lot Qualifications
The FLQ processes and testing are in this and the SSP equipment specification. FLQ is used to mitigate the risk of rejecting the baked Packcrete in the container's body and lid during production. FLQ requires material property testing confirmation using sample pipes and SSSP castings baked Packcrete to have a density of 22.4 ± 3 lb/ft^3. FLQ is only completed after the Company has reviewed the FLQ testing results in comparison to acceptance criteria documented in RP-802282-0002, and the Form A SACN is signed by either the STR or TR or both. Once the Company has approved the SACN, it may be used for production parts. Equipment replacement of like-for-like process equipment does not need to be re-qualified.

7.1.4 Change Control—Hardware or Process Settings for Mixing, Vibrating, Curing, and Baking
Any hardware change to the mixing or vibrating hardware shall be documented on a new Form A and reapproved by the Company. Each vibration force setting, time duration, temperature, and mixing recipe variable for the process qualification (PQ) shall be recorded on Forms C, D, E, and SSP and shall be repeated during production and documented on Forms D, E, and SSP. The Seller is responsible to follow this specification to generate a process that meets the baked density acceptance range. Hardware settings for the mixer rpm and mixing time for each additive are fixed using Form A.

7.1.5 Mixing Recipe Amounts and Adjustments

This section defines the amounts of materials needed to mix Packcrete. To mix Packcrete, the first step in the mixing operation is to add water and Airalon 3000 to the mixing bin and mix until the mixture is saturated with tiny bubbles as shown in Fig. 3. The second step is to add Portland cement to the mixture and mix until a sloppy wet bubbly cement mixture is achieved. The third step is to add vermiculite to the mixture and mix until the vermiculite is fully coated with the wet cement mixture. The fourth step is to stop the mixer and verify the vermiculite is fully coated, as shown in Fig. 4. Mixing beyond the point when the vermiculite is fully coated will lead to higher wet and baked densities. The fifth step is to perform the ASTM C860, Sect. 6.2, Ball-In-Hand Test, to verify that the proper amount of water is in the mixture.

The Packcrete recipe in this section is based on the maximum weight of vermiculite that the WM70PE mixer can mix without bogging down or stopping. The vermiculite dry weight percent of 37.5% should be used as a starting recipe for the 4.5-gal sample casting to generate a recommended wet density range of 53.9 ± 2.4 lb/ft^3 (51.5 to 56.3 lb/ft^3) that should yield a required baked density range of 22.4 ± 1 lb/ft^3 (21.4 to 23.4 lb/ft^3). The 4.5-gal samples are smaller volumes; therefore, the density target range is different from the FLQ and production process ranges (i.e., recommended wet density range of 53.9 ± 5.6 lb/ft^3 and a recommended baked density range of 22.4 ± 3 lb/ft^3). The wet density will vary from batch to batch. If an adjustment to the average wet density recipe is needed, it must be made with written Company approval following Form A by adjusting the vermiculite dry weight percent between 35.5 and 39.5%, which should change the average wet density by about ±1 lb/ft^3. Higher vermiculite dry weight percent results in lower amounts of Portland cement and lower densities.

Note: AEA—Airalon.

Fig. 3. Mixing Packcrete.

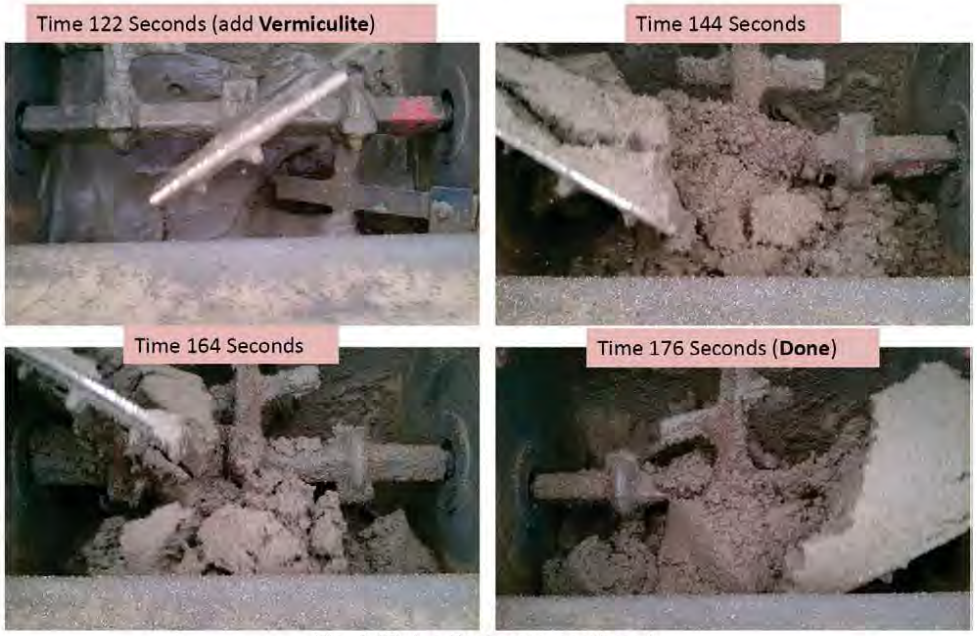


Fig. 4. Mixing Packcrete, continued.

Table 3 provides the nominal recipe for a large batch (2.7 ft^3) and a small batch (1.8 ft^3). Table 4 provides the maximum adjustments needed to increase and decrease the wet density by ~1 lb/ft^3. Each value in the tables is calculated by the equations in this section. The vermiculite dry weight percent also determines the Portland cement dry weight percent, and each dry weight requires its own amount of water to pass the ASTM C860, Sect. 6.2, Ball-In-Hand Test. In Table 4, adjustments in the amount of Portland cement and water in pounds were needed to increase or decrease the wet density of the starting mixture, with the vermiculite and Airalon 3000 remaining fixed. Adjusting the wet density from 52.9 to 55.0 lb/ft^3 requires the addition of 6.42 lb of Portland cement and 3.85 lb (6.42 lb × 0.6) of water. The amount of water needed for the casting was based upon passing the ASTM C860, Sect. 6.2, Ball-In-Hand Test, during development. If the Ball-In-Hand Test fails, the water content must be adjusted accordingly.

The Tables 3 and 4 values are calculated using these equations:

For 22.5 lb of vermiculite and a nominal vermiculite dry weight percent of 37.5%, the amount of cement is calculated on a dry weight percent as follows:

Cement = verm × (1/%V – 1) = verm × (1/0.375 – 1) = verm × 1.6667
Cement = 22.5 × 1.6667 = 37.5 lb

The water mass is calculated by the following equation.

Water = verm × 3.11 + cement × 0.6
Water = 22.5 × 3.11 + 37.5 × 0.6 = 92.48 lb

The Airalon 3000 is measured by a graduated cylinder and is calculated using the following equation:

Airalon = verm / 0.375 (lb/ml) = 22.5 lb / 0.375 (lb/ml) = 60 ml

Table 3. Nominal recipe for a large batch and a small batch at wet density of 53.9 lb/ft3

Material	Target wet density	Airalon 3000	Vermiculite	Vermiculite [a]	Portland cement	Water	Volume
Units	lb/ft3	ml	dry wt %	lb	lb	lb	ft3
Tolerance	±2.4	±2		±0.1	±0.1	±0.3	
Average large mixer load	53.9	60	37.5%	22.5	37.5	92.48	~2.7
Average small mixer load	53.9	40	37.5%	15.0	25.0	61.65	~1.8

[a] All mixer load sizes must be qualified before use. Use the vermiculite weight ratio to calculate the Airalon 3000, Portland cement, and water weights.

If the Packcrete setup described in Sect. 7.1.1 generates a wet density that is too high, the Seller may increase the amount of vermiculite to 39.5% weight percent to reduce the wet density. If the Packcrete wet density is too low, the Seller may reduce the amount of vermiculite to 35.5% weight percent to increase the wet density. Once changes have occurred in the Packcrete recipe, a new Form A shall be generated and new LQ testing shall be performed, as described per Sect. 7.1.2.

Table 4. Extreme recipes for a large Packcrete batch at wet densities of 52.9 and 55.0 lb/ft3

Material	Target wet density	Airalon 3000	Vermiculite	Vermiculite [a]	Portland cement	Water	Volume
Units	lb/ft3	ml	Dry wt %	lb	lb	lb	ft3
Tolerance	±2.4	±2		±0.1	±0.1	±0.3	
Lower density mixer load	52.9	60	39.5%	22.5	34.46	90.65	~2.7
Higher density mixer load	55.0	60	35.5%	22.5	40.88	94.50	~2.7

[a] All mixer load sizes must be qualified before use. Use the vermiculite weight ratio to calculate the Airalon 3000, Portland cement, and water weights.

7.2 SETUP APPROVAL CONTROL NUMBER (FORM A) FOR PROCESS QUALIFICATION

The purpose of the Packcrete setup process is to define and control the required mixer recipe material weights, mixer rotation speed, and mix times to properly mix and cast Packcrete. Form A (Attachment E) identifies the SACN that defines these recipe and mixing settings. The Seller shall create a new Form A for any unique vermiculite weight % or process setup change as defined in Sect. 7.1. The first time through the PLQ process, use the nominal recipe found in Table 3. If needed, the Packcrete recipe may be modified following the requirements in Sect. 7.1.5 up to the limits found in Table 4.

7.2.1.1 Using Form A, record the SACN.

7.2.1.2 Record the vermiculite wt %, mix volume (estimated), water weight, Airalon 3000, Portland cement, and vermiculite in accordance with Sect. 7.1.5. This defines the nominal recipe. Adjustments require written Company approval using Form A.

7.2.1.3 Record the serial number, manufacturer, and model number of the water filter in accordance with Sect. 5.5.

7.2.1.4 Record the mixer serial number, manufacturer, model number, speed control setting, and blade rotation speed in accordance with Sect. 6.2.2.

7.2.1.5 Record the vibration equipment serial number, manufacturer, model number, vibration speed setting, and vibration time in accordance with Sects. 6.2.3 and 7.3.1.6.

7.2.1.6 Use the Form A setup on a practice casting, such as the 4.5-gal pail or 30-gal drum, and document the results using the forms in Appendix E. The Seller may also proceed to preliminary lot qualifying of raw materials by

casting a set of six sample pipes per Sect. 9. Set up the casting following the requirements in Sect. 7.3 and perform casting following the requirements in Sect. 7.4.

7.2.1.7 Provide Form A that defines the mixing setup with the casting Forms C, D, E, and F (Appendix E) or form(s) in the SSPES that control the mixing, vibration casting, furnace, and baking to the Company as proof that baked density was within the acceptable limits. The Company TR and/or STR shall sign and concur with either wet ink or pdf electronic signatures on Form A for approval once the PLQ testing results have been confirmed to be acceptable. If needed go to the shipping container specification to cast a simulated shipping container used to cut testing samples for PQ.

7.2.1.8 FLQ and Company approval are required before any container production may start. Confirmatory testing results of a set of six sample pipes and testing samples cut from a SSSP cut and tested following Sect. 9.

7.3 PROCESSING PREPARATION FOR SAMPLES AND PARTS

The purpose of processing samples and parts is to create and document a controlled Packcrete casting that follows an approved mixing setup defined on Form A. The same processes are used for casting samples and parts, with the vibration force being adjusted for EWCW of the container and on partial fillings of containers being vibrated for 10 s and turned off and vibrated for 1 min after filling is completed. These and other processing forms data are recorded on Forms C, D, and E or form(s) in the SSPES (for the SSSP).

7.3.1 Setup—Mixing, Vibration Casting, and Curing Samples and Parts

The active mixing setup approved settings for that casting are on Form A (Attachment E) and identified by the SACN shall be followed for that container size. The Packcrete setup approval process is documented in Sect. 7.2 prior to proceeding to the PLQ process of casting the 30-gal drum documented in Sect. 7.5. The 4.5-gal pail Form C and 30-gal drum Form D have also been used to train and become familiar with Packcrete processing.

A concrete curing vibrator such as McMaster-Carr 7693T18, may be used to vibrate the Packcrete after pouring in a casting that is too large to move or use a vibration table to minimize large air bubbles. Additional vibrators and methods may be used to obtain acceptable Packcrete density in a simulated casting. Specific models of vibrators shall only be used if their use and applicable settings are qualified per the SSPES and documented in approved procedures.

Each unique EWCW of a sample or part shall have the vibration table force set as shown in Sect. 7.3.1.6 for the VIBCO SCR-1000. For a different VIBCO vibration motors use, contact the Company for the proper settings. For samples, document the casting information on the proper Forms C, D, and E (Attachment E) or form(s) in the SSPES. Follow the SSPES for casting in shipping containers. For optional samples, use Forms C, D, and E or form(s) in the SSPES to record casting data. Adjustments shall be made to the casting vibration force settings based on the EWCW of the sample. The Seller shall complete the following steps:

7.3.1.1 Ensure that the mixer specified on Form A for SACN is properly cleaned in accordance with Sect. 6.1, and inspect its working surfaces for residues or foreign materials (e.g., oil, grease, or non-Packcrete material affixed to the surfaces) and excess waste material; clean if required.

7.3.1.2 Verify that the mixer blades are operating within the qualified mixer rotation speed range for the qualified mixing times. Determining total mixing rotations requires both the mixer speed and the time that the mixer runs at that rotation speed. The total number of rotations of the mixer blades shall be controlled by settings on Form A by SACN for each mix time and recipe ingredient. The mixer rotation speed and/or mix times may be modified to obtain the total number of mixer blade rotations. For the WM70PE mixer, see Sect. 6.2.2. Other mixer rotation speeds and times shall be qualified as needed.

7.3.1.3 Ensure that the mixer can transfer the Packcrete from the mixer into the container on the vibration table. If not, adjust the locations. Hand loading is also acceptable.

7.3.1.4 Verify that the force counter weights of the vibration table are set to generate a vibration of ~2.1 times the wet cast weight estimate per Sect. 7.3.1.6. Record this setting on the casting form. The speed setting is specified on Form A for the SACN.

7.3.1.5 Verify that the vibration setting on the table speed is set as specified on Form A for the SACN. The vibration casting frequency for SCR-1000, or a Company-approved equal, shall be held fixed at 80% of 4000 rpm speed, generating ~53 Hz (3200 vpm) to properly cast Packcrete (Sect. 6.2.3). Ensure that the speed setting

is fixed and not free to change. Higher vibration forces (Sect. 7.3.1.6), frequency, and durations result in higher wet and baked densities.

7.3.1.6 Vibration force is defined by the manufacturer and shown in Attachment D for the VIBCO SCR-1000. (The table in Attachment D was used to select a force at a setting and to create an equation that defines the forces between the settings.) Verify that the force eccentric counter weights of the vibration table (shown in Fig. 5) are set in accordance with Table 5 or the equations in the section generated from the force settings in Attachment D. The vibration intensity (vibration force / wet cast weight estimate) must be around 2.1±.6 times the EWCW. Since the EWCW is ~38 lb for the 4.5-gal metal pail, 74 lb for the 30-gal drum EWCW is ~255 lb with a vibration force of 532 lb, the PQ for each size casting must have the unique vibration force modified for that casting. To generate force settings between the table values, use the following equation to estimate the vibration force at a set value:

For the VIBCO SCR−1000

$VForce = -33.9 \times Set\ No.^2 + 449.6 \times Set\ No. - 380$ lbf

$VForce = -33.9 \times 1.1^2 + 449.6 \times 1.1 - 380 = 74$ lbf (Set No.@ 1.1)

Use a 2.1 vibration intensity force multiplier for the EWCWs and round to the nearest tenth for loads less than 500 lb. If the EWCW is between 500 to 730 lb, the maximum vibration force setting of SCR-1000 is 6, and the vibration force is 1100 lb. For containers over 730 lb, a different vibration source must be developed.

For the VIBCO SCR-1000

$Set\ No. = 6.63 - (150612 - 285 \times EWCW)^{.5} / 67.8$

$Set\ No. = 6.63 - (150612 - 285 \times 38)^{.5} / 67.8$

Set No. = 1.1 (EWCW@38 lb)

Table 5. Vibration settings

Casting	SCR-1000 Set No. [a]	Vibration force [b] (lb)	Estimated wet cast weight [c] (lb)	Vibration intensity
4.5-gal metal pail	1.1	74	38	1.94
30-gal metal drum	2.5	532	255	2.09

[a] Vibration force setting numbers for the VIBCO SCR-1000 are shown in Attachment D. For other vibration motors, document the changes in the specific shipping package equipment specification and contact the Company for force settings and approval.

[b] Recommended vibration force settings for the VIBCO SCR-1000 shown in Attachment D. Vibrate for 10 s for partial fills and 1 min after filling is completed.

[c] The EWCW is for one full casting mold using an estimated wet casting density of 53.9 lb/ft3.

Fig. 5. VIBCO SCR−1000 default eccentric counter weight set at 3 (675 lb).

7.3.1.7 Inspect the inner surfaces of the empty container. Ensure that it is free of oil, grease, free liquids, and waste material; clean as needed per Sect. 6.1.

7.3.1.8 Prepare the Packcrete raw materials by performing the following actions:

7.3.1.8.1 Transfer the SACN from Form A to Form B.

7.3.1.8.2 Transfer the required measurement amounts from Form A to Form B.

7.3.1.8.3 Record the water chlorine measurement on Form B each day.

7.3.1.8.4 Verify that the mixing area has acceptable environmental setup per Sect. 6.3.1.

7.3.1.8.5 Verify that the mixing area has acceptable mixing water per Sect. 6.3.2.

7.3.1.8.6 Verify that the curing area has acceptable environmental setup per Sect. 6.3.3.

7.3.1.8.7 Verify that the bags of materials were stored properly and are not damaged per Sect. 6.3.4.

7.4 PROCESS—MIXING AND VIBRATION CASTING, CURING, AND BAKING FOR SAMPLES AND PARTS

The active mixing setup approval settings on Form A (Attachment E) identified by the SACN from Sect. 7.2 shall be followed once approved. Mixers and vibration table speed setting are qualified following Form A for the rpm or frequency (Sect. 7.3.1.5). The vibration force (Sect. 7.3.1.6) must be calculated for each unique casting size. Record the vibration force setting on casting Forms C, D, and E (Attachment E) or form(s) in the SSPES for each casting. Place a check on the casting form next to the setting once the vibration motor is set. For optional samples Forms C, D, and E or form(s) in the SSPES are used to record casting data. Adjustments shall be made to the casting vibration force settings based on the wet cast weight estimate.

7.4.1 Process—Mixing and Vibration Casting for Samples and Parts

The Seller shall complete the following steps:

7.4.1.1 Weigh and record the container weight “clean and empty” on Forms C, D, and E (Attachment E) or form(s) in the SSPES.

7.4.1.2 Weigh and record the container weight "filled with water" on Forms C and D or form(s) in the SSPES. For Form E, the "filled with water" weight is replaced with a calculated volume and wet cast weight estimate. Record the container volume.

7.4.1.3 Record the MCN, SACN, Vermiculite wt. %, Water Filter replacement date and weather is current on Form B.

7.4.1.4 Verify that the mixer speed rpm is set according to SACN.

7.4.1.5 On Form B, record daily mix water's chlorine value and check that it is acceptable.

7.4.1.6 Weigh and record the mixing water's temperature on Form B and the air temperature.

7.4.1.7 Inspect material bags for visible damage; discard damaged bags (such as water damage) and check that they are acceptable.

7.4.1.8 Weigh and record the Portland cement and vermiculite to the recipe on Form A for the SACN using a certified scale and record on Form B.

7.4.1.9 Measure the amount of Airalon 3000 shown in the recipe on Form A for the SACN in a graduated cylinder and record on Form B.

7.4.1.10 Add water and Airalon 3000 to the mixer and mix for at least 1 min, add Portland cement to the mixer and mix for at least 1 min, and add vermiculite to the mixer and mix for 50–70 s in accordance with the SACN recorded on Form A. For each mix, record the MCN and the SACN on a unique mixing Form B.

7.4.1.11 Ensure that the mixture is uniform and thoroughly mixed with minimal visible dry material and free liquids remaining in the mixer. If required, adjust the mix times until the mixture is uniform and modify the SACN and send it for Company approval.

7.4.1.12 If the mix looks too dry or wet, perform the ASTM C860, Sect. 6.2, Ball-In-Hand Test. If the test fails, adjust the water content accordingly, record any changes to be applied on the next mixer batch, generate a new Form A to request approval for a new SACN, and discard the mixer load. Contact the Company to approve the new Form A and new SACN.

7.4.1.13 Record the vibration table force setting on the casting Forms C, D, and E or form(s) in the SSPES in accordance with Table 5 in Sect. 7.3.1.6 if applicable. If other vibration sources are used document them in SACN (Form A).

7.4.1.14 Set the vibration speed setting on the table (SCR-1000 @ 80%) per Sect. 7.3.1.5 and record it on Forms C, D, and E or form(s) in the SSPES. Ensure that the speed setting is fixed and not free to change.

7.4.1.15 Start and stop the vibration table based on the vibration cycle time. For partial castings, vibrate the container 10 s and stop. Once the casting is full, vibrate for 1 min and record the vibration setting, vibration force, and vibration intensity on Forms C, D, and E or form(s) in the SSPES.

7.4.1.16 While the casting is wet, scrape the casting opening, clean the container, and measure and record the actual wet cast weight on Forms C, D, and E or form(s) in the SSPES.

7.4.1.17 Calculate the wet density, record the wet density on Forms C, D, and E or form(s) in the SSPES and verify that the wet density is within the acceptable limits on the casting forms. Section 7.1.5 defines the recommended wet density range. If the wet density is not within the acceptable limits, it is recommended to discard the container load, adjust the vermiculite dry weight percent and water weight as defined in Sect. 7.1.5, obtain written Company approval by repeating the SACN Form A, and repeat steps starting with Sect. 7.4.1.1. If the adjustment limits are met and the wet density is still out of specification, contact the Company.

7.4.2 Process—Curing for Samples and Parts

The Seller shall complete the following steps:

7.4.2.1 If the curing area has an acceptable environment as defined in Sect. 6.3 and the cast wet density is acceptable, move to curing area.

7.4.2.2 Cover the casting with plastic and initial cure for 4–30 h.

7.4.2.3 For sample pipes, after initial curing and before baking, the plug in the sample pipe will need to be removed. Scrape both ends of the casting to a flatness of 0.02 in. The flush cast side needs to be finished to a depth of 0.3 ± 0.05 in. and the plug side needs to finished to a height of 4.5 ± 0.05 in. from the fill hole end. This flatness can be obtained by using a drill press and large flat bottom bit made from sheet metal and welded to a small rod. The bit should just fit inside the sample pipe, and as the drill bit turns, the sample pipe is slid in a small circle, scraping the bottom of the casting flat. Remove the scraped Packcrete shavings from the sample pipe before baking.

7.4.2.4 After scraping, clean the parts, cover them with plastic, and store in the curing area until fully cured.

7.4.2.5 Cure at least 7 days before baking based upon the estimated BCN − MCN and record cure time on Forms C, D, E, and SSP.

7.4.2.6 Weigh and record the before baking weight on Forms C, D, and E or form(s) in the SSPES.

7.4.3 Process—Baking for Samples and Parts

The Seller shall complete the following steps.

7.4.3.1 Using a large vented furnace separate the castings as much as possible to ensure proper airflow and radiation heat transfer for each casting.

7.4.3.2 Place the cured castings into the furnace.

7.4.3.3 Record the BCN on Forms C through E for all casting parts in the furnace.

7.4.3.4 For parts, on Form F, record the number of each casting loaded into the furnace. Calculate the sub-total volume of each casting type and the total volume of the furnace load for the BQCN.

7.4.3.5 Calculate and record the actual cure time on Forms C, D, and E or form(s) in the SSPES for all casting parts before the furnace is started. Assure the cure time is over 7 days.

7.4.3.6 Set the initial furnace set point temperature to 200°F.

7.4.3.7 Hold the temperature at 200°F for 4 h and record date and times on Form F.

7.4.3.8 Increase the furnace set point temperature to 275°F.

7.4.3.9 Hold the temperature at 275°F for 1 h and record date and times on Form F.

7.4.3.10 Increase the furnace set point temperature to 350°F.

7.4.3.11 Hold the temperature at 350°F for 1 h and record date and times on Form F.

7.4.3.12 Increase the furnace set point temperature to 425°F.

7.4.3.13 Hold the temperature for at 425°F 1 h and record date and times on Form F.

7.4.3.14 Increase the furnace set point temperature to 500°F.

7.4.3.15 Hold the temperature at 500°F steady state and record date and times on Form F.

7.4.3.15.1 For baking small samples, a qualified baking time of at least 40 h has been shown to be successful. Record the 500°F bake time on Form F. Optionally, the samples may be placed in the furnace with simulated shipping package specific parts following Form F.

7.4.3.15.2 Record the 500°F baking time on Form F for the volume of castings in the furnace by placing a bottom center thermocouple (BCT) to measure the temperature of the bottom center of the simulated shipping package specific parts inner liner for the current furnace loading located at the coolest location in the furnace (near the door edge seals). For the 30-gal drum, place the BCT in the center of the casting, 6-in. deep. Record the minimum 500°F holding time when the BCT temperature is >425°F and no increase in the BCT over 2°F in 6 h of baking. This minimum 500°F baking time shall be recorded along with the furnace cubic foot casting volume to qualify the unique furnace load with the BQCN plus the volume in cubic feet.

7.4.3.15.3 A qualified baking time at 500°F shall be used for simulated shipping package specific parts, and samples of equal or less casting volume identified by the BQCN and recorded on Form F. The BCT is not required.

7.4.3.16 After the minimum baking time is met for 500°F, turn off the furnace and let the castings slowly cool down with the door closed for at least 8 h.

7.4.3.17 Remove castings and allow cooling in air until they reach ambient temperature.

7.4.3.18 Weigh and record the after baking weights on Forms C, D, and E or form(s) in the SSPES.

7.4.3.19 Calculate and record the baked density on Forms C, D, and E or form(s) in the SSPES using the equation at the bottom of the form.

7.4.3.20 Verify that the baked density is within the recommended acceptable limits at the bottom of the form.

7.4.3.20.1 For an SACN casting with the acceptable baked density, submit completed Forms A, B, C, and F for 4.5-gal pail sample to the Company for approval with the PLQ testing results. If approved, go to Sect. 7.6.

7.4.3.20.2 For an unacceptable baked density and this is the first failure, go to Sect. 7.4.1 and repeat this process.

7.4.3.20.3 For an unacceptable baked density and multiple failures have occurred, go to Sect. 7.1.4 or 7.1.5 and adjust the weight percent of vermiculite in the mixture and repeat the SACN casting in Sect. 7.4.1.

7.4.3.20.4 For an unacceptable baked density and multiple failures have occurred and the vermiculite weight percent is at the acceptable bounds shown in Sect. 7.1.5, contact the Company for guidance.

7.5 SETUP APPROVAL PROCESS VERIFICATION—4.5-GAL PAIL OR 30-GAL DRUM

The 4.5-gal pail or 30-gal drum have been used to verify the mixing setup control number (SACN) process that generates an acceptable wet and baked density following the requirements in Sects. 7.3 and 7.4. The 4.5-gal pail needs Forms A, B, C, and F while the 30-gal drum needs Forms A, B, D, and F (Attachment E) are needed to document this effort. Use these small castings if needed to verify the lots of material and process settings. Once these are verified, proceed to shipping package specific specification and perform a process and LQ castings.

7.6 PACKCRETE PIPE SAMPLES FOR PRELIMINARY AND FINAL LOT QUALIFICATION

Pipe samples are required for both preliminary and final lot qualifications. The pipe sample casting requires a different stand-alone vibration table setup that vibration casts at least two pipe samples for each mixer load going into the production run mixes. This stand-alone table needs a maximum force of 100 lb and a speed of 3200 vibrations per minute, generating a frequency of 53 Hz. VIBCO supplies a standalone table that meets these requirements. The SACN used will be different than the SACN for the VIBCO SCR-1000. Follow Sects. 7.3 and 7.4 and use Forms A, B, E, and F (Attachment E) to document pipe sample casting. Section 8 describes pipe sample preparation requirements, and Sect. 9 describes pipe sample testing. Send the manufacturing and testing results to the Company for evaluation. Once the testing data is accepted by the Company, the current Form As will be approved and signed by the Company.

8. PACKCRETE PLQ AND PRODUCTION TEST SAMPLES

The purpose of this section is to describe exception(s) to the processing steps described in detail in Sect. 7 for each type of sample if additional Packcrete testing samples are needed. Each unique vibration casting process is addressed.

In addition to its unique casting control form [Forms C, D, and E or form(s) in the SSPES], Forms A, B, and F are needed for each sample and each type of sample to ensure that vibration force is adjusted to generate a vibration intensity approximately 2.1 times the estimated wet weight as required in Sect. 7.3.1.6. This ensures that the samples for the 4.5-gal pail, 30-gal drum, sample pipes, SSSP are set to the proper force setting.

Each Packcrete sample shall be marked and tracked from its origin.

8.1 PACKCRETE 4.5-GAL PAILS

Form C defines the data required to vibration cast the 4.5-gal pails according to the requirements in Sect. 7.5 and is used to gain casting experience.

8.2 PACKCRETE PRODUCTION SAMPLING SET

The production sampling set shall consist of a 30-gal drum (Sect. 8.5) or SSSP casting following the SSPES and six pipes (Sect. 8.7). This sample set shall be tested in accordance with Sects. 9.2–9.6. The results should be sent to the Company. The 30-gal drum may only be used to replace the SSSP casting in the production sampling set once equivalences has been demonstrated with test results.

8.3 PACKCRETE 30-GAL SAMPLE DRUM

Each 30-gal sample drum manufacturing method shall follow the requirements in Sects. 7.3 and 7.4. Mark and record the Packcrete 30-gal sample drum information on Form D (Attachment E).

8.4 PACKCRETE BRICK SAMPLES PER ASTM C862

Packcrete bricks (9 × 4.5 × 2.5 in.) manufactured for tests that comply with the requirements of ASTM C862 shall be cut from a 30-gal casting that meets the requirements of both Sect. 7 and ASTM C862, note 7.

8.5 PACKCRETE SAMPLE PIPES

Each pipe sample manufacturing method shall be qualified as defined in Sect. 7. Mark and record the unique pipe sample information on Form E (Attachment E). A watertight plug should be inserted into one end 4.8-in. deep from the fill hole. The Packcrete shall be cast into the pipe sample flush and scraped following the instructions in Sect. 7.4.2.3.1. The EWCW of a single pipe sample is ~7.5 lb.

9. PACKCRETE FINAL LOT QUALIFICATION PROPERTIES LIMITS

Chemical and mechanical properties shall be evaluated to document and qualify the lot of raw materials for use in producing Packcrete. Some of these values are defined in Sects. 5–7, and others are not. This section defines additional testing and references RP-802282-0002 for the acceptance ranges. The PLQ test samples may be taken from a 30-gal drum. FLQ test samples may be taken from a SSSP and a set of six sample pipes. Additional material test sample production is defined in Sect. 8 when directed by the Company. A 30-gal drum (preliminary) or SSSP (final) and a six pipe sample set are used for this testing.

9.1 WET AND BAKED DENSITIES

The casting specification uses the wet density as a manufacturing guide to help control the baked density; therefore, the wet density is not important to the safety of the shipping package. The baked density for each casting shall be within the acceptable range of 22.4 ± 3 lb/ft^3, as defined in Sect. 7. The density of the containers will be tested by the Seller for 100% of the castings in accordance with Company-approved procedures.

9.2 DYNAMIC IMPACT CRUSH STRENGTH

Determination of the dynamic impact crush strength involves a set of high-speed compression impact tests performed by the Company using cast sample pipes, as defined in Sect. 8.6. A total of six sample pipes are needed for these tests. These tests shall be tested at each temperature in accordance with "Instructions for Operating 20K-Pound MTS High-Rate Load Frame and Thermotron Test Chamber and Performance of High-Rate Impact Tests," from Y/DW-2345. The acceptable bounding values are listed in RP-802282-0002.

9.3 CHEMICAL COMPOSITIONS OF THE CONSTITUENTS

Three samples taken from a 30-gal drum (preliminary) or SSSP (final) are needed for verifying the chemical composition. Each sample shall be oven dried at 45°C. Oxide analysis X-ray fluorescence spectrometry samples shall be fused at 1000°C with $Li_2B_4O_7/LiBO_2$. X-ray fluorescence oxide analysis shall meet the precision

and accuracy requirements for rapid methods per ASTM C114-11b requirements. The Packcrete chemical composition acceptable bounding values are listed in RP-802282-0002.

9.4 THERMAL CONDUCTIVITY

Three samples cut from a 30-gal drum (preliminary) or SSSP (final) casting with an acceptable baked density are needed for verifying the thermal conductivity. The thermal conductivity of the samples is measured following ASTM C1113. The thermal conductivity is measured at 20, 100, 200, 300, 400, 500, 600, 700, and 800°C. The three test values shall be averaged at each temperature. These averaged values shall be between the acceptable values listed in RP-802282-0002.

9.5 SPECIFIC HEAT CAPACITY

Three samples cut from a 30-gal drum (preliminary) or SSSP (final) casting with an acceptable baked density are needed for verifying the specific heat capacity. The specific heat capacity shall be tested from 35 to 995°C and in 10°C increments following ASTM E1269 requirements. The three test values shall be averaged at each temperature. These values shall be between the acceptable values listed in RP-802282-0002.

9.6 LINEAR THERMAL COEFFICIENT OF EXPANSION

Three samples cut from a 30-gal drum (preliminary) or SSSP (final) casting with an acceptable baked density are needed for verifying the linear thermal coefficient of expansion. The linear thermal coefficient of expansion shall be tested following ASTM E228 requirements at a temperature range of −170 to 290°C at 10°C increments. The average of the three tests values from −40 to 150°C shall be between the acceptable values listed in RP-802282-0002.

9.7 ELASTIC MODULUS

The elastic modulus for Packcrete is derived from dynamic impact strength testing results defined in Sect. 9.2, and this property has been found to not be important to the safety of the shipping package. The average test values shall be between the acceptable values listed in RP-802282-0002.

9.8 POISSON'S RATIO

Uncompressed (elastic) and compressed (plastic) Poisson's ratio in the past has been assumed based upon similar types of material and the state of the material. The exact value is not important to the safety of the shipping package. Further explanation is found in RP-802282-0002.

ATTACHMENTS

ATTACHMENT A: SUBMITTAL CHECK LIST

Instructions to Supplier for Preparation of Submittals

Note 1 –All correspondence shall be addressed to the Technical Representative identified by the Company. The Supplier shall forward submittals via transmittal letter to the Company at the address specified in the contract.

Note 2 – The submittal must have adequate detail so that full compliance with the requirements may be determined. For example, a simple off-the-shelf item to be used in an assembly may only need a manufacturer's cut-sheet to show compliance, but a factory acceptance test (FAT) developed and submitted by the Seller must have each test step detailed with acceptance criteria consistent with the requirements.

a. Review submittal before transmitting to the Company to verify conformance with requirements of the contract documents (e.g., field measurements, field construction criteria, or manufacturer's catalog numbers).
b. Coordinate submittals with the work requirements and the contract documents.
c. Organize Submittals
    - Do not use highlight marker or color coding on submittals.
    - The minimum resolution used for scanning submittals shall be 300 dpi x 300 dpi.
    - For submittals containing color information important to the record, a 24-bit color setting should be used.
    - Submittals are to be legible and in the format specified on the submittal checklist.
    - Pen and ink changes are to be made in non-erasable ink, legible, dated and initialed.
    - Mark specific options provided for the work, and cross out options not provided.
    - Each submittal shall be sent as a single pdf file unless otherwise specified.
d. Label submittals with the applicable item number, reference, and requirement description as summarized in the Submittal Checklist.
    NOTE: Unlabeled submittals will be returned to the Seller without review.
e. Include with submittals a transmittal letter that identifies individual documents by specification section/paragraph number and purpose(s) of submittal (i.e., for substitution, review, information, approval, etc.)
    - Transmittal for submittals shall be numbered using the purchase order number followed by a 4-digit sequential number. (Example: 430001111-0001).
    - Embedded comments or questions that are not included on the transmittal may not be addressed/resolved by the Company.
f. Direction will be given at the time of award to either upload submittals to a company provided URL address or send by email to a company provided email address.
g. If using a company provided URL to upload submittals, notify the Company via email when submittals have been placed.

UCN-22212V (3-15)

Instructions to Supplier for Preparation of Submittals, Continued

h. If a submittal is being resubmitted, then reference the applicable item number, reference, and requirement description and identify it as a resubmittal.
i. Company response will only be returned to the Supplier for those submittals with a Submittal Purpose of "For Action," unless it is determined that a submittal transmitted "For Information" is not acceptable.
j. AFTER written approval is obtained, THEN proceed with work requiring approved submittals.
k. Maintain a copy of the company-approved submittal and status page on file.

RFWD Completion Instructions

INITIATING ENTITY

The following fields are to be completed by the INITIATING ENTITY. The purpose of Block No.1 through 20 is the identification of the Waiver/Deviation/Change. For Waivers and Deviations, the Initiating Entity is the Supplier. For Changes, the Initiating Entity is Y-12.

1. **REQUEST TYPE –** Check the appropriate block:
   - DEVIATION (Supplier initiated, prior to production)
   - WAIVER (Supplier initiated, during or after production)
   - CHANGE (Y-12 initiated, after award of contract)

2. **SHEET/FORM PAGES –** Complete Page of Page(s), including any attachments or supporting documents. Each page's Sheet/Form block must be completed (i.e., Page 1 of 2; Page 2 of 2; Page 3 of 3; Pages 10 of 10, etc.).

3. **3.a NUMBER –** An identifying, sequential numbering system acceptable to supplier and Y-12 (e.g., Purchase Order Number + sequential number – [examples 430001234-1, 430001234-2,etc].
   3.b SAP DMS NUMBER – Y-12

4. **SUPPLIER –** Supplier Name associated with the Waiver, Deviation, or Change.

5. **PURCHASE ORDER (P.O.) NUMBER/ITEM NUMBER –** From the Y-12 issued P.O. and the item number associated with the P.O.

6. **PROGRAM/PROJECT –** Program or project name, if applicable.

7. **DOCUMENT NUMBER and REVISION –** Drawing or Specification Number and Revision.

8. **COMPONENT NAME –** Name take from Y-12 design document(s).

9. **PART OR IDENTIFYING NUMBER –** Part Name or unique reference number.

10. **SERIAL OR LOT NUMBER –** Check the appropriate box and enter the Serial Number or Lot Number, if applicable.

11. **LOT SIZE –** Total quantity of parts affected by the WAIVER/DEVIATION/CHANGE.

12. **SPECIFICATION REFERENCE NUMBER –** Paragraph number or drawing reference/location of characteristic(s) to be waived/deviated/changed (each characteristic requires individual line).

13. **SPECIFICATION REQUIREMENT –** Requirement(s) extracted from the specification/drawing.

14. **DESCRIPTION OF WAIVER/DEVIATION/CHANGE –** Written explanation of what characteristic is to be waived/deviated/changed (e.g., technical or material requirement is violated, requirement in supplier document is violated, nonconformance cannot be corrected by continuing the original process or rework, item does not conform to the original requirement, but can be restored to condition that it will function unimpaired, Y-12 is directing the Supplier to make a change to what is specified in the contract document(s), etc.).

Y60-015, 4.2,4.3,4.7,4.8 & 4.11
UCN-13816B INST (01-15)

RFWD Completion Instructions (continuation)

15. **SUPPLIER PLAN FOR CORRECTIVE ACTION –** Written explanation of corrective action(s) taken or planned to address each waiver/deviation characteristic identified which may include disposition recommendations such as accept/use-as-is, rework to specification, repair to usable condition, return to vendor, reject/scrap, etc., if applicable. This block does not apply to Y-12 initiated changes. (NOTE: If more SPEC. REF. NOs. are needed , a TAB key at the last entry of Block No.15 will insert an additional line, else "mouse click" to Block No. 16).

16. **INITIATING ENTITY REPRESENTATIVE –** Name (print/signature) of the authorized representative of the Initiator (Supplier or Y-12) submitting the Waiver/Deviation/Change.

17. **TITLE –** Title of the Initiating Entity Representative from Block No.16.

18. **COMPANY –** Company affiliation of the Initiator (Y-12 or Supplier).

19. **DATE –** Date Waiver/Deviation/Change initiated.

Responding Entity Evaluation

The following fields are to be completed by the RESPONDING ENTITY EVALUATOR. The purpose of Block 20 through 23 is the evaluation of the proposed Waiver/Deviation/Change. For Waivers and Deviations, the Responding Entity is Y-12. For Changes, the Responding Entity is the Supplier.

20. **SPECIFICATION REFERENCE NUMBER –** Item(s) transposed from Block No.12 above, to be evaluated.

21. **EVALUATION COMMENTS –** Written evaluation of each Waiver/Deviation/Change requested by the Initiating Entity.

22. **EVALUATOR/DATE –** Name (print/signature) of the Evaluator for the responding Entity and the Date of the evaluation. The Evaluator is one who is technically qualified to evaluate the proposed Waiver/Deviation/Change.

23. **RECOMMENDED DISPOSITION –** Based on the evaluation and the comments provided in Block 21, the Evaluator's recommendation to either Accept or Reject each Waiver/Deviation/Change Item. For Waivers and Deviations, this represents the Y-12 Evaluator's intended recommendation to other Y-12 functions/organizations for acceptance or rejection of each proposed waived/deviated item. For Changes, this represents the Supplier's intended acceptance or rejection of each proposed change initiated by Y-12.

Y-12 Representative

24. **ARE DESIGN DRAWINGS(S), SPECIFICATIONS, OR DATA SHEET(S) CHANGES REQUIRED –** Indicate (Yes or No) if changes to the original contract documents or supporting/operational documents are warranted because of the Waiver/Deviation/Change.

Y60-015, 4.2,4.3,4.7,4.8 & 4.11
UCN-13816B INST (01-15)

RFWD Completion Instructions (continuation)

Approvals

Y-12 approvals require the same affected functions/organizational approval as the original document (Applicability is determined by the original document approvals and the governing document procedures). The Technical Representative is responsible for identifying and obtaining the appropriate approvals and processing the RFWDC form.

25. **ENTITY** – The required list of approvers may include:
    - Y-12 Customer/Program Manager (i.e., end user)
    - Y-12 Technical Representative
    - Y-12 Design Authority Representative, as applicable (otherwise, N/A)
    - Y-12 Project Representative, as applicable (otherwise, N/A)
    - Y-12 Quality Engineer, as applicable (otherwise, N/A)
    - Design Engineering, as applicable (otherwise, N/A)
    - Product/Packaging Engineering, as applicable (otherwise, N/A)
    - Procurement Representative, as applicable (otherwise, N/A)
    - Y-12 Other – List additional function positions required to approve, if applicable.
    - Supplier Representative – Person with overall responsibility and authority to approve information and dispositions as documented on this form.

26. **NAME** – Name (print/signature) of each person fulfilling the roles denoted in Block No. 25.

27. **DATE** – Date of approval signature.

28. **APPROVE/REJECT RECOMMENDED DISPOSITION** – Based on the information provided in Block No. 21, each Approver is to approve or reject the Recommended Disposition noted in Block No. 23. Checking the Approved block means the Approver accepts all recommended dispositions provided in Block No. 23. Checking the Rejected block means the Approver rejects one or more of the recommended dispositions provided in Block No. 23.

Note: Communication between the supplier and Y-12 for RFWDC's must be handled by the Y-12 Subcontract Administrator.

Y60-015, 4.2,4.3,4.7,4.8 & 4.11
UCN-13816B INST (01-15)

ATTACHMENT C: AIRALON 3000 INFRARED ANALYSIS

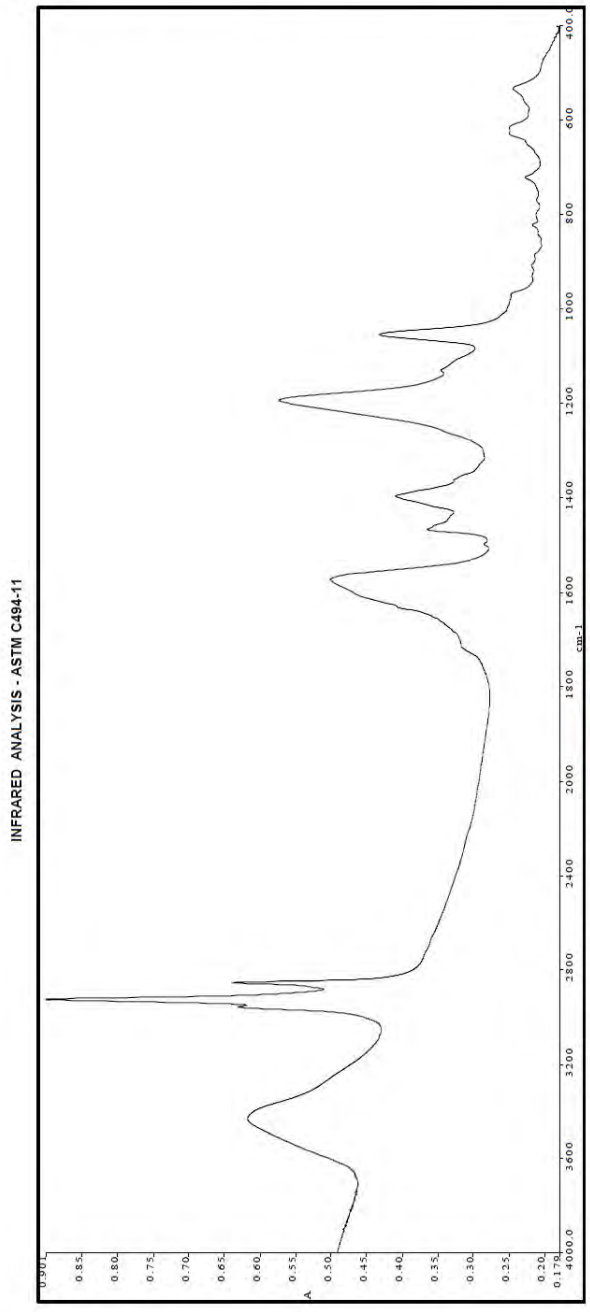

Figure 1 Infrared spectrum of Airalon 3000 Lot No. H0610D750921 (CTL ID 3446802); KBr disk per ASTM C494-11

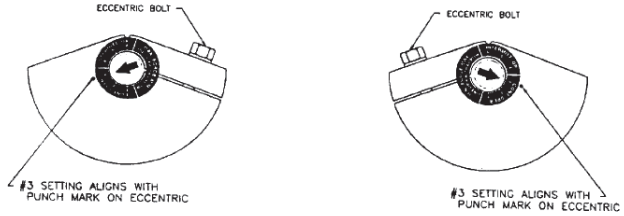
APPROVED
By hsmith at 3:31 pm, 9/23/13

Notes:
1. This scan represents specifically the sample submitted.
2. The scan was conducted on a Perkin Elmer Spectrum 100 FT-IR Spectrometer.
3. ASTM C260 does not specify a test method for infrared analysis, therefore the infrared analysis was conducted by ASTM C494 modified to use the ASTM C233 residue.
4. This report may not be reproduced except in its entirety.

ATTACHMENT D: VIBCO VIBRATION FORCE SETTINGS

CENTRIFUGAL FORCE (IMPACT)



All the electric vibrators have eccentrics attached to the motor shaft. Some are permanently fixed and some are adjustable as per below.

Model 2P (see 2P-75, 2P-100, US-450, SCR-200 below), 4P, 6P, 8P, FC, SFC, US-900, 1600, SCR-500, 1000 vibrators have adjustable eccentrics to give higher or lower impact to suit the application. They are adjustable as follows: Remove the end covers, both sides of the vibrator. The eccentrics will then be in view. There are two different systems of eccentrics. **First system:** The outside eccentric is secured to the inside one with a socket head cap screw. There is either 3 or 6 holes in the outside eccentric. Remove the set screw and turn eccentric to desired position, the diagram below will tell the force at the different positions. **NOTE:** The eccentric should be set at the same number on each side of the vibrator to give uniform vibration.

Second system: The eccentrics are clamped onto the shaft. They are also marked from 1 to 6. Loosen bolt holding eccentrics to shaft and swing eccentric on shaft, line up desired number (force as per table below) with arrow stamped in shaft. Secure bolt firmly. **NOTE:** Set eccentrics on both sides of vibrator on the same number.

Force (Impact) at Different Eccentric Settings in Lbs.

Model	1	2	3	4	5	6	Model	1	2	3	4	5	6
2P-75	50	75*	100

6P-300	0	100	225*	250	275	300	FC-100	75	150*	300			
6P-500	50	150	225*	300	400	500	FC-400	150	300*	450			
6P-1000	200	500	625*	750	875	1000	* Normal setting - higher settings for intermittent use only						

To Adjust Eccentric Settings:

1. Remove both end covers of vibrators.
2. Loosen the bolt that holds the eccentric to the shaft.
3. Turn the eccentric on the shaft to adjust force output. Align the arrow on the shaft to the desired setting. The higher the number, the greater the force.
   NOTE: Both ends of vibrator must be at same setting.
4. Tighten eccentric bolts and reinstall end covers.
5. Figures above show eccentrics at factory setting (#3 setting).

ATTACHMENT E: PACKCRETE PROCESSING FORMS

Form A Packcrete Setup Approval
Form B Packcrete Mixing for Samples and Parts
Form C Packcrete Sample 4.5-Gal Pail Vibration Casting Control
Form D Packcrete Sample 30-Gal Drum Vibration Casting Control
Form E Packcrete Sample Pipes Vibration Casting Control
Form F Packcrete Furnace and Baking

Form A ***Packcrete Setup Approval***	Specification Number	Revision
	Issue date (mm/dd/yy)	Revision date (mm/dd/yy)
Caster's company name (Seller's name)	Setup Approval Control Number (SACN) [a] SA _____	
Check control mix times ☐ ☐ ☐ Water and Airalon—at least 1 min, Portland cement—at least 1 min more, vermiculite—50–70 s more.		

Equipment	Manufacturer	Model No.	Serial No.	Operator	Witness
Mixer					
Vibration table					

Measurement	Comments	Measure	Units	Operator	Witness

Type III Portland cement				lb		
Verify vermiculite bag quality [e]	Pass	Fail				
Vermiculite, Type 1, Grade 3				lb		
Wet density	Target 53.9 ± 5.6 lb/ft^3 (48.3–59.5 lb/ft^3)			lb/ft^3		

[a] M, P, or SA alpha prefix plus a 10-digit control number is used to document the starting date and time of the Mixing process using a 24-h format (i.e., M1021081515 is used for October 21, 2008, at 3:15 p.m.).
[b] SACN—Setup Approval Control Number is obtained from Form A and indicates the date and time that the setup approval was started.
[c] Potable water that has been filtered through at least a 20-micron filter and has chlorine content <4 mg/l (4 ppm, 0.0004% by mass). Record the date the filter shall be replaced and check the box to document its maintained.
[d] Record the water weight and temperature within 10 min from completion of the weighing process.
[e] Record the bags quality. A damaged bag that appears to have been wet or to have been torn open and is leaking prior to shift start shall not be used.

Form C ***Packcrete Sample 4.5-Gal Pail*** ***Vibration Casting Control***		Specification Number	Revision
		Issue date (mm/dd/yy)	Revision date (mm/dd/yy)
Caster's company name (Seller's name)		Y-12 observers present	
Mix Control Number (MCN) [a] M_ _ _ _ _ _ _ _ _ _		Serial Number	

Measurement	Comment	Measure	Units	Operator	Witness
Clean and empty	Estimated 2.96 lb		lb		
Filled with water [b]	Estimated 42.46 lb		lb		
Water temperature [b]			°F		
Container volume	Estimated 0.634 ft^3		ft^3		
Vibration table force setting [c]	#1.1, 74 lbf		lbf		
Wet cast weight	Estimated 38 lb		lb		
Vibration intensity ~ 2.1	Force / Wet Weight				
Vibration table speed setting [c]	80%		%		
Full vibration time	1 min		min		
Wet cast weight	Target 36.69–39.73 lb		lb		
Wet density [d]	Target 53.9 ± 2.4 lb/ft^3		lb/ft^3		
Measured wet density (51.5 to 56.3 lb/ft^3) acceptance				Accept	Reject [d]
Scrape the top and weigh			lb		
Cure time (at least 7 days)	BCN – MCN		days		
Before baking weight			lb		
Baking Control Number (BCN) [a]					
After baking weight			lb		
Baked density [e]	Target 22.4 ± 1 lb/ft^3		lb/ft^3		
$\frac{Baked_Density}{Wet_Density}$					
Measured baked density (21.4 – 23.4 lb/ft^3) acceptance				Accept	Reject [d]

[a] M, or B alpha prefix plus a 10-digit control number is used to document the starting date and time of the process using a 24 h format (i.e., M1021081515 or B1021081515 is used for October 21, 2008, at 3:15 p.m.).
[b] Record the water weight and temperature within 10 min from completion of the weighing process.
[c] Document the vibration force (Sect. 7.3.1.6), frequency (Sect. 7.3.1.5) settings and duration are set.
[d] The recommended wet density of 51.5–56.3 lb/ft^3 and baked density of 21.4–23.4 lb/ft^3 is to ensure castings on Form F have a baked density within 19.4–25.4 lb/ft^3. The Seller may waive these recommendations and proceed at risk. Upon rejection, contact the Company and send the casting records.

$$\text{Volume} = \frac{(WithWater - CleanAndEmpty)}{62.3}\ ft^3 @ 70°F \qquad \text{Wet density} = \frac{(WetCast - CleanAndEmpty)}{\text{Volume}}\ lb/ft^3$$

$$\text{Baked density} = \frac{(AfterBaking - CleanAndEmpty)}{\text{Volume}}\ lb/ft^3$$

$\frac{Baked_Density}{Wet_Density}$					
Measured baked density (19.4 – 25.4 lb/ft^3) acceptance				Accept	Reject [d]

[a] M alpha prefix plus a 10-digit control number is used to document the starting date and time of the process using a 24 h format (i.e., M1021081515 is used for October 21, 2008, at 3:15 p.m.).
[b] Record the water weight and temperature within 10 min from completion of the weighing process.
[c] Document the vibration force (Sect. 7.3.1.6), frequency (Sect. 7.3.1.5) settings and duration are set.
[d] The recommended wet density of 48.3–59.5 lb/ft^3 and baked density of 19.4–25.4 lb/ft^3 is to ensure castings.
[e] For partial casts, vibrate the drum 10 s and stop. Once full, vibrate for 1 min.

$$\text{Volume} = \frac{(WithWater - CleanAndEmpty)}{62.3}\ ft^3 @ 70°F$$

$$\text{Wet density} = \frac{(WetCast - CleanAndEmpty)}{\text{Volume}}\ lb/ft^3$$

$$\text{Baked density} = \frac{(AfterBaking - CleanAndEmpty)}{\text{Volume}}\ lb/ft^3$$

Total volume (ft^3)							

Comments

[a] B and BQ are alpha prefix plus a 10-digit control number is used to document the start date and the time of baking and process qualification using a 24-h format (i.e., B1021081515 is used for October 21, 2008, at 3:15 p.m.). For the BQCN-Vol, the "-Vol" represents the maximum total oven casting volume in cubic feet that is qualified (i.e., BQ1021081515-150 is qualified for a casting load of 150 ft^3).

[b] The sample baking cycle time and temperature data could be presented both in a digital and graphical form. For example, an Excel file showing the original data and time verses temperature plots shall be acceptable.

[c] BCT—bottom center thermocouple. Calculate the baked density as shown on Form F following this furnace heating cycle phase. Record the 500°F holding time when the core temperature is >425°F and no increase in the BCT over 2°F in 6 h of baking.

Acceptance of Vermiculite for Packcrete Qualification	NA

11. DESCRIPTION OF DOCUMENT REVISION (ATTACH SKETCH, MARKUP OF ORIGINAL DOCUMENT, OR CONTINUATION SHEET(S) AS REQUIRED)

The sentence in Sect. 5.4.1, Pg. 14, Par. 1, Sent. 1 should be changed to read "...a bulk density between 6.4 and 8.7 lb/ft3." instead of "...a bulk density between 6.4 and 8 lb/ft3."

During fabrication of MD-2 packagings, a larger acceptance range of the Vermiculite's bulk density allowed for an acceptable baked density and caused no adverse effects on the mechanical and chemical properties of Packcrete.

See RFWD 62 generated from MD-2 fabrication for further detail.

TABLE

Table 1. Recommended vibration settings 15

1. SCOPE

This specification incorporates aspects of SPC M801794-0003, *Packcrete Preliminary Lot Qualification*. The Seller shall produce a preliminary lot qualification, via SPC M801794-0003, for casting Packcrete in "generic" applications. The preliminary lot qualification provides the quality assurance and technical requirements for qualifying the Seller for casting Packcrete in a "specific" application known as the ES-3100 shipping package.

This specification provides the Seller's production requirements for production units of the ES-3100 shipping package. Since these two specifications must work closely together in sequence in order to document and accomplish final lot qualification (FLQ), and production processing, the information in the two specifications that applies to both will be referenced when necessary in this specification.

The Company (Y-12 National Security Complex) will provide training and direct oversight for the casting Packcrete when the Subcontractor does not have prior Packcrete casting experience.

The product produced from this specification is protected under U.S. Patent 6,299,950 B1. The U.S. Government has rights in this product pursuant to Contract No. DE-NA0001942 between the U.S. Department of Energy and Consolidated Nuclear Security, LLC.

1.1 General Description of the Item

Packcrete is a fireproof, lightweight cast refractory. It is comprised of water, Airalon 3000 (air entraining agent), Portland cement, and vermiculite defined in SPC M801794-0003. A full-scale sample section of Packcrete is shown in Fig. 1 with a centimeter scale.

Fig. 1. Full-scale close-up view of a baked Packcrete section.

1.2 Background

The ES-3100 is a Type-B shipping package for fissile hazardous materials that must comply with strict manufacturing standards. Packcrete is a noncombustible impact and thermal barrier that will be cast into the ES-3100 shipping container to protect the containment vessel from damage. Figure 2 shows the Packcrete casting as a light brown color.

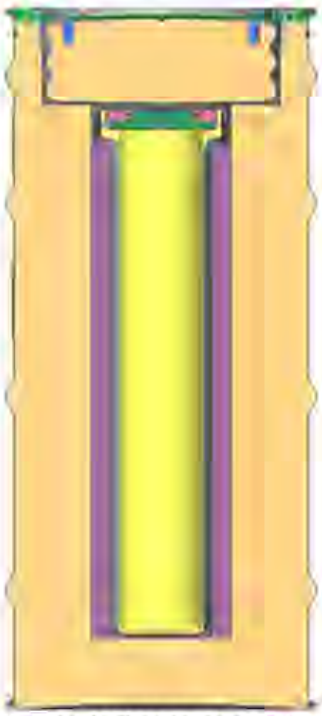

Fig. 2. ES-3100 shipping container.

2. REFERENCES

2.1 Definitions

See SPC M801794-0003 for definitions that are not included here. Those definitions also apply to this work in this specification.

Confinement Boundary Assembly (CBA) – An assembly with an assigned serial number that is made from components uniquely manufactured following JS-YMN3-801580-A002 (*Equipment Specification ES-3100 Drum Assembly*) and process serial-numbered components specified in M2E801580A002 (*Body Weldment*) and M2E801580A008 (*Top Plug Weldment*).

ES-3100 body – The ES-3100 body is defined by M2E801580A002. The body has an estimated empty weight of 88 lb without the bottom cover and 103 lb with the welded bottom cover. The estimated fillable Packcrete volume is 4.8 ft^3.

ES-3100 plug –The ES-3100 top plug is defined by M2E801580A008. The top plug has an estimated empty weight of 7.4 lb without the bottom sheet and 9.6 lb with the welded bottom sheet. The estimated fillable Packcrete volume is 0.43 ft^3.

SES3100 body – A simulated ES-3100 (SES3100) body for casting a mock-up of the ES-3100 drum assembly made from two standard carbon steel drums. The simulated ES-3100 consists of a 55-gal carbon steel open-head drum which has a 20-gal carbon steel drum secured to the bottom center. The 20-gal drum is secured by tack welding or suitable fasteners. The lid of the 55-gal drum has an opening 15" in diameter through which Packcrete can be poured into the drum. The SES3100 body has an estimated empty weight of 77 lb and a fillable Packcrete volume of ~4.7 ft^3. The SES3100 body is used to qualify the casting process.

SES3100 plug – The SES3100 plug for casting a mock-up of the ES-3100 top plug made from cylindrically rolled carbon steel sheet welded to a circular carbon steel sheet bottom. The rolled carbon steel cylinder is 0.06-in. thick with an inner diameter of 14.0-in. and height of 5.0-in. The carbon steel sheet bottom is 0.06-in. thick with a diameter of 14.12-in. The SES3100 has an estimated empty weight of 6.6 lb and a fillable Packcrete volume of ~0.45 ft^3. The SES3100 plug is used to qualify the casting process.

2.2 Codes/Standards/Orders/Regulations

ASME NQA-1-2017	Quality Assurance Requirements for Nuclear Facility Applications
10 CFR Part 71	Packaging and Transportation of Radioactive Material
ASTM C114	Standard Test Methods for Chemical Analysis of Hydraulic Cement
ASTM C136	Standard Test Method for Sieve Analysis of Fine and Coarse Aggregates
ASTM C150/C150M	Standard Specification for Portland Cement
ASTM C233/C233M	Standard Test Method for Air-Entraining Admixtures for Concrete
ASTM C260/C260M	Standard Specification for Air-Entraining Admixtures for Concrete
ASTM C494/C494M	Standard Specification for Chemical Admixtures for Concrete
ASTM C516	Standard Specification for Vermiculite Loose Fill Thermal Insulation
ASTM C520	Standard Test Methods for Density of Granular Loose Fill Insulations
ASTM C860	Standard Test Method for Determining the Consistency of Refractory Castable Using the Ball-In Hand Test
ASTM C862	Standard Practice for Preparing Refractory Concrete Specimens by Casting
ASTM C1113	Standard Test Method for Thermal Conductivity of Refractories by Hot Wire (Platinum Resistance Thermometer Technique)
ASTM E70	Standard Test Method for pH of Aqueous Solutions with the Glass Electrode
ASTM E228	Standard Test Method for Linear Thermal Expansion of Solid Materials with a Push-Rod Dilatometer
ASTM E1269	Heat Capacity by Differential Scanning Calorimetry
ANSI/ISO/IEC 17025	General requirements for the competence of testing and calibration laboratories

2.3 Applicable Documents

The following documents apply when casting Packcrete into the ES-3100 shipping containers.

JS-YMN3-801580-A002	*Equipment Specification ES-3100 Drum Assembly*
M2E801580A002	*Body Weldment*
M2E801580A008	*Top Plug Weldment*
SPC M801794-0003	*Packcrete Preliminary Lot Qualification*

3. ITEM REQUIREMENTS

Packcrete must be cast into a stainless-steel shell specified in M2E801580A002 and M2E801580A008, collectively known as the CBA. The manufacturing controls are based on a finished baked density of 22.4 ± 3 lb/ft^3 that controls the proper thermal and impact properties. The in-process serial numbers for the plug and drum body shall be recorded on Form ES3100 of Attachment C, "Packcrete Processing Form". The final CBA serial number shall include references to the in-process serial numbers.

3.1 Performance Requirements

The Seller has no responsibilities for performance of Packcrete beyond the measured density of 22.4 ± 3 lb/ft^3 when the requirements of this specification are completed.

3.2 Fabrication and Assembly Requirements

See production processing in Sect. 7.8.

3.3 Schedule

A manufacturing plan with written, step-by-step process plans shall be submitted to the Company [Y-12 National Security Complex, Consolidated Nuclear Security, LLC (CNS)] for approval and used by the Seller to comply with requirements in this specification. At a minimum, the plan shall include:

- material control and materials to be procured,
- subtiers to be used, and control thereof,
- quality program used to buy and manufacture,
- major fabrication steps and sequence of operations,
- Packcrete sampling schedule (see note below),
- hold points to be determined for Company involvement,
- all in-process inspection/examination, and
- dimensional inspections and testing.

Note: Additional Packcrete sample sets are required for future material testing. As such, a Packcrete sample set must be generated at the end of test unit production, at the end of full-scale production, and as required during full-scale production. A Packcrete sample set is to consist of one 30-gal drum and eight sample pipes as described in SPC M801794-0003.

3.4 Deliverables and Submittals Documents

There are two types of submittals associated with this specification: (1) approval data documents and (2) certification data documents. The submittal schedule, submittal format, number of copies, and submittal purpose are shown in Attachment A, "Submittal Checklist." Some of these quality records are generated following SPC M801794-0003.

All records shall be identified based on ES-3100 assembly serial numbers. The Seller shall maintain quality-related documentation in accordance with requirements in the purchase order and this specification. The Company reserves the right to request any such documentation and to witness all aspects of the manufacturing process in accordance with this specification.

3.4.1 Approval Data Documents

Approval data documents are identified in Attachment A. Approval data documents include written procedures and personnel qualifications, which must be approved by the Company prior to conducting the work defined in Sect. 7.

With each submittal transmitted to the Company, the Seller will include an updated submittal checklist using an Excel spreadsheet. The checklist shall identify all of the documents to be submitted and the status of each. All submitted documents shall be identified with document title, document number, revision level, computer filename, and submission date. The reply date of and disposition by the Company shall be included in the Excel spreadsheet for documents already submitted and dispositioned by the Company.

The Seller shall generate documentation in compliance with the Company-approved quality assurance plan (QAP). All records shall be identified based on the component serial numbers traceable to the CBA serial number.

The Company reserves the right to request any additional documentation used in fabrication or raw material qualification.

Procedures shall be submitted to the Company for approval prior to use in accordance with Attachment A and shall identify all mixing and vibrating equipment models and settings required to complete the casting process. Approvals of submittals must be received from the Company prior to implementing any activities involving these procedures. Submittal version control must be exercised to ensure correct and approved versions are used. All fabrication activities used to make Packcrete must be described in approved written procedures.

3.4.2 Certification Data Documents

Certification data documents are identified in Attachment A and documentation of measurements, testing, and calculations created during the performance of the work described in Sect. 7 are documented in Form ES3100 of Attachment C.

Certification data documents include raw material test reports in accordance with the requirements of Sect. 5.

The Seller shall provide a certification data package that connects all specified processing data collected to the particular ES-3100 serial number prior to delivery of the ES-3100 assemblies.

3.5 Packaging, Handling, Shipping, and Storage Requirements

3.5.1 Receiving and Material Storage Instructions

Packcrete raw materials procured per this specification shall be marked and received with a traceable Certificate of Conformance (COC).

3.5.2 Damaged Packages

The Seller shall not accept and/or use damaged packages of Packcrete raw materials. Damaged packages are those that are visually determined to be wet, have been wet, have been torn open, or are leaking.

3.5.3 Storage of Raw Materials

Packcrete raw materials shall be stored in a dry location and protected from damage and moisture with an air temperature range of 70 ± 20°F and compliant with the manufacturers recommended practices.

3.6 Marking and Identification Requirements

Packcrete as a material is not marked in any way. The procurement and processing records (forms) for Packcrete raw materials and procedures used shall be tracked by the manufacturing serial numbers for the drum body and plug.

3.7 Requests for Waiver or Deviation

Any requested exceptions, deviations, or proposed changes to the requirements of this specification by the Seller after award and before acceptance shall be submitted using UCN-13816B. The Seller shall request an electronic copy of the form with instructions from the subcontract technical representative or subcontract administrator.

4. QUALITY ASSURANCE REQUIREMENTS

The Seller shall have implemented and maintain a quality system in accordance with ASME NQA-1 2008, 1a-2009, Part 1, Sections 1-18 and/or 10 CFR 71 Subpart H and DOE O 414.1D Attachment 3, with respect to Suspect Counterfeit Items. A copy of the Seller's QA Program Manual shall be submitted with the bid in accordance with Attachment A for review and approval. The Seller shall comply and conduct all work in accordance with their Quality Assurance program and this Equipment Specification.

The Seller shall submit a QAP for the scope of this work that describes the quality assurance policies and practices to be implemented in fabricating the ES3100 shipping container, and identifying, controlling, and verifying the quality of Packcrete processes (weighing, mixing, pouring, vibrating, curing, and baking). The Seller's QAP shall ensure full compliance with all requirements, tests, inspections, reports, documentation, and approvals contained within this specification. The Seller's QAP shall include the requirements for the process controls for the operations, the qualifications of the operator(s) and witness(es), and verification records. In addition, Seller's Quality Assurance (QA) Program shall comply with Subpart 2.14, Quality Assurance Requirements for Commercial Grade items and Services. Company will provide the critical characteristics for any items or services to be dedicated.

4.1 Final Acceptance Test Method

The final acceptance test method includes verification that 100% of the ES-3100 shipping packages contain Packcrete with a finished baked density of 22.4 ± 3 lb/ft^3 and the process used to achieve that density followed the prescribed steps included in Sect. 7.

Final acceptance will be based on compliance with the approval data documents as verified through surveillance activities by the Company, compliance with the technical requirements in this specification as verified through surveillance activities by the Company, and final review and acceptance of the certification data package documents that apply to Packcrete.

4.2 Inspection/Testing Requirements

See Sect. 7 and 8 for additional information.

4.3 Surveillance and Audits

The Company shall reserve the right to evaluate the Seller's QAP and subtiers to ensure compliance with this specification at the Company's discretion. The Company shall be allowed to witness any of the processes associated with this specification during the performance of the contract.

4.3.1 Quality Hold Points

4.3.1.1 Raw Material Lots Must Be Qualified

Before any materials are used in FLQ castings and production castings, the material test reports shall show that the materials meet the testing requirements and acceptance criteria specified in SPC M801794-0003, Sect. 5.4. Documentation of the material qualifications from SPC M801794-0003 shall be part of the certification data package for this specification.

4.3.1.2 Components Must Pass Geometric Inspection Requirements

Before the ES-3100 drum body weldment (M2E801580A002) and top plug (M2E801580A008) are cast with Packcrete, the Seller must have evidence (a Company-approved inspection report plan) that the design requirements, which cannot be verified after the casting, have been met. Additional precautions must be taken to ensure that the bottom diameter of the drum (casting opening) stays within a tolerance of ±0.03 in. prior to casting the Packcrete (M2E801580A002) and within a tolerance of ±0.12 in. throughout casting, weighing, handling, vibrating, curing, and baking of the Packcrete filled drum.

The Seller shall not cast Packcrete into the drum body or top plug until (1) the Company has reviewed and provided its documented approval of the Certified Material Test Reports for the metals involved, (2) the Company has reviewed and provided its documented approval of the diamond I dimensional data on the metal parts that cannot be verified after casting, and (3) the authorized nuclear inspector has reviewed and provided its documented approval of the welds that cannot be verified after casting.

4.3.1.3 Company Approval that Raw Materials and Setup are Lot Qualified

Each change to the final setup approved on Form A (SPC M801794-0003) must be documented on a new Form A and reapproved by the Company. These changes may include hardware, mixing amounts, mixing rotation speed, mixing times, vibration speed setting (Sect. 7.3), and vibration time. Vibration force changes for each unique casting shall be documented on Form ES3100 of this specification.

Modifications to the vermiculite dry weight percent shall require FLQ testing and written Company approval. Changing from one lot of raw materials to another shall require FLQ testing and written Company approval. Approval requires positive testing results of FLQ testing defined in SPC M801794-0003 in Sect. 9. Several months of lead time will be needed to perform these tests and for the results to be evaluated by the Company

4.3.2 Quality Observations

The Company reserves the right to perform quality observations of the Packcrete casting process at any time. Observations will include, but not be limited to, LQs, first article evaluation casting, and initial production casting.

4.4 Acceptance Criteria

The acceptance criteria for fabrication and assembly requirements are based on the baked density of 22.4 ± 3 lb/ft$_3$, and evidence that Packcrete was cast in compliance with this specification.

4.5 Personnel Qualifications/Certifications

Personnel qualified and trained as operators and witnesses shall be able to follow and perform written instructions and procedures and accurately record operations involving weighing, mixing, casting, vibrating, curing, and baking processes.

4.6 Training and Qualification of Personnel

Note: If the Subcontractor does not have prior experience in Packcrete casting, the Company will provide training and direct oversight on the processes.

The Seller shall provide the Company (1) a plan for qualifying and training personnel and (2) documented evidence that personnel have been qualified and trained in accordance with the Seller's procedures approved by the Company to ensure their competence in the use of process procedures and specifications. The Seller must ensure all operators use and follow written procedures for the respective processes. Submit the training plans for Company approval.

4.6.1 Operator and Witness Training and Qualifications

Each operator and witness who performs Packcrete processing activities shall be trained and qualified. This requires the operator and witness to (1) have read the operating procedures and (2) have experience making the measurements, filling out the forms, and successfully performing the activity. Operator and witness qualifications shall be documented and submitted to the Company for approval with the casting forms as evidence that personnel have been qualified and trained.

4.6.1.1 Packcrete mixing and vibration casting training shall consist of successfully completing mixing and casting activities described in Sects. 7.2 and 7.3.

4.6.1.2 Packcrete curing and baking process training shall consist of successfully completing curing and baking activities described in Sect. 7.4.

4.7 Documentation Retention

Documentation of all inspection and test results shall be maintained by the Seller for 3 years after acceptance by the Company. The Company shall have access to this documentation to ensure compliance with all requirements. The Seller shall not destroy quality records without notifying the Company in advance to confirm that the Company does not have a need for the records.

4.8 Nonconformance Control

The Seller shall have an approved procedure for the control of non-conformances, waivers, and deviation requests during the execution of this specification. A nonconforming component shall not be used unless it has been specifically approved by the Company (see Sect. 3.12). The disposition of a nonconforming component shall be documented. Any nonconforming component shall be clearly identified, and each nonconformance report shall be traceable to the actual component affected. A copy of each approved nonconformance report for a component shall be provided to the Company as a part of the certification data package.

5. PACKCRETE RAW MATERIAL REQUIREMENTS

This section defines the requirements for Packcrete raw material procurement, receiving, storage, sampling, testing, and acceptance.

5.1 Procuring Packcrete Raw Materials

The Seller shall procure the Packcrete raw materials (i.e., vermiculite, Portland cement, and Airalon 3000) in accordance with the requirements in Sect. 5.4.

5.2 Receiving and Material Storage Instructions

Packcrete raw materials procured per this specification shall be marked and received with a traceable Certificate of Conformance (COC).

5.2.1 Damaged Packages

The Seller shall not accept and/or use damaged packages of Packcrete raw materials. Damaged packages are those that are visually determined to be wet, have been wet, have been torn open, or are leaking.

5.2.2 Storage of Raw Materials

Packcrete raw materials shall be stored in a dry location and protected from damage and moisture with an air temperature range of 70 ± 20°F and compliant with the manufacturers recommended practices.

5.3 Sample Plan for Third Party Testing

Packcrete raw materials must be purchased in accordance with Sect. 5.4. The plan will require each lot of sampled material to be tested by an independent third party. A sample plan must be created by the Seller to determine the definition of appropriate lot and sample size(s) in order to achieve reasonable assurance that the sample size chosen provides an adequate representation of the purchased item(s) quality. The sample plan shall comply with guidelines as directed by the Company. The lot size is defined in Sect. 5.4.

5.4 Material Procurement and Acceptance Criteria

Packcrete raw MTRs shall be provided with the COCs. The Seller shall also provide a CMTR from a qualified third party testing laboratory in accordance with the requirements in this section.

Note 1: One lot of Airalon 3000 is comprised of a single 55-gal drum that is (1) marked with a manufacturer's lot number and (2) noted in the manufacturer's COC.

Note 2: One lot of Portland cement is comprised of bags received against the same purchase order that have a date code (1) noted in the COC and (2) within the time period noted on the MTR provided with the manufacturer's COC.

Note 3: One lot of vermiculite is comprised of bags received against the same purchase order that have the same manufacturer's lot number noted in the manufacturer's COC.

5.4.1 Vermiculite Acceptance Criteria

The raw material manufacturer shall provide a COC package that includes the following, as a minimum: (1) the Buyer's purchase order number; (2) the date(s) of manufacture; (3) a statement that the material complies with ASTM C516; (4) a signature by the supplier's official or quality manager; and (5) a Certificate of Analysis in accordance with ASTM C516 for bulk density and grading. The COC shall also include the lot numbers in the order and the number of bags for each lot number.

All bags in the order shall come from a single manufacturing run in order to ensure consistency from bag to bag in terms of chemical composition, bulk density, and particle size distribution.

The manufacturer shall mark each bag as being vermiculite, Type 1, Grade 3, per ASTM C516 requirements. The manufacturer shall also mark each bag with (1) the lot number, (2) the manufacturing line identifier, and (3) a date code showing when the material was manufactured and bagged.

The manufacturer shall maintain quality records that connect the lot number, manufacturing line identifier, or date codes to the raw materials, manufacturing processes, operating procedures, and other manufacturing specifics associated with the manufacturing run.

Bagged vermiculite shall be stored in an area where vibrations from adjacent equipment and handling or movement are minimized, and be stored and transported in a manner that protects the bags and materials from exposure to water.

Bulk density and grading shall be independently tested by a third party testing laboratory in accordance with ASTM C516 (Type 1, Grade 3 Fine). When tested in accordance with Sect. 9.1.1 of ASTM C516 and ASTM C520, third party testing must show each sample has a bulk density between 6.4 and 8 lb/ft3. When tested in accordance with Sect. 9.1.2 of ASTM C516 and ASTM C136, all samples must have a particle size distribution that complies with Table 1.

Table 1. Particle size distribution acceptance criteria

U.S. Sieve No.	Weight % passing through the sieve
8	90 to 100
16	40 to 82
30	0 to 35
50	0 to 20
100	0 to 10
200	0 to 2

If all samples do not pass the bulk density and particle size distribution acceptance criteria, the lot shall be rejected by the Seller and the Company should be notified.

5.4.2 Portland cement Acceptance Criteria

The manufacturer shall provide a COC package for each purchase order that includes the following, as a minimum: (1) the Buyer's purchase order number; (2) the date(s) of manufacture; (3) a statement that the material complies with ASTM C150; (4) a signature by the supplier's official or quality manager; (5) an MTR in accordance with ASTM C150; and (6) a statement that all bags in the order were bagged during the time period stated in the MTR. The COC package shall also include the lot number in the order and the numbers of bags in each lot number.

The manufacturer shall mark each bag as being Portland cement, Type III, per ASTM C150 requirements. The manufacturer shall also mark each bag with a date code showing the week and year the material was bagged. All bags in the order/lot shall have a date code that is within the valid time period stated in the MTR.

The manufacturer shall maintain quality records that connect the lot number or date codes to the raw materials, manufacturing processes, operating procedures, and other manufacturing specifics associated with the manufacturing run.

The packaging practices of the manufacturer are acceptable unless stated otherwise in the Buyer's purchase order. Material shall be stored and transported in a manner that protects the bags and materials from exposure to water.

A CMTR shall be provided from a third party independent testing laboratory showing that all samples comply with ASTM C150, Table 1, Type III standard chemistry requirements when tested in accordance with the test methods specified in ASTM C114, Table 1.

If all samples do not pass the acceptance criteria, the lot shall be rejected by the Seller, and the Company should be notified.

5.4.3 Airalon 3000 Acceptance Criteria

The manufacturer shall provide a COC package with each purchase order that must include the following as a minimum: (1) the Buyer's purchase order number; (2) the date(s) of manufacture; (3) a statement attesting to the fact that the material complies in concentration, composition, and performance to ASTM C260 requirements; (4) a statement providing the chloride content of the material; and (5) a signature by the supplier's official or quality manager. The COC package shall also include the lot number, the date codes, and the number of containers in the order for each date code.

The manufacturer shall mark each container as being Airalon 3000 per ASTM C260 requirements. The manufacturer shall also mark each container with (1) the lot number and (2) a date code showing when the material was manufactured and containerized.

The manufacturer shall maintain quality records that connect the lot number or date codes to the raw materials, manufacturing processes, operating procedures, and other manufacturing specifics associated with the manufacturing run.

A CMTR shall be provided from a third party independent testing laboratory that shows that each 55-gal drum of Airalon 3000 complies with the acceptance criteria in Table 2.

Table 2. Airalon 3000 55-gal drum acceptance criteria

Reference	Test	Original lot	Acceptance criteria*
ASTM C494, C260, or C233	Infrared analysis**	Attachment C in SPC M801794-0003	Essentially similar to Attachment C in SPC M801794-0003
ASTM C494, C260, or C233	Specific gravity	1.01 S.G	0.91 to 1.13 S.G.
ASTM C260 or C233	pH	10.25 pH	9.15 to 11.48 pH
ASTM C260 or C233	Residue (solids)	3.15 wt %	2.82 to 3.52 wt %

*The acceptance criteria are based on the measurements of the original lot and a 12% range.
**ASTM C260 for air-entraining admixtures does not require infrared analysis. Therefore, the infrared analysis for chemical composition testing is determined by ASTM C494 using the oven-dried residue as determined by ASTM C260/C233. If the sample does not pass the acceptance criteria, the Airalon 3000 55-gal drum shall be rejected, and the Company shall be notified.

5.5 Mixing Water

Water that has been filtered through at least a 20-micron filter and has a chlorine content that is <4 mg/L (4 ppm, 0.0004% by mass) shall be used for the mixing of Packcrete. Record the manufacturer, model number, and serial number of the water filter showing that it is at least a 20 micron filter on Form B (Attachment E). The water temperature shall be between 50 and 80□F. Form B in Attachment E shall be used to document and record the water temperature and that the chlorine requirements are met each day before mixing starts.

6. FACILITY AND PROCESS EQUIPMENT REQUIREMENTS

A written plan shall be submitted to the Company for approval that defines the cleaning process, including cleaning solutions used, equipment, and work and storage environments.

6.1 Cleaning Instructions

NO CHLORINE PRODUCTS (sodium hypochlorite) shall be used in the cleaning materials. Potable water shall be used and, if required, some mild soap (tri-sodium phosphate) may be included to clean all processing equipment and manufactured drum bodies and lids before casting. Chlorine is known by many names on the ingredient list (e.g., sodium hypochlorite, hypochlorite, chloramine, bleach, hydrochloric acid, trihalomethanes, and generic disinfection by-products). Not all cleaning products list their ingredients; therefore, only cleaning materials that disclose all ingredients shall be used.

If the mixer sits for >15 min between mixer batches, the mixer shall be flushed thoroughly with potable water before reuse. Before the start of mixing operations described in Sect. 7, the mixer shall be clear of foreign materials or loose previous mixing residues from the inner surface of the mixer.

Manufactured drum bodies and lids that have passed geometric inspection must be cleaned and protected prior to the casting operation to prevent the introduction of foreign materials into the assemblies. The assemblies shall be inspected and wiped clean prior to casting to ensure no visible contaminants are present inside the casting cavity.

6.2 Equipment Requirements

All process equipment used for mixing, casting, and baking of the Packcrete shall be (1) identified in the Seller's operating procedures with the operational tolerances and (2) in good working condition. See SPC M801794-0003 Section 6.2 for these requirements.

6.3 Work Environments

The temperature and humidity of the material storage, casting, and curing environments can have a major impact on casting densities. Variations in mixing air, water, and curing temperatures can also influence the baked density. The Company requires controlled work and material storage environments.

6.3.1 Mixing and Casting

Mixing and casting operations shall be performed out of direct sunlight and rain with an air temperature of 70 ± 20°F.

6.3.2 Mixing and Casting Water

Mixing and casting operations shall be performed with water that complies with the requirements in Sect. 5.5.

6.3.3 Curing Storage

Curing storage shall be in an environment with an air temperature of 70 ± 20°F with the containers covered with plastic.

6.3.4 Portland Cement and Vermiculite Storage

Bags of Portland cement and vermiculite that have been opened for more than one work shift shall be discarded unless they are stored in a waterproof container in a dry location.

7. PACKCRETE PROCESSING

This specification utilizes portions of SPC M801794-0003. If conflicts occur between this specification and SPC M801794-0003, this specification shall supersede. SPC M801794-0003 uses casting Forms A, B, C, D, E, and F, and this specification uses casting Form ES3100. The casting forms from both equipment specifications become part of certification data for this specification.

SPC M801794-0003, *Packcrete Preliminary Lot Qualification*

Form A	Packcrete Setup Approval
Form B	Packcrete Mixing for Samples and Parts
Form C	Packcrete Sample 4.5-Gal Pail Vibration Casting Control
Form D	Packcrete Sample 30-Gal Drum Vibration Casting Control
Form E	Packcrete Sample Pipes Vibration Casting Control
Form F	Packcrete Furnace and Baking

SPC M801580-0003, *ES-3100 Packcrete Final Lot Qualification and Production Processing*

Form ES3100	Packcrete Vibration Casting SES3100 and ES-3100 for Body and Plug

ES-3100 Packcrete FLQ and production processing is shown in Fig. 3.

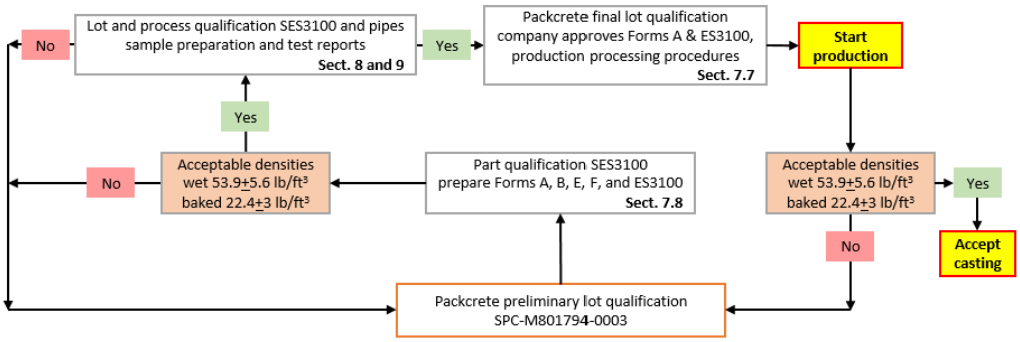

Fig. 3 ES-3100 Packcrete FLQ and production processing.

7.1 Processing Setup Requirements

See SPC M801794-0003, Section 7.1 for these requirements.

7.2 Mixing Setup Approval Control Number

See SPC M801794-0003, Section 7.2 for these requirements.

7.3 Processing Preparation for SES3100, ES-3100, and Samples

The purpose of the processing preparation for samples and parts is to create and document a controlled Packcrete casting that follows an approved mixing setup defined on Form A (SPC M801794-0003, Attachment E). The same processes are used for casting samples and parts with the vibration force being adjusted for the EWCW of the container. A partially filled container is vibrated for 10 s, vibrator is turned off, and a completely filled container is vibrated for 1 min (SPC M801794-0003, Sect. 7.3). These and other processing data are recorded on Forms C, D, E, and F in SPC 801794-0003 and Form ES3100 (Attachment C).

Table 1. Recommended vibration settings

Casting	SCR-1000 Set No. [a]	Vibration force [b] (lb)	Estimated wet cast weight [c] (lb)	Vibration intensity [d]
SES3100 plug	1.1	74	31	2.39
ES-3100 plug	1.1	74	31	2.39
SES3100 body	3.1	688	330	2.08
ES-3100 body	3.3	735	347	2.12

[a] Vibration force setting numbers for the VIBCO SCR-1000 are shown in Attachment D in SPC M801794-0003. For other vibration motors, document the changes in Form A of SPC M801794-0003 and Form ES3100 and contact the Company for force settings and approval.
[b] Recommended vibration force settings for the VIBCO SCR-1000 are shown in Attachment D in SPC M801794-0003. Vibrate 10 s for partial fills and 1 min after filling is completed.
[c] The EWCW is for one full casting mold using an estimated wet casting density of 53.9 lb/ft^3.
[d] The vibration intensity has a tolerance of ±0.6 that may change the setting number and the vibration force.

7.4 Process—Mixing and Vibration Casting, Curing, and Baking for Samples and Parts

Process mixing and vibration casting, curing, and baking for samples and parts are found in SPC M801794-0003, Section 7.4.

7.5 Setup Approval Process Verification—4.5-gal Pail or 30-gal Drum

The 4.5-gal pail or 30-gal drum have been used to verify the mixing setup control number (SACN) process that generates an acceptable wet and baked density following the requirements in Sects. 7.3 and 7.4. The 4.5-gal pail needs Forms A, B, C, and F from SPC M801794-0003, while the 30-gal drum needs Forms A, B, D, and F (Attachment E) from SPC M801794-0003 are needed to document this effort. Use these small castings if needed to verify the lots of material and process settings. Once these are verified, proceed to shipping package specific specification and perform a process and LQ castings.

7.6 Lot Qualification and Packcrete Sample Pipes

Pipe samples are required for both preliminary and final lot qualifications. The pipe sample casting requires a different stand-alone vibration table setup that vibration casts at least two pipe samples for each mixer load going into the production run mixes. This stand-alone table needs a maximum force of 100 lb and a speed of 3200 vibrations per minute, generating a frequency of 53 Hz. VIBCO supplies a standalone table that meets these requirements. The SACN used will be different than the SACN for the VIBCO SCR-1000. Follow Sects. 7.3 and 7.4 and use Forms A, B, E, and F (Attachment E) to document pipe sample casting. Section 8 describes pipe sample preparation requirements, and Sect. 9 describes pipe sample testing. Send the manufacturing and testing results to the Company for evaluation. Once the testing data is accepted by the Company, the current Form As will be approved and signed by the Company.

7.7 Final Lot Qualification Castings—SES3100 Body and Plug

The purpose of FLQ is to create and document a full-scale test of Packcrete casting (SES3100 body or plug) to validate (qualify) the raw materials, equipment, and process necessary to achieve an acceptable end product with an acceptable baked density. Furthermore, raw material testing shall be performed in accordance with Sect. 9 in SPC M801794-0003 before the raw materials are released for production processing. After the Company accepts the SES3100 castings and documentation, the Seller may proceed to the production process documented in Sect. 7.8. Optional samples for testing and their required forms are described in Sect. 8, but they will use the setup and processes described in Sect. 7.6 (SPC M801794-0003).

Process qualification (PQ) acceptance testing requires test articles from an SES3100 body and plug and sample pipes qualified in accordance with Sect. 9 (SPC M801794-0003). Section 8 of SPC M801794-0003 defines how the samples are to be made, and Sect. 9 (SPC M801794-0003) describes how the samples are to be tested. After the Company has evaluated the testing results, the Seller may be approved to start production castings or may be asked to reject the lots of raw materials and repeat the SES3100 FLQ process. During production, additional sample testing may be necessary to gather information to assure the process can be repeated on parts.

Each PQ shall document the entire manufacturing process using the materials that have successfully completed the material testing and are approved by the Company on Form A (SPC M801794-0003). The Packcrete setup approval process is documented in Sect. 7.2 (SPC M801794-0003). The Packcrete mixing setup shall follow the approved setup on Form A (SPC M801794-0003). Additional adjustments to the vibration force shall be made in accordance with Sect. 7.3 to properly manufacture a SES3100 body and plug Packcrete castings.

7.7.1 Setup—Mixing and Vibration Casting an SES3100 Body or Plug

To cast the SES3100 container, the active Setup Approval Control Number (SACN) mixing setup approval settings on Form A (SPC M801794-0003) shall be identified and followed. The Packcrete setup approval process is documented in Sect. 7.2 (SPC M801794-0003). It is required that the Seller complete casting using an SES3100 body and plug and record data on Forms B and F in SPC M801794-0003 and Form ES3100 (Attachment C) prior to proceeding to the production process described in Sect. 7.8.

The Seller shall complete setup in accordance with Sect. 7.3 for an SES3100 body or plug, recording data measurements on Form E (checking the appropriate boxes for PQ and body or plug).

7.7.2 Process—Mixing and Vibration Casting an SES3100 Body or Plug

For an SES3100 container, the active SACN mixing setup approval settings on Form A (SPC M801794-0003) shall be identified and followed. The Packcrete setup approval process documented in Sect. 7.2 (SPC M801794-0003) shall be followed for an SES3100 body or plug and the data recorded on Forms B and F in SPC M801794-0003 and Form ES3100 (Attachment C) prior to proceeding to the production process described in Sect. 7.8.

Each unique casting of a container must have the vibration force calculated as described in Sect. 7.3 that shall match the "body" or "plug" setting on Form ES3100 (Attachment C) with the vibration force adjusted to the proper setting. The Seller shall complete Sect. 7.4.1 (SPC M801794-0003) for an SES3100 body or plug, recording measurements on Forms A, B, and F in SPC M801794-0003 and Form ES3100 (checking the appropriate boxes for PQ and body or plug).

7.7.3 Process—Curing an SES3100 Body or Plug

The Seller shall follow the requirements in Sect. 7.4.2 (SPC M801794-0003) for curing an SES3100 body or plug and record measurements on Form ES3100 (checking the appropriate boxes for PQ and body or plug).

7.7.4 Process—Baking an SES3100 Body or Plug

After casting, initial curing, scraping, and final curing, place a thermocouple in at least one SES3100 body at the top center of the casting with the tip 5- to 6-in. deep to record the core temperature. It is acceptable to use a rod or drill to generate the proper depth thermocouple hole. The SES3100 body shall be baked with the core temperature thermocouple in place to determine the minimum baking time at 500°F. A bottom center thermocouple (BCT) can be used to determine the temperature of the bottom center of the inner liner for the current furnace loading. The minimum baking time at 500°F may be determined by no increase in the BCT over 2°F in 6 h of baking. Each SES3100 body has ~4.7 ft^3 of casting and will lose ~148 lb of water. If required, the furnace set point temperature may need to be adjusted to ensure that the temperature near the package is within the tolerance of ±10°F for the setting requirement.

7.7.4.1 Calculate and record the baked density using the equation at the bottom of Form ES3100. The acceptable baked density is 22.4 ± 3 lb/ft^3 (19.4–25.4 lb/ft^3) for the SES3100 casting.

7.7.4.2 If the baked density is acceptable, follow Sect. 9 (SPC M801794-0003) and send samples for lot qualification testing. Submit completed SES3100 Forms A, B, and F in SPC M801794-0003 and Form ES3100 (Attachment C) with the sample pipe casting Forms A, B, E, and F in SPC M801794-0003 to the Company for approval. Once Company has approved, production processing may start following Sect. 7.8.

7.8 Production Processing an ES-3100 Body or Plug

The purpose of the production process is to create and document the production Packcrete casting (ES-3100 body or plug) based on approved lot qualified materials and processes documented in Sect. 7.7. This practice has validated the raw materials, equipment, and processes necessary to achieve an acceptable end product and baked density. Optional samples may be required for testing and their required forms are described in Sect. 8, but they will use the setup and processes described in Sect. 7.6 (SPC M801794-0003). Each production process shall follow an approved Form A (SPC M801794-0003) identified by a SACN. The production processing shall be documented on Forms B and F in SPC M801794-0003 and Form ES3100 (Attachment C).

NOTE: It is important that the runout (roundness) of the drum body casting opening stays within ±0.03 in. prior to the Packcrete casting process as stated on M2E801580A002. In-process inspections are used to verify that the container stays acceptable during the casting and baking processes. Failure to meet the diametrical tolerance after the Packcrete casting and baking is grounds for rejection.

7.8.1 Setup—Mixing, Vibration Casting, and Curing an ES-3100 Body or Plug

Each production process shall follow an approved Form A (SPC M801794-0003) identified by a SACN and PQ as described in Sect. 7.6 (SPC M801794-0003).

The Seller shall complete the following steps:

7.8.1.1 Vibration table force and speed settings shall meet the requirements defined in Sect. 7.3, and they shall be documented on Form ES3100.

7.8.1.2 Processing as described in Sect. 7.3 shall be completed for an ES-3100 body or plug, recording measurements on Form B in SPC M801794-0003 (checking the appropriate boxes for production process and body or plug).

7.8.2 Process—Mixing and Vibration Casting an ES-3100 Body or Plug

Each production process shall follow an approved Form A in accordance with Sect. 7.4 (SPC M801794-0003) that is identified by a SACN.

The different vibration table force settings are shown in Sect. 7.3, shall match the "body" or "plug" setting in Table 1, and shall be documented on Form ES3100.

The Seller shall complete Step 7.4.1 (SPC M801794-0003) for an ES-3100 body or plug, recording measurements on Form B (SPC M801794-0003) and Form ES3100 (checking the appropriate boxes for production process and body or plug).

The Seller shall record on Form ES3100 that the drum casting opening and drum plug sheet metal diameters are within the manufacturing tolerances of ±0.12 and ±0.06, respectively. These measurements must be made after weighing and handling and before casting.

7.8.3 Process—Curing an ES-3100 Body or Plug

Each production process shall follow an approved Form A identified by a SACN and PQ described in Sect. 7.4 (SPC M801794-0003) and recorded on Form B (SPC M801794-0003).

The Seller shall complete the steps described in Sect. 7.4.2 (SPC M801794-0003) for an ES-3100 body or plug and record measurements on Form ES3100 (checking the appropriate boxes for production process and body or plug).

7.8.4 Process—Baking an ES-3100 Body or Plug

After casting, initial curing, scraping, and final curing, place a BCT on the bottom center of the inner liner of the ES-3100 body. The BCT shall be used to determine the temperature of the bottom center of the inner liner for the current furnace loading. The minimum baking time at 500°F may be determined by no increase in the BCT over 2°F in 6 h of baking. If required, the furnace set point temperature may be adjusted to ensure that the temperature near the package is within the tolerance of ±10°F for the setting requirement.

Each ES-3100 body and plug has ~4.8 ft^3 of casting and will lose ~151 lb of water. Therefore, each unique furnace loading must be qualified with thermocouple readings to determine the minimum baking time at 500°F for that volume of castings, or real time temperature measurements may be recorded. For real time temperature measurements, the ES-3100 body shall be baked with the BCT in place to determine the temperature of the bottom center of the inner liner for the current furnace loading. A real time measurement furnace may be used in the future as a Baking Qualification Control Number-Vol (BQCN-Vol) that controls the minimum baking time for a volume of cast material loaded into the furnace. The cast Packcrete volume in cubic feet is recorded on Form F (SPC M801794-0003). The BQCN-Vol time at 500°F may be used for oven loads up to the qualified volume without real time measurements being required.

The Seller shall complete the final following steps.

7.8.4.1 Complete the steps in Sect. 7.4.3 (SPC M801794-0003) for an ES-3100 body or plug and record measurements on Form ES3100 (Attachment C) and Form F in SPC M801794-0003 (checking the appropriate boxes for production process and body or plug).

7.8.4.2 Calculate and record the baked density of the cured mixture using the equation at the bottom of Form ES3100. The acceptable baked density is 22.4 ± 3 lb/ft^3 (19.4–25.4 lb/ft^3).

7.8.4.2.1 If the baked density is not acceptable, reject the part and contact the Company for information and future casting improvements.

7.8.4.2.2 If the baked density is acceptable, follow the instructions in Attachment A and submit completed Forms A–F (SPC M801794-0003) and Form ES3100 to the Company for approval.

7.8.4.2.3 Weld the covers on to complete the drum body weldment or top plug weldment in accordance with M2E801580A002 or M2E801580A002 and JS-YMN3-801580-A002.

7.8.4.3 Insert copies of the approved raw material test reports; SACN, SES3100 casting, and lot qualification reports; and production casting forms into the certified data package that are used to define the production process in accordance with the instructions in Attachment A.

7.8.4.4 Verify that the stainless-steel shell, as shown in M2E801580A002 and M2E801580A008, have passed geometric inspection before casting begins.

8. PACKCRETE LOT QUALIFICATION AND PRODUCTION TEST SAMPLES

The Packcrete lot qualification and production test samples requirements are found in SPC M801794-0003. The 30-gal drum may be used to replace the SES3100 casting in the production sampling set once equivalences have been demonstrated with test results.

9. PACKCRETE MATERIAL LOT QUALIFICATION PROPERTIES LIMITS

Packcrete material lot qualification properties limits are found in SPC M801794-0003.

ATTACHMENTS

ATTACHMENT A: SUBMITTAL CHECKLIST

Instructions to Supplier for Preparation of Submittals

Note 1 --All correspondence shall be addressed to the Technical Representative identified by the company. The Supplier shall forward submittals via transmittal letter to the Company at the address specified in the contract.

Note 2 -- The submittal must have adequate detail so that full compliance with the requirements may be determined. For example, a simple off-the-shelf item to be used in an assembly may only need a manufacturer's cut-sheet to show compliance, but a factory acceptance test (FAT) developed and submitted by the Seller must have each test step detailed with acceptance criteria consistent with the requirements.

a. Review submittal before transmitting to the Company to verify conformance with requirements of the contract documents (e.g., field measurements, field construction criteria, or manufacturer's catalog numbers).
b. Coordinate submittals with the work requirements and the contract documents.
c. Organize Submittals
   - Do not use highlight marker or color coding on submittals.
   - The minimum resolution used for scanning submittals shall be 300 dpi x 300 dpi.
   - For submittals containing color information important to the record, a 24-bit color setting should be used.
   - Submittals are to be legible and in the format specified on the submittal checklist.
   - Pen and ink changes are to be made in non-erasable ink, legible, dated and initialed.
   - Mark specific options provided for the work, and cross out options not provided.
   - Each submittal shall be sent as a single pdf file unless otherwise specified.
d. Label submittals with the applicable item number, reference, and requirement description as summarized in the Submittal Checklist. Unlabeled submittals will be returned to the Seller without review.
e. Include with submittals a transmittal letter that identifies individual documents by specification section.
   - Transmittal for submittals shall be numbered using the purchase order number followed by a 4-digit sequential number. (Example: 430001111-0001).
   - Embedded comments or questions that are not included on the transmittal may not be addressed/resolved by the Company.
f. Direction will be given at the time of award to either upload submittals to a company provided URL address or send by email to a company provided email address.
g. If using a company provided URL to upload submittals, notify the Company via email when submittals have been placed.
h. After review of a submittal, the Company will assemble comments and provide a status on the documents. An example of this submittal status stamp is shown below.

DOCUMENT REVIEW STATUS		
1	☐ Work may proceed.	
2	☐ Revise & resubmit. Work may proceed subject to incorporation of changes indicated.	
3	☐ Revise & resubmit. Work may not proceed.	
4	☐ Review not required. Work may proceed.	
Permission to proceed does not constitute acceptance or approval of design details, calculations, analysis, test methods developed or selected by the supplier and does not relieve supplier from full compliance with contractual obligations.		
REVIEWED BY:	Print Name/Signature :	Date:

i. If a submittal is being resubmitted, then reference the applicable item number, reference, and requirement description and identify it as a resubmittal.
j. Company response will only be returned to the Supplier for those submittals with a Submittal Purpose of "For Action," unless it is determined that a submittal transmitted "For Information" is not acceptable.
k. AFTER written approval is obtained, THEN proceed with work requiring approved submittals.
l. When approval submittals are required, work done before Company approval is at the Seller's risk.
m. Maintain a copy of the company-approved submittal and status page on file.

2. STRUCTURAL EVALUATION

The ES-3100 package is used to ship highly enriched uranium (HEU) in the following forms: oxide; oxide with thorium; bulk and broken metal shapes; uranyl nitrate crystals (UNX); and unirradiated research reactor fuel elements and components, and uranium compounds. Content will be packed in various size convenience cans made of stainless, tin-plated carbon steel, aluminum, or nickel alloy, and polyethylene, glass, or Teflon fluorinated ethylene propylene (FEP) bottles. The cans shall have a diameter of ≤ 12.7 cm (5 in.) and heights of ≤ 25.4 cm (10 in.). Two or more cans having a diameter of ≤ 12.7 cm (5 in.) and a maximum height of ≤ 25.4 cm (10 in.) may be brazed together to form a can assembly of up to 76.2 cm (30 in.) in height (Fig. 1.4). Any combination of these cans shall be allowed in a single package, as long as the total length of the can stack (with spacers when required) does not exceed the inside working height of the containment vessel. Any closure on the convenience can is allowed. Containment vessel arrangements that utilize closed metal cans with diameters >10.8 cm (4.25 in.) will provide for at least 43 $in.^3$ of free or void volume for gas expansion and offgassing of material at temperatures associated with Normal Conditions of Transport (NCT) or Hypothetical Accident Conditions (HAC). The contents that cannot be packaged in the proposed cans due to the contents' overall dimensions, such as the unirradiated research reactor fuel elements and components, will be bundled together and protected on each end with an open-ended can (Fig. 1.4). When space is available inside the containment vessel, stainless-steel metal scrubbers will be placed on the top and bottom of this partially canned assembly, or an empty convenience can will be placed on the top or bottom of this assembly inside the containment vessel. Solid form HEU contents that will not fit in a convenience can may be bagged only with no convenience can required around the content. However, the usage of convenience cans for these contents is not prohibited. Stainless-steel metal scrubbers may be placed on the top and bottom of this assembly inside the containment vessel. Additionally, glass bottles with enriched uranium oxide may be packed inside metal convenience cans. These glass bottles with enriched uranium oxide containing UO_2-Mg will be treated as pyrophoric material and packaged in a sealed and inerted container. Polyethylene, nylon, or Teflon bags may be used inside or outside any convenience can as long as the loading restrictions in Sect. 1.2.2.8 are met. If Teflon bottles are used as convenience containers, the total amount of offgassing material (including Teflon bottles, polyethylene, nylon, or Teflon bagging, and lifting slings) is limited to 1490 g per package. If metal cans, polyethylene bagging, nylon bagging, Teflon bagging or polyethylene bottles are used as convenience containers, the total amount of offgassing material (including polyethylene bottles, polyethylene bagging, nylon bagging, Teflon bagging, and lifting slings) is limited to 500 g per package (see Sect. 6.2.4, Item 7). The maximum payload inside the containment vessel will be as follows and as shown in Table 2.1: (1) 24-kg oxide or compounds (up to 100% enrichment in ^{235}U); (2) HEU oxide shall be in the form of U_3O_8-Al, UO_2-Mg, UO_2-ZrO_2, UO_2, UO_3, U_3O_8, UO_2-Th, or UO_2-ThO_2 ; (3) 24 kg of UNX crystals; (4) 35.2 kg of uranium metal and alloy (up to 100% enrichment in ^{235}U); (5) HEU metal and alloy may be in the form of broken pieces, ingots, buttons, small castings, cylinders, or fuel elements (rods, plates, or tubes); and (6) the maximum weight of all contents, including nuclear material, convenience containers, polyethylene bags, nylon bags, Teflon bags, spacers, slings, etc., shall not exceed 40.82 kg (90 lb). Uranium and transuranic isotopic allowances are defined in Chap. 4. As shown in Chap. 1, some thorium (^{232}Th) compounds or oxides mixed with uranium are proposed for transport. Shipping of ^{232}Th is bounded by the analysis using uranium for containment or hydrogen gas generation as shown in Appendices 4.5.1 and 3.5.4 due to the following: (1) the A_2 of ^{232}Th is unlimited; (2) the decay energy of ^{232}Th is less than all other uranium isotopes; and (3) the half-life of ^{232}Th is significantly longer than the uranium isotopes. Mass limits and total weights for each shipping arrangement are defined and described in Sect. 2.1.3. The 40.82-kg (90-lb) maximum containment vessel content weight and 35.2-kg (77.60-lb) HEU content weight limits have been established as a bounding case for the maximum structural, thermal, and

containment limit for the shipping package. There is no minimum content weight requirement. The content masses and forms used for the proposed content do not take into consideration limits based on shielding and subcriticality.

As described in the following sections, design analysis, similarity, drop simulations, and the full-scale testing documented herein demonstrates that the ES-3100 package is in compliance with the requirements of Title 10 Code of Federal Regulations (CFR) 71 and Title 49 CFR 100–178 when it is used to ship contents described above. The maximum bounding activity of the contents (35.2 kg of HEU) is 7.2554×10^{-1} TBq (19.6092 Ci) and occurs 10 years after initial fabrication. When the maximum activity-to-A_2 value is reached at ~70 years from material fabrication, the corresponding activity is 7.2456×10^{-1} TBq (19.5827 Ci). The corresponding maximum number of A_2s carried is 4.7528×10^{3}. This information is further discussed in Chap. 4.

Table 2.1. Proposed HEU contents for shipment in the ES-3100

Form	Chemical or physical description	Total weight of HEU contents kg (lb)
HEU oxide	U_3O_8-Al, UO_2-Mg, UO_2, UO_3, U_3O_8, product oxides (UO_2, UO_3, U_3O_8) mixed with ThO_2, ZrO_2, or thorium metal	24 (52.91)
Uranyl nitrate crystals	$UO_2(NO_3)_2 \cdot 6H_2O$	24 (52.91)
HEU metal and alloy	Specific geometric shapes (spheres, cylinders, square bars or slugs) or broken metal pieces, rods, plates, or tubes	35.2 (77.60)

2.1 DESCRIPTION OF STRUCTURAL DESIGN

2.1.1 Discussion

The principal structural members of the shipping package consist of the following: the drum assembly, the containment vessel, packaging material, and the contents. Each of these will be described and discussed in the following sections.

2.1.1.1 Drum assembly

The drum assembly of the shipping package is defined as the structure that maintains the position of and provides protection to the impact and thermal barrier surrounding the containment vessel. Preserving the location of the containment vessel within the packaging prevents reduction of the shielding and subcriticality effectiveness. The drum assembly for the ES-3100 consists of an internally flanged Type 304 or 304L stainless-steel 30-gal modified drum with two Type 304 or 304L stainless-steel inner liners, one filled with noncombustible cast refractory insulation and impact limiter (Kaolite 1600 or Packcrete) and one filled with noncombustible cast neutron absorber (Cat 277-4), a stainless-steel top plug with cast refractory insulation, silicone rubber pads, silicon bronze hex-head nuts, and a stainless-steel lid and bottom (Drawing M2E801580A031, Appendix 1.3.7). The nominal weight of these components is 131.89 kg (290.76 lb).

The drum's diameters (inner diameter of 18.25 in.) and corrugations meet the requirements of Military Standard MS27683. All other dimensions are controlled by Drawing M2E801580A004 (Appendix 1.3.7). Modifications to the drum from MS27683 include the following: (1) the overall height was increased; (2) the drum was fabricated with two false wire open ends; and (3) a

0.27-cm (12-gauge, 0.1046-in.)–thick concave cover was welded to the bottom false wire opening (Drawing M2E801580A005, Appendix 1.3.7). Four 0.795-cm (0.313-in.)–diam equally spaced holes are drilled in the top external sidewall to prevent a pressure buildup between the drum and inner liner. The holes are sealed with a plastic plug to provide a moisture barrier for the cast refractory insulation during NCT. The cavity created by the inner liner for placement of a containment vessel is a three-tiered volume. The uppermost tier accommodates the top plug and has an inside diameter of 37.52-cm (14.77-in.) and is 13.26-cm (5.22-in.) deep. The second tier has an inside diameter of 21.84-cm (8.60-in.) that is 5.59-cm (2.20-in.) deep. The third tier has a 15.85-cm (6.24-in.) inside diameter that is 78.31-cm (30.83-in.) deep.

The volume between the mid liner and the drum and the top plug's internal volume is completely filled with the noncombustible cast refractory insulation called Kaolite 1600 from Thermal Ceramics, Inc. or Packcrete. Kaolite properties, such as mechanical, thermal conductivity, and impact, are presented in Y/DW-1661, ORNL-TM-2003/49, Y/DW-1890, and Y/DW-1972. Material properties for Packcrete are presented in RP 802282-0002. The volume inside the center liner tube is filled with a noncombustible cast neutron poison (absorber) material called Cat 277-4, which is created by mixing Cat 277-0 material from Shieldwerx (SWX-277-0) and boron carbide (B_4C). The material is composed of aluminum, magnesium, calcium, boron, carbon, silicon, sulfur, sodium, iron, and water. The final mixture will have an average density of 110 lb/ft^3. Cat 277-4 properties, such as thermophysical, mechanical, and neutron activation, are presented in ORNL/TM-2004/290, Y/DW-1987, Y/DZ-2585, COR-NDA-04-93, and Y/DV-1914. BoroBond4, another noncombustible neutron absorber, was used only in prototype test packages instead of Cat 277-4. The drum body, inner liners, and lid are fabricated from 0.15-cm (16-gauge, 0.0598-in.)–thick Type 304 or 304L stainless-steel sheet. A rolled stainless-steel flange with a 5.08 × 5.08 × 0.64-cm (2 × 2 × 0.25-in.)–thick modified stainless-steel structural angle is welded around the top of the mid inner liner. The mid inner liner is then welded to the inside surface of the drum along this flange. Eight ⅝-11-UNC-2A studs welded to the drum and silicon bronze nuts provide the structural attachment for the drum lid, and are torqued to 40.67 ± 6.78 N·m (30 ± 5 ft-lb) at assembly. The drum lid's diameter and shape meet the requirements of Military Standard MS27683. All other dimensions are controlled by Drawings M2E801580A006 and M2E801580A007, Appendix 1.3.7. The stiffener ring (Find Number 3 on Drawing M2E801580A006, Appendix 1.3.7) provides the lid with an inner flange. The stiffener ring was incorporated in the ES-3100 package for use during handling and transport to protect the lid closure studs and nuts. During transport, the stiffener ring helps position drum tie-down adapters that are used for tie-down of a single unit configuration in Safeguards Transporters (SGTs) in accordance with the National Nuclear Security Administration (NNSA) Technical Manual. The drum is marked by two stainless-steel data plates. The data plate lettering and mounting requirements on the drum are shown on Drawings M2E801580A010 and M2E801508A031 (Appendix 1.3.7), respectively. Painting and marking requirements for the drum are shown on Drawing M2E801580A001 (Appendix 1.3.7). Two lugs are welded to the mid inner liner and project through the drum lid at assembly. Each lug has a 0.953-cm (0.38-in.)–diam hole through which a tamper-indicating device (TID) can be threaded.

The volume between the drum and mid-liner is filled with a lightweight noncombustible cast refractory material called Kaolite 1600 or Packcrete. The top plug is also filled with either of these materials and represent the thermal insulation and impact-limiting barrier. The material is composed of portland cement, water, and vermiculite and has an average density of 358.8 kg/m^3 (22.4 lb/ft^3). The procedures for manufacturing and documenting Kaolite 1600 material, JS-YMN3-801580-A003 (Appendix 1.3.4), and Packcrete material, SPC M801794-0003 (Appendix 1.3.11) and SPC M801580-0003 (Appendix 1.3.12), are referenced on Drawings M2E801580A002 and M2E801580A008 (Appendix 1.3.7) for the drum assembly weldment and top plug weldment, respectively. The insulation has a maximum continuous service temperature limit of 871°C (1600°F) due to the presence of the vermiculite and portland cement.

The volume between the most inward liner and the mid-liner is filled with a noncombustible cast neutron-absorber (poison) material from Thermo Electronic Corp. called Cat 277-4. The material is a high alumina borated concrete composed of aluminum, magnesium, calcium, boron, carbon, silicon, sulfur, sodium, iron, and water. The final mixture has an average density of 1681.9 kg/m^3 (105 lb/ft^3). The procedure for manufacturing and documenting the installation of this material, JS-YMN3-801580-A005 (Appendix 1.3.5), is referenced on Drawing M2E801580A002 (Appendix 1.3.7). This neutron-absorber material has a maximum continuous service temperature limit of 150°C (302°F) in order to retain the bound mass of water in the final cured mixture for subcriticality control.

The top plug is fabricated in accordance with Drawing M2E801580A008 with an overall diameter of 36.50 cm (14.37 in.) and a height of 13.41 cm (5.28 in.). The plug's rim, bottom sheet, and top sheet are fabricated from 0.15-cm (16-gauge, 0.0598-in.)–thick Type 304 or 304L stainless-steel sheet per American Society of Mechanical Engineers (ASME) SA-240. Four lifting inserts are welded into the top sheet for loading and unloading operations. Again, the internal volume of the top plug is filled with Kaolite 1600 or Packcrete material.

Three silicone rubber pads complete the drum assembly. One pad is placed on the bottom of the most inward liner to support the containment vessel during transport. Another pad is placed on the top shelf of the mid-liner to support the top plug during transport. The final pad is placed over the top of the containment vessel during transport. The pads are molded to the shapes as defined on Drawing M2E801580A009 (Appendix 1.3.7). The material is silicone rubber with a Shore A durometer reading of 22 ± 5.

2.1.1.2 Containment boundary

The containment vessel's body, lid assembly, and inner O-ring provide the containment boundary (Fig. 1.3). The O-ring material is ethylene propylene diene monomer (EPDM) [see Tables 2.7 and 2.15]. Two methods of fabrication may be used to fabricate the containment vessel body of the ES-3100 package as shown on Drawing M2E801580A012 (Appendix 1.3.7). The first method uses a standard 5-in., schedule 40 stainless-steel pipe per ASME SA-312 Type TP304L, a machined flat-head bottom forging per ASME SA-182, Type F304L, and a machined top flange forging per ASME SA-182, Type F304L. The nominal outside diameter of the 5-in. schedule 40 pipe is machined to match the nominal wall thickness of 0.100 in. Each of these pieces is joined with circumferential welds as shown on Sheet 2 of Drawing M2E801580A012 (Appendix 1.3.7). The top flange is machined to match the schedule 5-in. pipe, to provide two concentric half-dovetailed O-ring grooves in the flat face, to provide locations for two 18-8 stainless-steel dowel pins, and to provide the threaded portion for closure using the lid assembly. The second method of fabrication uses flow forming to create the complete body (flat bottom, cylindrical body, and flange) from a single forged billet or bar with final material properties in accordance with ASME SA-182, Type F304L. The top flange area using this fabrication technique is machined identically to that of the welded forging method. The lid assembly, which completes the containment boundary structure, consists of a sealing lid, closure nut, and external retaining ring (Drawing M2E801580A014, Appendix 1.3.7). The containment vessel sealing lid (Drawing M2E801580A015, Appendix 1.3.7) is machined from Type 304 stainless-steel bar with final material properties in accordance with ASME SA-479. The containment vessel closure nut (Drawing M2E801580A016, Appendix 1.3.7) is machined from a Nitronic 60 stainless-steel bar with material properties in accordance with ASME SA-479. These two components are held together using an external retaining ring made from Type 302 stainless steel. A weld is used to seal around a plug that is inserted inside the hole used for machining the pathway for leak testing between the O-rings. Since this plug and weld are outside the containment boundary, the weld is not important to safety. However, it is important to operation because its sealing capability is needed to properly conduct the preshipment leak test. This weld is addressed in Paragraph 3.4 of the containment vessel equipment specification

(JS-YMN3-801580-A001, Appendix 1.3.3). In this specification, the weld is inspected visually and using dye penetrant. The requirements of Subsections NB-5110 and NB-5350 of the *ASME Boiler and Pressure Vessel Code* (ASME Code) also apply. The sealing lid is further machined to accept a ⅜-16 swivel hoist ring bolt to facilitate loading and unloading, to provide a leak-check port between the elastomeric O-rings, and notched along the perimeter to engage two dowel pins. The lid assembly, with the O-rings in place on the body, are joined together by torquing the closure nut and sealing lid assembly to 162.70 ± 6.78 N·m (120 ± 5 ft-lb). The sealing lid portion of the assembly is restrained from rotating during this torquing operation by the two dowel pins installed in the body flange. A leak-check port is located between the O-rings in the containment vessel to facilitate a pressure rise or drop leakage test following assembly or 10 CFR 71 compliance testing. This port is sealed during transport using a modified VCO threaded plug. Only the inner O-ring is considered a part of the containment boundary.

There are no penetrations of, connections to, or fittings for the sealed containment boundary. To meet the requirements for package certification, the containment boundary must remain intact during all conditions of transport. This integrity must be demonstrated by test or other acceptable methodology for NCT and HAC as described in 10 CFR 71.

2.1.1.3 Packaging materials

Contents may be packed in four ways: first, various size convenience cans made of stainless steel, tin-plated carbon steel, aluminum, or nickel-alloy, and polyethylene bottles or Teflon FEP bottles may be used (including bottles inside metal cans); second, contents that cannot be packaged in the proposed cans due to the contents' overall dimensions, such as the unirradiated research reactor fuel elements, will be bundled together and protected on each end with an open-ended can (Fig. 1.4); third, solid form contents that will not fit in a convenience can may be bagged only with no convenience can required around content (however, usage of convenience can is allowed); fourth, glass bottles with enriched uranium oxide (UO_2-Mg) will be packed inside a sealed and inerted container and treated as pyrophoric contents.

The convenience cans shall have a diameter of ≤ 12.7 cm (5 in.) and a height of ≤ 76.2 cm (30 in.). Any combination of these cans shall be allowed in a single package, as long as the total length of the can stack (with spacers and pads as required) does not exceed the inside working height of the containment vessel (~31 in.). Any closure on the convenience can is allowed. Multiple short cans may be brazed together. Containment vessel arrangements that utilize closed metal cans with diameters >10.8 cm (4.25 in.) will provide for at least 55 $in.^3$ of free or void volume for gas expansion and offgassing of material at temperatures associated with NCT or HAC. The polyethylene bottles have a diameter of ~12.54 cm (4.94 in.) and a height of ~22.1 cm (8.7 in.). A total of three polyethylene bottles may be loaded into the containment vessel. The Teflon FEP bottles have a diameter of ~11.91 cm (4.69 in.) and a height of ~23.88 cm (9.4 in.). A total of three Teflon FEP bottles may be loaded into the containment vessel. Polyethylene, nylon, or Teflon bags may be used inside or outside any convenience can or bottle. In some packing arrangements, silicone rubber pads may be used between convenience cans. Also, some arrangements will require can spacers between cans (see Table 1.3). These spacers are thin stainless-steel cans filled with the noncombustible cast neutron poison. Each convenience can and spacer is equipped with a stainless-steel band clamp and nylon coated wire for loading and unloading operations. The spacers are ~10.49 cm (4.13 in.) in diameter by 4.45 cm (1.75 in.) in height and have a maximum weight of ~0.71 kg (1.56 lb). In order to minimize displacement of convenience containers during transport, stainless-steel scrubbers or polyethylene, nylon, or Teflon bags may be added on the top or bottom of the last can or bottle in the containment vessel.

When bundling fuel elements, stainless-steel metal scrubbers will be placed on the top and bottom of this partially canned assembly, or an empty convenience can will be placed on the top or bottom of this assembly inside the containment vessel.

If partial loading configurations are employed and empty cans or bottles are used, these empty cans or bottles will require a minimum 0.32-cm (⅛-in.)–diam hole to be placed through the lid.

2.1.2 Design Criteria

The ES-3100 packaging/content combination addressed in this safety analysis report for packaging (SARP) is intended to ship contents with a maximum activity of 7.2554×10^{-1} TBq (19.6092 Ci) at 10 years from initial fabrication; the maximum number of A_2s carried is 4.7528×10^{3} at 70 years following initial fabrication (Table 4.4). Based on the guidance from U.S. Nuclear Regulatory Commission (NRC) Regulatory Guide 7.11, *Fracture Toughness Criteria of Base Material for Ferritic Steel Shipping Cask Containment Vessels with a Maximum Wall Thickness of 4 Inches (0.1 m)*, this package is classified in NUREG-1609 (Table 1.1) and Table 2.2 as a Category I shipping package. Therefore, the containment vessel is designed (using nominal dimensions for each component), fabricated, and inspected in accordance with the ASME Code, Sect. III, Div. 1, Subsection NB. The design and subsequent verification comply with the requirements of 10 CFR 71. The structural requirements for the packaging under NCT are addressed in Sect. 2.6. The structural requirements for the packaging under HAC are addressed in Sect. 2.7.

Table 2.2. Category designations for Type B packages

Contents form	Category I	Category II	Category III
Normal form	>3000 A_2 or >1.11 PBq (30,000 Ci)	Between 3000 A_2 and 30 A_2, and not >1.11 PBq (30,000 Ci)	<30 A_2 and <1.11 PBq (30,000 Ci)

The drum assembly of the shipping package is defined as the structure that maintains the position of and provides protection to the impact barrier, thermal barrier, and neutron poison surrounding the containment vessel. Because the location of the containment vessel in the packaging is stable, the shielding and subcriticality effectiveness of the package is not reduced. The drum assembly for the ES-3100 consists of an internally flanged Type 304 or 304L stainless-steel 30-gal modified drum with two Type 304 or 304L stainless-steel inner liners, one filled with noncombustible cast refractory insulation and impact limiter and one filled with noncombustible cast neutron absorber; a stainless-steel top plug with cast refractory insulation, silicone rubber pads, silicon bronze hex-head nuts, and a stainless-steel lid and bottom (Drawing M2E801580A001, Appendix 1.3.7). The drum assembly is maintained when there are no breaches in the drum surface, the lid remains attached, the relative position of the containment vessel is not altered significantly, and no substantial amount of insulation is exposed following testing stipulated in 10 CFR 71.71 and 73. The drum assembly's design requirements for compliance testing are as follows:

1. The drum lid shall remain attached to the drum under all loading conditions.
2. No opening in the drum shall occur large enough to pass a 10-cm cube [10 CFR 71.43(a)].
3. The outer drum's effective diameter shall exceed requirements to maintain subcriticality and shielding effectiveness.
4. The drum assembly shall provide the structural and thermal protection needed to ensure the containment vessel meets the test leakage criteria for both NCT and HAC of $\leq 1.0 \times 10^{-7}$ ref-cm^3/s.
5. Neutron poison remains in place and retains the amount of water needed to maintain subcriticality.

In accordance with NUREG/CR-3854, Part 4.2 for a Category I shipping package, an acceptable specification for a drum used in any of the component safety groups is U.S. Department of Transportation (DOT) Specification 17C or better. It should be noted that the Specification 17C package is no longer included in the DOT regulations (49 CFR 178). The drum used in the ES-3100 is fabricated in accordance with the dimensional requirements of MS27683 and modified as shown on Drawing M2E801580A004 (Appendix 1.3.7). The fabrication requirements for the ES-3100 drum assembly are shown in JS-YMN3-801580-A002 (Appendix 1.3.2). Material, fabrication, and quality control criteria are generally equivalent to those imposed for a DOT Specification 17C drum. The drum weld seam is pressure tested to 68.95 kPa (10 psi) gauge in accordance with MIL-D-6054F. As discussed in Sect. 1.2.1.1, the drum used for the ES-3100 is equivalent to or better than that stipulated by NUREG/CR-3854 for a Category I shipping package. In accordance with DOE, a performance-based package is an approved, quality-controlled, hazardous material container that has been tested or analyzed to demonstrate its ability to maintain confinement and/or containment of its contents under both normal use and credible accident conditions as stipulated in 10 CFR 71. The drum assembly and containment vessel have been maintained for the ES-3100 shipping package as demonstrated by test results documented in the test report (ORNL/NTRC-013) and the analytical comparisons discussed in Sects. 2.6 and 2.7.

The codes and standards used for design, analysis, and fabrication of the containment vessel's components are satisfied by complying with the appropriate paragraphs in Sect. III, Div. 1, Subsection NB, and Sect. IX of the ASME Code. Nominal dimensions, not minimum dimensions, were used in the design analysis of the containment vessel components. Though not explicitly expressed, the load combinations and tests stated in NRC Regulatory Guide 7.8, *Load Combinations for the Structural Analysis of Shipping Casks*, are used in the structural evaluation of the containment vessel for both NCT and HAC as depicted in Table 2.3. Acceptance criteria for the containment vessel stresses are shown in Table 2.4 and locations are depicted in Fig. 2.1.

The design internal pressure of 699.82 kPa (101.5 psi) gauge for the containment vessel was determined based on its stress capability before the ASME Code evaluations shown in DAC M900000-0002 and DAC-M900000-0003 were started. The containment vessel is tested with an internal pressure of 1034.21 kPa (150 psi) gauge or 1.48 times the design pressure, which exceeds the requirement stipulated in Sect. III, Paragraph NB-6221 (a minimum hydrostatic test pressure of 1.25 times the design pressure) and the regulatory requirement of 10 CFR 71.85(b) (1.5 times the maximum normal operating pressure). As shown in Table 2.6, the containment vessel design stresses are well below the allowable stresses (see Fig. 2.1 for stress locations). Therefore, this ES-3100 containment vessel is capable of shipping at a higher internal pressure. The external pressure requirement from 10 CFR 71.73(c)(6) is 150 kPa (21.7 psi) gauge. These design and operating pressures were used to calculate the stresses (DAC-M900000-0002 and DAC-M900000-0003) in all components of the containment vessel, which are well below the allowable limits at all operating conditions. The maximum normal operating pressure calculated for NCT in accordance with 10 CFR 71.4 and 10 CFR 71.71(c)(1) for the bounding load case is 210.29 kPa (30.50 psia). For conservatism and for use in subsequent analyses in Sects. 2 and 4 during NCT, the maximum gas temperature and the maximum normal operating pressure in the containment vessel are rounded up to 90°C (194°F) and 210.29 kPa (30.50 psia), respectively. The maximum internal gauge pressure calculated for NCT is 185.29 kPa (26.87 psi), which is the maximum normal operating pressure minus the reduced external pressure condition of 10 CFR 71.71(c)(3) [210.29−25.00 kPa] (Sect. 2.6.3). A summary of the package's design, NCT, and HAC pressures and temperatures is presented in Appendices 3.5.1 and 3.5.2. Allowable stress intensity limits and calculated stresses at the design evaluation conditions for the containment vessel are summarized in Tables 2.4–2.6. The stresses used in the design of all metal containment vessel components are in the elastic range of the material properties. For conditions addressed by analysis, the margin of safety (M.S.) is calculated and defined as:

$$\text{Margin of Safety} = \text{Allowable Stress} / \text{Actual Stress} - 1.$$

Table 2.3. Summary of load combinations for normal and hypothetical accident conditions of transport

Normal or accident condition	Applicable initial condition								Fabrication stresses	SARP reference

Closure nut thread load, kg (lb)	1.696×10^3 (3740)	20	9.072×10^2 (2000) [d]	37	3.353×10^4 (73,911) [g]

[a] Stresses are calculated using pressures, gasket and closure nut preload, and nominal dimensions for all containment vessel components (DAC-M900000-0003). Calculated stresses for external pressure were determined by multiplying the stress at the design conditions by a factor equal to the ratio of external pressure to design pressure plus the contribution from preload. Allowable stress values are taken from Table 2.5 up to 176.7°C (350°F).

[b] Margin of safety = allowable stress/actual stress.

[c] Stress interpreted as the sum of $P_l + P_b$; allowable stress intensity value is $1.5 \times S_m$.

[d] Stress and shear load in these areas is dominated by the 162.7 ± 6.8 N·m (120 ± 5 ft-lb) preload. Pressure ignored.

[e] Stress interpreted as the primary membrane stress (P_m); allowable stress intensity value is S_m.

[f] Allowable external pressure [kPa (psi)].

[g] Allowable shear capacity is defined as $0.6 \times S_m \times$ thread shear area for the body material. Thread shear area = 38.026 cm^2 (5.894 $in.^2$). Allowable shear capacity is defined as $1.2 \times S_m \times$ thread shear area for the closure nut material.

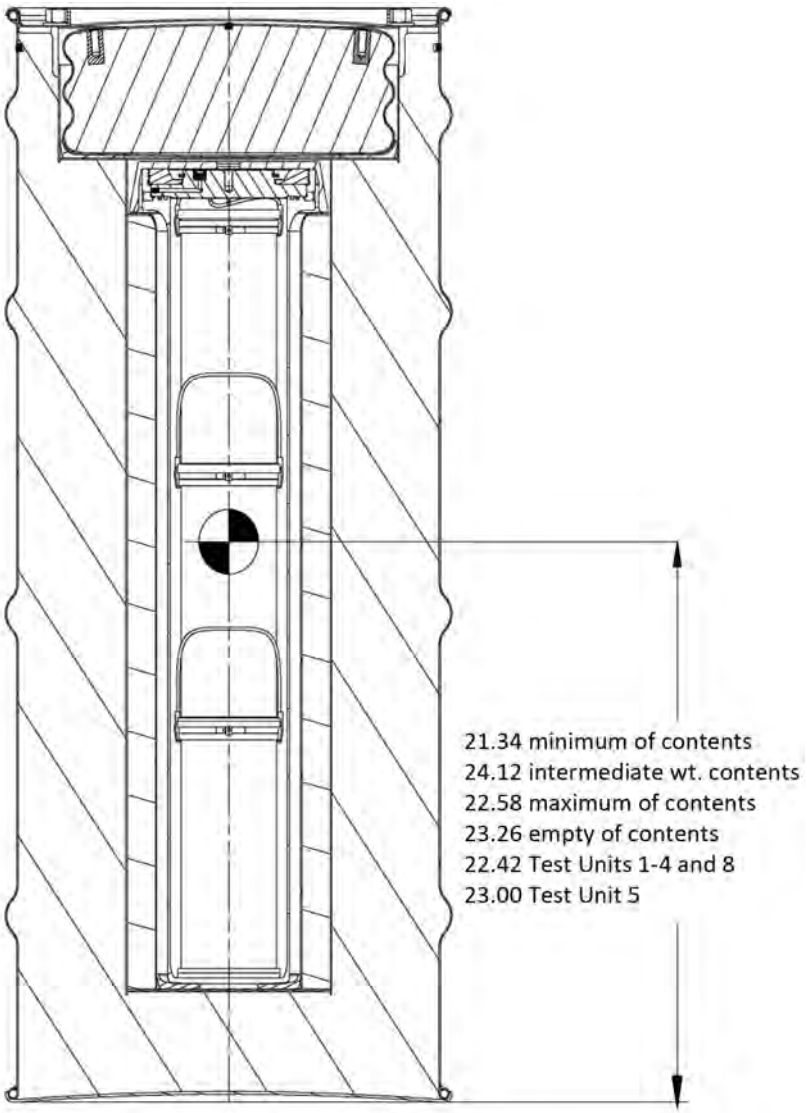
In NRC Regulatory Guide 7.11, below Table 1, the following quote is found: "Although NUREG/CR-1815 (Ref. 2) addresses the use of ferritic steels only, it does not preclude the use of austenitic stainless steels. Since austenitic stainless steels are not susceptible to brittle failure at temperatures encountered in transport, their use in containment vessels is acceptable to the staff and no tests are needed to demonstrate resistance to brittle failure." According to NRC Regulatory Guide 7.11, because the containment vessel is manufactured from Type 304L stainless steel (which is an austenitic stainless steel), "no tests are needed to demonstrate resistance to brittle failure." Therefore, brittle or fatigue failures are not anticipated under any design, transport, accident, or storage condition (Sects. 2.6 and 2.7). Material specifications for the ES-3100 packaging components are listed in Table 2.7.

Table 2.7. ES-3100 packaging material specifications

Component	Specifications
	Drum assembly
Drum washers	1.375 OD × 0.812 ID × 0.25 in. thick, 300 Series stainless steel
Drum threaded weld studs	5/8-11 × 7/8 long, ARC FT, Type 304 or 304L stainless-steel studs
Drum hex nuts	⅝-11 UNC-2B, silicon bronze C65100
Drum lid weldment	Modified 30-gal, 16-gauge (MS27683) lid, Type 304 or 304L stainless steel; and an 11-gauge-thick sheet, Type 304 or 304L stainless steel, ASME SA-240
Drum weldment	Modified 30-gal, 16-gauge (MS27683), Type 304 or 304L stainless steel, ASME SA-240, manufactured per Drawing M2E801580A004 (Appendix 1.3.7)
Drum plugs	Nylon plastic plug, Micro Plastic, Inc.
	Impact limiter, insulation enclosure, neutron absorber, and drum packing material
Insulation and impact limiter (not removable)	Lightweight cast refractory insulation, Kaolite 1600 or Packcrete, 358.8 ± 48.1 kg/m^3 (22.4 ± 3 lb/ft^3) density, cast in stainless-steel shells in the drum and top plug
Neutron absorber	Cat 277-4, 1681.9 + 240.3/−80.1 kg/m^3 (105 + 15/−5 lb/ft^3) density
Top plug (removable)	Type 304 or 304L stainless steel, ASME SA-240 (body), ASME SA-479 (lifting inserts)
Inner liners	Type 304 or 304L stainless steel, ASME SA-240 (body), ASME SA-479 (modified angle)
Silicone pads	Silicone rubber, 22 ± 5 Shore A, color black/gray
Aluminum foil duct tape	McMaster Carr Part # 7616A21, temperature range −40 to 121°C (−40 to 250°F)
	Containment vessel
Containment vessel plug	Part # 04-2126, Modified VCO threaded plug with O-ring, brass
Containment vessel hoist ring	3052T56, Swivel hoist ring, alloy steel (not used for shipment)
Containment vessel	Method 1: Type TP304L stainless steel ASME SA-312 (seamless pipe body); Type F304L, stainless steel, ASME SA-182 (flange and end cap); Type 304, stainless steel, ASME SA-479 (sealing lid), Nitronic 60 stainless steel per ASME SA-479, UNS-S21800 (closure nut) Method 2: Type F304L stainless-steel ASME SA-182 (body, flange, and end cap); Type 304, stainless steel, ASME SA-479 (sealing lid), Nitronic 60 stainless steel per ASME SA-479, UNS-S21800 (closure nut) All components per *ASME Boiler and Pressure Vessel Code*, Sect. II, Part D, Table 2A

Table 2.7. ES-3100 packaging material specifications

Component	Specifications
Containment vessel O-rings	Elastomer, ethylene propylene diene monomer, Specification M3BA712A14B13F17 in ASTM D 2000 per SPC M801580-0002 (Appendix 1.3.9)
Containment vessel lid assembly retaining ring	Smalley Steel Ring Co., Part #WSM-400-S02, Type 302 stainless steel
Containment vessel O-ring lubricant	Clear dimethyl siloxane polymer
Containment vessel closure nut lubricant	Krytox #240AC
Containment vessel body dowel pins	0.2501/0.2503-in. OD × 0.50-in. long, 18-8 stainless steel
	Containment vessel packing material
Convenience cans	Stainless steel, aluminum, or tinned carbon steel with stainless-steel can handles and nylon-coated stainless-steel wire; nickel-alloy (200 series, passivated) in nylon mesh bag
Convenience bottles	Polyethylene, glass, or Teflon FEP
Silicone rubber pads	Silicone rubber, 22 ± 5 Shore A, color black/gray
Can spacers	Stainless-steel can filled with Cat 277-4
Bagging	Polyethylene, nylon, and Teflon
Metal scouring scrubbers	Stainless steel, McMaster Carr Part #7361T13



2.1.3 Weights and Centers of Gravity

The weights of the packaging components for the actual proposed contents ready for shipment and the test units are provided in Tables 2.8 and 2.9. The values listed for the test weights are the actual data recorded during compliance testing. The remaining weights listed for the shipping package are calculated weights. Nominal dimensions and densities were used in the calculations. Miscellaneous parts (nuts and washers) are included.

The range of the centers of gravity for the ES-3100 shipping package with the various HEU arrangements and the test packages is shown in Fig. 2.2. A summary of the calculations is provided in Table 2.10.

2.1.4 Identification of Codes and Standards for Package Design

Based on the discussion in Sect. 2.1.2, the shipping package has been designed and analyzed and will be fabricated, tested and maintained to the requirements of a Category I package. In accordance with the references from NUREG/CR-1815, Table 2.11 describes the appropriate codes and standards that are and will be used to comply with Category I packaging. These requirements have been extracted from NUREG/CR-3854 and NUREG/CR-3019.

Note: Dimensions are in inches.

Fig. 2.2. ES-3100 shipping package center of gravity locations.

Table 2.8. Packaging weights for various ES-3100 shipping package arrangements

Item [a, b]	Three 10-in. tall can configuration [kg (lb)] [c, d]	Six 4.875-in. tall can configuration [kg (lb)]	Five 4.875-in. tall can configuration [kg (lb)]	Six 4.75-in. tall can configuration [kg (lb)]	Three 8.75-in. tall can configuration [kg (lb)] [e]	Three 8.7-in. tall bottle configuration [kg (lb)]	Three 9.4-in. tall bottle configuration [kg (lb)]	Empty containment vessel configuration [kg (lb)]	ES-3100 with maximum weight contents [kg (lb)]

[a] Calculated weight using Pro/ENGINEER software with nominal dimensions and densities.
[b] Shipping weight increases by ~2.5 lb if a radio-frequency identification tag is included.
[c] The weight of this configuration bounds the weight of the bundled fuel rods, tubes, or plates with open-ended cans on either end.
[d] The weight of this configuration bounds the weight of the three 25.4-cm (10-in.)–high cans brazed together containing fuel rods, tubes, or plates.
[e] The weight of this configuration bounds the weight of the two 22.2-cm (8.75-in.)–high cans that are brazed together containing the TRIGA fuel elements.
[f] Weight excluding tamper indicating device.

Table 2.9. Compliance test unit weights

Item	Test Unit [a] [kg (lb)]						
	1	**2**	**3**	**4**	**5**	**6**	**8**
Drum body assembly [b]	126.6 (279)	127.9 (282)	127.9 (282)	127.9 (282)	128.8 (284)	--	128.4 (283)
Top plug	9.5 (21)	9.5 (21)	9.53 (21)	8.6 (19)	9.5 (21)	--	10.9 (24)
Drum silicone support pads	0.9 (2)	0.9 (2)	0.9 (2)	0.5 (1)	0.9 (2)	--	1.3 (2.8)
Containment vessel [c]	15.4 (34)	15.0 (33)	15.0 (33)	14.5 (32)	15.0 (33)	15.0 (33)	14.5 (32)
Mock-up test contents [d]	49.9 (110)	49.9 (110)	50.3 (111)	49.9 (110)	3.6 (8)		49.9 (110)
Contents						6.3 (14) [e]	
Total test unit weight	**202.3 (446)**	**202.8 (447)**	**203.7 (449)**	**201.8 (445)**	**157.4 (347)**	**21.3 (47)**	**204.6 (451)**

[a] Total weight may be different from sum of individual component weights due to scale tolerance of ±0.45 kg (1 lb).
[b] This weight includes the drum, mid liner, inner liner, cast refractory, cast neutron absorber, bottom, lid, washers and nuts.
[c] This weight includes containment vessel cylindrical body, end cap, flanged top, and lid assembly.
[d] This weight includes convenience cans, silicone rubber pads, can handles, spacers (if required), and HEU mockup.
[e] This weight was added to reduce buoyancy of containment vessel during 15-m (50-ft) immersion test.

2.2 MATERIALS

2.2.1 Material Properties and Specifications

The mechanical properties and specifications of the packaging materials are presented in Tables 2.12–2.17. See the drawings in Appendix 1.3.7 for details of all components. Design temperature ranges are listed where they are required to establish the allowable stresses used in the design calculations for the containment vessel (DAC-M900000-0002 and DAC-M900000-0003). Service temperature ranges for the remaining shipping container components were obtained from the references shown in Tables 2.12–2.17.

Kaolite 1600 property values are presented in Table 2.14, and additional Kaolite property and source information is presented in the Kaolite material safety data sheet, ORNL-TM-2003/49, Y/DW-1890, Y/LF-565, and the e-mail communication from Moody to Bales (Moody 2004). Packcrete material properties are presented in RP 802282-0002. ORNL/TM-2004/290, Y/DW-1987, Y/DZ-2585, COR-NDA-04-93, and Y/DV-1914 contain the Cat 277-4 property and source information. Y/DW-1968 contains detailed technical data on strength and thermal expansion of BoroBond4. (BoroBond4 was used in the prototype test units, but it is not used in the package to be certified.)

2.2.2 Chemical, Galvanic, or Other Reactions

A package must be of materials and construction to ensure that there will be no significant chemical, galvanic, or other reaction among the packaging components, among package contents, or between the packaging components and the package contents, including a possible reaction resulting from inleakage of water, to the maximum credible extent. Account must be taken for the behavior of materials under irradiation.

Table 2.10. Calculated center of gravity for the various ES-3100 shipping arrangements

Content description	Distance from drum's bottom (in.)
Cylinders, bars, slugs, broken metal—35,200 g (77.60 lb) maximum—no can spacers	
3 full 4.88-in. cans + 3 empty 4.88-in. cans	21.139
2 full 4.88-in. cans + 4 empty 4.88-in. cans	21.405
1 full 4.88-in. can + 5 empty 4.88-in. cans	22.066
3 full 10-in. cans	22.071
2 full 10-in. cans + 1 empty 10-in. can	21.762
1 full 10-in. can + 2 empty 10-in. cans	22.075
3 full 8.75-in. cans	21.875
2 full 8.75-in. cans + 1 empty 8.75-in. can	21.662
1 full 8.75-in. can + 2 empty 8.75-in. cans	22.060
Cylinders, bars, slugs, broken metal—35,200 g (77.60 lb) maximum—with can spacers	
3 full 8.75-in. cans + 2 spacers	22.245
2 full 8.75-in. cans + 1 empty 8.75-in. can + 2 spacers	21.802
1 full 8.75-in. can + 2 empty 8.75-in. cans + 2 spacers	22.072
3 full 4.88-in. cans + 2 empty 4.88-in. cans + 3 spacers	21.471
2 full 4.88-in. cans + 3 empty 4.88-in. cans + 3 spacers	21.500
1 full 4.88-in. can + 4 empty 4.88-in. cans + 3 spacers	22.028
UNX crystals 24,000 g (52.91 lb) maximum—with no spacers	
3 full 8.94-in.–high Teflon FEP bottles + bagging	22.674
2 full 8.94-in.–high Teflon FEP bottles + 1 empty 8.94-in.–high Teflon FEP bottle + bagging	22.383
1 full 8.94-in.–high Teflon FEP bottle + 2 empty 8.94-in.–high Teflon FEP bottles + bagging	22.543
Oxide—24,000 g (52.91 lb) maximum—with no spacers	
6 full 4.75-in.–high nickel cans + bagging	22.631
5 full 4.75-in.–high nickel cans + 1 empty 4.75-in.–high nickel can + bagging	22.434
4 full 4.75-in.–high nickel cans + 2 empty 4.75-in.–high nickel cans + bagging	22.343
3 full 4.75-in.–high nickel cans + 3 empty 4.75-in.–high nickel cans + bagging	22.366
2 full 4.75-in.–high nickel cans + 4 empty 4.75-in.–high nickel cans + bagging	22.511
1 full 4.75-in.–high nickel can + 5 empty 4.75-in.–high nickel cans + bagging	22.787
Oxide—24,000 g (52.91 lb) maximum—with no spacers	
3 full 8.7-in.–high polyethylene bottles + bagging	22.372
2 full 8.7-in.–high polyethylene bottles + 1 empty 8.7-in.–high polyethylene bottle + bagging	22.210
1 full 8.7-in.–high polyethylene bottle + 2 empty 8.7-in.–high polyethylene bottles + bagging	22.480

Table 2.11. Applicable codes and standards for Category I packaging

	Containment *ASME Boiler and Pressure Vessel Code*, Sect. III, Subsection NB	Criticality [a]
Materials		Cat 277-4 [a]
Base materials	NB-2000 (except NB-2300) and NB-4100	
Welding materials	NB-2400	
Fabrication		
Forming, fitting, aligning, and joint preparation	NB-4200	
Welding	NB-4400	
Qualification of procedures and personnel	NB-4300	
Examination	NB-5000	[b]
Acceptance testing	NB-6000	[c]
Quality assurance	Subpart H in Title 10, CFR, Part 71	

[a] NUREG/CR-3854 states, "The designer may specify a neutron-absorber material by a commercial trade name or as a mixture of elements or common compounds. When appropriate, qualification data should be included to demonstrate that the material functions as specified. When special absorber materials are used to control criticality, an acceptance test should be performed for each container to ensure that the absorber material has been properly installed."

[b] NUREG/CR-3854 states, "Packages designed to transport fissile material which contain neutron-absorber material should be tested to demonstrate the presence of the neutron-absorber material. The test description should include information similar to that requested for gamma shield testing 3.2.1. Fabrication records of the absorber material and its installation and testing should be maintained."

[c] NUREG/CR-3854 states, "Gamma scanning or probing may be used to demonstrate the soundness of the neutron absorber. Alternatively, ultrasonic testing may be used. Whatever method is used, the following information should be provided in the test procedure:

(1) Description of the measuring technique including the electronics;
(2) The source type and strength used to measure the neutron absorber effectiveness;
(3) The standards and methods used to calibrate the source, sensors, and other pertinent equipment;
(4) The grid pattern used to check the neutron absorber;
(5) The type of gamma sensor used to measure the neutron absorber effectiveness;
(6) The specific test requirements and measurements;
(7) The acceptance criteria."

Analysis. Starting with the outer components, the packaging consists of the drum (austenitic Type 304 stainless steel), weld studs (austenitic stainless steel), nuts (silicon bronze), insulation (cast refractory), neutron absorber (Cat 277-4), silicone support pads, containment vessel (austenitic Type 304L stainless steel), closure nut (Nitronic 60), silicone support pads, can spacers (stainless steel and Cat 277-4), stainless-steel scrubbers, convenience cans (stainless steel, tin-plated carbon steel, aluminum, or nickel-alloy [series 200, passivated]), polyethylene or Teflon FEP bottles, glass bottles inside convenience can, polyethylene, nylon, or Teflon bags, and the HEU contents.

The cast refractory insulation (Kaolite 1600 – original design) is contained between the drum and mid-liner and within the top plug assembly's stainless-steel sheet metal. Due to the alkaline nature of this material, greater permanence of the surrounding structure is assured. Also, this material has been used successfully for years as an insulation heat treatment liner adjacent to metal surfaces of furnaces. Since the Packcrete cast refractory insulation is fabricated from the same base materials as Kaolite 1600 and is located in the same locations, the same nonreactive condition with metals is expected.

The cast neutron absorber (Cat 277-4) is contained between the most inward liner and mid-liner. During the casting process, the chlorine content is limited to 100 parts per million. The small quantity of chlorine will not affect the stainless-steel liners.

The nuts used to attach the drum to the lid are silicon bronze. All other metal components of the packaging are stainless steel, Nitronic 60, or tinned steel. All stainless-steel components are passivated per ASTM A 380, Paragraph 6.4, and Table A2.1, Part II. Prior to assembly, the packaging will be kept inside a building or transported between buildings in an enclosed truck. The assembled components are protected from the weather and inspected at the time of packaging; therefore, the package will not contain any free water (other than absorbed water in the encapsulated Kaolite or Packcrete) at the time it

is loaded for transport. Under NCT, the only moisture present will be the relative humidity or moisture absorbed by the cast refractory or neutron-absorber materials. When the package is subjected to a water-spray type environment, some water may leak into the cavity formed by the inner liner and occupied by the containment vessel. To minimize the possibility of any potentially corrosive situation, a visual examination of the interior surface of the inner liner and the exterior surface of the containment vessel shall be conducted prior to packing and following transport of the shipping package (see Chap. 7). Any free water present and any corrosion discovered shall be promptly removed.

The ES-3100 containment vessel is fabricated from ASME SA-182, Type 304L stainless steel that is solution annealed and quenched, cleaned, and passivated (JS-YMN3-801580-A001, Appendix 1.3.3). This low carbon (<0.03 wt % carbon) grade of austenitic stainless steel is more resistant to the precipitation of chromium carbide precipitation along the grain boundaries, due to its low carbon content. The solution anneal relieves residual stresses resulting from the method of fabrication and it ensures that the alloy is not susceptible to intergranular corrosion as demonstrated by testing in accordance with ASTM A 262. Cleaning and passivation treatments in accordance with ASTM A 380 enhance the thin, chromium-oxide film that forms on the alloy surface. During content loading operations (Sect. 7.1.1.2) and periodic maintenance (Sect. 8.2.5.2) the interior and exterior surfaces of the containment vessel are routinely inspected for signs of moisture, corrosion, and physical damage.

During immersion under HAC, water can enter the holes at the top of the drum, be absorbed into the cast refractory material, and fill all void spaces within the drum and inner liner. The insulating value of the insulation material may be decreased, and an overall weight increase would occur. The most important consideration is that the containment boundary remain intact and leaktight. This situation has been evaluated by completely immersing the containment vessel in a tank simulating 0.9- and 15-m (3- and 50-ft) immersion depths. The containment vessel remained intact and water tight, as demonstrated by the analysis and testing discussed in Sect. 2.7.

Physical contact between the convenience cans and the containment vessel wall, bottom, or top is minimized when the silicone support pads are used. The polyethylene or Teflon FEP bottles may be in contact with the stainless steel of the containment vessel, but will not react. During normal shipping operations, the cans and bottles will provide separation of the HEU contents from the containment vessel walls. The contents that cannot be packaged in the proposed cans due to the contents' overall dimensions, such as the unirradiated research reactor fuel elements, will be bundled together and protected on each end with an open-ended can (Fig. 1.4). When space is available inside the containment vessel, stainless-steel metal scrubbers will be placed on the top and bottom of this partially canned assembly, or an empty convenience can will be placed on the top or bottom of this assembly inside the containment vessel. Some solid form content may only be packed inside polyethylene, nylon, or Teflon bagging only. The bagging will prevent the uranium material from contacting the stainless-steel containment vessel. Stainless-steel metal scrubbers may be placed on the top and bottom of this assembly. Additionally, glass bottles with enriched uranium oxide (UO_2-Mg) will be packed inside sealed and inerted containers and treated as a pyrophoric content. The passivated nickel-alloy cans are galvanically similar to the stainless steel of the containment vessel and thus will not react. Aluminum clad components, alloys, and convenience cans oxidize quickly when exposed to moisture in the air. Therefore, there will not be any galvanic reaction between the aluminum and the containment vessel materials. Additionally, polyethylene, nylon, or Teflon bagging may be used around the convenience container as required by packaging personnel (in some cases the HEU is bagged inside the convenience container). Therefore, galvanic corrosion between the containment vessel wall and convenience containers or contents is highly unlikely. In addition, with the exception of UNX crystals, the environment inside the containment vessel is free of electrolytic solutions, further ensuring that there will be no galvanic reactions occurring inside the containment vessel.

For pyrophoric considerations, broken metal and alloy pieces shall be of a size that: (a) the specific surface area does not exceed 1 cm^2/g, or (b) will not pass freely through a mesh size of ⅜ in. (9.53 mm). Incidental small particles which do not pass the size restriction tests, and powders, foils, turnings, and wires may only be shipped if they are in a sealed, inerted container. Enriched uranium oxide in glass bottles (UO_2-Mg) will be shipped in a sealed, inerted container.

The material testing documented in Y/DZ-2720 does not identify the composition of the volatiles or gases generated during testing. Since Teflon FEP, a fluorine-containing polymer, is used to transport uranyl nitrate crystals and one of the uranium compounds is uranium tetrafluoride (UF_4), the possible development of a corrosive environment inside the containment vessel is investigated. Based on the following literature, FEP is notable among polymers for its high thermal stability. It decomposes at temperatures above ~260°C (500°F). In air or in oxygen, FEP decomposes in one way at lower temperatures and in another at higher temperatures. In this discussion, "oxygen" implies oxygen at a pressure of 300 torr. In air, the partial pressure of oxygen is near 150 torr. Below ~525°C, the decomposition of FEP is first order, and the main decomposition product is hexafluoropropylene (C_3F_6), although tetrafluoroethylene (C_2F_4) is a near second in abundance (Leidecker, Teflon thermal decomposition). The carbon-fluorine compound is one of the strongest compounds found in organic chemistry (its dissociation energy is 460 kJ/mol). The carbon chain is nearly completely covered by fluorine atoms and is, therefore, protected against external influences. This results in the exceptionally high chemical resistance of FEP (Daikin America). Based on the preceding statements, it is reasonable to conclude that most, if not all, of the gas coming from any decomposition of the Teflon FEP bottles would be hexafluoropropylene and tetrafluoroethylene rather than fluorine gas. The maximum temperature predicted (NCT or HAC) inside the ES-3100 containment vessel at the location near the Teflon FEP bottles is 198.04°C (388.48°F). This temperature is considerably below the lower limit of the FEP decomposition temperature [260°C (500°F)]. Due to the difference between the decomposition temperature of FEP [260°C (500°F)] and the maximum predicted temperature from testing [198.04°C (388.48°F)], essentially no C_3F_6 or C_2F_4 and no fluorine is expected to form during transport. Uranium tetrafluoride is a solid composed of agglomerating particles with a texture similar to baking soda. It is nonvolatile, nonhydroscopic, and only slightly soluble in water. A corrosive environment with fluorine as the base is not anticipated for either the uranium tetrafluoride compound or the Teflon bottles. It should be noted that the offgassing rate and quantity used for Teflon FEP at lower temperatures in Appendices 3.5.1 and 3.5.2 are very conservative estimates. The actual values shown for the Teflon bottle sample in Y/DZ-2720 may have resulted from the cumulative tolerance in the testing setup and data recording and not from actual offgassing.

Uranyl nitrate crystals are formed by dissolving uranium metal or any of the uranium oxides in nitric acid and the UNX crystalline precipitates are acquired through a variety of extraction, filtration, and purification processes. The UNX crystals are soluble in water, forming a weak nitric acid solution. Anhydrous uranyl nitrate [Formula: $UO_2(NO_3)_2$; molecular weight: 394.0; Chemical Abstract Service (CAS) Registry No. 10102-06-4] dissolves in water and when exposed to moist air it forms a mixture of the uranyl nitrate hydrates. Uranyl nitrate hexahydrate (UNH) [Formula: $UO_2(NO_3)_2 \cdot 6H_2O$; molecular weight: 502.1; CAS Registry No. 13520-83-7] separates out of solutions of uranyl nitrate at room temperature. The formation of uranyl nitrate hydrates in solution can be influenced by the addition of nitric acid. The higher the nitric acid concentration, the less water molecules take part in the hydrate formation (e.g., trihydrates, dihydrates). Thermal decomposition of UNX crystals has been studied in detail in support of nuclear fuel reprocessing. As presented for shipment, the UNX crystals exist as crystalline solids; however, the melting point for UNH, trihydrate, and dihydrate is reported as ~60°C, 113°C, and 184°C, respectively (Marshall 1951). Heating of UNH crystals up to 200°C results in a stepwise release of water molecules of crystallization (Dash 1999 and Kozlova 2007), which in a closed system results in the partial dissolution of the crystals. During transport of UNH crystals, crystalline solids and a saturated solution of uranyl nitrate will coexist at a temperature above ~60°C (MCW-1424). Given that the NCT maximum containment vessel temperature with insolation is 89.60°C (193.28°F) and the HAC maximum predicted temperature inside the containment vessel at the

location near the Teflon bottles is 198.04°C (388.48°F), the uranyl nitrate dihydrate and lower hydrates will remain in a solid phase during transportation. However, the trihydrate and higher hydrate crystals will release water molecules of crystallization upon heating above their melting point, thus converting them into a lower hydrate species, which require a successively higher temperature to release additional water molecules. The melting point for hexahydrate (~60°C) will be exceeded during NCT and HAC, and the melting point for trihydrate (~113°C) crystals will be exceeded during HAC. The solubility of uranyl nitrate is reported in ARH-724 ADD to be 55.9 and 81.1 lb $UO_2(NO_3)_2$ per 100 lb of saturated solution at 77 and 191°F, respectively. Released water molecules will partially dissolve the UNX crystals forming a weak nitric acid solution (<5% HNO_3). Upon cooling, the uranyl nitrate hydrate melt will recrystallize to a solid form.

While the Teflon bottles have proven to be fully capable of containing UNX crystals during normal shipping operations, there has been no effort to qualify these convenience containers under NCT and HAC testing conditions stipulated in 10 CFR 71.71 and 10 CFR 71.73, respectively. Consequently, solid/liquid UNX contents are therefore assumed to be in contact with the containment vessel internals. The general bulk corrosion can be estimated with published corrosion data for Type 304L stainless steel in nitric acid. Conservatively assuming an exposure to 5% nitric acid for 51 weeks at 200°F (NCT) and 1 week at 300°F (HAC) with corrosion rate data from NiDI Technical Series No. 10 075 (corrosion rate ranges of 0.000–0.005 and 0.005–0.020 in. per year at 200°F and 300°F, respectively), the estimated general corrosion would be 0.0001–0.0053 in. per 12-month exposure. However, given the conservative seal times stipulated in Table 1.3a, these corrosion rates would be reduced to 0.0001–0.0020 in. per 4-month exposure and to 0.0001–0.0012 in. per 2-month exposure. For comparison purposes, using corrosion rate data (0.0000–0.0039 and 0.0039–0.0394 in. per year at 212°F and 302°F, respectively) from the Outokumpu Corrosion Handbook, the estimated general corrosion rates would be 0.0001–0.0046 in. per 12-month exposure, 0.0001–0.0021 in. per 4-month exposure, and 0.0001–0.0014 in. per 2-month exposure. The average general corrosion would be 0.0025 in. per 12-month exposure, 0.0011 in. per 4-month exposure, and 0.0007 in. per 2-month exposure. Under the maximum seal time limit authorized (4 months in Table 1.3a), the average corrosion rate of ~0.001 in. or even the maximum corrosion rate of ~0.002 in. would not have a significant impact on the containment vessel integrity. It should be noted that these calculated corrosion rates are conservative given that the nitric acid concentration will progressively decrease during the exposure interval (i.e., as the nitric acid reacts) and that the maximum HAC temperature was imposed for 1 week with the maximum NCT temperature imposed for the remaining balance of the exposure interval.

As opposed to general corrosion in which all parts of the exposed surface corrode at approximately the same rate, pitting corrosion occurs when discrete areas of the alloy undergo localized attack while the bulk material remains virtually unaffected. Pitting corrosion can occur under acidic conditions involving a high concentration of chlorides, aeration, and moderately high temperatures. It can be inhibited by approaches commonly used to reduce corrosion in general: environment, alloy composition and structure, potential, and temperature. Various inorganic chemicals, including nitrates, will inhibit pitting when added to corrosive solutions. Type B and fissile material packages of UNX solutions with free acid are routinely transported in accordance with NRC requirements [e.g., NRC Certificate of Compliance Nos. 9250 and 9291 for the Model No. 5X22 Package and Liqui-Rad (LR) Transport Unit Package, respectively]. UNX crystals have been routinely transported in stainless-steel containment vessels in accordance with NRC requirements [e.g., NRC Certificate of Compliance Nos. 9250 and 9315 for the Model No. 5X22 Package and ES-3100 Package, respectively]. There have been no reported occurrences of pitting corrosion issues related to the transportation of UNX crystals or solutions in these referenced packages. Routine visual inspections of the ES-3100 containment vessel internals during loading and maintenance operations will identify general or pitting corrosion problems before they would present any significant impact on the containment vessel integrity.

The containment boundary remains intact even when the drum and inner liner are filled with water; therefore, the package is acceptable to the maximum credible extent from the standpoint of chemical, galvanic, or other reactions.

2.2.3 Effects of Radiation on Materials

All materials are affected to some extent by ionizing radiation, although low exposure levels do not typically cause appreciable effects (i.e., changes in the physical and mechanical properties). Upon exposure to ionizing radiation, a fraction of the incident energy is dissipated by interactions with the orbital electrons or nuclei of individual atoms. In sufficient quantities, the cumulative effects of these interactions may result in properties that differ from those of the unirradiated material. The radiation effects in a given material are proportional to the dose (amount of radiation absorbed), irrespective of the type of radiation.

The contents of the ES-3100 package are not irradiated, and the calculated total dose rates (Chap. 5) are well below those required to significantly damage any of the package materials by radiolytic interactions. The safety-related packaging components most vulnerable to radiation-induced degradation are the containment vessel EPDM O-rings. According to the *Parker O-Ring Handbook*, practically all elastomers suffer no change of their physical properties at a cumulative dose up to 1×10^6 rad. In addition, select EPDM compounds have been successfully tested at 1×10^7 rad of gamma radiation. Based on the calculated dose rate of 0.5 rad/h (Sect. 5.4.4), the maximum cumulative dose for the containment boundary O-ring location would be $<5 \times 10^3$ and $<1 \times 10^4$ rad for an exposure period of 1 or 2 years, respectively. Since the maximum absorbed dose is well below the 1×10^6 rad threshold, there will be no significant degradation of the O-ring material properties due to irradiation. Also, no significant degradation or activation of the other packaging materials of construction is expected at the calculated total dose rates.

Section 4.5.2.3 of NUREG-1609 requires the applicant to demonstrate that any combustible gases generated in the package during a period of one year do not exceed 5% (by volume) of the free gas volume in any confined region of the package. No credit should be taken for getters, catalysts, or other recombination devices. Appendix 3.5.4 evaluates the various packaging arrangements for the generation of hydrogen gas due to the radiolysis of water vapor, free water, interstitial water, polyethylene, nylon, or Teflon bags, and polyethylene or Teflon bottles. When the content mass and the material composition are limited as shown in Appendix 3.5.4, the combustible gas concentration limit stated in NUREG-1609 is not exceeded. Getters, catalysts, or other recombination devices are not employed in any of the containment vessel packaging arrangements.

2.3 FABRICATION AND EXAMINATION

2.3.1 Fabrication

2.3.1.1 Drum assembly fabrication

The drum assembly is fabricated in accordance with JS-YMN3-801580-A002 (Appendix 1.3.2), JS-YMN3-801580-A003 (Appendix 1.3.4), SPC M801794-0003 (Appendix 1.3.11), SPC M801580-0003 (Appendix 1.3.12) and JS-YMN3-801580-A005 (Appendix 1.3.5). The latter four specifications control the casting of the Kaolite 1600, Packcrete, and Cat 277-4 materials inside the drum liners and the top plug.

The drum assembly and top plug are fabricated according to the design drawings (Appendix 1.3.7), and the portions of the codes, standards, and regulations to the extent described below:

1. *ASME Boiler and Pressure Vessel Code*, Sect. VIII, Div. 1, 2001 ed. with 2002 and 2003 addenda;
2. *ASME Boiler and Pressure Vessel Code*, Sect. II, Parts A and C, 2001 ed. with 2002 and 2003 addenda;
3. *ASME Boiler and Pressure Vessel Code*, Sect. IX, 2001 ed. with 2002 and 2003 addenda;
4. Military Standard MS27683, *Drum, Metal—Shipping and Storage 16 to 80 Gallons*; and
5. ASTM A 380, *Standard Practice for Cleaning, Descaling, and Passivation of Stainless Steel Parts, Equipment, and Systems*.

Detailed dimensional requirements and the materials of construction are called out on the drawings in Appendix 1.3.7. Except for the weld studs, documented certified material test reports (CMTRs) are provided for all materials used in weldments for the fabrication of the drum, including weld filler metal. The CMTRs are traceable to heat numbers and demonstrate compliance with the SA or SFA Series material specifications called out. For all other materials, documented Certificates of Compliance (CoCs) are provided certifying that the materials provided comply with the requirements stated on the drawings and specifications. All welding is done in accordance with welding procedure specifications that are written and performance qualified in accordance with the ASME Code, Sect. IX. All welders are performance qualified to weld using these procedures, and their qualifications are documented in accordance with the ASME Code, Sect. IX. The welding fabrication requirements stated in the ASME Code, Sect. VIII, Div. 1, Paragraphs UW-26–UW-48, are met. All butt welds in rolled sheet, pipe, and angle joints are full penetration butt welds. With the exception of the seam welds in the drum body, all welds shall be done by the gas tungsten arc welding (GTAW), gas metal arc welding (GMAW), plasma arc welding, or a capacitor discharge stud welding process. The weld filler metal used in the fabrication of the drum assembly is procured to comply with the SFA specifications of Sect. II, Part C, of the ASME Code that are stated in the welding procedure specifications. Weld filler metal is traceable to heat numbers, and CMTRs are furnished for each heat of weld wire filler. The control of weld filler permits a weld examiner to be able to determine the heat number of the weld filler used in any weld on the drum assembly. Weld symbols are provided on the drawings, indicating for each weld the type of weld and the dimensions of weld. These weld symbols are interpreted in accordance with AWS A2.4.

2.3.1.2 Containment boundary fabrication

The containment boundary consists of the containment vessel, lid assembly, and inner O-ring. The containment vessel is manufactured in accordance with the applicable requirements in the ASME Code, Sect. III, Div. 1, Subsection NB, for Class 1 Components as described on the drawings in Appendix 1.3.7 and JS-YMN3-801580-A001 (Appendix 1.3.3). The containment vessel is fabricated according to the design drawings and the following codes, standards, and regulations as described in JS-YMN3-801580-A001.

1. *ASME Boiler and Pressure Vessel Code*, Sect. III, Div. 1, Subsections NB and NCA, Class 1 Components, 2001 ed. with 2002 and 2003 addenda;
2. *ASME Boiler and Pressure Vessel Code*, Sect. II, Parts A and C, 2001 ed. with 2002 and 2003 addenda;
3. *ASME Boiler and Pressure Vessel Code*, Sect. IX, 2001 ed. with 2002 and 2003 addenda; and
4. ASTM A 380, *Standard Practice for Cleaning, Descaling, and Passivation of Stainless Steel Parts, Equipment, and Systems*.

Detailed dimensional requirements and the materials of construction are called out on the drawings in Appendix 1.3.7. CMTRs are provided for the materials used to fabricate these components in accordance with NCA-3860 of the ASME Code. The suppliers of these materials will meet the requirements of NCA-3800 of the ASME Code. Such parts are traceable to each containment vessel by means of a serial number. The fabricator maintains control of materials to ensure this traceability. Other metallic materials and the O-ring seals are supplied with CoCs in accordance with NCA-3862(g) and (h) of the ASME Code. The weld filler metal used in the fabrication, and repair welding as permitted, of the containment vessels meets the requirements of ASME Code, Sect. III, Subsection NB, Paragraph NB-2400. It is procured to comply with the SFA specifications of Sect. II, Part C, of the ASME Code that is stated in the fabricator's welding procedure specifications. Weld metal is procured traceable to heat numbers, and CMTRs are furnished for each heat of weld wire filler used. The results of the delta ferrite determination are included in the CMTR for the weld filler metal (see Paragraph NB-2433). There are two containment vessel assemblies shown on Drawing M2E801580A012 (Appendix 1.3.7), Parts M2E801580A012-1 and M2E801580A012-4. Part M2E801580A012-4 is fabricated by welding a forged bottom and forged top flange to a cylindrical shell machined from seamless pipe as shown on the drawing. All welds on the containment vessels are accomplished by either the GTAW or GMAW process, manual or automatic, at the discretion of the fabricator unless specifically called out on the drawings. Backing rings, even if removed after the weld has been made, are not used. As previously stated, weld symbols are provided on the drawings, indicating the type of weld and dimensions of the weld. These weld symbols are interpreted in accordance with AWS A2.4. The forming, fitting, and alignment requirements stated in Paragraph NB-4200 are met in the fabrication of the containment vessels unless more stringent requirements are called out on the design drawings.

The preferred fabrication method for the containment vessel body (Part M2E801580A012-1) is from a single forged billet or bar by any process that meets the requirements stated in JS-YMN3-801580-A001 (Appendix 1.3.3) and shown on the design drawings. The formed, heat treated, and finished machined containment vessel body shall meet the applicable requirements of ASME SA-182 for Grade F304L for a forged component. After final forming, parts are solution annealed and quenched per the requirements of ASME SA-182 for Grade F304L. A certified heat treatment report is provided stating the following information for each furnace charge: the serial numbers of the containment vessel bodies heat treated in the furnace charge, the time and date of the heat treating, the person responsible for the heat treating, the time-temperature profile of the furnace and representative parts of the furnace charge, the quench medium, and all other pertinent details of the heat treating. Such a heat treating report is required for all heat treating, both in-process annealing and final heat treatment.

2.3.2 Examination

2.3.2.1 Examination of the drum assembly fabrication

The drum and top plug assemblies are examined and tested according to the design drawings and the applicable portions of the codes, standards, and regulations described below:

1. *ASME Boiler and Pressure Vessel Code*, Sect. VIII, Div. 1, 2001 ed. with 2002 and 2003 addenda;
2. *ASME Boiler and Pressure Vessel Code*, Sect. V, 2001 ed. with 2002 and 2003 addenda; and
3. SNT-TC-1A-1992, *Recommended Practice for Nondestructive Testing Personnel Qualification and Certification*, American Society for Nondestructive Testing, December 1992.

All welded or weld-repair surfaces shall be visually examined by a qualified weld examiner for indications of inclusions, cracks, or porosity using a written weld examination procedure. Weld examiners are qualified to perform visual weld inspections in accordance with SNT-TC-1A, *Personnel Qualification and Certification in Nondestructive Testing*, or ANSI/ASNT CP-189, *Qualification and Certification of Nondestructive Testing Personnel*, published by the American Society for Nondestructive Testing. The ASME Code, Sect. IX, is to be employed as the applicable requirement. Section VIII of the ASME Code is invoked for acceptance criteria for Code-specified examinations, which are to be performed in accordance with the provisions of ASME Code, Sect. V. Any indication of inclusions, cracks, or porosity in the welds is cause for rejection. The item may be reworked to meet the specifications. The weld examination procedures, the weld examiners' qualifications, and the weld examination reports are submitted to Consolidated Nuclear Security, LLC (CNS) for record keeping. The acceptance criteria for joint fit-up and alignment or for visual examination of welds are given in the ASME Code, Sect. VIII, Div. 1, Paragraphs UW-31 through UW-36. In addition, any visible defects such as lack of fusion, lack of penetration, linear or crack-like defects, and visible porosity, are cause for rejection. Straightening, flattening, and forming by mechanical or thermal means of some features and components after welding may be required to ensure proper assembly. The surfaces of areas of the weldment that have been reworked are visually examined to ensure that no cracks are present or that the weldment has not been degraded. Welds that are adjacent to these areas are also visually examined. The acceptance criterion is that no cracks are found. The areas worked and the visual inspections are noted on the dimensional inspection report. The external seam weld of the drum assembly is pressure tested by attaching removable lids on both the top and bottom false wire locations and injecting water and air inside the assembly up to the final pressure of 170.30 kPa (24.7 psia). After all testing, inspection, and final machining are complete, the drum assembly and top plug are dimensionally inspected. The dimensions and features such as flatness and run-out to be inspected are indicated on the design drawings. A written inspection report is prepared, submitted, and maintained for each ES-3100 drum assembly.

The above examination criteria address the stainless-steel components. However, the drum assembly also consists of the Kaolite 1600 or Packcrete material and the Cat 277-4 neutron poison. Acceptance criteria for the Kaolite 1600 installation are addressed by JS-YMN3-801580-A003 (Appendix 1.3.4) and the acceptance criteria for the Packcrete installation are addressed by SPC M801794-0003 (Appendix 1.3.11) and SPC M801580-0003 (Appendix 1.3.12). These specification controls and documents the raw materials used for mixing, casting and vibration methodology, and the baking of the material inside the drum assembly. The final acceptance criterion is achieved by producing a cast Kaolite 1600 or Packcrete material density of 358.8 ± 48 kg/m^3 (22.4 ± 3 lb/ft^3). Acceptance criteria for the installation of Cat 277-4 neutron poison are addressed in JS-YMN3-801580-A005 (Appendix 1.3.5). This specification also controls and documents the raw materials used for mixing, casting, and vibration methodology, and the final density of the casting [1682 +240/−80 kg/m^3 (105 +15/−5 lb/ft^3)]. Further examination criteria to verify the concentration and homogeneity of the Cat 277-4 in each drum assembly are also provided in JS-YMN3-801580-A005. The various parameters specified in NUREG/CR-3854 and in Table 2.11 for a neutron poison are addressed in detail in this specification.

2.3.2.2 Examination of the containment vessel fabrication

The containment vessel is examined and tested according to the design drawings and applicable portions of the following codes, standards, and regulations as described below:

1. *ASME Boiler and Pressure Vessel Code*, Sect. III, Div. 1, Subsections NB and NCA, Class 1 Components, 2001 ed. with 2002 and 2003 addenda;
2. ANSI N14.5-1997, *American National Standard for Radioactive Materials—Leakage Tests on Packages for Shipment*;

3. *ASME Boiler and Pressure Vessel Code*, Sect. V, Subsection A, Article 10, Appendix IX, "Helium Mass Spectrometer Test—Hood Technique," 2001 ed., and 2002 and 2003 addenda;

4. *ASME Boiler and Pressure Vessel Code*, Sect. V, Article 6, "Liquid Penetrant Examination," 2001 ed., and 2003 addenda; and

5. SNT-TC-1A-1992, *Recommended Practice for Nondestructive Testing Personnel Qualification and Certification*, American Society for Nondestructive Testing, December 1992.

Procured materials are examined in accordance with the applicable paragraphs of NB-2500 and meet the stated acceptance criteria. The results of these examinations are included with the CMTRs provided to CNS. All welded or weld-repair surfaces are visually examined by a qualified weld examiner for indications of inclusions, cracks, or porosity. The ASME Code, Sect. IX, provides the applicable requirements. Section III of the ASME Code is invoked for acceptance criteria for Code-specified examinations, which are to be performed in accordance with ASME Code, Sect. V. Prior written approval is obtained for any weld repair on materials, and the weld repair areas are both surface and volumetrically examined. The repair area is noted in a sketch supplied with the CMTR for the material that was weld repaired, and the documented results of the weld examination are provided to CNS. The markings on the weldment materials are not removed until after all weld examination is complete. The heat numbers of base metals and weld filler are required on all weld examination reports. Control of weld filler by the fabricator makes it possible for a weld examiner to determine the heat number of the weld filler used in any weld on the containment vessel.

As previously stated, the containment vessel body may be fabricated by two different methods (Appendix 1.3.7, Drawing M2E801580A012). Part M2E801580A012-4 is fabricated by welding a forged bottom and forged top flange to a cylindrical shell machined from seamless pipe as shown on the drawing. Prior to welding these components, all weld preparation areas and the surfaces within one inch of the weld are examined visually and with liquid penetrant. The acceptance criteria for these examinations are those stated in Paragraphs NB-5130(a) through NB-5130(d). The requirements in ASME Code, Paragraphs NB-5110, NB-5120, NB-5210, NB-5220, NB-5260, and NB-5300 apply to the containment vessels. The plug weld shown on Drawing M2E801580A015 (Appendix 1.3.7) shall be examined visually and with penetrant. The requirements in Paragraphs NB-5110 and NB-5350 apply to the plug weld. Materials used in the penetrant examination of welds and in the final surface examinations of finished components shall be specifically recommended by their suppliers for use with austenitic stainless steels, and copies of the certification of contaminant content of materials used shall be supplied with the examination reports (ASME Code, Sect. V, Article 6, T-641). Repair welding shall meet the applicable requirements of NB-2500. Certified written weld examination reports together with the corresponding material surface examination reports and weld map shall be submitted as stated in the procurement specification for the containment vessel. Weld examination reports for all weld and surface examinations shall include the containment vessel serial number, a weld map showing the location of the weld and examination area, the welder's name, the examiner's name, the time and date of the weld examination, the examination procedure number(s) used, the WPS number, the heat numbers of the joined materials, the heat number of the weld filler, and examiner's remarks. The examiner's remarks shall include the results of the examination and the acceptance or rejection of the weld based on the stated criteria. One set of radiographs shall be provided with the radiographic examination reports. If a weld or surface is rejected, a description of the defect and a sketch showing the location shall be provided.

The nonwelded containment vessel body, Part M2E801580A012-1, shall be formed from a single forged billet or bar by any process that meets the requirements stated in JS-YMN3-801580-A001 (Appendix 1.3.3) and shown on the design drawings (Appendix 1.3.7). The formed, heat treated, and finished machined containment vessel body shall meet the applicable requirements of ASME SA-182 for Grade F304L for a forged component. Mechanical properties are verified by testing of coupons. The test coupons are to be machined from the same heats of materials used to form the containment vessel bodies

and shall have the same or greater amount of cold work (plastic strain) as the containment vessels will have as a result of the forming process. The mechanical tensile testing of coupons shall be done in accordance with ASME SA-370. A minimum of six test coupons shall be tested for each final heat treatment furnace charge. The first set of three test coupons, chosen at random, shall be tested without being heat treated. The second set of three or more test coupons shall be heat treated together with the containment vessel bodies and then tested. The heating rates and maximum temperatures of the test coupons shall be representative of the entire furnace charge. Test coupons are not required to be heat treated with intermediate processing annealing steps but are required in the final heat treatment furnace charge. The results of all the testing of the sample coupons shall be documented, certified, and reported to CNS. The mechanical properties test report shall contain the following information: (1) a descriptor of the furnace charge which the test coupons are to represent; (2) the times and dates of the heat treating and the testing; (3) the person responsible for the testing; (4) a statement that these coupons are tested prior to or after heat treatment; (5) a description of the testing, including a sketch of the tensile test specimen; (6) the make, model, serial number, and current calibration data of the machine(s) used in the testing; (7) reference to the written testing procedure that was used; (8) the resulting measured yield strength, ultimate strength, percent elongation and percent reduction in area; and (9) any pertinent remarks.

2.4 GENERAL REQUIREMENTS FOR ALL PACKAGES

The general design standards for all packages in accordance with 10 CFR 71.43(a) through (c) are addressed in the following paragraphs.

2.4.1 Minimum Package Size—10 CFR 71.43(a)

Requirement: The smallest overall dimension of a package shall not be <10 cm (4 in.).

Compliance: The drum's outside diameter over the rolled rings is 49.20 cm (19.37 in.), and the outside height including the lid is 110.49 cm (43.50 in.). The minimum outside diameter of the ES-3100 containment vessel is 13.36 cm (5.26 in.), and the overall height is 82.30 cm (32.40 in.). Therefore, the packaging meets this requirement.

2.4.2 Tamper-Indicating Feature—10 CFR 71.43(b)

Requirement: The outside of the package must incorporate a feature, such as a seal, that is not readily breakable and that, while intact, would be evidence that the package has not been opened by unauthorized persons.

Compliance: The removable drum head is attached to the body by eight ⅝-11-UNC-2B silicon bronze nuts and ⅝-in. nominal washers. Two 0.51-cm (0.20-in.)–thick lugs with 0.953-cm (0.38-in.)–diam holes (Drawing M2E801580A005, Appendix 1.3.7) project through slots in the drum lid and provide attachment for TIDs. These TIDs consist of a stainless-steel cable with an aluminum crimp closure or equivalent. The requirement is satisfied by the TIDs, which are installed as specified in Sect. 7.1.2.2. The TID is only required when the containment vessel has HEU in the package. It is not required for empty shipments, but may be installed if required by site-specific requirements.

2.4.3 Positive Closure—10 CFR 71.43(c)

Requirement: Each package must include a containment system securely closed by a positive fastening device that cannot be opened unintentionally or by pressure that may arise within the package.

Compliance: The fastened lid on the drum with tamper-indicating features provides assurance that the drum assembly will not be unintentionally breached. The containment vessel is sealed using the lid assembly and closure nut to ensure that it will be breached only through a deliberate effort, and then only after the drum assembly has been breached. The design of the containment vessel is analyzed in DAC-M900000-0003 for a differential pressure of 699.82 kPa (101.5 psi) internal and 150 kPa (21.7 psi) external. The internal design pressure exceeds the maximum differential pressure of 185.29 kPa (26.87 psi) [210.29 − 25] attained during NCT (Sect. 2.6.3). The containment vessel is also analyzed in DAC-M900000-0002 for a differential pressure of 1378.95 kPa (200 psi) internal. This internal pressure exceeds the maximum HAC (Appendix 3.5.2) pressure differential of 1105.23 kPa [160.3 psi (175 psia -14.7 psia)]. In addition, calculation results are provided in Sects. 2.6.1 and 2.7.4.3 to demonstrate that the stresses in the containment vessel and closure nut threads do not exceed the stress limits established by the ASME Code for NCT and HAC. Therefore, the containment boundary will not be breached during any mode of transport due to pressurization of the containment boundary.

2.5 LIFTING AND TIE-DOWN STANDARDS FOR ALL PACKAGES

This section addresses the requirements of 10 CFR 71.45, "Lifting and Tie-Down Standards for All Packages."

2.5.1 Lifting Devices

Requirement. Any lifting attachment that is a structural part of a package must be designed with a minimum safety factor of three against yielding when used to lift the package in the intended manner, and it must be designed so that failure of any lifting device under excessive load would not impair the ability of the package to meet other requirements of 10 CFR 71, Subpart E. Any other structural part of the package that could be used to lift the package must be capable of being rendered inoperable for lifting the package during transport, or must be designed with strength equivalent to that required for lifting attachments.

Analysis. The ES-3100 packages, as delivered for transport, have no lifting devices or structural parts that can be used for lifting. Therefore, the lifting devices requirements of 10 CFR 71.45 are not applicable.

2.5.2 Tie-Down Devices

Requirement. If there is a system of tie-down devices that is a structural part of the package, the system must be capable of withstanding, without generating stress in any material of the package in excess of its yield strength, a static force applied to the center of gravity of the package having a vertical component of two times the weight of the package with its contents, a horizontal component along the direction in which the vehicle travels of ten times the weight of the package with its contents, and a horizontal component in the transverse direction of five times the weight of the package with its contents. Any other structural part of the package that could be used to tie down the package must be capable of being rendered inoperable for tying down the package during transport, or must be designed with strength equivalent to that required for tie-down devices. Each tie-down device that is a structural part of a package must be designed so that failure of the device under excessive load would not impair the ability of the package to meet other requirements of this part.

Analysis. The ES-3100 package, as delivered for transport, has no tie-down devices that are structural parts of the package. Therefore, the tie-down requirements of 10 CFR 71.45 are not applicable. The package is secured in the conveyance using blocking, bracing, and tie-down equipment that meets industry-standard practices to prevent shifting during NCT. When using an SGT, safe tie-down and transport of the package is accomplished by methods explained in the NNSA Technical Manual. For single-unit tie-down, a drum tie-down adapter is positioned on top of the drum and two chains, passing through the adapter, are attached to equipment positioned on the floor of the transport vehicle. The welded ring on the drum lid helps to initially position this drum tie-down adapter as well as prevent inadvertent assembly damage to the studs and nuts. Another method of securing the ES-3100 package is by the use of a Cargo-Restraint Transporter or Cargo Pallet Assembly. In these methods, a frame is positioned around the base and top of either five or six packages. These frames are then chained or locked to the floor as depicted in the NNSA Technical Manual. Tension is applied to the chains to eliminate any slack. The downward load resulting from the chain tensioning is insignificant when compared to the compression loading as specified in 10 CFR 71.71(c)(9).

2.6 NORMAL CONDITIONS OF TRANSPORT

This section demonstrates compliance with 10 CFR 71.43(f) and with 10 CFR 71.51(a)(1) and (b) following the tests and NCT conditions stipulated in 10 CFR 71.71. Package structural evaluation is performed by the combination of full-scale testing, similarity, and analysis as described in the following sections. A summary of 10 CFR 71.71 tests for the ES-3100 package is shown in Table 2.18. The essentially unyielding surface used for the 1.2-m (4-ft) drop test was the indoor drop test pad at the National Transportation Research Center (NTRC). All 9-m (30-ft) drop and crush tests were conducted at the outside drop pad at NTRC. The indoor pad consists of a 5.08-cm (2-in.)–thick steel plate embedded inside a reinforced concrete pad ~127-cm (50-in.) thick. The outside drop pad consists of a 10.16-cm (4-in.)–thick steel plate embedded inside a reinforced concrete pad ~167.6-cm (66-in.) thick. An article has been prepared by the NTRC staff to describe the integrity of these test pads (Shappert 1991). It is shown that the package will not experience any loss in shielding effectiveness or spacing and will not release any radioactive content or undergo leakage of water into the containment vessel during exposure to NCT. The four tests (water spray, free drop, compression, and penetration) made on Test Unit-4 (TU-4) were conducted in the 20.8 to 22.4°C (69.4 to 72.4°F) range, with the 1.2-m drop test conducted at 22.4°C (72.4°F). The maximum regulatory reference air leakage rate is $\leq 1.4025 \times 10^{-4}$ ref-cm^3/s. Compliance with this permitted activity release limit is not dependent on filters or mechanical cooling systems. Following NCT compliance testing, the package was subjected to the sequential HAC test battery. Original compliance testing was conducted on test units fabricated using Kaolite 1600 as the thermal barrier and impact-absorbing material. Due to the lack of Kaolite 1600 material from the manufacturer that meets specified density requirements, a substitute inorganic castable refractory material, identified as Packcrete, was developed. To confirm the thermal-insulating and impact-limiting material equivalency of Packcrete to the previously used Kaolite 1600 material, numerous material properties were evaluated and the results are documented in RP 802282-0002. These material tests have shown that the Packcrete is functionally equivalent to Kaolite 1600. Therefore, the test results and conditions analyzed in this section using Kaolite 1600 are also applicable to Packcrete.

The ES-3100 package was tested in accordance with a test plan developed by the NTRC at the Oak Ridge National Laboratory (ORNL) [ORNL/NTRC-013]. Testing of ES-3100 prototype units was performed at the NTRC facility, except as noted below. Six full-scale test units were assembled with content weights ranging from 3.6 kg (8 lb) to 50.3 kg (111 lb). One of these test units (TU-4) was subjected to the tests specified in 10 CFR 71.71(c)(5) through (c)(10) excluding (c)(8) prior to the HAC sequential tests stipulated in 10 CFR 71.73 and shown in Table 2.18. Tables 2.18 and 2.19 summarize the testing procedure and the drop orientations for each ES-3100 test unit. The contents used as surrogate

payloads for the test units are shown on Drawings M2E801580A029 and M2E801580A027. In the light-weight configuration, the contents consist of three 25.4-cm (10-in.)-high convenience cans with handles, and four silicone rubber pads. These convenience cans, handles and silicone rubber pads are identical to those proposed for transport. The bottom convenience can was filled with steel grit until the convenience can and grit assembly weighed ~3 kg (6.6 lb). The actual weight of the steel grit was 2.77 kg (6.11 lb). The total content weight for the light-weight content configuration including the convenience cans, silicone rubber pads, can handles, and steel grit was ~3.6 kg (8 lb). In the heavy-weight configurations, the surrogate payload consists of three steel cylindrical shaped components with handles, two can spacers filled with neutron-absorbing material and handles, and six silicone rubber pads. These components weighed a total of ~50 kg (110.2 lb). These different weight assemblies bound the range of possible content configurations and structural deformation resulting from compliance testing.

Title 10 CFR 71.71(b) specifies that the tests for NCT be conducted at the most unfavorable ambient temperature within the range of −29 to 38°C (−20 to 100°F). The drum is fabricated from Type 304 stainless steel, and the containment vessel is fabricated from Type 304L stainless steel, which is particularly suitable for low-temperature service. The Izod impact strength for the stainless steel used in the package components remains constant over a large range [specifically, from 21.11 to −195.5°C (70 to −320°F)] (*Stainless Steel Handbook*). Tensile strength increases from a minimum of 4.826×10^5 to 1.696×10^6 kPa (70,000 to 246,000 psi), and the yield strength increases ~10% over the same temperature range. The EPDM O-rings in the containment vessel have a normal service temperature range of −40 to 150°C (−40 to 302°F) [Table 2.15]. The normal service temperature range of the drum and containment vessel is −40 to 426.7°C (−40 to 800°F) [ASME Code, Sect. II, Part D]. At −29°C (−20°F), the impact-limiting material has been shown by tests to be stiffer than at 22.4°C (72.4°F).

Table 2.18. Summary of NCT—10 CFR 71.71 tests for ES-3100 package

Test [a]	TU-1 (heavy) 12° slap-down	TU-2 (heavy) side drop	TU-3 (heavy) center of gravity over top corner	TU-4 (heavy) top down	TU-5 (light) 12° slap-down
Operational leak test (CALT5 or VTI Smart Station)	1	1	1	1	1
NCT—10 CFR 71.71(c)(5) Vibration				5	
NCT—10 CFR 71.71(c)(6) Water spray				2	
NCT—10 CFR 71.71(c)(7) 1.2 m (4 ft) free drop	2	2	2	3	2
NCT—10 CFR 71.71(c)(9) Compression				6	
NCT—10 CFR 71.71(c)(10) Penetration				4	

[a] The numbers 1 through 6 indicate the sequence of the tests.

This condition has been evaluated by the compliance testing conducted on TU-2. TU-2 was chilled prior to being subjected to any structural testing (i.e., 1.2-m NCT drop, 9-m HAC drop, HAC crush, and HAC puncture tests). This unit was chilled to a nominal temperature of −40°C (−40°F). This was accomplished by placing the unit in an environmental chamber in Building 5800 at ORNL with initially setting of the chamber at ~ −57°C (−70°F) for 24 h. After this initial period, the control on the environmental chamber was set to ~ −43°C (−45°F) for another 48 h. Prior to the initiation of structural testing of this unit, it was removed from the environmental chamber and placed in an insulated box. Once transported to the NTRC, sequential structural testing as shown in Table 2.19 was performed as quickly as possible. The other test units were first subjected to the free drop from 1.2 m (4 ft) test prior to the HAC testing of 10 CFR 71.73. These additional tests were conducted to show that the NCT testing would not reduce the effectiveness of the package to withstand HAC testing. The reduction in tensile strength of the stainless steel from 22.4 to 38°C (73 to 100°F) is only ~2%, and the impact-limiting material test trends show that the impact-limiting material may become slightly softer. However, these slight reductions in tensile strength and absorption characteristics should not affect the results significantly compared to those conducted at 38°C (100°F).

Table 2.19. Summary of HAC—10 CFR 71.73 tests for the ES-3100 package

Test [a]	TU-1 (heavy) 12° slap-down	TU-2 (heavy) side drop	TU-3 (heavy) center of gravity over top corner	TU-4 (heavy) top down	TU-5 (light) 12° slap-down	TU-6 [b] 15-m immersion
10 CFR 71.73(c)(1) Free drop 9 m (30 ft)	1	1	1	1	1

[a] The numbers 1–11 indicate the sequence of the tests.
[b] TU-6 is only a containment vessel with ballast to ensure nonbuoyancy.

Title 10 CFR 71.71(b) also states that the initial internal pressure within the containment system during NCT drop testing shall be considered as the maximum normal operating pressure. The maximum normal operating pressure is defined in 10 CFR 71.4 as the maximum gauge pressure that would develop in the containment system in a period of 1 year under the heat conditions specified in 10 CFR 71.71(c)(1). The internal pressure developed under these conditions in the ES-3100 containment vessel is calculated in Appendix 3.5.1 and discussed in Sects. 2.6.1.1 and 3.3.2. As noted in these sections, the internal pressure is calculated and rounded up to 210.29 kPa (30.50 psia). Since the decay heat of the proposed contents is ~5 W, little or no impact on the pressure or temperature of the package components will result during NCT. As shown in DAC-M900000-0003, the design absolute pressure of the containment vessel is 801.17 kPa (116.2 psia), and the hydrostatic test pressure stipulated in JS-YMN3-801580-A001 is 1135.57 kPa (164.7 psia). Thus, increasing the internal pressure of the containment vessel to a maximum of 210.29 kPa (30.50 psia) during NCT would have no detrimental effect. Table 2.20 provides a summary of the pressures and temperatures in the various shipping configurations. As discussed in Sect. 2.6.1.4, the containment vessel and the closure nut stresses for this pressure condition are well below the allowable stress values.

Table 2.20. Summary of temperatures and pressures for NCT

Average gas evaluation temperature °C (°F)	Containment vessel absolute internal pressure kPa (psia)
−40 (−40) [a]	76.74 (11.13)
25.0 (77) [b]	101.35 (14.70)
89.60 (193.28) [c]	133.30 (19.333) [d]
89.60 (193.28) [c]	208.75 (30.276) [e]
90.00 (194) [f]	210.29 (30.50) [f]

[a] Analysis conducted with no decay heat load in accordance with 10 CFR 71.71(c)(2).
[b] Assembly temperature and pressure.
[c] These values have been calculated in DAC M801940-0002 with 5-W decay heat and insolation.
[d] This value has been calculated in Appendix 3.5.1 for containment vessel arrangements Number 1 and 11.
[e] This value has been calculated in Appendix 3.5.1 for containment vessel arrangement Number 7.
[f] The values have been calculated in Appendix 3.5.1 and rounded up for conservatism.

Title 10 CFR 71.71(c) specifies that the package service temperature must extend from −40 to 38°C (−40 to 100°F) with insolation. As shown in Sect. 3.3.1 and calculated in DAC M801940-0002, the upper service temperature with insolation is calculated and rounded up to 90°C (194°F) for an empty ES-3100 containment vessel. Thermal cycling of the packages from 90°C (194°F) to −40°C (−40°F) is considered an unlikely event, and the change would occur over a long period of time.

In any event, the 130°C (234.00°F) thermal cycle would not result in brittle fracture or fatigue failure in the packaging. The acceptability of the packaging against brittle fracture is discussed in Sect. 2.6.2. The only concern for fatigue or endurance failure is related to the cyclic pressure changes in the containment vessel as the temperature varies from low to high. A 25°C (77°F) ambient temperature normally exists for the containment vessel during assembly. The containment vessel is sealed at an absolute pressure of ~101.35 kPa (14.70 psi). The internal absolute pressure at an average gas temperature of 90°C (194.0°F) is 210.29 kPa (30.50 psi) for the ES-3100 containment vessel (Table 2.20). The absolute internal pressure at −40°C or −40°F is 76.74 kPa (11.13 psi) for the containment vessel. Therefore, the maximum cyclic pressure differential for the containment vessel from low to high temperatures is (210.29 − 76.74) kPa or 133.55 kPa (19.37 psi). This cyclic pressure is insignificant

when considering the integrity of the containment vessel as shown by the stress levels discussed in Sect. 2.6.1.3.

The ES-3100 package has been tested to determine the effectiveness of the package following a sequential NCT 1.2-m (4-ft) drop test and an HAC test battery. Testing conducted on TU-4 showed that there would be no loss or dispersal of radioactive contents, no significant increase in external surface radiation levels if the actual contents had been subjected to these tests, and no substantial reduction in the effectiveness of the packaging to survive the HAC testing. Thus, the requirements of 10 CFR 71.43(f) are satisfied.

Because some contents may be transported by air, the following criteria and guidance have been incorporated into various sections of this SARP.

1. International Atomic Energy Agency (IAEA) SSR-6, para. 621, states: "Packages containing radioactive material, to be transported by air, shall be capable of withstanding, without loss or dispersal of radioactive contents from the containment system, an internal pressure that produces a pressure differential of not less than the maximum normal operating pressure plus 95 kPa."

2. In order to also comply with 49 CFR 173.410(i)(2), the range of temperature evaluated will be from −40 to 55°C (ambient temperature).

3. According to IAEA SSG-26, para. 621.3, the evaluation at an ambient temperature of 55°C does not consider the solar radiation input; however, self-heating of the package is taken into account.

A thermal analysis has been conducted that predicts various temperatures of the shipping package evaluated at an ambient temperature of 55°C (131°F) with no insolation but does include 5 W of internal decay heating. The results are shown in Table 3.15 for this condition. The maximum temperature predicted for the containment vessel is 64.44°C (147.99°F). This temperature will be used in subsequent analyses as the maximum average gas temperature inside the containment vessel during air transport. An analysis has been conducted in Appendix 3.5.1 to determine the maximum normal operating pressure (MNOP) for air transport. Table 9 in Appendix 3.5.1 shows the results of this analysis, where the MNOP is determined to be 22.68 kPa (3.29 psig) for air transport. This value of 22.68 kPa (3.29 psig) is bounded by the value determined for ground transportation shown in Table 2.20. To comply with IAEA SSR-6, para. 621, an analysis is shown in Appendix 4.5.2 using an upstream pressure of 117.68 kPa (17.07 psia) and a downstream pressure of 0 kPa (0 psia). This provides the maximum pressure differential of 22.68 kPa + 95 kPa (3.29 + 13.78 psi). The analysis in Appendix 4.5.2 for air transport shows that the leaktight criteria obtained on test units is substantially below the calculated results for air transport. Therefore, the requirements of 10 CFR Part 71.51(a)(1) are satisfied. The containment vessel has also been evaluated at the maximum pressure differential shown in Table 9 of Appendix 3.5.1. The margin of safety for each component is significantly large enough to conclude that this maximum pressure differential determined for air transport does not degrade the structural integrity of the containment vessel (Table 2.21a).

2.6.1 Heat

Requirement. An ambient temperature of 38°C (100°F) in still air and insolation, as stated in 10 CFR 71.71(c)(1).

Analysis. An increase in ambient temperature to 38°C (100°F) with insolation will have no effect on the ability of the containment vessel to provide containment.

The maximum normal operating pressure is defined in 10 CFR 71.4 as the maximum gauge pressure that would develop in the containment system in a period of 1 year under the heat conditions specified in 10 CFR 71.71(c)(1). The internal pressure developed under these conditions in the ES-3100 containment vessel is calculated in Appendix 3.5.1 and discussed in Sects. 2.6.1.1 and 3.3.2. As noted in these sections, the internal pressure varies with temperature. Based on the isotopic determination of the proposed contents, a conservative maximum decay heat of 5 W is used for the maximum internal heat load in evaluating the package for NCT (Sect. 3.1.2). The maximum calculated and rounded internal absolute pressure in the containment vessel with insolation and using the bounding case parameters is 210.29 kPa (30.50 psia). The design absolute pressure of the containment vessel is 801.17 kPa (116.20 psia), and the hydrostatic test pressure is 113.55 kPa (164.7 psia). Thus, increasing the internal pressure of the containment vessel to a maximum of 210.29 kPa (30.50 psia) during NCT would have no detrimental effect. Table 2.20 provides a summary of the pressures and temperatures for the various shipping configurations. As discussed in Sect. 2.6.1.4, the containment vessel and closure nut stresses for these pressure conditions are well below the allowable stress values. If the package is exposed to solar radiation at 38°C (100°F) in still air, the conservatively calculated temperatures at the top of the drum, on the top surface of the containment vessel, and on the containment vessel near the O-ring sealing surfaces are 119.38°C (246.88°F), 89.60°C (193.28°F), and 89.53°C (193.15°F), respectively (Sect. 3.3.1 and Table 3.16). For conservatism, the O-ring sealing surface temperature will be assumed to be 89.60°C (193.28°F). Nevertheless, these temperatures are within the service limits of all packaging components, including the O-rings. The normal service temperature range of the EPDM O-rings used in the containment vessel is −40 to 150°C (−40 to 302°F) [Table 2.15].

2.6.1.1 Summary of pressures and temperatures

An ambient temperature of 25°C (77°F) is assumed for the packaging at assembly. Since there are four ventilation holes near the top of the drum, and holes in the liner encapsulating the neutron poison material that are not hermetically sealed, the drum assembly will not become pressurized as the temperature increases. The containment vessel is sealed; thus, the internal pressure will change with temperature. Maximum calculated pressures at various temperatures (Sect. 3.3.1) are listed in Table 2.20.

2.6.1.2 Differential thermal expansion

The drum, inner liners, and containment vessel are all constructed of Type 304 or 304L stainless steel. Radial and vertical expansion among these components will not cause any interferences or thermally induced stresses due to design clearances at assembly. Due to similarities of the coefficient of thermal expansion between Type 304/304L and the containment vessel closure nut material (ASME SA-479), the compression of the O-rings does not change appreciably during the temperature excursion from 25°C (77°F) to the maximum adjusted temperature of 93.33°C (200.00°F).

The Kaolite 1600 or Packcrete insulation and Cat 277-4 material is poured and cast in place during the fabrication of the drum weldment (Drawing M2E801580A002, Appendix 1.3.7). Although some contraction of these materials may occur during curing, it is assumed for analysis purposes that a zero gap will exist between the Kaolite or Packcrete and the bounding drum and mid liner, and a zero gap exists between the Cat 277-4 and the two liners. Due to differences in coefficients of thermal expansion, some radial and axial interferences are expected due to thermal growth of the inner liners. These radial and axial interferences and induced stresses are calculated in DAC M801940-0003 using Packcrete as well as Kaolite 1600. The results are summarized in Table 2.20a. The computed thermal stresses are compared to the allowable stress for the drum material. The ASME BPVC, Sect. VIII, Division 1, UG-22(h) is used to evaluate the stresses in the drum and inner liner walls caused by temperature gradients and differential thermal expansion. An allowable stress of 3 × S as provided by UG-23 is compared to the calculated stresses. The “S” value is taken from the ASME BPVC, Sect. II, Part D,

Subpart 1, Table 1A, for ASME SA-240, Type 304, stainless steel up to 300°F and has a value of 15 ksi (Table 2.12). Therefore, the allowable stress for these calculations is 45 ksi. These results show that the stresses induced by either insulation are minimal and do not reduce the effectiveness of the drum assembly.

The effects of differences in coefficient of thermal expansion between the HEU contents and their associated convenience cans, polyethylene or Teflon FEP bottles are not addressed. No credit is taken for the ability of the convenience can or bottle to maintain its structural integrity during transport. Section 4 of this document assumes the HEU content is in the form of an aerosol and all is available for release; therefore, no credit for the convenience can, polyethylene, nylon, or Teflon bagging, or bottle is taken. Based on assembly clearances and the flexibility of the polyethylene or Teflon FEP bottles, no radial or vertical interferences will develop during NCT. Based on assembly clearances and insignificant differences in the coefficient of thermal expansion between the stainless-steel, tin-plated carbon steel, aluminum, or nickel-alloy convenience cans and the stainless-steel containment vessel, no radial or vertical interferences will develop during NCT testing.

Table 2.20a. Maximum calculated stress in the drum assembly components during NCT hot conditions (100°F, decay heat, solar insolation)

Case [a]	Time from initial solar application (h)	Drum angle	Drum side wall	Drum bottom	Drum inner liner	Drum lid weldment
		Calculated Von Mises stress (ksi) [b, c]				
3	34.85	7.48				
3	2.21		10.40			
3	0.74			5.47		
3	0.08				15.57	
6	0.25					11.82
Allowable stress (3 × S) [d]		45 ksi				

[a] Simulations discussed in DAC M801940-0003.
[b] The values shown are the maximum calculated for either insulation material.
[c] Stress, case number, and time from initial solar application extracted from Table 8-1 of DAC M801940-0003.
[d] Allowable stress up to 300°F where "S" (15 ksi) is from Table 2.12 for the stainless-steel drum assembly components.

2.6.1.3 Stress calculations

During normal conditions, stresses are only imposed by changes in internal pressure of the containment vessel as the temperature varies slowly over the operating range (Table 2.20). Stress levels imposed on the package during NCT are insignificant, as shown in Tables 2.21, 2.21a, and 2.22. These tabulated stresses were determined by multiplying the stress at the design conditions (DAC-M900000-0003 and Table 2.6) by a factor equal to the ratio of operating pressures to design pressures and adding any contribution from the closure nut preload. This methodology is based on linear elastic material behavior. As shown in Sect. 2.6.1.4, all stresses in the containment vessel components are well below the ASME Code allowable stress intensity limits.

2.6.1.4 Comparison with allowable stresses

NCT containment vessel stresses are calculated in accordance with the load combinations listed in Table 2.3 and their values are shown in Tables 2.21, 2.21a, and 2.22. The hot environment, cold environment, reduced external pressure, increased external pressure condition, and vibration normally incident to transport are addressed in Sects. 2.6.1, 2.6.2, 2.6.3, 2.6.4, and 2.6.5, respectively. The fatigue or endurance limits for austenitic stainless steel are normally assumed to be about one-half the ultimate tensile strength (*Design Guidelines for the Selection and Use of Stainless Steel*, pp. 17–18). For Type 304 stainless steel, one-half the ultimate tensile strength is 2.4×10^5 kPa (35,000 psi). Tensile and compressive hoop stresses of the magnitude shown in Tables 2.21, 2.21a, and 2.22 are insignificant compared to the endurance limit of 2.4×10^5 kPa (35,000 psi). As shown in Tables 2.21, 2.21a, and 2.22, the containment vessel stresses during NCT are insignificant. Even at the maximum test temperature and internal pressure (Sect. 3.4.3), the stresses in the containment boundaries were insignificant when compared with the allowable stress intensities shown in Tables 2.4 and 2.5. Corresponding calculated stress regions are shown in Fig. 2.1. Thermal expansion or contraction issues are addressed in Sects. 2.6.1.2 and 2.6.2.

2.6.2 Cold

Requirement. An ambient temperature of −40°C (−40°F) in still air and shade, as required by 10 CFR 71.71(c)(2).

Analysis. The drum is fabricated from Type 304 stainless-steel sheet (Table 2.7). As discussed in Sect. 2.6, stainless steel is excellent for low-temperature service, particularly regarding tensile and impact strength. The thermal insulation (Kaolite 1600 or Packcrete) is a lightweight noncombustible cast refractory made from portland cement and vermiculite. The only moisture available for freezing at −40°C (−40°F) would be moisture that had not been removed during the curing and cool-down phase of fabrication. Because there will be no free water present for freezing and the insulation is a bonded mass of random fibers and cement, the properties of the insulation will not change appreciably. The matrix may become less flexible when subjected to the cold temperature, but the inner liner will remain in the position in which it was placed at the time of fabrication. The Kaolite 1600 or Packcrete insulation and Cat 277-4 materials are poured and cast in place during the fabrication of the drum weldment (Drawing M2E801580A002, Appendix 1.3.7). Although some contraction of these materials may occur during curing, it is assumed for analysis purposes that a zero gap will exist between the Kaolite or Packcrete and the bounding drum and mid liner and a zero gap exists between the Cat 277-4 and the two liners. Due to differences in the coefficient of thermal expansion, some radial and axial interference is expected due to contraction of the outer drum and inner liners. These radial and axial interferences and induced stresses are calculated in DAC M801940-0003 for both Kaolite 1600 and Packcrete. The resulting maximum stresses for these drum components are shown in Table 2.22a. The computed thermal stresses are compared to the allowable stress for the drum material. The ASME BPVC, Sect. VIII, Division 1, UG-22(h) is used to evaluate the stresses in in the drum and inner liner walls caused by temperature gradients and differential thermal expansion. An allowable stress of 3 × S as provided by UG-23 is compared to the calculated stresses. The “S” value is taken from the ASME BPVC, Sect. II, Part D, Subpart 1, Table 1A, for ASME SA-240, Type 304L, stainless steel at -40°F and has a value of 16.7 ksi (Table 2.12). Therefore, the allowable stress for these calculations is 50.1 ksi. These results show that the stresses induced are minimal and do not reduce the effectiveness of the drum assembly.

Table 2.21. ES-3100 containment vessel evaluation for both hot and cold conditions

Stress locations shown in Fig. 2.1	Hot conditions [10 CFR 71.71(c)(1)] containment vessel stress [a] @ 108.94 kPa (15.80 psi) gauge		Cold conditions [10 CFR 71(c)(2)] containment vessel stress [a] @ −24.61 kPa (−3.57 psi) gauge		Allowable pressure, stress, or shear capacity [a]
	kPa (psi) or kg (lb)	M.S. [b]	kPa (psi) or kg (lb)	M.S. [b]	kPa (psi) or kg (lb)
Top flat portion of sealing lid (center of lid)	1.777×10^3 (258)	112	4.015×10^2 (58)	498	1.999×10^5 (29,000) [c]
Closure nut ring (away from threaded portion)	5.323×10^3 (772)	20.3	1.902×10^4 (2759) [d]	5.7	1.081×10^5 (15,675) [c]
Top flat head (sealing surface region)	4.510×10^3 (654)	44	7.088×10^3 (1028) [d]	28	1.999×10^5 (29,000) [c]
Cylindrical section (middle) internal pressure	3.032×10^3 (440)	37			1.120×10^5 (16,250) [e]
Cylindrical section (middle) external pressure			2.461×10^1 (3.57)	31	7.584×10^2 (110) [f]
Cylindrical section (shell to flange interface)	4.220×10^3 (612)	40	9.483×10^2 (138)	177	1.682×10^5 (24,400) [c]
Cylindrical section (shell to bottom interface)	9.115×10^3 (1322)	18	2.060×10^3 (299)	82	1.682×10^5 (24,400) [c]
Body flange threads load, kg (lb)	9.072×10^2 (2000) [d]	29	9.072×10^2 (2000) [d]	29	2.608×10^4 (57,500) [g]
Body flange thread region (under cut region)	2.839×10^4 (4117) [d]	5.9	2.839×10^4 (4117) [d]	5.9	1.682×10^5 (24,400) [c]
Flat bottom head (center)	7.620×10^3 (1105)	22	1.722×10^3 (250)	98	1.682×10^5 (24,400) [c]
Closure nut thread load, kg (lb)	9.072×10^2 (2000) [d]	37	9.072×10^2 (2000) [d]	37	3.353×10^4 (73,911) [g]

[a] Stresses are calculated using pressures, gasket and closure nut preload, and nominal dimensions for all containment vessel components (DAC-M900000-0003). Calculated stresses for external pressure were determined by multiplying the stress at the design conditions by a factor equal to the ratio of external pressure to design pressure plus the contribution from preload. Allowable stress values are taken from Table 2.5 up to 176.7°C (350°F).

[b] Margin of safety = allowable stress/actual stress.

[c] Stress interpreted as the sum of $P_l + P_b$; allowable stress intensity value is $1.5 \times S_m$.

[d] Stress and shear load in these areas is dominated by the 162.7 ± 6.8 N·m (120 ± 5 ft-lb) preload. External pressure component is ignored.

[e] Stress interpreted as the primary membrane stress (P_m); allowable stress intensity value is S_m.

[f] Allowable external pressure [kPa (psi)].

[g] Allowable shear capacity is defined as $0.6 \times S_m \times$ thread shear area for the body material. Thread shear area = 38.026 cm^2 (5.894 $in.^2$). Allowable shear capacity is defined as $1.2 \times S_m \times$ thread shear area for the closure nut material.

Table 2.21a. ES-3100 containment vessel evaluation for internal pressure developed during air transport in accordance with IAEA SSR-6, Paragraph 620

Stress locations shown in Fig. 2.1	Containment vessel stress [a] @ 117.68 kPa (17.07 psi) gauge		Allowable pressure, stress, or shear capacity [a]
	kPa (psi) or kg (lb)	M.S. [b]	kPa (psi) or kg (lb)
Top flat portion of sealing lid (center of lid)	1.920×10^3 (279)	104	1.999×10^5 (29,000) [c]
Closure nut ring (away from threaded portion)	5.751×10^3 (834)	18.8	1.081×10^5 (15675)[c]
Top flat head (sealing surface region)	4.872×10^3 (707)	41	1.999×10^5 (29,000) [c]
Cylindrical section (middle) internal pressure	3.276×10^3 (475)	34	1.120×10^5 (16,250) [e]
Cylindrical section (shell to flange interface)	4.536×10^3 (658)	37	1.682×10^5 (24,400) [c]
Cylindrical section (shell to bottom interface)	9.848×10^4 (1428)	22	1.682×10^5 (24,400) [c]
Body flange threads load, kg (lb)	9.072×10^2 (2000) [d]	29	2.608×10^4 (57,500) [f]
Body flange thread region (under cut region)	2.839×10^4 (4117) [d]	5.9	1.682×10^5 (24,400) [c]
Flat bottom head (center)	8.233×10^3 (1194)	20	1.682×10^5 (24,400) [c]
Closure nut thread load, kg (lb)	9.072×10^2 (2000) [d]	37	3.353×10^4 (73,911) [f]

[a] Calculated stresses were determined by multiplying the stress at the design conditions (Table 2.6) by a factor equal to the ratio of operating pressures to design pressures (independent of pressure direction) plus contributions from preload. Allowable stress values are taken from Table 2.5 up to 176.7°C (350°F).

[b] Margin of safety = allowable stress/actual stress.

[c] Stress interpreted as the sum of $P_l + P_b$; allowable stress intensity value is $1.5 \times S_m$.

[d] Stress and shear load in these areas are dominated by the 162.7 ± 6.8 N·m (120 ± 5 ft-lb) preload.

[e] Stress interpreted as the primary membrane stress (P_m); allowable stress intensity value is S_m.

[f] Allowable shear capacity is defined as $0.6 \times S_m \times$ thread shear area for the body material. Thread shear area = 38.026 cm^2 (5.894 $in.^2$). Allowable shear capacity is defined as $1.2 \times S_m \times$ thread shear area for the closure nut material.

Table 2.22. NCT ES-3100 containment vessel stress compared to the allowable stress at reduced and increased external pressures

Stress locations shown in Fig. 2.1	Reduced external pressure [10 CFR 71.71(c)(3)] containment boundary stress [a] @ 185.29 kPa (26.87 psi) gauge		Increased external pressure [10 CFR 71.71(c)(4)] containment boundary stress [a] @ −63.26 kPa (−9.18 psi) gauge		Allowable pressure, stress, or shear capacity [a]
	kPa (psi) or kg (lb)	M.S. [b]	kPa (psi) or kg (lb)	M.S. [b]	kPa (psi) or kg (lb)
Top flat portion of sealing lid (center of lid)	3.023×10^3 (438)	66	1.033×10^3 (150)	194	1.999×10^5 (29,000) [c]
Closure nut ring (away from threaded region)	9.055×10^3 (1313)	11.9	1.902×10^4 (2759) [d]	5.7	1.081×10^5 (15675) [c]
Top flat head (sealing surface region)	7.671×10^3 (1113)	26	7.088×10^3 (1028) [d]	28	1.999×10^5 (29,000) [c]
Cylindrical section (middle) internal pressure	5.157×10^3 (748)	22			1.120×10^5 (16,250) [e]
Cylindrical section (middle) external pressure			6.329×10^1 (9.18)	12	7.584×10^2 (110) [f]
Cylindrical section (shell-to-flange interface)	7.141×10^3 (1036)	24	2.438×10^3 (354)	69	1.682×10^5 (24,400) [c]
Cylindrical section (shell-to-bottom interface)	1.550×10^4 (2249)	11	5.297×10^3 (768)	32	1.682×10^5 (24,400) [c]
Body flange threads load, kg (lb)	9.980×10^2 (2200) [d]	26	9.072×10^2 (2000) [d]	29	2.608×10^4 (57,500) [g]
Body flange thread region (under cut region)	3.101×10^4 (4498) [d]	5.4	2.839×10^4 (4117) [d]	5.9	1.682×10^5 (24,400) [c]
Flat bottom head (center)	1.296×10^4 (1880)	13	4.428×10^3 (642)	38	1.682×10^5 (24,400) [c]
Closure nut thread load, kg (lb)	9.980×10^2 (2200) [d]	34	9.072×10^2 (2000) [d]	37	3.353×10^4 (73,911) [g]

[a] Stresses are calculated using pressures, gasket and closure nut preload, and nominal dimensions for all containment vessel components (DAC-M900000-0003). Calculated stresses for external pressure were determined by multiplying the stress at the design conditions by a factor equal to the ratio of external pressure to design pressure plus the contribution from preload. Allowable stress values are taken from Table 2.5 up to 176.7°C (350°F).

[b] Margin of safety = allowable stress/actual stress.

[c] Stress interpreted as the sum of $P_l + P_b$; allowable stress intensity value is $1.5 \times S_m$.

[d] Stress and shear load in these areas is dominated by the 162.7 ± 6.8 N·m (120 ± 5 ft-lb) preload. External pressure component is ignored.

[e] Stress interpreted as the primary membrane stress (P_m); allowable stress intensity value is S_m.

[f] Allowable external pressure [kPa (psi)].

[g] Allowable shear capacity is defined as $0.6 \times S_m \times$ thread shear area for the body material. Thread shear area = 38.026 cm^2 (5.894 $in.^2$). Allowable shear capacity is defined as $1.2 \times S_m \times$ thread shear area for the closure nut material.

Table 2.22a. Maximum calculated stress in the drum assembly components during NCT cold conditions (-40°F, no decay heat, no solar insolation)

Case [a]	Time from initial solar application (h)	Drum angle	Drum side wall	Drum bottom	Drum inner liners	Drum lid weldment
		Calculated Von Mises stress (ksi) [b, c]				
7	0.25	3.11				
8	1.94		9.61			
8	0.74			4.54		
8	0.74				16.09	
8	0.08					7.77
Allowable stress (3 × S) [d]		50.1 ksi				

[a] Simulations discussed in DAC M801940-0003.
[b] The values shown are the maximum calculated for either insulation material.
[c] Stress, case number, and time from initial solar application extracted from Table 8-1 of DAC M801940-0003.
[d] Allowable stress up at -40°F where "S" (16.7 ksi) is from Table 2.12 for the stainless-steel drum assembly components.

The containment vessel is fabricated from Type 304L stainless steel, which is suitable for low-temperature service, particularly regarding impact resistance. This material does not show a transition from ductile to brittle failure at this temperature [−40°C (−40°F)]. The ASME Code, Sect. III, Subsection NB-2311, exempts impact testing of Type 304L stainless steels. The Izod impact strength for Type 304 stainless steel is 149.14 N·m (110 ft-lb) from 21.11 to −195.5°C (70 to −320°F). The tensile strength increases from ~4.826×10^5 to 1.696×10^6 kPa (70,000 to 246,000 psi) between 21.11 and −195.5°C (70 and −320°F), and the yield strength increases ~10% over the same range. NRC Regulatory Guide 7.6, Part B, states, "these designs were made of austenitic stainless steel which is ductile even at low temperatures. Thus, this guide does not consider brittle fracture." The drum, inner liner, top plug, and containment vessel are made from austenitic stainless steel. Similarly, the containment vessel closure nut material is a galling and wear resistant austenitic stainless steel. Therefore, brittle fracture of these structural materials at −40°C (−40°F) is not possible.

The specified O-rings used in the containment vessel have a continuous service temperature range of −40 to 150°C (−40 to 302°F) [Table 2.15]. The low temperature extreme has been verified by compliance testing of TU-2 (Sect. 2.7.1.2). TU-2 was pre-chilled to a nominal temperature of −40°C (−40°F). This was accomplished by placing the units in an environmental chamber in Building 5800 at ORNL and initially setting the chamber control to −56.7°C (−70°F) for 24 h. After this initial period, the control on the environmental chamber was set to −42.8°C (−45°F) for at least 48 h. Prior to the initiation of structural testing of this unit, it was removed from the environmental chamber and placed in an insulated box and transported to NTRC for testing.

As previously noted, the containment vessels will be assembled for shipment in a temperature environment of ~25°C (77°F). If the package should be exposed to −40°C (−40°F) for an extended period, all components will equalize near this low temperature. The absolute internal pressure inside the containment vessel would decrease to a pressure of 76.74 kPa (11.13 psi), assuming no decay heating (Table 2.20). Therefore, the pressure differential across the containment vessel at −40°C (−40°F) is −24.61 kPa (−3.57 psia) {[76.739 − 101.35 kPa] (11.13 − 14.7 psia)}. Due to similarities between the coefficient of thermal expansion for Type 304 or 304L stainless steel and the containment vessel closure nut material (ARMCO NITRONIC, ASME SA-479), the compression of the O-rings does not change appreciably during the temperature excursion from 25°C (77°F) to −40°C (−40°F). The calculated stresses shown in Tables 2.21 and 2.21a were determined by multiplying the stress at the design

conditions (DAC-M900000-0003 and Table 2.6) by a factor equal to the ratio of operating pressure to design pressure and adding any contribution from the closure nut preload. This methodology is based on linear elastic material behavior. As shown in Sect. 2.6.1.4, all stresses in the containment vessel components are well below the ASME Code allowable stress intensity limits. As demonstrated by the information presented above, the packaging is acceptable for NCT at −40°C (−40°F).

2.6.3 Reduced External Pressure

Requirement. An absolute external pressure of 25 kPa (3.5 psi) is required by 10 CFR 71.71(c)(3).

Analysis. Reducing the absolute external pressure from ambient pressure to 25 kPa (3.5 psi) will have no effect on the drum assembly because the plastic plugs and aluminum tape covering the ventilation holes for the Cat 277-4 will allow the internal pressure of the drum assembly to equalize. This reduced pressure and a maximum internal pressure produces the maximum pressure differential across the containment vessel of 185.29 kPa (26.87 psi) [210.29 − 25]. The containment vessel is designed and fabricated in accordance with Sects. III and IX of the ASME Code for an internal pressure differential of 699.82 kPa (101.5 psi) as shown in DAC-M900000-0003. A summary of the resulting stress intensities at various locations identified in Fig. 2.1 on the containment vessel in comparison with the ASME Code allowable limits for this condition is shown in Table 2.22. These tabulated stresses were determined by multiplying the stress at the design conditions (DAC-M900000-0003 and Table 2.6) by a factor equal to the ratio of operating pressures to design pressures and adding any contribution from the closure nut preload. This methodology is based on linear elastic material behavior. As shown in Table 2.22, all stresses in the containment vessel components are well below the ASME Code allowable stress intensity limits. Therefore, the ES-3100 packaging is acceptable for NCT at an absolute external pressure of 25 kPa (3.5 psi).

2.6.4 Increased External Pressure

Requirement. An absolute external pressure of 140 kPa (20 psi) is required by 10 CFR 71.71(c)(4).

Analysis. Increasing the absolute external pressure from ambient pressure to 140 kPa (20 psi) would have no effect on the drum assembly because the plastic plugs and aluminum tape covering the ventilation holes for the Cat 277-4 will allow the internal pressure of the drum assembly to equalize. At this increased external pressure, the maximum pressure differential across the containment vessel would be −63.26 kPa (76.74 − 140 kPa) [−9.18 psi], assuming the vessel's absolute pressure and temperature to be 76.74 kPa (11.13 psi) and −40°C (−40°F), respectively. Each containment vessel is designed and fabricated in accordance with Sects. III and IX of the ASME Code for a minimum external pressure of 150 kPa (21.7 psi) gauge. A comparison of the resulting stress intensities at various locations on the containment vessel (Fig. 2.1) with the ASME Code allowable limits for this condition is shown in Table 2.22. These tabulated stresses were determined by multiplying the stress at the design conditions (DAC-M900000-0003 and Table 2.6) by a factor equal to the ratio of operating pressures to design pressures and adding any contribution from the closure nut preload. This methodology is based on linear elastic material behavior. As shown in Table 2.22, all stresses in the containment vessel components are well below the ASME Code allowable stress intensity limits. Therefore, the ES-3100 packaging is acceptable for NCT at an external absolute pressure of 140 kPa (20 psi).

2.6.5 Vibration

Requirement. Vibration normally incident to transportation is required by 10 CFR 71.71(c)(5).

Analysis. Vibration testing on a prototypical ES-3100 package (TU-4) was conducted in accordance with the ES-3100 test plan and documented in the test report (ORNL/NTRC-013). Testing was conducted with the package restrained as shown in Fig. 2.3. The containment vessel was assembled with the mock-up content weighing 49.90 kg (110 lb). The total weight of the test unit was 201.8 kg (445 lb). The unit was subjected to an endurance test with random vibrations modeled after the power spectral density plot for the SGT vibration envelope in the vertical axis (Cap 2002). At this level of vibration intensity, the test compares with MIL-STD-810F. MIL-STD-810F is a standard random vibration test for basic transportation vibrations generated by a large truck or tractor-trailer combination. MIL-STD-810F defines 60 min of testing as equal to 1609 km (1000 miles) of common carrier transportation. Assuming that the two random vibration tests are similar in intensity, TU-4 had ~6436 km (4000 miles) of simulated random vibration testing. Based on a nominal shipping distance of 3218 km (2000 miles), TU-4 was subjected to a test that was approximately two times more severe than that required by 10 CFR 71.71(c)(5). As shown by the following paragraphs, containment, shielding effectiveness, and subcriticality were maintained even when the package was subjected to such an arduous environment.

The test was run at ~22.8°C (73°F) rather than at the high or low temperatures specified for NCT. This was reasonable because the thermal coefficients of expansion of the flange and closure nut materials are very close. Therefore, the temperature extremes would not have a significant effect on the closure tightness.

Summarizing 10 CFR 71.43(f), the tests and conditions of NCT shall not substantially reduce the effectiveness of the packaging to withstand HAC sequential testing. The effectiveness of the ES-3100 to withstand HAC sequential testing is not diminished through application of the tests and conditions stipulated in 10 CFR 71.71. The justification for this statement is provided by physical testing of both the ES-2M (GAB1296-2) and ES-3100 (ORNL/NTRC-013) test packages. Due to the similarities in design, fabrication, and construction materials of the ES-2M and the ES-3100 packages, the physical characteristics of the Kaolite 1600 and Packcrete will hold true for both designs. The integrity of the Kaolite 1600 and Packcrete is not significantly affected by the NCT vibration and 1.2-m drop tests. Prior to testing the ES-2M design, each test unit was radiographed to determine the integrity of the Kaolite 1600 impact and insulation material. Following casting of the material inside the drum, some three-dimensional curving cracks were seen in some packages near the thinner top sections from the bottom of the liner to the bottom drum edge. After vibration testing, radiography of the ES-2M TU-4 showed that the lower half of the impact limiter was broken into small pieces. In order to evaluate these findings, TU-4 was reassembled and subjected to HAC sequential testing. After vibration and impact testing, many three-dimensional curving cracks were seen around the impact areas, and the inner liner was visibly deformed. Nevertheless, TU-4 maintained the adequate spacing required for shielding effectiveness and subcriticality. Temperatures at the containment boundary were also similar to other packages not subjected to vibration testing prior to HAC testing. No inleakage of water was recorded following immersion. Additionally, TU-4 of the ES-3100 test series was subjected to tests and conditions stipulated in 10 CFR 71.71(c)(5) through (c)(10), excluding (c)(8). Following completion of both the NCT and HAC tests, the containment vessel was removed, and a full-body helium leak test was conducted to the leaktight criterion ($\leq 2 \times 10^{-7}$ cm^3/s) in accordance with ANSI N14.5-1997.

Note: MD-1 test unit removed during actual testing.

Fig. 2.3. ES-3100 vibration testing arrangement.

Following compliance testing of the ES-3100 shipping package, minor changes were incorporated into the proposed design as described in Sect. 2.7.1.5. During the vibration test, the shipping package is restrained from movement in the vertical direction with a tie-down arrangement similar to that used on an SGT for a single package. Based on the acceleration spectral density presented in the letter from J. S. Cap to G. W. Crowder (Cap 2002), the largest contributor to shipping package motion is in the vertical direction. Since the containment vessel and contents are not restrained within the inner liner cavity, the containment vessel is free to bounce up and down. In the vertical direction, the top plug and the bottom of the inner liner restrict the movement of this vessel. Because the inner liner contour has not changed with respect to the containment vessel, and there are clearances between the containment vessel flange and the inner liner in the vertical direction, the cast neutron poison and inner liner are not directly impacted by the movement of the containment vessel. Therefore, changes in the neutron poison and minor radial dimension changes in the mid liner will not affect the outcome of vibration testing. Based on the success of the previously tested units and the fact that these proposed changes will have little or no effect on testing, vibration normally incident to transport does not reduce the effectiveness of the packaging during HAC testing. Thus, the requirements of 10 CFR 71.43(f) are satisfied.

Procedures will be followed to ensure that the packaging is assembled as specified (Chap. 7). The drum, lid, and fasteners are refurbished as required before each use. The ⅝-in.–diam flange nuts

on the drum are torqued to 40.67 N·m (30 ft-lb) nominal. The closure nut on the containment vessel is torqued to 162.7 N·m (120 ft-lb) nominal. The package is acceptable for vibration normally incident to transport in an SGT.

2.6.6 Water Spray

Requirement. A water spray that simulates exposure to rainfall of ~5.08 cm (2 in.) per hour for at least 1 h is required by 10 CFR 71.71(c)(6).

Analysis. A water spray of 5.08 cm (2 in.) per hour was directed from above and around the periphery of the ES-3100 TU-4 for a minimum of 1 h as shown in Fig. 2.4. The drum had four plastic plug-sealed ventilation holes near the top that prevent water from entering the insulation cavity. Aluminum duct tape covering the installation holes in the mid liner prevents water from entering the neutron poison cavity. There was evidence of water leakage into the volume between the containment vessel and the inner liner at the conclusion of the test. Water entered this cavity through the holes provided in the lid for the TID lugs, but none penetrated the containment boundary. The criticality analysis shown in Chap. 6 was conducted with moderation by water to the most reactive credible extent and close full reflection of the containment system by water on all sides. Because the package remained subcritical under these conditions, the ES-3100 package is acceptable for use under the water spray conditions of NCT.

Fig. 2.4. Water spray test arrangement for TU-4.

2.6.7 Free Drop

Requirement. A free drop of 1 m (4 ft) onto a flat, essentially unyielding, horizontal surface in a position for which maximum damage is expected is required by 10 CFR 71.71(c)(10). This test shall be made between 1½ and 2½ h after the conclusion of the water spray test (Sect. 2.6.6).

Analysis. The ES-3100 test package, TU-4, previously sprayed with water (Sect. 2.6.6) with a measured gross weight of 201.85 kg (445 lb) and containing a content weight of 49.90 kg (110 lb), was tested in accordance with 10 CFR 71.71(c)(7). The temperature and pressure at the time of the drop test was 22.8°C (73°F) and ~101.35 kPa (14.70 psi), respectively. As discussed in Sect. 2.6, the response of the test package would not have been significantly different if it had been tested at the extremes of the temperature range dictated by 10 CFR 71.71(b) with the containment vessel at the maximum normal operating pressure.

The essentially unyielding surface used for this test was the indoor drop test pad at the NTRC. All 9-m (30-ft) drop and crush tests were conducted at the outside drop pad at the NTRC. The indoor pad consists of a 5.08-cm (2-in.)–thick steel plate embedded inside a reinforced concrete pad ~127-cm (50-in.) thick. The outside drop pad consists of a 10.16-cm (4-in.)–thick steel plate embedded inside a reinforced concrete pad ~167.6-cm (66-in.) thick. An article has been prepared by the NTRC staff to describe the integrity of these test pads (Shappert 1991).

TU-4 was dropped from 1.2 m (4 ft) in a vertical position, with the drum's top initially striking the unyielding surface (Fig. 2.5). This attitude was assumed to be the most vulnerable orientation for producing damage to the sealing surfaces of the containment vessel and for introducing buckling into the cylindrical portion of the containment vessel body. The long axis of the drum was 0° from vertical. The test package made a free fall, with initial contact on the drum's lid. Damage consisted of shortening the drum height from 110.81 cm (43⅝ in.) to 110.49 cm (43½ in.) There were no breaks in the drum assembly. Additional details and sketches can be obtained from the test report (ORNL/NTRC-013). Based on the HAC analytical structural deformation results shown in Sect. 2.7.8, the drop test damage would be nearly identical had this test been conducted on the proposed configuration using the Cat 277-4 neutron absorber. On this basis, the ES-3100 package meets the requirements of 10 CFR 71.71(c)(7).

In addition to the tests conducted on TU-4, all test units (except TU-6) were initially subjected to a free drop of 1.2 m (4 ft) onto a flat, essentially unyielding horizontal surface. As shown in Table 2.18, the orientations for these drops were two drops bottom to lid slapdown with the long axis of the drum ~12° from parallel to the drop pad; one drop with the long axis of the test unit parallel to the drop pad; two drops with the center of gravity drop over the drum/lid interface with the long axis of the drop rotated ~24.6° from perpendicular to the drop pad; and one with the long axis of the drum perpendicular to the drop pad. Package description, damage from testing, and drop orientation concerns are discussed in Sect. 2.7.1 for each test unit. Following the 1.2-m (4-ft) drop, each of these test units was subjected to the full HAC sequential test battery. The robustness of the ES-3100 containment vessel was demonstrated through whole boundary helium leak testing to $\leq 2.0 \times 10^{-7}$ cm^3/s (leaktight). This helium leak test eclipses the required criteria for both NCT and HAC based on the bounding case contents. Visual inspection of the containment boundaries showed no distortion or deformation from testing. Therefore, based on the various drop orientations, the severity of the HAC test sequence, and the testing conducted on TU-4, the ES-3100 shipping package has been shown to meet the requirements of 10 CFR 71.43, 71.51(a)(1), and 71.71(c)(7).

Fig. 2.5. NCT free drop test on TU-4.

2.6.8 Corner Drop

Requirement. 10 CFR 71.71(c)(8) requires a free drop onto each corner of the package in succession, or in the case of a cylindrical package, onto each quarter of each rim, from a height of 0.3 m (1 ft) onto a flat, essentially unyielding, horizontal surface. This test applies only to fiberboard, wood, or fissile material rectangular packages not exceeding 50 kg (110 lb) and fiberboard, wood, or fissile material cylindrical packages not exceeding 100 kg (220 lb).

Analysis. This test is not applicable because the range of package weights for the ES-3100 [146.88 kg (323.79 lb) to 187.81 kg (414.05 lb)] exceeds the weight restrictions defined in the preceding paragraph for fissile material cylindrical packages.

2.6.9 Compression

Requirement. Title 10 CFR 71.71(c)(9) requires that packages weighing up to 5000 kg (11,000 lb) must be subjected for a period of 24 h to a compressive load applied uniformly to the top and bottom of the package in the position in which the package would normally be transported. The compressive load must be the greater of the following:

1. the equivalent of five times the weight of the package or

2. the equivalent of 13 kPa (2.0 psi) multiplied by the vertically projected area of the package.

Analysis. The proposed maximum weight of the ES-3100 shipping package is calculated to be 187.81 kg (414.05 lb) [Table 2.8]. As shown on Drawing M2E801580A010 (Appendix 1.3.7), the data plate states that the maximum gross weight of the ES-3100 shipping package is 190.51 kg (420 lb). In accordance with Item 1 above, the minimum compressive load would be 5 × 190.51 kg or 952.55 kg (2100 lb). The vertically projected area of the package is 1891 cm^2 (293.16 $in.^2$) or the area of the lid weldment. Based on Item 2 above, the minimum compressive load would be 13 kPa × 1891 cm^2 or 250.72 kg (552.75 lb). Therefore, the approach stipulated in Item 1 above represents the greatest compressive load for this configuration. A conservative 1043 kg (2300 lb) compressive load was uniformly applied to the top and bottom of TU-4 for at least 24 h (Fig. 2.6). The test package had been sprayed with water as noted in Sect. 2.6.6. No change in height or diameter of the test unit resulted from the test.

Due to the design of the ES-3100 drum lid, the applied compressive load was distributed equally around the lid and supported primarily through the outer drum contour and Kaolite 1600 substrate. Little or no load is transferred to the neutron poison (BoroBond4 in TU-4) and internal liners. Therefore, the changes in the design of the liners and neutron poison proposed for this shipping package should not impact the outcome resulting from compression testing. Based on the results of compliance testing of TU-4, the insignificant changes in the design, and the possible substitution of Kaolite 1600 with Packcrete the ES-3100 package meets the requirements of 10 CFR 71.71(c)(9).

Fig. 2.6. Compression test on TU-4.

2.6.10 Penetration

Requirement. Impact of the hemispherical end of a vertical steel cylinder of 3.2-cm (1.25-in.) diam and 6-kg (13-lb) mass dropped from a height of 1 m (40 in.) onto the exposed package surface that is expected to be most vulnerable to puncture is required by 10 CFR 71.71(c)(10). The long axis of the cylinder must be perpendicular to the package surface. **Analysis.** A 6-kg (13-lb) steel cylinder was dropped from 1 m (40 in.) onto the surface of TU-4, which was previously subjected to water spray, free drop, vibration and compression tests. The penetration bar impacted the side of the drum at the welded seam near the package's center of gravity. The bar did not penetrate the drum, but an indentation 0.64-cm (0.25-in.) deep was recorded at the drum seam weld as shown in Fig. 2.7. The magnitude of this indentation is insignificant. Based on the HAC analytical structural deformation results shown in Sect. 2.7.8, the magnitude of indentation would be nearly identical had this test been conducted on the proposed configuration using the Cat 277-4 neutron absorber. On this basis, the ES-3100 package meets the requirements of 10 CFR 71(c)(10).

Fig. 2.7. Penetration test damage on TU-4.

2.7 HYPOTHETICAL ACCIDENT CONDITIONS

This section demonstrates compliance with 10 CFR 71.73, "Hypothetical Accident Conditions." It shows that the package will experience no loss in shielding effectiveness or spacing and no release of radioactive content or leakage of water into the containment vessel during HAC. A summary of the tests and analyses conducted on the ES-3100 configuration is shown in Table 2.23. Original compliance testing was conducted on test units fabricated using Kaolite 1600 as the thermal barrier and impact-absorbing material. Due to the lack of Kaolite 1600 material from the manufacturer that meets specified density requirements, a substitute inorganic castable refractory material, identified as Packcrete, was developed. To confirm the thermal-insulating and impact-limiting material equivalency of Packcrete to the previously used Kaolite 1600 material, numerous material properties were evaluated and the results are documented in RP 802282-0002. These material tests have shown that the Packcrete is functionally equivalent to Kaolite 1600. Therefore, the test results and conditions analyzed in this section using Kaolite 1600 are also applicable to Packcrete.

Title 10 CFR 71.51 requires that the ES-3100 package satisfy the standards under HAC specified in 10 CFR 71.73. For the tests specified in 10 CFR 71.73, six test packages were subjected to the five sequential tests: free drop, crush, puncture, thermal, and immersion. The configuration for TU-1 through TU-4 used full-scale shipping packages with steel mock-ups similar to the maximum contents to be shipped in the ES-3100 configuration. TU-5, also a full-scale shipping package, was dropped with a mock-up of the lightest component proposed for shipping at that time. All test units were first subjected to the NCT free drop from 1.2 m (4 ft). In addition to the 1.2-m (4-ft) drop, TU-4 was also subjected to the full battery of tests in accordance with applicable paragraphs of 10 CFR 71.71(c)(5) through (c)(10) except (c)(8). These preliminary tests were conducted to provide evidence that the ES-3100's ability to withstand HAC testing was not degraded through NCT testing. Demonstration of the ES-3100 package's ability to satisfy the requirements of HAC is provided in the following sections. A summary of the test results is provided in each area of Sect. 2.7; details are documented in the test report (ORNL/NTRC-013).

Although physical testing of the ES-3100 containers was performed generally at or near room temperature except for TU-2, the effectiveness of the Kaolite insulating material at various temperature extremes was examined through the use of laboratory testing and structural analysis of a similar package, the ES-2LM (DAC-EA-900000-A002). For low-temperature service, Kaolite specimens were tested at −28.89 and −40°C (−20 and −40°F). These tests showed little change in the response of the material as compared to room temperature. Furthermore, structural analyses for bounding soft and stiff material cases were run. The Kaolite 1600 data used in these bounding analyses were from laboratory experiments that used a heavily cured sample (stiff) and a sample to which borax had been added (soft) [Y/DW-1661]. Following the production run for the ES-2100 and DPP-2 shipping containers, new casting specimens were available for compression testing. In order to reduce the total cost of Kaolite testing, specimens were tested to approximately −40°C (−40°F) to cover both the cold conditions stipulated in 10 CFR 71.71(c)(2) and the −29°C (−20°F) temperature stipulated in 10 CFR 71.71(b)(1) and at 38°C (100°F). The results of Kaolite specimen testing are documented in Y/DW-1890 and Y/DW-1972. Upon further review of the data, the new test data was somewhat stiffer in the cold/high-density specimens than the data previously used in Y/DW-1972. Therefore, in order to encompass the extremes of all existing data, additional drop simulation sequences using the new bounding curves have been conducted on the ES-3100 package as documented in DAC-EA-801699-A001 and DAC-EA-801699-A002. In addition to the analytical effort, TU-2 was pre-chilled to a nominal temperature of −40°C (−40°F). This was accomplished by placing the unit in an environmental chamber in Building 5800 at ORNL and initially setting the chamber control to −56.7°C (−70°F) for 24 h. After this initial period, the control on the environmental chamber was set to −42.8°C (−45° F) for at least 48 h. Prior to the initiation of structural testing of this unit, the unit was removed from the environmental chamber and placed in an insulated box

and transported to the NTRC. High-temperature [up to 38°C (100°F)] behavior was not addressed. However, in light of the fact that the insulation material is typically used as a cast refractory insulation in furnace applications and that structural tests were performed in the range of 20.8 to 30.6°C (69.4 to 87°F) or just 7.4 to 17.2°C (13 to 30°F) below the high-temperature limit, it is not anticipated that any decline in impact absorption would be detrimental at 38°C (100°F).

Extensive computer impact simulation and analysis was conducted using LS-DYNA software. The results are documented in DAC-EA-801699-A001 and DAC-EA-801699-A002. Early in the design phase, simulation was used to determine areas of large structural deformation and stress concentrations. Prior to the compliance testing in accordance with 10 CFR 71.71, simulation was used to determine the drop orientation that would cause the most structural damage to the drum assembly and thereby propose a worst-case scenario for potential breeching of the containment vessel. Prior drop test programs have shown the slapdown orientation to cause the most structural degradation of a drum-style container. Computer software LS-DYNA was used to simulate a 9-m (30-ft) drop orientation at a slapdown angle of 12° with a friction factor of $\mu = 0.0$ as calculated using the computer code Slapdown, Version 05.20.93. Slapdown calculated that no matter what friction factor was assumed, the lid-end velocity peaked at ~14° (DAC-EA-801699-A001, Appendix 6.11). The maximum lid-end velocity versus the slapdown angle is presented in Fig. 6.11.6 of DAC-EA-801699-A001, and the logic for the development of this figure is explained in Appendix 6.11 of DAC-EA-801699-A001. Because of the mitigating effects of the length-to-diameter ratios and the relative closeness of the 12° increase in velocity to the maximum values (shown in DAC-EA-801699-A001, Fig. 6.11.6), the 12°slapdown is considered the worst-case slapdown. Based on the correlation of data obtained from preliminary drop tests of the similar ES-2M configuration and computer-simulated drops, several orientations were eliminated from the drop test matrix (Table 2.23). Several other impact simulations have been conducted using a wide range of material properties for the impact limiter material (Kaolite 1600) to determine the variance in structural deformation. Results of these simulations are documented in DAC-EA-900000-A002, Sect. 5.6. Although the analysis shows some variance, the magnitude of difference was not large enough to degrade the performance of the drum assembly and containment boundary. Due to the similarities in design, fabrication, and material used in construction of the shipping packages, these same results would hold true for the ES-3100 package with Kaolite 1600 or Packcrete.

Title 10 CFR 71.73(b) requires that the HAC tests, except for the water immersion tests, be conducted at the most unfavorable ambient temperature within the range of −29 to 38°C (−20 to 100°F). This requirement was previously discussed in Sect. 2.6 for NCT, in which it was concluded that the tests performed at 70 to 90°F ambient temperatures should provide essentially the same results, except for thermal, as those made at any ambient temperature between −29 to 38°C (−20 to 100°F). Buckling failures are not anticipated for this package design. This assumption is based on the fact that no evidence of buckling occurred when the package was subjected to the compression test in accordance with 10 CFR 71.71(c)(9); the water immersion tests in accordance with 10 CFR 71.73(c)(5) and 71.73(c)(6); and the 1.2- and 9-m drop test conducted on TU-4. ASME Code calculations further substantiate that buckling failures of the containment vessel are not anticipated for this package design (DAC-M900000-0003).

Title 10 CFR 71.73(b) states that the HAC initial pressure within the containment vessel during testing shall be considered as the maximum internal normal operating pressure. The internal pressures in the ES-3100 containment vessel at various temperatures for NCT are discussed in Sects. 3.3.1 and 3.3.2 and tabulated in Table 2.20. The maximum normal absolute operating pressure due to insolation and the bounding case parameters is 210.29 kPa (30.50 psia) for the containment vessel. This pressure is well below the design internal gauge pressure of 699.82 kPa (101.5 psi). Increasing the internal pressure in the containment vessel to 210.29 kPa (30.50 psia) before free drop (Sect. 2.7.1), crush (Sect. 2.7.2), puncture (Sect. 2.7.3), or water immersion (Sect. 2.7.5) testing would have no detrimental effect on the containment vessel's structural integrity due to the low stresses shown in Tables 2.21 and 2.21a. Temperature and pressure increases in the containment vessel due to the compliance thermal tests are discussed and evaluated in Sects. 2.7.4 and 3.4.3. A summary of these pressures is presented in Appendix 3.5.2.

Summarizing 10 CFR 71.43(f) and 71.55(d)(4), the tests and conditions of NCT will not substantially reduce the effectiveness of the packaging to withstand HAC sequential testing. The effectiveness of the ES-3100 to withstand HAC sequential testing is not diminished through application of the tests and conditions stipulated in 10 CFR 71.71. The justification for this statement is provided by physical testing of both the ES-2M and ES-3100 test packages, and the analytical structural deformation predicted in DAC-EA-801699-A001 and DAC-EA-801699-A002 (summarized in Sect. 2.7.8). Due to the similarities in design, fabrication, and material used in construction of both the ES-2M and the ES-3100 package, the physical characteristics of the Kaolite 1600 will hold true for both designs. The integrity of the Kaolite 1600 is not significantly affected by the NCT vibration and 1.2-m (4-ft) drop tests. Prior to testing the ES-2M design, each test unit was radiographed to determine the integrity of the Kaolite 1600 impact and insulation material. Following casting of the material inside the drum, some three-dimensional curving cracks were seen in some packages near the thinner top sections from the bottom of the liner to the bottom drum edge. After vibration testing, radiography of the ES-2M TU-4 showed that the lower half of the impact limiter was broken into small pieces. In order to evaluate these findings, TU-4 was reassembled and subjected to HAC sequential testing. After vibration and impact testing, many three-dimensional curving cracks were seen around the impact areas, and the inner liner was visibly deformed. Nevertheless, the ES-2M TU-4 maintained the adequate spacing required for shielding effectiveness and subcriticality. Temperatures at the containment boundary were also similar to other packages not subjected to vibration testing prior to HAC testing. No inleakage of water was recorded following immersion. Additionally, TU-4 of the ES-3100 test series was subjected to tests and conditions stipulated in 10 CFR 71.71(c)(5) through (c)(10), excluding (c)(8). Following completion of these NCT tests, the test unit was subjected to the full HAC test battery. Following these tests, the containment vessel was removed and subjected to a full-body helium leak test. Criteria for a leaktight condition were achieved. Based on the success of these units, vibration normally incident to transport does not reduce the effectiveness of the packaging during HAC testing. Thus, the requirements of 10 CFR 71.43(f) and 71.55(d)(4) are satisfied.

Table 2.23. Test and analysis summary for the ES-3100 package [a]

Container	NCT water spray, compression, penetration, vibration	1.2-m (4-ft) drop	9-m (30-ft) drop and crush test				1.2-m (4-ft) puncture drop	Preheat >38°C (100°F)	HAC thermal burn test	O-ring cavity leak check (operational)	Full-body helium leak test [b]	0.9-m (3-ft) immer. test	15-m (50-ft) immer. test
			Top drop	Center of gravity over lid corner	Bottom to lid slapdown	Side drop

Impact analysis		YES	YES	YES	YES	YES							
Thermal analysis	YES [d]							YES	YES [d]				

[a] Numbering refers to sequence of activities.
[b] Full-body helium leak test conducted following HAC testing. Leakage value recorded after 20 min of the test period.
[c] TU-1 was puncture tested in four different orientations.
[d] Thermal analysis was conducted to determine time for cooling to −40°C and to evaluate the application of decay heating and insolation during the cool-down phase.

2.7.1 Free Drop

Requirement. A free drop of 9 m (30 ft) onto a flat, unyielding, horizontal surface, striking the surface in a position for which maximum damage is expected is required by 10 CFR 71.73(c)(1).

Analysis. Six test packages were drop tested from 9 m (30 ft) in accordance with 10 CFR 71.73(c)(1) with the setup as shown in Fig. 2.8. A description of the drop pad is presented in Sect. 2.6.7. Four different drop positions were used in the testing based on the analytical results from LS-DYNA drop simulations. The ES-3100 test units were designated as TU-1 through TU-5. TU-4 was subjected to the full NCT testing (water spray, 1.2-m (4-ft) drop, compression, penetration, and vibration) prior to HAC testing. The gross weight of the ES-3100 test units varied between 157.4 kg (347 lb) and 204.6 kg (451 lb). Mock-up components weighing between 3.6 kg (8 lb) [TU-5] and 50.3 kg (111 lb) [TU-3] were used during testing. Discussion of the damage to each test package resulting from the 9-m (30 ft) drop is given in subsequent paragraphs. Rationale for the four drop positions is included in the discussion for each test unit. Minor changes to the mid liner and the substitution of the neutron poison from BoroBond4 to Cat 277-4 are further evaluated in Sect. 2.7.8.

Fig. 2.8. 9-m drop test arrangement for all test units.

2.7.1.1 End drop

TU-4, weighing 201.8 kg (445 lb), was dropped from 9-m (30 ft) with the long axis of the drum perpendicular to the impact surface within 0.2°. The mock-up components are shown on Drawing M2E801580A027. The concern for this drop orientation was that the containment vessel assembly would crush, buckle or compress the insulation to a thickness that would result in excessive O-ring temperatures during the thermal testing cycle. Following initial impact, the package bounced very little before landing on its side. The damage to the drum consisted of reducing the overall height from 43.5 in. [following the 1.2-m (4-ft) drop] to a minimum 42.63 in. The diameter of the drum was measured at six locations along the long axis of the package and at two radial locations. The measurements and pictorials of the damage are recorded on Test Form 1 of Procedure TTG-PRF-08 shown in the test report data sheets (ORNL/NTRC-013) and are summarized in Tables 2.24 and 2.25 and Fig. 2.9.

Fig. 2.9. 9-m drop test damage on TU-4.

2.7.1.2 Side drop

TU-2, weighing 202.8 kg (447 lb), was chilled to −40°C (−40°F) prior to conducting the drop tests. This unit was sequentially dropped from 1.2 m (4 ft), 9 m (30 ft), crushed from 9 m (30 ft), and puncture tested with the long axis of the drum parallel to the impact surface. The mock-up component used in TU-2 is shown on Drawing M2E801580A027; it weighed 49.9 kg (110 lb). There were two concerns for this drop orientation. The primary concern was that the containment vessel assembly would crush or compress the insulation to a thickness that would result in excessive O-ring temperatures during the thermal testing cycle. Another concern was that the cold temperatures might cause excessive loads and deformation in the containment vessel body during impact. This, in turn, might cause leaking above the regulatory limit to occur. The test package made a free fall with initial contact occurring between the rolling hoops of the drum and the impact surface with the ambient temperature at 24.2°C (75°F). Since it was important to evaluate the package at the regulatory minimum temperature, individual results of each test were not recorded. Time required to measure the package between drops would have allowed the package to further increase in temperature. Tables 2.26, 2.27, and 2.28 and Fig. 2.10 show cumulative results of damage to TU-2 from drop testing.

2.7.1.3 Corner drop

TU-3, weighing 203.7 kg (449 lb), was dropped from 9 m (30 ft), with the long axis of the drum at an oblique angle of 24.8° (desired angle was 24.6°) from the impact surface. The mock-up component used in TU-3 is shown on Drawing M2E801580A027; it weighed 50.3 kg (111 lb). The primary concern for this drop orientation was that the combination of plastic deformation at impact on the corner of the drum and the crushing or compacting of the adjacent insulation by the containment vessel flange would result in excessive O-ring temperatures during thermal testing. Another concern was that the mock-up contents would be forced against the containment vessel lid at impact. This, in turn, might yield the flange or closure nut, resulting in loss of containment. The test package made a free fall, with initial contact occurring between the top rim of the drum and the impact surface with the ambient temperature at 28°C (82.4°F). A secondary contact occurred between the bottom drum rim and the impact surface. No drum studs, nuts, or washers were lost due to the impact. The lid was still firmly attached to the drum assembly, with no visible separations or rips; thus, the position of the containment vessel inside the drum (and therefore the contents of the shipping container) was maintained. A general description of damage to TU-3 is summarized in Tables 2.29 and 2.30. A picture of the damage is shown in Fig. 2.11.

2.7.1.4 Oblique drops

Two oblique (slapdown) drops were conducted in the same attitude with maximum and minimum content weights to determine the structural response on the package in accordance with NRC Regulatory Guide 7.8. Paraphrasing Regulatory Position 1.6, a local structural response might be greater during an impact test if the weight of the contents were less than the maximum. Therefore, TU-1 and TU-5 contained the maximum and minimum weight configurations, respectively.

2.7.1.4.1 TU-1 slapdown

TU-1, weighing 202.3 kg (446 lb), was dropped from 9 m (30 ft) with the long axis of the unit at an oblique angle of 12.2° (desired angle was 12°) to the essentially unyielding surface. The mock-up component used in TU-1 is shown on Drawing M2E801580A027; it weighed 49.90 kg (110 lb). Based on Sect. 3.1 of NRC Regulatory Guide 7.8, the structural performance of the package must be evaluated for the minimum and maximum weight of the contents. Therefore, this unit was tested above the maximum proposed content weight to see if the containment vessel would react differently from the much lighter mock-up content used in TU-5 in a similar drop orientation. The primary concern was that the orientation would cause greater angular acceleration of the contents near the package top. This in turn would cause the containment vessel to crush or compress the insulation to a thickness that would result in excessive O-ring temperatures during the thermal testing cycle. The test package made a free fall with initial contact occurring between the rolling hoops of the drum and the impact surface with the ambient temperature at 28°C (82.4°F). No drum studs, nuts, or washers were lost due to the impact. The lid was still firmly attached to the drum assembly, with no visible separations or rips; thus, the position of the containment vessel inside the drum (and therefore the contents of the shipping container) was maintained. A general description of damage is provided in Tables 2.31, 2.32, and 2.33 and Fig. 2.12.

2.7.1.4.2 TU-5 slapdown

TU-5, weighing 157.4 kg (347 lb), was dropped from 9 m (30 ft), with the long axis of the drum at an oblique angle of 12.5° (desired angle was 12°) from the impact surface. The mock-up component (Drawing M2E801580A029), weighing 3.6 kg (8 lb), was the hardware; the majority of the mass was located near the bottom of the containment vessel (ORNL/NTRC-013). Based on Sect. 3.1 of NRC Regulatory Guide 7.8, the structural performance of the package must be evaluated for the minimum and maximum weight of the contents. Therefore, this unit was tested at the minimum proposed weight to see if the containment vessel would react differently from the much heavier mock-up content used in TU-1 in a similar drop orientation. The test package made a free fall with initial contact occurring between the bottom rim of the drum and the impact surface with the ambient temperature at 30.6°C (87°F). A secondary contact occurred between the top drum lid and the impact surface. No drum studs, nuts, or washers were lost during this impact test. The lid was still firmly attached to the drum assembly, with no visible separations or rips; thus, the position of the containment vessel inside the drum (and therefore the contents of the shipping container) was maintained. A general description of damage is provided in Tables 2.34, 2.35, and 2.36 and Fig. 2.13.

Fig. 2.13. 1.2- and 9-m drop test damage to TU-5.

2.7.1.5 Summary of results

Damage resulting from physical testing is quantitatively described including photographs in Sect. 2.7.1. The full-scale test units were fabricated in accordance with drawings created for production hardware. During the procurement process for the full-scale test units, several small changes were suggested by the manufacturer to improve the efficiency and to reduce the cost of fabrication. These changes were incorporated and tested. However, following compliance testing the following changes have been made to the proposed production hardware. First, a change in the neutron poison from BoroBond4 to Cat 277-4 has been adopted; second, the mid liner design has been changed to a continuous shell by reducing the diameter of the step in the inner liner for the containment vessel flange from 22.35 cm (8.8 in.) to 21.84 cm (8.6 in.); and third, the silicone rubber pad thickness on the drum assembly bottom liner was increased by ~0.15 cm (0.06 in.). The second change increased the amount of Kaolite 1600 around the containment vessel flange, increased the final volume of the neutron poison, and slightly decreased the volume of the Kaolite 1600 adjacent to the neutron poison. The third change was made to stiffen the rubber pad so it would remain in place during vibration normally incurred during transport. In order to evaluate the impact of these changes, analytical drop simulations were conducted and documented in DAC-EA-801699-A001 and DAC-EA-801699-A002. The drop simulations were conducted in the same attitude and temperature regime as those conducted during the compliance testing phase for certification. The results of the structural deformation from compliance testing, drop simulation using BoroBond4, and drop simulations using Cat 277-4 material are presented in Sect. 2.7.8. The analytical structural deformation results shown in Tables 2.52–2.61 are nearly identical for the two neutron poisons. The analytical results are also well representative of the results recorded during compliance testing. Analytical strain prediction in the structural components is also compared. Although there are minor differences between simulations, the overall magnitude of the strains is very similar. The thermal aspects of these changes are addressed in Chap. 3. NCT and HAC results predicted for an undamaged package show that the change in neutron poison actually reduces the final temperature of the containment vessel components. Therefore, the substitution of Cat 277-4 material and the minor changes in the inner and mid liners for production hardware should not reduce the effectiveness of the packaging when subjected to the regulatory requirements of 10 CFR 71, and the results of compliance testing would be analogous.

2.7.2 Crush

Requirement. Title 10 CFR 71.73(c)(2) requires that the specimen be subjected to a dynamic crush test in which the specimen is placed on a flat, essentially unyielding, horizontal surface so as to suffer maximum damage by the drop of a 500-kg (1100-lb) mass from 9 m (30 ft) onto the specimen. The mass must consist of a solid mild steel plate 1 m (40 in.) by 1 m (40 in.) and must fall in a horizontal attitude. The crush test is required only when the specimen has a mass ≤ 500 kg (1100 lb), an overall density ≤ 1000 kg/m^3 (62.4 lb/ft^3) based on external dimensions, and radioactive contents >1000 A_2 not as special form radioactive material. For packages containing fissile material, the radioactive contents >1000 A_2 criterion does not apply.

Analysis. Six test packages were subjected to the dynamic crush test from 9 m (30 ft) in accordance with 10 CFR 71.73(c)(2). The previously drop-tested packages (described in Sect. 2.7.1) were restrained in the orientation used for drop testing. Discussion of the damage to each test package that resulted from the crush test is given in subsequent paragraphs, with details given in the test reports (ORNL/NTRC-013). Rationale for the three drop positions is included in Sect. 2.7.1 for each test unit. The impact of the steel plate only increased the overall concern for each orientation.

TU-1, weighing 202.3 kg (446 lb), was positioned in a horizontal attitude with the damaged portion of the test unit, resulting from prior drop tests, placed on the drop pad (0° mark facing down on

test pad). The 500-kg (1100-lb) crush plate was centered over the sealing lid location on the containment vessel and dropped from 9 m (30 ft) and squarely contacted the top false wire of the drum at an ambient temperature of 29°C (84.2°F). Following initial impact, the package bounced very little before landing on its side. No drum studs, nuts, or washers were lost due to the impact. The lid was still firmly attached to the drum, with no visible separation or rips; thus, the position of the thermal barrier and neutron poison was maintained. A summary of the resulting damage is shown in Tables 2.37, 2.38, and 2.39. Since the length of the crush plate did not encompass the entire length of the test package, a crush edge indentation is recorded in Table 2.39. A pictorial of the damage is shown in Fig. 2.14.

Fig. 2.14. Cumulative damage following 9-m crush on TU-1.

TU-2 (chilled package), weighing 202.8 kg (447 lb), was positioned in a horizontal attitude with the long axis of the drum parallel with respect to the drop pad. The damaged portion of the test unit, resulting from prior drop tests, was placed nearest the drop pad (0° mark facing down on pad). The 500-kg (1100-lb) crush plate was centered over the test unit's center of gravity and dropped from 9 m (30 ft) squarely onto the top false wire of the drum at an ambient temperature of 26.8°C (80.4°F). Following initial impact, the package bounced very little before landing on its side. No drum studs, nuts, or washers were lost due to the impact. The lid was still firmly attached to the drum, with no visible separation or rips; thus, the position of the thermal barrier and neutron poison was maintained. A summary of the cumulative damage is shown in Tables 2.26, 2.27, and 2.28 in Sect. 2.7.1.2. Figure 2.10 is a photograph of the damage.

TU-3, weighing 203.7 kg (449 lb), was positioned in the same oblique attitude as previously drop tested from 9 m (30 ft). The long axis of the drum was at an oblique angle of 24.7° (desired angle was 24.6°) from the impact surface with the damaged portion of the lid in contact with the drop pad (0° mark in contact with pad). The 500-kg (1100-lb) crush plate was dropped from 9 m (30 ft) with the center of gravity of both the plate and test unit in line at an ambient temperature of 30.5°C (86.9°F). The initial impact of the plate was with the edge of the drum bottom. A secondary contact occurred between the bottom drum rim and the impact surface. One drum stud was sheared from the test unit; however, the lid was still firmly attached to the drum, with no visible separation or rips. Therefore, the thermal barrier and neutron poison was maintained in position. Tables 2.40, 2.41, and 2.42 describe the measured damage which is recorded on Test Form 3 (ORNL/NTRC-013). A photograph of the damage to TU-3 is shown in Fig. 2.15.

TU-4, weighing 201.8 kg (445 lb), was positioned vertically with the previously damaged drum top in contact with the drop pad. The 500-kg (1100-lb) crush plate was dropped from 9 m (30 ft) and squarely contacted the bottom of the test unit. The center of the 500-kg (1100-lb) crush plate was positioned over the radial test unit's center of gravity, in this case over the center of the drum's bottom at an ambient temperature of 29.8°C (85.6°F). Following initial impact, the package bounced very little before landing on its side. No drum studs, nuts, or washers were lost due to the impact. The lid was still firmly attached to the drum, with no visible separation or rips; thus, the position of the thermal barrier and neutron poison was maintained. A summary of the resulting damage is shown in Tables 2.43 and 2.44, and a photograph is shown in Fig. 2.16.

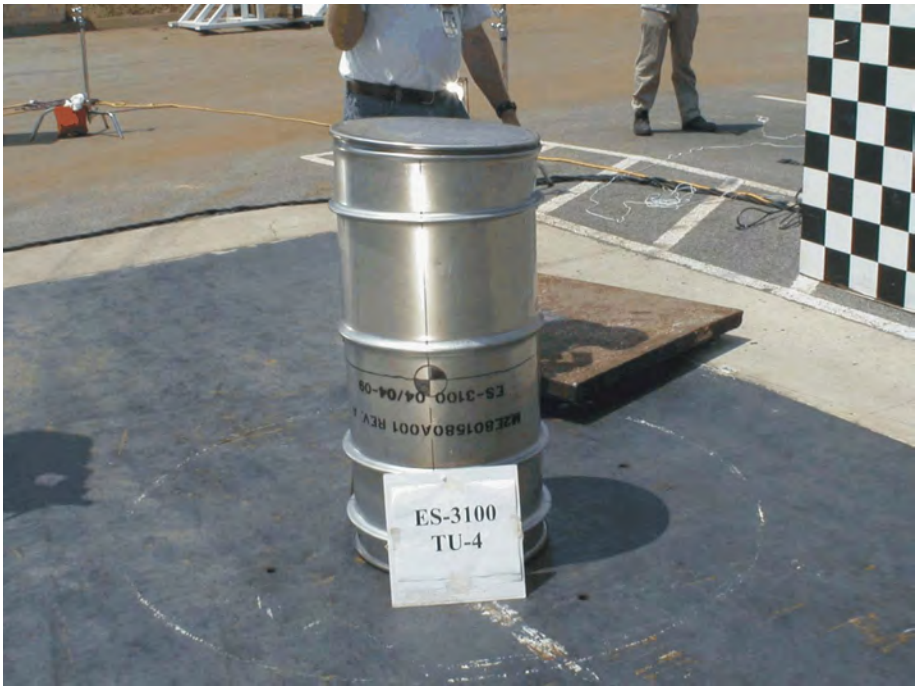

Fig. 2.16. Cumulative damage from 9-m drop and crush testing on TU-4.

TU-5, weighing 157.4 kg (347 lb), was positioned in a horizontal attitude with the damaged portion of the test unit resulting from prior drop tests placed on the drop pad (0° mark facing down on test pad). The 500-kg (1100-lb) crush plate was centered over the test unit's center of gravity and dropped from 9 m (30 ft) squarely onto the top false wire of the drum at an ambient temperature of 29.6°C (85.3°F). Following initial impact, the package bounced very little before landing on its side. No drum studs, nuts, or washers were lost due to the impact. The lid was still firmly attached to the drum, with no visible separation or rips; thus, the position of the thermal barrier and neutron poison was maintained. A summary of the resulting damage is shown in Tables 2.45, 2.46, and 2.47. Figure 2.17 is a photograph of the damage. Since the length of the crush plate did not encompass the entire length of the test package, additional indentations are recorded on Test Form 3 (ORNL/NTRC-013).

Fig. 2.17. Cumulative damage from 9-m drop and crush testing on TU-5.

Conclusion. As noted in the discussion above, plastic deformation of the drum occurred in all test packages at the impacted areas. However, the position of the impact-limiting material (Kaolite) and neutron poison material (BoroBond in TU-1 through TU-5) was maintained in all test packages. The largest area of deformation along the side of the test packages was a flat measuring 31.75 cm (12.50 in.) wide at the drum's top rolling hoop and ending with a width of 26.67 cm (10.50 in.) at the drum bottom in TU-5. Since the Packcrete material is functionally equivalent to the Kaolite 1600 material, similar results would be expected for Packcrete.

2.7.3 Puncture

Requirement. A free drop of 1 m (40 in.) from a position to obtain maximum damage onto the upper end of a solid, vertical, cylindrical, 15-cm (6-in.)–diam mild steel bar mounted on an unyielding horizontal surface, is required by 10 CFR 71.73(c)(3). The bar must be ≥20 cm (8 in.) long with the top end rounded to 6-mm (0.25-in.) maximum radius. The long axis of the bar must be vertical.

Analysis. The six units previously dropped and crushed from 9-m (30 ft) [Sects. 2.7.1 and 2.7.2] were dropped from 1 m (40 in.) in accordance with 10 CFR 71.73(c)(3). The puncture bar was bolted to the steel plate of the inside drop pad surface at NTRC (see Sect. 2.6.7 regarding the indoor drop test pad). A description of the drop orientations and results are shown in Table 2.48. Figures 2.18–2.24a show the results of puncture testing.

Conclusion. Although all test units were deformed by this puncture test, no drum surfaces were breached, thereby maintaining the integrity of the thermal barrier and neutron poison. Again, due to the fact that Packcrete is functionally equivalent to Kaolite 1600, similar results would be expected.

2.7.4 Thermal

Requirement. Exposure of the specimen fully engulfed, except for a simple support system, in a hydrocarbon fuel/air fire of sufficient extent and in sufficiently quiescent ambient conditions to provide an average emissivity coefficient of at least 0.9, with an average flame temperature of at least 800°C (1475°F) for a period of 30 min, or any other thermal test that provides the equivalent total heat input to the package and that provides a time-averaged environmental temperature of 800°C (1475°F). The fuel source must extend horizontally at least 1 m (40 in.) but may not extend more than 3 m (10 ft) beyond any external surface of the specimen, and the specimen must be positioned 1 m (40 in.) above the surface of the fuel source. For purposes of calculation, the surface absorptivity must be either that value which the package may be expected to possess if exposed to the fire specified or 0.8, whichever is greater; and the convective coefficient must be that value which may be demonstrated to exist if the package were exposed to the fire specified. Artificial cooling may not be applied after cessation of external heat input, and any combustion of materials of construction must be allowed to proceed until it terminates naturally.

Analysis. The six test units previously subjected to both NCT and HAC drop testing were thermally tested in accordance with 10 CFR 71.73(c)(4). To determine the maximum temperatures reached during thermal testing, temperature-indicating patches were placed at various locations throughout the test packages at assembly. The temperature range for each patch used is identified in Table 2.49. When the temperature of an indicator was reached, the color would change to black (i.e., blackout temperature). The range of possible blackout temperatures of the patches was from 51.67 to 260°C (125 to 500°F). For TU-1 through TU-5, Table 2.49 defines the number and location of the temperature-indicating patches. A temperature adjustment to compensate for conducting the HAC compliance tests with BoroBond4 and substituting Cat 277-4 for the production shipping containers was evaluated. This adjustment was determined by using an undamaged package and subjecting it to a thermal environment representative of that required by 10 CFR 71.73(c)(4). Based on the analytical results shown in DAC-PKG-801699-A001 and DAC-PKG-801940-A001, the containment vessel in a package using Cat 277-4 would be 2.5 to 8°F cooler than a package with BoroBond4. Therefore, the results from TU-5 are used without further adjustment due to the change in neutron poison.

Prior to the beginning of the thermal test, the No. 3 furnace at Timken Steel Company in Latrobe, Pennsylvania, was characterized for temperature and heat recovery times. Oxygen content in stack gases of the furnace was not monitored because it was not anticipated that any of the package's materials of construction were combustible. There was some burning of the silicone pads which are placed between the inner liners and the top plugs of the packages. However, it should be noted that this furnace employs "pulsed" fire burners. This type of burner is unique in that the natural gas flow rate is varied based on furnace controller demands, but the flow of air through the burners is constant, even when no gas is flowing, thereby ensuring a very rich furnace atmosphere capable of supporting any combustion of package materials of construction. The support stand was welded to a large steel plate which had been placed on the floor of the furnace prior to heating. This steel plate acted as the radiating surface at the bottom of the furnace as well as providing the ability to hold the test stand rigidly in place. Before heating the furnace, workers practiced loading and unloading test packages from the cold furnace to assure that the furnace door would not remain open >90 s during each loading. In fact, the maximum time the door was open during any loading was 64 s.

Table 2.49. Thermax temperature-indicating patches for test units

Patch location	Internal surface	External surface	Temperature range °C (°F)	Test report figure [a]
Inner liner of drum assembly		8 (full range [b]) 10 (5B & 5C)	52 to 260 (125 to 500) "B" 77–127 (171–261) [c] "C" 132–182 (270–360) [d]	5.3
Top plug weldment		4 (full range)	52 to 260 (125 to 500)	5.31
Containment vessel body flange	8 (4B & 4C)	8 (4B & 4C)	"B" 77–127 (171–261) "C" 132–182 (270–360)	5.28
Containment vessel body (end cap and cylinder)		5 (B)	"B" 77–127 (171–261)	5.28
Containment vessel sealing lid	4 (B)	4 (B)	"B" 77–127 (171–261)	5.29
Test mock-up components		6 (B)	"B" 77–127 (171–261)	5.26 & 5.27

[a] ORNL/NTRC-013.
[b] Full range labels consist of two strips; the first strip spans from 1250–3000°F in 250°F increments, and the second strip spans from 3250–5000°F in 250°F increments.
[c] Temperature-indicating labels described as "B" labels read between 1710°F and 2610°F in increments of between 90°F and 110°F.
[d] Temperature-indicating labels described as "C" labels read between 2700°F and 3600°F in increments 90°F and 110°F.

A total of 18 thermocouples was installed on the furnace surfaces and on the test package support stand (ORNL/NTRC-013). All units were tested in a horizontal attitude with the end of the package facing the right and left side walls of the furnace. The test units were thermally tested with the 0° mark on the drum facing the floor of the furnace.

TU-1 through TU-5 were preheated to >38°C (100°F) by placing the packages in an environmental chamber, which was heated by a torpedo-type kerosene space heater controlled by a mechanical bulb thermostat with a control range of 38 to 93°C (100 to 200°F). The general construction of the environmental chambers was similar: a welded steel frame with fiberglass insulation panels or blankets. The set-point temperature of the environmental chambers was monitored and adjusted for the duration of the preheat cycle. Initially, the thermostat was set to 66°C (150°F) for ~23 h to 24 h. The thermostat set point was then reduced to ≥43°C (110°F) for the remainder of the preheat cycle. All of packages were preheated for at least 47 h. Six thermocouples were attached to the exterior surface of each test package after preheating. Metal retainer clips were welded to the drum to hold the thermocouples in place. The thermocouple tips were inserted underneath the metal clips and the wire was wrapped around the metal clip. To eliminate any radiant heat exchange between the thermocouples and the furnace walls, the tips and metal clips were covered with a ceramic coating.

No test package was loaded into the furnace until all functioning thermocouples on the furnace walls and support stand had a reading of 800°C (1475°F) or higher. All packages were placed in the preheated furnace on the support stand positioned with the long axis horizontal, the package lid facing toward a furnace side wall and oriented as described above. These packages were exposed to the radiation environment for a minimum of 30 min after all functioning furnace thermocouples, and at least five of the six test package exterior surface thermocouples, reached 800°C (1475°F). During the testing, the thermocouple temperature data were recorded every 15 s.

A minimum of 24 h prior to the beginning of all testing, the furnace was turned on with a set-point temperature of 871°C (1600°F). After each test, the furnace was allowed to reheat for a minimum of 45 min after obtaining the set-point temperature before testing the next unit. The furnace control temperature data recorder ran continuously for the duration of the preheat. No test package was loaded into the furnace until all functioning thermocouples on the furnace walls and support stand had a reading of 800°C (1475°F) or higher.

Each test package was removed from the furnace and placed in an area where it was not exposed to artificial cooling. As the furnace door was opened for each test unit, smoking or flaming was visible from the TID lug hole at 0°. Flaming continued on some packages for 22 min and smoking continued up to 1 h on others. All of the packages were allowed to cool naturally to room temperature. The post-thermal test weights of each unit were recorded on Test Form 1 (ORNL/NTRC-013). The drums were disassembled, and the damage was photographed. The post-thermal test weight of each loaded containment vessel was also recorded. Each package was visually inspected, and the condition of the package and any observations were recorded.

After the containment vessels were removed from TU-1 through TU-5, two different leak tests were performed on each containment vessel. An operational leak test was conducted between the O-rings using either a CALT5 leak tester or a VTI smart station vacuum decay leak detector. Following this operational leak test, a full body helium leak test was conducted. Details of these leak tests are provided in the test report (ORNL/NTRC-013) and the results are summarized in Table 2.23. All six containment vessels were then removed from the drum assembly and immersed under a head of water of at least 0.9 m (3 ft) in a horizontal position for a period of ≥8 h. Following the immersion test of 10 CFR 71.73(c)(6), the containment vessels of TU-1 through TU-5 were opened to remove the contents, gather available data, and look for signs of water in-leakage. No water in-leakage was detected in any of the units.

The blackout temperatures on the surface of the containment boundaries, inner liners, and mock-up components used in TU-1 through TU-5 are given in the test report (Test Form 5 for each test unit). Maximum blackout temperatures recorded on the surface of all test units are tabulated in Table 2.50. These values and temperature adjustments are discussed in Sect. 3.4.3.

Conclusion. All six test packages were intact following the 30-min exposure to the high- temperature thermal environment as required in 10 CFR 71.73(c)(4). Examination during disassembly showed that the containment vessel surfaces, flanges, fasteners, sealing surfaces, and O-rings were not damaged by the thermal testing. All six containment vessel assemblies met the subsequent 0.9-m (3-ft) water immersion test and maintained a full-body helium leak rate $\leq 2.0 \times 10^{-7}$ cm^3/s. Following compliance testing, minor changes were made to the mid liner, and the neutron poison was changed from BoroBond4 to Cat 277-4. In order to evaluate the impact of these changes, extensive analytical drop simulations were utilized. The models, material properties, and drop orientations are described in DAC-EA-801699-A001 and DAC-EA-801699-A002. Results comparing structural deformation and maximum strains in the various material of construction are shown in Sect. 2.7.8. Based on the HAC analytical structural deformation results shown in Sect. 2.7.8, similar compliance test results would be expected had testing been conducted on packages employing the new proposed Cat 277-4 neutron poison. Therefore, the requirements of 10 CFR 71.73(c)(4) were satisfied, and containment was maintained.

Table 2.50. Maximum HAC temperatures recorded on the test packages' interior surfaces

2.7.4.1 Summary of pressures and temperatures

The ES-3100 shipping packages will typically be loaded at an ambient temperature and absolute pressure of ~25°C (77°F) and 101.35 kPa (14.70 psi), respectively. If the temperature of the package increases during shipment due to external temperature or insolation, the drum will not pressurize because four ventilation holes are drilled near the top of the drum, and the drum is not sealed at the drum lid–flange interface. The containment vessel is sealed at assembly. The internal pressure will increase due to transport temperatures, insolation (Sect. 3.3.1), decay heating, and the temperatures during HAC (Sect. 3.4.3). Temperature and pressures are summarized in Tables 3.5 and 3.7.

The maximum HAC adjusted internal absolute pressure in the containment vessel of the ES-3100 has been calculated and rounded up to 1206.58 kPa (175.00 psia). This predicted pressure is based on a conservative maximum average gas temperature of 167.39°C (333.31°F) as shown in Sect. 3.4.3 and Appendix 3.5.2.

2.7.4.2 Differential thermal expansion

The drum, inner liner, and containment vessel are all constructed of Type 304 or 304L stainless steel. Because of design clearances used during assembly, radial and vertical expansion among these components will not cause any interferences or thermally induced stresses. Due to similarities of the coefficient of thermal expansion between Type 304 or 304L and the containment vessel closure nut (ASTM A 479 and ARMCO Nitronic 60), the compression of the O-rings and the closure nut and containment vessel thread load do not change appreciably during the temperature excursion from 25°C (77°F) to the maximum adjusted containment vessel temperature of 198.04°C (388.48°F) [Sect. 3.4.3].

The Kaolite 1600 or Packcrete insulation and Cat 277-4 neutron poison are poured and cast in place during the fabrication of the drum assembly weldment (Drawing M2E801580A002, Appendix 1.3.7). This process produces a zero gap between the insulation and the bounding drum and inner liner and zero gap between the neutron poison and the mid and inner liners. Because of differences in coefficients of thermal expansion, some radial and axial interferences are expected from thermal growth of the liners. These radial and axial interferences have been addressed by the HAC thermal test. The results show that the stresses induced are minimal and do not reduce the effectiveness of the drum assembly.

Since there are ample clearances between the various size convenience containers and HEU contents, no induced thermal stresses from differences in coefficient of thermal expansion will exist.

2.7.4.3 Stress calculations

The temperature gradient on the containment vessel was essentially uniform from top to bottom during the thermal tests (Table 2.50). The gradient around the periphery of the six test units was also essentially uniform and similar to the vertical gradient. As noted in the ES-3100 test report, the temperatures recorded on the containment vessels of all the test units were fairly uniform, both vertically and circumferentially. The maximum temperature variation on the containment vessels was ~50°F (from the test temperatures reported in Table 2.50). No damage would be expected on the containment vessel from thermal stresses resulting from a temperature differential of this magnitude. This conclusion is based on the guidelines given in the ASME Code, Sect. III, Div. 1. Thermal stress is defined as a self-balancing stress produced by a nonuniform distribution of temperature (ASME Code, Sect. III, Paragraph NB-3213.13). This paragraph further states that there are two types of thermal stresses: general thermal stress and local thermal stress. An example of a general stress is that produced by an axial temperature distribution in a cylindrical shell (ASME Code, Paragraph NB-3213.9). This general stress is further classified as a secondary stress (that is, a normal stress or a shear stress developed by the constraint of adjacent materials or by self-constraint of the structure) [ASME Code, Paragraph NB-3213.9]. Paragraph NB-3213.9 further states that the basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions that cause the stress to occur, and failure from a single application would not be expected. An example of a local thermal stress is a small hot spot in the wall of a pressure vessel (ASME Code, Paragraph NB-3213.13). Local thermal stress is associated with almost complete suppression of the differential expansion and thus produces no significant distortion. Such stresses are considered only from a fatigue standpoint. Fatigue will not result from a one-time cyclic event such as an accidental fire.

The principal effect of the elevated temperature on stress levels is caused by the increase in the internal pressure. The calculated stresses as shown in Table 2.51 were determined by multiplying the stress at the evaluation conditions (DAC-M900000-0002) by a factor equal to the ratio of operating pressures to evaluation pressures and adding any contribution from the closure nut preload. This methodology is based on the application of linear elastic material behavior. As shown in Sect. 2.7.4.4, all

stresses in the containment vessel components (based on nominal dimensions for the components) are well below the ASME Code allowable stress intensity limits.

2.7.4.4 Comparison with allowable stresses

As noted in Sect. 2.7.4.3, the differential stresses resulting from temperatures recorded during HAC are negligible. Also, as shown in Table 2.51, stresses of this low magnitude do not affect the adequacy of the packaging. Corresponding calculated stress regions are shown in Fig. 2.1.

2.7.5 Immersion—Fissile Material

Requirement. In those cases for which water leakage into the containment boundary has not been assumed for criticality analysis, the specimen must be immersed under a 0.9-m (3-ft) head of water in an attitude for which maximum leakage is expected, as required by 10 CFR 71.73(c)(5).

Analysis. The containment vessels for the ES-3100 test packages (TU-1 through TU-5) were removed from their respective drum assemblies following the thermal tests described in Sect. 2.7.4. After examination for damage (distortion, warpage, heating), the volume between the O-rings was pressurized, and the O-ring seals were leak checked in accordance with either the CALT5 manufacturer's instructions manual using the CALT5 leak tester or the VTI instructions manual using the VTI smart station vacuum decay leak detector. Following the O-ring cavity check, the containment vessel lids were drilled and tapped for a full-body helium leak check. The seals remained functional on all vessels, and the integrity of the containment vessel structure was maintained (indicated by a helium leak rate $\leq 2.0 \times 10^{-7}$ cm^3/s). Following these leak tests, each unit was then submerged under a 0.9-m (3-ft) head of water for at least 8 h. No water leakage into the vessel was seen in any of the test units. The results of this test are recorded on the data sheet of Procedure TTG-PRF-14 shown in test report ORNL/NTRC-013 for units TU-1 through TU-5. It should be noted that the criticality analysis does assume water leakage into the ES-3100 containment vessel; however, the 0.9-m (3-ft) immersion tests were performed anyway.

2.7.6 Immersion—All Packages

Requirement. A separate, undamaged specimen must be immersed under water at a pressure equivalent to a 15-m (50-ft) head of water, as required by 10 CFR 71.73(c)(6). This requirement may be satisfied by an external pressure of 150 kPa (21.7 psi) gauge.

Analysis. Immersion under a 15-m (50-ft) head of water would result in water entering the drum because the plastic plugs covering the four ventilation holes could fail, and the drum/lid flange is not gasketed. The ES-3100 containment vessel has been designed and tested for an external pressure of 150 kPa (21.7 psi) gauge and an internal gauge pressure of 699.82 kPa (101.5 psi), using nominal dimensions for all vessel components. Each containment vessel design incorporates an O-ring seal of verified integrity to provide assurance that no water will penetrate the containment boundary. The containment vessel of TU-6 was subjected to this 15-m (50-ft) water immersion test. No visible signs of water leakage into the containment boundary were recorded.

2.7.7 Deep Water Immersion Test (for Type B Packages Containing More than 10^5 A_2)

The amount of A_2s proposed for transport is ~4753. Therefore, the deep water immersion test is not applicable.

Table 2.51. HAC ES-3100 containment vessel stress compared to the allowable stress

Stress locations shown in Fig. 2.1	Thermal condition 10 CFR 71.73 (c)(4) [a] @1105.23 kPa (160.30 psi) gauge & 167.39°C (333.31°F)		Internal pressure evaluation [a, b] @ 1378.95 kPa (200 psi) gauge	Allowable pressure, or stress [a] up to 204.44°C (400°F)
	kPa (psi)	M.S. [c]	kPa (psi)	kPa (psi)
Top flat portion of sealing lid(edge of hole in center of lid)	1.902×10^4 (2,758)	10.1	2.173×10^4 (3,152.2)	1.924×10^5 (27,900) [d]

Cylindrical section (middle) external pressure			1.496×10^2 (21.7)	7.584×10^2 (110) [f]
Cylindrical section (shell-to-flange interface)	4.353×10^4 (6,314)	3.8	4.975×10^4 (7,215.9)	1.634×10^5 (23,700) [d]
Cylindrical section (shell-to-bottom interface)	1.009×10^5 (14,639)	1.6	1.153×10^5 (16,730)	1.634×10^5 (23,700) [d]
Body flange threads joint	1.726×10^5 (25,031)	1.9	1.972×10^5 (28,607)	2.608×10^4 (47,400) [g]
Body flange thread region (under cut region)	8.065×10^4 (11,698)	2.0	9.218×10^4 (13,369)	1.634×10^5 (23,700) [c]
Flat bottom head (center)	8.436×10^4 (12,236)	1.9	9.642×10^4 (13,984)	1.634×10^5 (23,700) [c]
Closure nut threads joint	4.467×10^4 (6,479)	4.6	5.105×10^4 (7404.1)	3.353×10^4 (29,700) [g]

[a] Stresses are calculated using pressures, gasket and closure nut preload, and nominal dimensions for all containment vessel components (DAC-M900000-0002). Allowable stress values are taken from Table 2.5 up to 204.44°C (400°F).
[b] Immersion conditions have been evaluated with results shown in Table 2.6 under the external pressure design evaluation column.
[c] Margin of safety = allowable stress/actual stress.
[d] Stress interpreted as the sum of $P_l + P_b$; allowable stress intensity value is $1.5 \times S_m$.
[e] Stress interpreted as the primary membrane stress (P_m); allowable stress intensity value is S_m.
[f] Allowable external pressure [kPa (psi)].
[g] Stress interpreted as the sum of $P_l + P_b + Q$; allowable stress intensity value is $3.0 \times S_m$.

2.7.8 Summary of Damage

After testing six full scale ES-3100 test packages under HAC, the drum, drum lid, and top plug were damaged as expected. The containment vessel flange, O-ring grooves, and closure nut were not damaged. Plastic deformation occurred in the six drum assemblies in the impact areas from the 1.2-m (3.9-ft) and 9-m (30-ft) drop, crush and subsequent puncture tests. No breaks were noted in the drum assembly, and no insulation was exposed. The resultant damage did not reduce the effective center-to-center package spacing to a point of criticality concern (Chap. 6).

The full-scale test units (TU-1 through TU-6) were fabricated in accordance with drawings created for production hardware. During the procurement process for the full-scale test units, several small changes were suggested by the manufacturer to improve the efficiency and to reduce the cost of fabrication. These changes were incorporated and tested. However, after compliance testing on the first seven test units, the following changes have been made to the proposed production hardware. First, a change in the neutron poison from BoroBond4 to Cat 277-4 has been adopted; second, the mid liner design has been changed to a continuous shell by reducing the diameter of the step in the inner liner for the containment vessel flange from 22.35 cm (8.8 in.) to 21.84 cm (8.6 in.); and third, the silicone rubber pad thickness on the drum assembly bottom liner was increased by ~0.15 cm (0.06 in.). The second change increased the amount of Kaolite 1600 around the containment vessel flange, increased the final volume of the neutron poison, and slightly decreased the volume of the Kaolite 1600 adjacent to the neutron poison. The third change was made to stiffen the rubber pad so it would remain in place during vibration normally incurred during transport. In order to evaluate the impact of the above changes on the original HAC test units (TU-1 through TU-5), analytical drop simulations were conducted and documented in DAC-EA-801699-A001 and DAC-EA-801699-A002. The drop simulations were conducted in the same attitude and temperature regime as those conducted during the compliance testing phase for certification. Temperature dependent material properties were used in the analysis. The results of the structural deformation from compliance testing, drop simulation using BoroBond4, and drop simulations using Cat 277-4 material are presented in the following tables and figures. The analytical structural deformation results shown in Tables 2.52–2.61 are nearly identical for the two neutron poisons. The analytical results are also well representative of the results recorded during compliance testing as depicted in Figs. 2.25–2.30. Analytical strain prediction in the structural components is also compared for the two neutron poisons. Although there are minor differences between the compliance testing and drop simulations, the overall magnitude of the strains is very similar. The thermal aspects of these changes are addressed in Chap. 3. NCT and HAC results predicted for an undamaged package show that the change in neutron poison actually reduces the final temperature of the containment vessel components. Therefore, the substitution of Cat 277-4 material and the minor changes in the inner and mid liners for production hardware should not reduce the effectiveness of the packaging when subjected to the regulatory requirements of 10 CFR 71.71 and 71.73, and the results of compliance testing would be analogous. Some of the test units lost ~0.45 kg (1 lb) of their gross weight due to boiling off of the water trapped in the refractory and BoroBond4 materials (Table 2.62).

Assuming all water loss is from the neutron poison, the BoroBond4 material lost ~9.4% of its water content. Using the temperature data recorded during HAC testing shown in Table 2.50 and applying the temperature adjustments discussed in Sect. 3.4.3, the average temperature of the neutron poison would be ~150°C (302°F). Since the ES-3100 test units were not fabricated packages with Cat 277-4, thermogravimetric analysis (TGA) was used to compare the neutron poison's propensity to lose water. The results of this analysis are shown in Y/DV-1914, *Summary of TGA Testing of Borated Concrete and Adhesive-Backed Silicone Foam*. Samples of both BoroBond4 and Cat 277-4 were TGA tested, and the results were compared at 150°C (302°F). The BoroBond4 samples lost ~ 61.6% of their original water content. The dry Cat 277-4 lost a maximum of only 6.61%. The BoroBond4 TGA samples lost ~6.5 times the amount of water lost by the ES-3100 test units during HAC compliance testing. Assuming comparable results would be expected for the Cat 277-4 material due to similarity in the structural configuration, installation methodology, and LS-DYNA drop simulation structural deformation results, the Cat 277-4 water loss would be only 1.02%. Criticality safety analysis assumes a greater percent loss; therefore, additional conservatism is being applied in this SARP.

The maximum blackout temperature recorded adjacent to the O-rings during testing was 127.22°C (241°F) [Table 2.50]. Using the adjustments discussed in Sect. 3.4.2, the maximum adjusted temperature at the containment boundary O-rings during shipment under HAC was calculated to be 186.79°C (368.23°F). As shown in Fig. 2-24 of the *Parker O-Ring Handbook*, these O-ring materials

can survive at the predicted temperature shown in Table 3.29 [186.79°C (368.23°F)] for ~ five hours. Based on the O-ring temperature curve shown in Fig. 7-24 of DAC M801940-0002, the O-ring temperature would have fallen ~40°F to 328°F over that 5 hour period. At ~328°F, the O-ring should be able to survive ~20 hours. The total length of time above the continuous service temperature of 150°C (302°F) for the EPDM O-ring is ~11 hours. Based on the predicted data and the curves from *Parker O-Ring Handbook*, the thermally tested packages with all the conservative adjustments would remain below the acceptable time at temperature limits. Therefore, these adjusted temperatures would not adversely affect the containment vessel O-rings.

Table 2.62. ES-3100 test package weights before and after 10 CFR 71.73(c)(4) HAC testing

Test Unit	Pre-test [a] weight [kg (lb)]	Post-test [a] weight [kg (lb)]	Thermal test weight loss [kg (lb)]	BoroBond4 or Cat 277-4 original weight [kg (lb)]	Water weight in BoroBond4 or Cat 277-4 [kg (lb)]	Water loss percent [d] (%)
1	202.3 (446)	202.3 (446)	0.0 (0)	20.7 (45.64) [b]	4.91 (10.82) [c]	0.00
2	202.8 (447)	202.8 (447)	0.0 (0)	20.5 (45.19) [b]	4.86 (10.72) [c]	0
3	203.7 (449)	203.2 (448)	0.45 (1)	20.5 (45.19) [b]	4.87 (10.74) [c]	9.31
4	201.8 (445)	201.4 (444)	0.45 (1)	20.4 (44.97) [b]	4.84 (10.66) [c]	9.38
5	157.4 (347)	156.9 (346)	0.45 (1)	20.6 (45.42) [b]	4.89 (10.77) [c]	9.29

[a] ORNL/NTRC-013.
[b] Weight of BoroBond4 and water obtained from casting data (Barton).
[c] This weight is based on TGA measurements and calculation showing that the minimum water percent is 23.71%.
[d] All weight loss attributed to loss of water in BoroBond4 or 277-4.

Following the thermal test, all six containment boundaries were subjected to leak testing of the O-ring cavity as well as the full-body helium leak check. To verify the entire containment boundary, all test units were drilled and tapped for a helium leak check using the procedure documented in the test report (ORNL/NTRC-013). The procedure consisted of creating a near vacuum inside the containment vessel and supplying a helium environment around the exterior of the assembly. The maximum recorded helium leak rate for any of these containment vessels was 2.0×10^{-7} cm^3/s as documented after 17 min of leak checking. This procedure measures leakage in the opposite direction to leakage from the vessel. It could be postulated that the additional pressure differential (ambient on the exterior and a near vacuum inside) would help to further compress the O-rings during this test. However, since the containment vessel closure nut is screwed down, the additional pressure does not compress the O-ring more than a few ten thousands of an inch based on mismatch between the internal and external threaded joint. Only rotation of the closure nut will alter O-ring compression significantly. Pictures taken of all containment vessel tops following testing showed that the closure nut had rotated a maximum of 0.15 cm (0.060 in.) [Fig. 2.31] from its original radial position obtained during assembly (Fig. 2.32) except for TU-4, which showed no rotation. Based on the pitch of the closure nut, this rotation translates into only 0.0009 cm (0.00035 in.) decompression of the O-rings. This compares to the original nominal compression of 0.064 cm (0.025 in.). According to the *Parker O-Ring Handbook*, the minimum squeeze for all seals, regardless of cross section, should be ~0.018 cm (0.007 in.). Using the nominal compression of 0.064 cm (0.025 in.) and subtracting the decompression from rotation and the minimal pressure differential compression, there is ample O-ring compression. Therefore, the leak test in either direction for this containment vessel arrangement is valid. As required in 10 CFR 71.73(c)(5), the containment vessels were submerged under a 0.9-m (3-ft) head of water following the leakage tests, with no water in-leakage permitted. Following this immersion test, the containment vessels were opened. The lid assembly, with the O-rings in place on the body, are joined together by torquing the closure nut and sealing lid assembly to 162.7 ± 6.8 N·m (120 ± 5 ft-lb). The lowest break-loose torque value of 40.7 N·m (30 ft-lb) was recorded for TU-4. Visual inspection following the testing indicated that neither the vessel bodies, the O-rings, the seal areas, nor the vessel lid assemblies were damaged during the tests. In TU-5, the convenience cans had buckled from the pressure differential caused during the leak testing operation. However, the containment vessel wall showed little or no signs of impact. Therefore, based on the success of these seven test units (including the containment vessel of TU-6) and the analytical drop simulation effort, the structural integrity of the ES-3100 package, with the previously mentioned modifications, meets all the applicable requirements of 10 CFR 71.73 for transport of the proposed contents.

Fig. 2.31. Containment vessel markings at assembly (swivel hoist ring removed prior to testing).

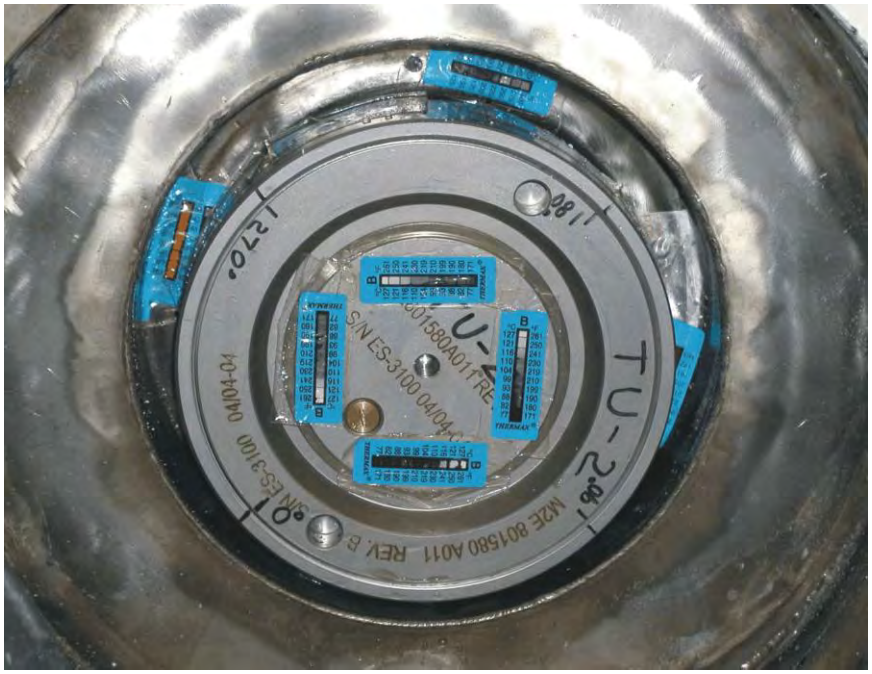

Fig. 2.32. Containment vessel marking after compliance testing.

2.8 ACCIDENT CONDITIONS FOR AIR TRANSPORT OF PLUTONIUM

The proposed contents to be shipped in the ES-3100 have only trace amounts of transuranic isotopes. Since the contents contain no more than an A_2 quantity of plutonium in any isotope or form and will be shipped in accordance with 10 CFR 71.5 per 10 CFR 71.88(a)(3), the requirements in 10 CFR 71.74 are not applicable.

2.9 ACCIDENT CONDITIONS FOR FISSILE MATERIAL PACKAGES FOR AIR TRANSPORT

The expanded tests specified in 10 CFR 71.55(f)(1), (2), or (3) for fissile material package designs for air transportation were not conducted. The issue of subcriticality is addressed in Chap. 6 with content mass limits as addressed in Sect. 1.2.2 for air transport.

2.10 SPECIAL FORM

The package does not include any special form of radioactive material. Hence, the requirements of 10 CFR 71.75 and 71.77 are not applicable.

2.11 FUEL RODS

The contents do not utilize cladding for the containment of radioactive materials. Therefore, this requirement is not applicable.

3. THERMAL EVALUATION

Design analysis, similarity, and full-scale testing (see Chap. 2) have demonstrated that the ES-3100 shipping package is in compliance with the applicable requirements of Title 10 Code of Federal Regulations (CFR) 71 (10 CFR 71) when used to ship highly enriched uranium (HEU) having a maximum gross weight up to 35.2 kg (77.60 lb). The ES-3100 has a nominal gross shipping weight that ranges from 146.88 kg (323.79 lb) to 187.81 kg (414.05 lb) for the empty and maximum weight containment vessel configurations shown in Table 2.8, respectively.

3.1 DESCRIPTION OF THERMAL DESIGN

The drum assembly of the shipping package is defined as the structure that maintains the position of and provides the impact and thermal barrier surrounding the containment boundary. Preserving the location of the containment boundary within the packaging prevents reduction of the shielding and subcriticality effectiveness. The nominal weight of the drum assembly is 131.89 kg (290.76 lb).

The ES-3100 package is evaluated for a maximum heat source of 5 W (Sect. 3.1.2); however, no active cooling systems or specific thermal design features are required. A lightweight cast refractory insulation between the inner liner and the drum provides thermal protection of the contents from external heat sources.

Thermal criteria are applied to the package in accordance with 10 CFR 71 for Normal Conditions of Transport (NCT) and Hypothetical Accident Conditions (HAC). These requirements specify that each package design provide containment, shielding, and criticality safety at temperatures ranging from −40 to 38°C (−40 to 100°F) with full insolation. Also, in accordance with *Packaging and Transportation of Radioactive Material* [10 CFR 71.43(g)], a package must be designed, constructed, and prepared for transport so in still air at 38°C (100°F) and in the shade no accessible surface of a package would have a temperature exceeding 50°C (122°F) in a nonexclusive use shipment, or 85°C (185°F) in an exclusive use shipment. In addition, each package will experience no significant reduction in effectiveness as the result of being exposed to a thermal radiation environment of 800°C (1475°F) for 30 min with an emissivity coefficient of at least 0.9.

The maximum internal pressures and thermal stresses for both NCT and HAC are discussed and calculated (Sects. 3.3.2, 3.3.3, and 3.4.3) for use in the structural evaluation. The calculated pressures are well below the design pressures of the package components, and the effect of thermal stresses on the package is negligible (Sects. 2.6.1.2 and 2.7.4.2).

Compliance with the NCT thermal requirements is shown by analysis (Sect. 3.3.1). Since the components to be shipped have a maximum decay heat load of 5 W, a thermal analysis was conducted for the ES-3100 package (DAC M801940-0002) using both Kaolite 1600™ and Packcrete material properties. The maximum predicted temperature on the exterior of the package, while stored at 38°C (100°F) in the shade, is 39.42°C (102.96°F) [Table 3.14, Node K]. The analysis shows that no accessible surface of the package would have a temperature exceeding 50°C (122°F). Therefore, the requirement of 10 CFR 71.43(g) would be satisfied. If the package is exposed to solar radiation at 38°C (100°F) in still air, the conservatively calculated temperatures at the top of the drum, center of containment vessel lid, and on the containment vessel near the O-ring sealing surfaces are 119.38°C (246.88°F), 89.60°C (193.28°F), and 89.53°C (193.15°F), respectively (Sect. 3.3.1 and Table 3.16). For

conservatism, the O-ring sealing surface temperature will be assumed to be 89.60°C (193.28°F). At the low-temperature range and neglecting decay heating, the package components would stabilize at −40°C (−40°F), which is within normal operating limits of the packaging materials (Sect. 2.2).

Six full-scale packages were subjected to the HAC thermal test following the drop, crush and puncture tests (Sects. 2.7.1 through 2.7.3). All of these test packages were exposed to a thermal radiation environment of >800°C (>1475°F) for well over 30 min in a furnace. Other temperature conditions before and during the thermal testing are given in ORNL/NTRC-013 for the furnace, test packages, and package supports. The maximum temperature recorded during the tests on the external surface of any of the containment vessels was 127.2°C (261°F). This containment vessel maximum temperature reading is the highest value shown in Table 3.4. This temperature was recorded on Test Unit (TU)-4 and TU-5 on the containment vessel sealing lid. The maximum internal temperature adjacent to the O-rings was 116°C (241°F). Temperature adjustments are then added to the containment vessel's maximum recorded temperature to correct for measuring accuracy, insolation heating before the thermal test, internal decay heating, insolation heating during cool down, location of crush plate damage, neutron poison substitution, thermal capacitance difference between mockups and actual contents, and impact limiting material variations. Detailed discussion of each temperature adjustment is provided in Sect. 3.4.3. Although TU-5 was tested with a mock-up that represented the lightest proposed content at that time, a new lower weight limit has been established (empty containment vessel). The containment vessel's recorded temperature values were lower on all other test units, which consisted of much heavier mock-up contents. Therefore, a temperature correction is needed for weight differences of the contents shipped and the tested weights.

3.1.1 Design Features

The drum assembly for the ES-3100 consists of an internally flanged Type 304L stainless-steel 30-gal modified drum with two Type 304L stainless-steel inner liners, one filled with noncombustible cast refractory insulation and impact limiter and one filled with noncombustible cast neutron poison; a stainless-steel top plug with noncombustible cast refractory insulation, silicone rubber pads, silicon bronze hex-head nuts, and a stainless-steel lid and bottom (Drawing M2E801580A031, Appendix 1.3.7). The drum's diameter (inner diameter of 18.25 in.) and corrugations meet the requirements of Military Standard MS27683. All other dimensions are controlled by Drawing M2E801580A004 (Appendix 1.3.7). Modifications to the drum from MS27683 include the following: (1) the overall height was increased; (2) the drum was fabricated with two false wire open ends; and (3) a 0.27-cm (12-gauge, 0.1046-in.)–thick concave cover was welded to the bottom false wire opening (Drawing M2E801580A005, Appendix 1.3.7). Four 0.795-cm (0.313-in.)–diam equally spaced holes are drilled in the top external sidewall to prevent a pressure buildup between the drum and inner liner. The holes are filled with a plastic plug to provide a moisture barrier for the cast refractory insulation during NCT. The cavity created by the inner liners is a three-tiered volume with a 37.52-cm (14.77-in.) inside diameter 13.26-cm (5.22-in.) deep, a 21.84-cm (8.60-in.) inside diameter 5.59-cm (2.20-in) deep, and an additional 15.85-cm (6.24-in.) inside diameter 78.31-cm (30.83-in.) deep. Drum and inner liner wall thickness is 0.15 cm (16 gauge, 0.0598 in.).

The volume between the drum and mid liner is filled with a lightweight noncombustible cast refractory material called Kaolite 1600 (Kaolite product data sheet) or Packcrete. Both materials are composed of portland cement, water, and vermiculite and have an average density of 358.8 kg/m^3 (22.4 lb/ft^3). The procedures for manufacturing and documenting Kaolite 1600 material, JS-YMN3-801580-A003 (Appendix 1.3.4), and Packcrete material, SPC M801794-0003 (Appendix 1.3.11) and SPC M801580-0003 (Appendix 1.3.12), are referenced on Drawings M2E801580A002 and M2E801580A008 (Appendix 1.3.7) for the drum body weldment and top plug weldment, respectively.

Both insulation types have a maximum continuous service temperature limit of 871°C (1600°F) due to the presence of the vermiculite and portland cement.

The volume inside the center liner tube is filled with a noncombustible cast neutron poison (absorber) material called Cat 277-4, which is created by mixing Cat 277-0 material from Shieldwerx (SWX-277-0) and boron carbide (B_4C). The material is composed of aluminum, magnesium, calcium boron, carbon, silicon, sulfur, sodium, iron, and water. The final mixture will have an average density of 1762 kg/m^3 (110 lb/ft^3). The procedure for manufacturing and documenting this material, JS-YMN3-801580-A005 (Appendix 1.3.5), is referenced on Drawing M2E801580A002 (Appendix 1.3.7). This neutron poison material has a maximum continuous service temperature limit of 150.0°C (302°F). At this temperature, the moisture inside the Cat 277-4 material remains an integral part of the composite material, and moisture content loss is negligible.

The top plug is fabricated in accordance with Drawing M2E801580A008 (Appendix 1.3.7), with an overall diameter of 36.50 cm (14.37 in.) and a height of 13.41 cm (5.28 in.). The plug's rim, bottom sheet, and top sheet are fabricated from 0.15-cm (16-gauge, 0.0598-in.)–thick Type 304/304L stainless-steel sheet per ASME SA-240. Four lifting inserts are welded into the top sheet for loading and unloading operations. The internal volume of the top plug assembly is filled with either Kaolite 1600 in accordance with JS-YMN3-801580-A003 (Appendix 1.3.4) or Packcrete in accordance with SPC M801794-0003 (Appendix 1.3.11) and SPC M801580-0003 (Appendix 1.3.12).

Three silicone rubber pads complete the drum assembly. One pad is placed on the bottom of the most inward liner to support the containment vessel during transport. Another pad is placed on the top shelf of the mid liner to support the top plug during transport. The final pad is placed over the top of the containment vessel lid and closure nut assembly. Pads are molded to the shapes as defined on Drawing M2E801580A009 (Appendix 1.3.7) using silicone rubber with a Shore A durometer of 22 ± 5.

3.1.2 Content's Decay Heat

The maximum decay heat and radioactivity of the contents (Chap. 4) are based on a maximum of 35.2 kg of HEU in the isotopic and mass distribution at fabrication as shown in Table 3.1.

Table 3.1. Isotopic mass and weight percent for the HEU contents [a]

Nuclide	Weight percent	Mass (g)
^{232}U	0.000004	0.001408
^{233}U	0.600000	211.200000
^{234}U	2.000000	704.000000
^{235}U	54.819996	19,296.638592
^{236}U	40.000000	14,080.000000
^{238}U	0.000000	0.000000
Transuranic	0.080000 [b]	28.160000
^{237}Np	2.500000	880.000000
Total	**100.000000**	**35,200.000000**

[a] Weight percent values of individual isotopes are those that generate the largest activity within the allowable ranges presented in Sect. 1.2.2.

[b] The transuranic weight percent of 0.080000 applies to ground transport only. The maximum transuranic weight percent in contents transported by air will be 0.004000.

Using the ORIGEN-S program (NUREG/CR-0200) for determining decay heat values and predicting the isotopic decay patterns from 0 to 70 years from original fabrication, the following decay heat loads are predicted and shown in Table 3.2. Isotopic mass distribution has been calculated in Chap. 4 and shown in Table 2 of Appendix 4.5.1. The maximum decay heat load is rounded up from 3.494 to 5 W, and 5 W is used in subsequent analyses for temperature predictions. Contributions from the transuranics and ^{237}Np at the bottom of Table 3.2 remain constant for the time period evaluated. The decay heat per gram value used for the transuranic isotopes was an average of the decay heat values for ^{238}Pu, ^{239}Pu, ^{240}Pu, ^{241}Pu, ^{242}Pu and ^{241}Am. As shown in Chap. 1, some Thorium (^{232}Th) compounds or oxides mixed with uranium are proposed for transport. Shipping of ^{232}Th is bounded by the analysis using uranium for containment or hydrogen gas generation shown in Appendix 3.5.4 due to the following: (1) the A_2 of ^{232}Th is unlimited; (2) the decay energy of ^{232}Th is less than all other uranium isotopes; and (3) the half-life of ^{232}Th is significantly longer than the uranium isotopes.

3.1.3 Summary Tables of Temperatures

3.1.3.1 NCT summary tables

Thermal evaluation of the ES-3100 package design for NCT was performed by analysis (DAC-PKG-801699-A001, DAC-PKG-801940-A001, and DAC M801940-0002). The ES-3100 shipping container has been conservatively evaluated empty of all containment vessel internal components for NCT. A summary of the maximum and minimum predicted temperatures for the drum assembly and containment vessel are shown in Table 3.3. A comprehensive discussion of the NCT evaluation is provided in Sect. 3.3.

3.1.3.2 HAC temperature summary tables

Thermal evaluation of the package design for HAC was performed by a combination of physical testing and analysis. Temperature indicators (patches) were placed on the surface of each containment vessel, inner liner, and mock-up component during thermal testing. The blackout temperatures that occurred during thermal testing are recorded for each test unit; the maximum blackout temperatures are listed in Table 3.4. In order to more accurately predict the final HAC temperatures, the blackout temperatures are increased to account for (1) the temperature interval between blackout dots; (2) the temperature increase due to the effects of applying solar insolation prior to the HAC thermal test; (3) the temperature increase due to the decay heat load of the actual contents being shipped; (4) the temperature increase due to the effects of applying solar insolation during post-HAC thermal test cool down; (5) effects of crushing at different locations along the body of the shipping package; (6) thermal capacitance difference in the proposed contents and hardware used during testing; and, (7) temperature difference resulting from variations in impact limiting material properties (Kaolite 1600 vs Packcrete). A summary of the maximum and minimum predicted temperatures for the drum assembly and containment vessel is shown in Table 3.5. A comprehensive discussion of the HAC evaluation is provided in Sect. 3.4.

Table 3.2. Decay heat for 35.2 kg of HEU content (watts)

Decay heat (Watts per gram)	Isotope	Decay time								
		0 years	5 years	10 years	20 years	30 years	40 years	50 years	60 years	70 years

[b] Maximum ethylene propylene diene monomer O-ring seal life at 186.79°C (368.23°F) is on the order of about 5 hours (*Parker O-Ring Handbook*, Fig. 2-24). Limit shown is for 1000 h of continuous service at a temperature up to 150°C (302°F).

3.1.4 Summary Tables of Maximum Pressures

3.1.4.1 Maximum NCT pressures

Table 3.6 summarizes the results from Appendix 3.5.1 in which the pressure of the containment vessel when subjected to the tests and conditions of NCT per 10 CFR 71.71 has been determined for the most restrictive containment vessel arrangements (CVAs) shipped in the ES-3100. The most restrictive CVAs are those in which the void volume inside the containment vessel is minimized based on content volumes and those CVAs that carry the largest mass of items that offgas at the predicted temperatures during NCT. Several convenience container heights are proposed for shipment (Fig. 1.4). Shipping configurations will use these containers in any configuration as long as it does not exceed the HEU weight limit and form and does not exceed the height constraint of the containment vessel. However, in order to determine the worst-case shipping configuration, the arrangements that minimize the void volume inside the containment vessel are analyzed as follows:

1. one shipment will contain six cans with external dimensions of 10.8-cm (4.25-in.) diam by 12.38-cm (4.875-in.)–high cans;

2. one shipment will contain five cans with external dimensions of 10.8-cm (4.25-in.) diam by 12.38-cm (4.875-in.)–high cans and three can spacers;

3. one shipment will contain three cans with external dimensions of 10.8-cm (4.25-in.) diam by 22.23-cm (8.75-in.) high and two can spacers;

4. one shipment will contain three cans with external dimensions of 10.8-cm (4.25-in.) diam by 25.4 cm (10 in.) high;

5. one shipment will contain six nickel cans with external dimensions of 7.62-cm (3.00-in.) diam by 12.07-cm (4.75-in.) high;

6. one shipment will contain three polyethylene bottles with external dimensions of 12.54-cm (4.94-in.) diam by 22.1-cm (8.7-in.) high;

7. one shipment will contain three Teflon bottles with external dimensions of 11.91-cm (4.69-in.) diam by 23.88-cm (9.4-in.) high;

8. one shipment will contain a brazed assembly of two cans with final external dimensions of 10.8-cm (4.25-in.) diam by 44.46-cm (17.50-in.) high. An empty can with external dimensions of 10.8-cm (4.25-in.) diam by 22.23-cm (8.75-in.) high will be placed on top or bottom of the 44.46-cm (17.50-in.)-high can;

9. one shipment will contain fuel rods, or tubes, or plates greater than 43.18 cm (17.00 in.) in length. These items are bundled together and protected on both ends with an open-ended can with external dimensions of ≤12.7-cm (5.0-in.) diam by ≤ 22.23-cm (8.75-in.) high. Total assembly height will be ≤77.47 cm (30.5 in.). If space is available inside the containment vessel, stainless-steel metal scrubbers will be added on the bottom and top of this assembly or an empty can will be placed on top or bottom of this partially canned assembly;

10. one shipment will contain three cans brazed together with external dimensions of 4.25-in. diam by ~30-in. high; and

11. one shipment will contain closed cans with diameters >4.25 in. In this situation, the void volume inside the loaded containment vessel must be ≥43 in.[3]

Table 3.6. Total pressure inside the containment vessel at 89.60°C (193.28°F)

[a] This assumes that the internal convenience cans, polyethylene or Teflon FEP bottles, and Cat 277-4 spacer cans are not sealed.
[b] n_a—molar quantity of dry air in the gas mixture;
n_v—molar quantity of water vapor in the gas mixture;
n_{po}—molar quantity of gas due to offgassing of the silicone rubber pads;
n_{bo}—molar quantity of gas due to offgassing of the polyethylene, nylon, or Teflon bags; polyethylene bottles; and lifting sling;
n_{tf}—molar quantity of gas due to offgassing of the Teflon bottles;
n_{H2}—molar quantity of hydrogen gas due to radiolysis of water;
n_{O2}—molar quantity of oxygen gas due to radiolysis of water; and
n_T—total molar quantity in the gas mixture.
[c] This value is the molar quantity of water vapor generated from the efflorescence of UNX crystals.

These arrangements are shown in Fig. 1.4. To determine the ES-3100's maximum normal operating pressure, the following assumptions have been used in the calculations:

1. the HEU contents are loaded into convenience cans, and convenience cans are placed inside the containment vessel at standard temperature (T_{amb}) and pressure (P_t) [25°C (77°F) and 101.35 kPa (14.7 psia)] with air at a maximum relative humidity of 100% for all configurations except for CVA 7; CVA 7 assumes the air is 100% dry;

2. the convenience cans and bottles are assumed to not be sealed to maximize the void volume inside the containment vessel;

3. convenience can and bottle geometry does not change during pressure increase inside containment vessel;

4. if metal convenience cans are used, the total amount of polyethylene, nylon, or Teflon bagging and lifting slings is limited to 500 g per containment vessel shipping arrangement;

5. the mass of offgassing material (polyethylene, nylon, or Teflon bagging , Teflon bottles, silicone pads, lifting slings) is assumed to be 1490 g for the offgassing evaluation of CVA 7;

6. CVA 11 uses metal cans and, therefore, is limited to 500 g of polyethylene, nylon, or Teflon bagging and lifting slings.

The offgassing material limits identified in assumptions 4 and 5 have been established based on the needs of shippers. All configurations are limited to 500 g of polyethylene, nylon, or Teflon in the form of bags, slings, and/or polyethylene bottles. When the requirement to ship material in Teflon bottles arose, the upper limit of 1490 g of offgassing material was established. This limit is a combination of three Teflon bottles (330 g per bottle) and the original 500-g allowance for polyethylene, nylon, or Teflon bagging material. These offgassing material limits have been used in calculations pertaining to containment vessel pressure, radioactive material leakage criteria, and criticality control. Therefore, portions of the safety basis for this shipping package have been based on these material limits.

NUREG-1609, Sect. 4.5.2.3, requires the applicant to demonstrate that any combustible gases generated in the package during a period of one year do not exceed 5% (by volume) of the free gas volume in any confined region of the package. No credit should be taken for getters, catalysts, or other recombination devices. The analysis conducted in Appendix 3.5.4 evaluates the different packaging arrangements for the generation of hydrogen gas due to the radiolysis of water vapor, free water, interstitial water, polyurethane, nylon, or Teflon bags, and polyurethane or Teflon bottles. By limiting the mass and the material composition as shown in Appendix 3.5.4, the combustible gas concentration limit stated in NUREG-1609 is not exceeded. These limits are further discussed and shown in Tables 1.3 and 1.3a. Getters, catalysts, or other recombination devices are not employed in any of the containment vessel packaging arrangements. The analysis conducted in Appendix 3.5.1 predicts the maximum normal operating pressure inside the containment vessel for the various packaging arrangements and masses discussed previously. This appendix also includes the hydrogen gas generation predicted by Appendix 3.5.4.

The uranyl nitrate crystals (UNX) in any hydrated state are very efflorescent and will lose water molecules at the temperature shown in Table 3.3 [89.60°C (193.28°F)]. As shown in Table 3.6, the containment vessel pressure is calculated to be 208.75 kPa (30.276 psia) with the contribution from UNX crystal efflorescence. This calculation is shown in greater detail in Appendix 3.5.1.

3.1.4.2 Maximum HAC pressures

Table 3.7 summarizes the results from Appendix 3.5.2 in which the pressure of the containment vessel when subjected to the tests and conditions of HAC per 10 CFR 71.73 has been determined for the most restrictive CVAs shipped in the ES-3100. The shipping configurations discussed in Sect. 3.1.4.1 are evaluated for HAC. To determine the maximum pressure generated inside the ES-3100's containment vessel due to HAC conditions, the following assumptions have been used in the calculations:

1. the initial pressure inside the containment vessel is the maximum normal operating pressure shown in Table 3.6 for each CVA at standard temperature [25°C (77°F)];

2. the convenience cans and bottles are assumed to not be sealed in order to maximize the void volume inside the containment vessel;

3. convenience can and bottle geometry does not change during pressure increase inside containment vessel or because of damage from compliance testing;

4. if metal convenience cans are used, the total amount of polyethylene, nylon, or Teflon bagging and lifting slings is limited to 500 g per containment vessel shipping arrangement;

5. the mass of offgassing material (polyethylene, nylon, or Teflon bagging, Teflon bottles, silicone pads, lifting slings) is assumed to be 1490 g for the offgassing evaluation of CVA 7;

6. CVAs that utilize closed convenience cans with a diameter greater than 10.8 cm (4.25 in.) will have a minimum void volume of ≥55 $in.^3$ for gas evolution and expansion;

7. hydrogen and oxygen molar quantities calculated in Appendix 3.5.1 are conservatively added to the gas mixture for HAC; and

8. the contribution in pressure generated by the efflorescence of UNX crystals is incorporated into the results for CVA 7.

Table 3.7. Total pressure inside the containment vessel at 167.39°C (333.31°F) [a] with efflorescence

11	8.3054E-05	1.6487E-05	4.0537E-04	0.0000E+00	3.4133E-06	1.7067E-06	0.0000E+00	5.1003E-04	174.949

[a] This assumes that the internal convenience cans, polyethylene or Teflon FEP bottles, and Cat 277-4 spacer cans are not sealed.
[b] n_{MNOP}—molar quantity of the gas mixture at maximum normal operating pressure at standard temperature [25°C (77°F)];
n_{po}—molar quantity of gas due to offgassing of the silicone rubber pads;
n_{bo}—molar quantity of gas due to offgassing of the polyethylene, nylon, or Teflon bags, polyethylene bottles, and lifting sling;
n_{tf}—molar quantity of gas due to offgassing of the Teflon bottles;
n_{r-H2}—molar quantity of hydrogen gas due to radiolysis of water;
n_{r-O2}—molar quantity of oxygen gas due to radiolysis of water;
n_{CE-WV}—molar quantity of water vapor due to efflorescence of UNX crystals; and
n_T—total molar quantity in the gas mixture.
[c] Efflorescence of UNX crystals as water vapor.

The offgassing material limits identified in assumptions 4 and 5 have been established based on the needs of shippers. All configurations are limited to 500 g of polyethylene, nylon, or Teflon in the form of bags, slings, and/or polyethylene bottles. When the requirement to ship material in Teflon bottles arose, the upper limit of 1490 g of offgassing material was established. This limit is a combination of three Teflon bottles (330 g per bottle) and the original 500 g allowance for polyethylene, nylon, or Teflon bagging material. These offgassing material limits have been used in calculations pertaining to containment vessel pressure, radioactive material leakage criteria, and criticality control. Therefore, portions of the safety basis for this shipping package have been based on these material limits.

3.2 MATERIAL PROPERTIES AND COMPONENT SPECIFICATIONS

3.2.1 Material Properties

Thermal properties at various temperatures for the stainless steel used in the fabrication of the drum, noncombustible cast refractory (Kaolite 1600) and Packcrete, noncombustible neutron poison [BoroBond 4 (initial design) or Cat 277-4 (final design)], silicone rubber pads, and air are listed in Table 3.8. Properties used to evaluate thermal stresses due to differences in coefficient of thermal expansion are listed in Table 3.9.

3.2.2 Component Specifications

Component specifications are listed in Tables 3.10 and 3.11.

Table 3.8. Thermal properties of the materials used in the thermal analysis

Material	Temperature (°F)	Thermal conductivity (Btu/h-in.-°F)	Density ($lb_m/in.^3$)	Specific heat (Btu/lb_m-°F)	Emissivity

[a] Incropera and DeWitt.
[b] ORNL/TM-2003/49.
[c] Based on a baked density of 19.4 lbm/ft^3 (0.011 lbm/$in.^3$). Specification JS-YMN3-801580-A003 (Appendix 1.3.4) requires a baked density of 22.4 ± 3 lbm/ft^3. Using a lower value for the Kaolite density results in higher temperatures on the containment vessel because the heat capacity of the Kaolite is minimized—allowing more heat to flow to the containment vessel; therefore, the thermal analyses are performed using a low-end density of 19.4 lbm/ft^3. The HAC analyses also consider a high-end density of 30 lbm/ft^3.

[e] RP 802282-0002 and DAC M801940-0002 for complete set of thermal properties for Packcrete as a function of temperature.
[f] ORNL/TM-2004/290. Specific heat values are presented in MJ/m^3-K and converted to mass-based units using a density of 105 lbm/ft^3.
[g] Based on a cured density of 100 lbm/ft^3 (0.0579 lbm/$in.^3$). Y/DW-1987, presents a range of measured densities between ~100 and 110 lbm/ft^3 for Cat 277-4. Therefore, in order to minimize the heat capacity of the material and allow more heat to be transferred to the containment vessel, the lower-end value is used. The HAC analyses also consider a high-end density of 110 lbm/ft^3.

Table 3.10. ES-3100 packaging material specifications

Component	Specifications
	Drum assembly
Drum washers	1.375 OD × 0.812 ID × 0.25 in. thick, 300 Series stainless steel
Drum threaded weld studs	5/8-11 × 7/8-in. long, ARC FT, Type 304 or 304L stainless-steel studs
Drum hex nuts	5/8-11 UNC-2B, silicon bronze C65100
Drum lid weldment	Modified 30-gal, 16-gauge (MS27683) lid, Type 304 or 304L stainless steel; and an 11-gauge-thick sheet, Type 304 or 304L stainless steel, ASME SA-240
Drum weldment	Modified 30-gal, 16-gauge (MS27683), Type 304 or 304L stainless steel, ASME SA-240, manufactured per Drawing M2E801580A004 (Appendix 1.3.7)
Drum plugs	Nylon plastic plug, Micro Plastic, Inc.
	Impact limiter, insulation enclosure, neutron absorber, and drum packing material
Insulation and impact limiter (not removable)	Lightweight cast refractory insulation, Kaolite 1600 or Packcrete, 358.8 ± 48.1 kg/m^3 (22.4 ± 3 lb/ft^3) density, cast in stainless-steel shells in the drum and top plug
Neutron absorber	Cat 277-4, 1681.9 + 240.3/−80.1 kg/m^3 (105 + 15/−5 lb/ft^3) density
Top plug (removable)	Type 304 or 304L stainless steel, ASME SA-240 (body), ASME SA-479 (lifting inserts)
Inner liners	Type 304 or 304L stainless steel, ASME SA-240 (body), ASME SA-479 (modified angle)
Silicone pads	Silicone rubber, 22 ±5 Shore A, color black/gray
Aluminum foil duct tape	McMaster Carr Part # 7616A21, temperature range −40 to 121°C (−40 to 250°F)
	Containment vessel
Containment vessel plug	Part # 04-2126, Modified VCO threaded plug with O-ring, brass
Containment vessel hoist ring	3052T56, Swivel hoist ring, alloy steel (not used for shipment)
Containment vessel	Method 1: Type TP304L stainless steel ASME SA-312 (seamless pipe body); Type F304L, stainless steel, ASME SA-182 (flange and end cap); Type 304, stainless steel, ASME SA-479 (sealing lid), Nitronic 60 stainless steel per ASME SA-479, UNS-S21800 (closure nut) Method 2: Type F304L stainless-steel ASME SA-182 (body, flange, and end cap); Type 304, stainless steel, ASME SA-479 (sealing lid), Nitronic 60 stainless steel per ASME SA-479, UNS-S21800 (closure nut) All components per *ASME Boiler and Pressure Vessel Code*, Sect. II, Part D, Table 2A
Containment vessel O-rings	Elastomer, ethylene propylene diene monomer, Specification M3BA712A14B13F17 in ASTM D 2000 per SPC M801580-0002 (Appendix 1.3.9)
Containment vessel lid assembly retaining ring	Smalley Steel Ring Co., Part #WSM-400-S02, Type 302 stainless steel
Containment vessel O-ring lubricant	Clear dimethyl siloxane polymer
Containment vessel closure nut lubricant	Krytox #240AC
Containment vessel body dowel pins	0.2501/0.2503-in. OD × 0.50-in. long, 18-8 stainless steel

Table 3.10. ES-3100 packaging material specifications

Component	Specifications
Containment vessel packing material	
Convenience cans	Stainless steel, aluminum, or tinned carbon steel with stainless-steel can handles and nylon-coated stainless-steel wire; nickel-alloy (200 series, passivated) in nylon mesh bag
Convenience bottles	Polyethylene, glass, or Teflon FEP
Silicone rubber pads	Silicone rubber, 22 ±5 Shore A, color black/gray
Can spacers	Stainless-steel can filled with Cat 277-4
Bagging	Polyethylene, nylon, or Teflon
Metal scouring scrubbers	Stainless steel, McMaster Carr Part #7361T13

Table 3.11. Component allowable service temperature and pressure

Component	Allowable service temperature range [°C (°F)]	Allowable pressure range [kPa (psia)]
Drum assembly		
Stainless-steel drum and lid	−40 to 871 (−40 to 1600) [a]	48.3 (7)
Silicon bronze nuts	−40 to 871 (−40 to 1600) [a]	N/A
Stainless-steel washers	−40 to 871 (−40 to 1600) [a]	N/A
Stainless-steel mid liner	−40 to 871 (−40 to 1600) [a]	N/A
Stainless-steel inner liner	−40 to 871 (−40 to 1600) [b]	N/A
Stainless-steel top plug weldment	−40 to 871 (−40 to 1600) [a]	N/A
Kaolite 1600	−40 to 871 (−40 to 1600) [a]	N/A
Packcrete	−40 to 871 (−40 to 1600) [a]	N/A
Cat 277-4	−40 to 150 (−40 to 302) [c]	N/A
Silicone rubber pads	−40 to 232 (−40 to 450)	N/A
Containment vessel		
Stainless-steel body and sealing lid	−40 to 427 (−40 to 800) [d]	149.62 (21.7) external 699.82 (101.5) internal
Nitronic 60 closure nut	−40 to 427 (−40 to 800) [d]	149.62 (21.7) external 699.82 (101.5) internal
Stainless-steel retaining ring	−40 to 427 (−40 to 800) [d]	N/A
Dowel pins	−40 to 427 (−40 to 800) [d]	N/A
Brass VCO plug (with O-ring)	−40 to 204 (−40 to 400) [e]	
Ethylene propylene diene monomer O-rings	−40 to 150 (−40 to 302) [e]	5.52×10^3 (800) with no backing rings [e]
Containment vessel silicone pads	−40 to 232 (−40 to 450)	N/A

[a] This limit is established by the proximity of the Kaolite 1600 or Packcrete material.
[b] This limit is established based on the fact that the inner liner material is identical to the drum material.
[c] This limit is established based on criticality limits of moisture loss.
[d] This limit is established by the *ASME Boiler and Pressure Vessel Code*.
[e] This limit is provided by the *Parker O-Ring Handbook* for each material's continuous service limit.

3.3 THERMAL EVALUATION UNDER NORMAL CONDITIONS OF TRANSPORT

Thermal evaluation of the package design for NCT was performed by analysis and documented in DAC-PKG-801699-A001, DAC-PKG-801940-A001, and DAC M801940-0002.

DAC-PKG-801699-A001 uses a two-dimensional axisymmetric finite element model of the ES-3100 shipping container constructed using MSC.Patran and imported as an orphaned mesh into ABAQUS/CAE for application of boundary conditions, interactions, and loads. MSC.Patran and ABAQUS/CAE have been benchmarked against physical test data for a Y-12 packaging application and shown to provide accurate results (DAC-PKG-801805-A003). The model was constructed of DCAX4 (four-node linear axisymmetric heat transfer quadrilateral) and DCAX3 (3-node linear axisymmetric heat transfer triangular) elements for evaluation for NCT and HAC. The actual contents of the ES-3100 shipping container were not specifically modeled—instead, the content source heat load (if desired) was modeled by applying a uniform heat flux to the inner surfaces of the containment vessel. This was a conservative approach in that package temperatures will not be reduced in a transient analysis by the heat capacity of the contents. Thermal properties of the materials used in the analysis are presented in Table 3.8. Prior to the change of neutron absorber from BoroBond4 to Cat 277-4, parameters, such as Kaolite 1600 density, BoroBond4 thermal conductivity, and decay heat loads, were varied to encompass the range of potential variations in material properties. The available thermal conductivity information on BoroBond4 was limited to moderate temperatures in the range of −3.89°C (25°F) to 40°C (104°F) [Hall 2004]. Using the available thermal conductivity data for BoroBond4, thermal analyses for NCT and HAC were performed and are documented in DAC-PKG-801699-A001. Nodal locations for temperatures presented are shown in Fig. 3.1.

Based on the results reported in DAC-PKG-801699-A001 and shown in Tables 3.12 and 3.13, it was determined that the higher temperatures occurred when the lowest density of the Kaolite 1600 was used. Therefore, a subsequent analysis using the proposed Cat 277-4 neutron absorber at 100 lb/ft^3 during NCT with a Kaolite 1600 density of 19.4 lb/ft^3 was conducted and documented in DAC-PKG-801940-A001. A two-dimensional axisymmetric finite element model of the ES-3100 shipping container was constructed using ANSYS software for application of boundary conditions, interactions, and loads. A schematic of the finite element model is presented in Fig. 3.2 with details of the upper and lower portions of the model shown in Figs. 3.3 and 3.4, respectively. The model consists of five materials: stainless steel (drum, liners, and containment vessel), Kaolite 1600, 277-4 neutron absorber, silicone rubber, and air in the gaps between the drum liner and containment vessel and between the drum liner and top plug. Degree-of-freedom “ties” are made at the interfaces of the different material regions in order to allow the heat to flow through the model. The actual contents of the ES-3100 shipping container are not specifically modeled—instead, the content source heat load (if desired) is modeled by applying a uniform heat flux to the inner surfaces of the containment vessel. This is a conservative approach in that package temperatures will not be reduced in a transient analysis by the heat capacity of the contents. Comparing results of similarly located nodes, the results from DAC-PKG-801940-A001 are slightly lower than the results for a given decay heat than those shown in Table 3.12. Therefore, the use of the Cat 277-4 properties will not have a negative impact on subsequent analysis.

Due to the lack of Kaolite 1600 material from the manufacturer that meets specified density requirements, a substitute inorganic castable refractory material, identified as Packcrete, was developed. To confirm the thermal-insulating and impact-limiting material equivalency of Packcrete to the previously used Kaolite 1600 material, numerous material properties were evaluated and the results are documented in RP 802282-0002. These Packcrete properties and the properties of 277-4 and low density Kaolite 1600 were then used in DAC M80194-0002 to determine the temperature profiles of the ES-3100 shipping package for NCT. A geometric model of the ES-3100 package is created using PTC Creo Parametric and imported into ANSYS Mechanical, where a two-dimensional (2-D) axisymmetric FEA model is constructed for application of boundary conditions, interactions, and loads. The ES-3100 convenience cans and content are not modeled in the DAC. Instead, a heat flux ranging from 0 to 5 W is applied

to the CV inner surfaces. Details of the upper and lower portions of the model are shown in Figs. 3.5 and 3.6, respectively. Nodal locations for temperatures presented are shown in Fig. 3.7.

3.3.1 Heat and Cold

The ambient temperature requirement for NCT is 38°C (100°F). The general standard of 10 CFR 71.43(g) states: "A package must be designed, constructed, and prepared for transport so that in still air at 38°C (100°F) and in the shade, no accessible surface of a package would have a temperature exceeding 50°C (122°F) in a nonexclusive use shipment, or 85°C (185°F) in an exclusive use shipment." Since the components to be shipped have an assumed decay heat load of 5 W, a thermal analysis was conducted for the ES-3100 package without full solar insolation. Results for steady-state condition at 38°C in the shade are shown in Table 3.14. The maximum predicted temperature, while stored at 38°C (100°F) in the shade, for the external drum assembly and the containment vessel is 39.42°C (102.96°F) and 47.79°C (118.02°F), respectively. The analysis shows that no accessible surface of the package would have a temperature exceeding 50°C (122°F). Therefore, the requirement of 10 CFR 71.43(g) would be satisfied for either transportation mode (exclusive use or nonexclusive use).

For materials to be shipped by air transport, the International Atomic Energy Agency (IAEA) SSR-6, para. 621, states: "Packages containing radioactive material, to be transported by air, shall be capable of withstanding, without loss or dispersal of radioactive contents from the containment system, an internal pressure that produces a pressure differential of not less than the maximum normal operating pressure plus 95 kPa." Therefore to comply with these IAEA SSR-6 requirements, a thermal analysis was conducted for the ES-3100 package at 55°C in the shade. Results for this steady-state condition at 55°C in the shade are shown in Table 3.15. These values for temperature and pressure are subsequently used in Chapter 4 to determine the leakage criteria that satisfies the requirements of ANSI N14.5.

If the package is exposed to solar radiation at 38°C (100°F) in still air with an internal decay heat load of 5W, the conservatively calculated temperatures at the top of the drum, on the top surface of the containment vessel, and on the containment vessel near the O-ring sealing surfaces, are 119.38°C (246.88°F), 89.60°C (193.28°F), and 89.53°C (193.15°F), respectively, for the ES-3100 (Table 3.16). These temperatures are within the service limits of all packaging components, including the O-rings. The normal service temperature range of the O-rings used in the containment boundary is −40 to 150°C (−40 to 302°F) for the ethylene propylene diene monomer (EPDM) O-rings [Table 3.11] in accordance with *Parker O-Ring Handbook.* Thus, the seal will not be affected by this maximum normal operating temperature. The acronyms for various material properties shown in Tables 3.14 through 3.16 are identified as follows:

ASH – average specific heat for Packcrete;
LSH – low specific heat for Packcrete;
HSH – high specific heat for Packcrete;
LTC – low thermal conductivity for Packcrete;
HTC – high thermal conductivity for Packcrete;
LD – low density for Packcrete;
HD – high density for Packcrete;
277LD – 277-4 material low density;
277HD – 277-4 material high density; and
Kaolite LD – Kaolite low material density.

These material properties are further discussed and identified in DAC M80194-0002.

[a] See Fig. 3.7 for pictorial of node locations.

Using the temperatures calculated for the conditions of 10 CFR 71.71(c)(1), Appendix 3.5.1 predicts that the absolute maximum normal operating pressure inside the containment vessel will be 208.75 kPa (30.276 psia). For conservatism and for use in Chaps. 2 and 4 during NCT, the maximum gas temperature and the absolute maximum normal operating pressure in the containment vessel are rounded up to 90°C (194°F), and 210.29 kPa (30.50 psia), respectively. The design absolute pressure of the containment vessel is 801.17 kPa (116.2 psia), and the hydrostatic test pressure is 1135.57 kPa (164.7 psia). Thus, increasing the internal pressure of the containment vessel to a maximum of 210.29 kPa (30.50 psia) during NCT would have no detrimental effect. Stresses generated in the containment vessel at this pressure are insignificant compared to the materials of construction allowable stress. Table 2.20 provides a summary of the pressures and temperatures for NCT. As discussed in Sect. 2.6.1.4, the containment vessel and vessel closure nut stresses for these pressure conditions are below the allowable stress values.

Prior to testing the ES-2M design (a similarly constructed shipping package), each test unit was radiographed to determine the integrity of the Kaolite 1600 impact and insulation material. Following casting of the material inside the drum, some three-dimensional curving cracks were seen in some packages near the top thinner sections from the bottom of the liner to the bottom drum edge. After vibration testing, radiography of the ES-2M TU-4 showed that the lower half of the impact limiter was broken into small pieces (GAB1296-2). To evaluate these findings, TU-4 was reassembled and subjected to HAC sequential testing (GAB1296-2). After vibration and impact testing, many three-dimensional curving cracks were seen around the impact areas, and the inner liner was also visibly deformed. Nevertheless, temperatures at the containment boundary were similar to other packages not subjected to vibration testing prior to HAC testing. No inleakage of water was recorded following immersion. Also, TU-4 of the ES-3100 shipping package was subjected to the full NCT test battery including vibration.

Following these tests, the containment vessel of the ES-2M TU-4 was removed, and a full body helium leak check was performed. The test unit passed the leak-tight criteria in accordance with ANSI N14.5-1997. The containment vessel was then reassembled into the previously tested drum assembly and subjected to the complete HAC testing. Based on the success of this unit and the similar design of the ES-2M, it can be concluded that vibration normally incident to transport does not reduce the effectiveness of the ES-3100 packaging during HAC testing. The ES-3100 has been tested to determine the effectiveness of the package following a sequential NCT 1.2-m (4-ft) drop test and HAC test battery. Throughout all of the vibration and structural testing, the effectiveness of the Kaolite 1600 material as an impact limiter and thermal insulation was not substantially reduced. Since Packcrete is essentially the same composition as Kaolite 1600, Packcrete should perform functionally equivalent to Kaolite 1600. Therefore, the substitution of Kaolite 1600 with Packcrete should not degrade the ability of the package to meet the requirements of 10 CFR 71.

Also, in accordance with 10 CFR 71.71(c)(2), the containment vessel pressure must be calculated at −40°C (−40°F). Given the initial conditions of temperature, relative humidity, no silicone rubber or polyethylene, nylon, or Teflon bag offgassing, the pressure is calculated as follows:

$$P_1 \text{ @ } 25°C = P_a + P_v + P_{fo},$$

where

P_a = 98.15 kPa (14.236 psia), (Appendix 3.5.1)
P_v = 3.20 kPa (0.464 psia), (Appendix 3.5.1)
P_{fo} = 0. (no offgassing, Appendix 3.5.1)

At −40°C (−40°F), the partial pressure of the water vapor is conservatively assumed to be zero. Therefore, the final pressure of the mixture at −40°C (−40°F) is calculated according to the ideal gas law based solely on the partial pressure of the air.

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2},$$

where

P_1 = 98.15 kPa (14.236 psia),
T_1 = 25°C (298.15 K),
T_2 = −40°C (233.15 K),
V_1 = V_2, and

rearranging and solving for P_2,

P_2 = $P_1 (T_2 / T_1)$,
= (98.15)(233.15 / 298.15),
= 76.76 kPa (11.13 psia).

The cold condition for NCT specified in 10 CFR 71.71 is an ambient temperature in still air and shade of −40°C (−40°F). The 35.2 kg (77.60 lb) of HEU contents in the ES-3100 package generates a maximum bounding decay heat load of 5 W. However, in accordance with Nuclear Regulatory Commission (NRC) Regulatory Guide 7.8, the thermal effects of this internal heat source are neglected during evaluation of the package performance at −40°C (−40°F). When exposed to this condition, the package component temperatures will stabilize over time at a temperature approaching −40°C (−40°F). The package has been examined for use at −40°C (−40°F) (Sect. 2.6.2). No detrimental effects on the package structure or sealing capability result from this minimum temperature requirement. The normal service temperature range of the EPDM O-rings used in the containment boundary is −40 to 150°C (−40 to 302°F) [Table 3.11] in accordance with the *Parker O-Ring Handbook*; thus, the seal will not be affected by this minimum package temperature in accordance with 10 CFR 71.71(c)(2). Leak testing conducted on TU-2 to the leak tight criteria stipulated by ANSI N14.5-1997 following compliance testing provides justification of the above statements.

Summarizing 10 CFR 71.43(f), the tests and conditions of NCT shall not substantially reduce the effectiveness of the packaging to withstand HAC sequential testing. The effectiveness of the ES-3100 to withstand HAC sequential testing is not diminished through application of the tests and conditions stipulated in 10 CFR 71.71. The justification for this statement is provided by physical testing of both the ES-2M and ES-3100 test packages. Due to the similarities in design, fabrication, and material used in construction of both the ES-2M and the ES-3100 package, the Kaolite 1600 physical characteristics will hold true for both designs. The integrity of the Kaolite 1600 is not significantly affected by the NCT vibration and 1.2-m (4-ft) drop tests. As previously stated, Packcrete is essentially the same composition as Kaolite 1600. Based on similarity of material properties, Packcrete should perform functionally equivalent to Kaolite 1600. Therefore, the substitution of Kaolite 1600 with Packcrete should not degrade the ability of the package to meet the requirements of 10 CFR 71.

3.3.2 Maximum Normal Operating Pressure

The stainless-steel drum and cast refractory system will not pressurize as a result of temperature increases because of four ventilation holes (0.795 cm [0.313 in.] in diameter) drilled in the drum side wall 3.81 cm (1.5 in.) from the flanged top and equally spaced around the drum. The holes are filled with nylon plugs, but they are not hermetically sealed. The inner liner encapsulating the noncombustible

neutron poison (Cat 277-4) will not pressurize as a result of temperature increases because of three ventilation holes (0.635 cm [0.25 in.] in diameter) and a slot (1.63 cm [0.64 in.] in width and 4.17 cm [1.64 in.] in length) drilled into this inner liner. These features are covered during transport with aluminum tape to prevent contamination of the neutron poison. This tape does not represent a hermetic seal.

The maximum normal operating pressure is defined in 10 CFR 71.4 as the maximum gauge pressure that would develop in the containment system in a period of one year under the heat conditions specified in 10 CFR 71.71(c)(1). The internal pressure developed under these conditions in the ES-3100 containment vessel is calculated in Appendix 3.5.1 for the most restrictive containment vessel configurations. For conservatism, the decay heat of 5 W was used for the maximum internal heat load in evaluating the package for NCT. The maximum calculated adjusted internal absolute pressure in the containment vessel with solar insolation and the bounding case parameters is 208.75 kPa (30.276 psia). This pressure incorporates offgassing of the silicone rubber pads, polyethylene bottles, Teflon bottles, and polyethylene, nylon, or Teflon bagging and hydrogen gas generation from the radiolysis of water and/or other packing materials. The initial environment inside the containment vessel when assembled is at ambient temperature and pressure with 100% relative humidity. The heat-transfer capability of the packaging is not degraded due to gap creation caused by differences in the fabrication material's coefficient of thermal expansion. Modeling assumed nominal gaps and position based on the engineering drawings of Appendix 1.3.7. Therefore, the maximum normal operating pressure is 107.39 kPa (15.576 psig). For conservatism and for use in Chapters 2 and 4 during NCT, the maximum gas temperature and the absolute maximum normal operating pressure in the containment vessel are rounded up to 90°C (194°F), and 210.29 kPa (30.50 psia), respectively.

For materials to be shipped by air transport, the IAEA SSR-6, para. 621, states: "Packages containing radioactive material, to be transported by air, shall be capable of withstanding, without loss or dispersal of radioactive contents from the containment system, an internal pressure that produces a pressure differential of not less than the maximum normal operating pressure plus 95 kPa." Therefore to comply with these IAEA SSR-6 requirements, an analysis of the ES-3100 package with a steady state condition at 55°C in the shade was conducted with results shown in Table 3.15. The maximum normal operating pressure in the ES-3100 CV is calculated in Appendix 3.5.1 using the highest temperature predicted for the containment vessel [64.44°C (147.99°F)] (Node V in Table 3.15) as the average gas temperature throughout the containment vessel void volume. In this case, the maximum pressure differential across the containment vessel boundary is the resultant pressure plus 95 kPa or 117.69 kPa (17.07 psi.). These values for temperature and pressure are subsequently used in Chapter 4 to determine the leakage criteria that satisfies the requirements of ANSI N14.5.

3.3.3 Maximum Thermal Stresses

The temperature of the package under NCT will vary from a low of −40°C (−40°F) throughout the package to a maximum of 119.38 and 89.60°C (246.88 and 193.28°F) on the surface of the drum and the containment vessel, respectively (Sect. 3.3.1). The slow temperature increase or decrease experienced in normal conditions between these limits will result in an essentially uniform temperature change throughout the package. All materials of construction are within this operating temperature range (Table 3.11). Most of the components of the packaging are completely unrestrained. Therefore, any thermal stresses in the packaging components as the temperature varies between the extremes listed above will have no effect on the ability of the packaging to maintain containment, shielding integrity, and nuclear subcriticality. The maximum stresses due to pressure under NCT for the containment vessel are given in Tables 2.21 and 2.22. These values are significantly below the allowable stresses for the packaging components. The Kaolite 1600 or Packcrete insulation and Cat 277-4 materials are poured and cast in place during the fabrication of the drum weldment (Drawing M2E801580A002, Appendix 1.3.7). This situation produces a zero gap between these materials and the bounding drum and inner liners. Due

to differences in coefficients of thermal expansion, some radial and axial interference is expected due to thermal growth or contraction of the inner liners. These radial and axial interferences and induced stresses are calculated in DAC M801940-0003. The results show that the stresses induced are minimal and do not reduce the effectiveness of the drum assembly. Further discussion of these stresses is provided in Sects. 2.6.1.2 and 2.6.2.

The containment vessel, which is Type 304L austenitic (iron-nickel-chromium) stainless steel, is designed and fabricated in accordance with Sects. III SubSect. NB and IX of the *ASME Boiler and Pressure Vessel Code*. The two sealing surfaces of each containment boundary are joined together by torquing the closure nut inside the containment vessel body to 162.7 ±6.8 N·m (120 ±5 lbf-ft). The O-ring material is EPDM.

The design temperature range of the containment vessel is −29 to 176.7°C (−20 to 400°F) (DAC-M900000-0002). However, the package has been evaluated to −40°C (−40°F) (Sect. 2.6.2). The thermal properties of the stainless-steel container body, lid, and closure nut are not critical at these temperatures. The O-ring seal is important for the containment properties of the containment vessel. The normal service temperature range for the EPDM O-ring is −40 to 150°C (−40 to 302°F) [Table 3.11] for 1000 h of continuous service.

3.4 THERMAL EVALUATION UNDER HYPOTHETICAL ACCIDENT CONDITIONS

3.4.1 Initial Conditions

Six full-scale packages were tested in the sequence shown in Table 2.19. Each ES-3100 test package was subjected to the 1.2-m (4-ft) drop test in accordance with 10 CFR 71.71(c)(5) prior to the sequential HAC tests in accordance with 10 CFR 71.73 (free drop, crush, puncture, thermal, and immersion tests). One of these units (TU-4) had previously completed the tests and conditions stipulated in 10 CFR 71.71(c)(5) through (c)(10), excluding (c)(8). Two different mock-up configurations were used to represent the minimum and maximum proposed shipping weight and to simulate various center of gravity locations. The structural and thermal interface between the mock-up component and the containment vessel was designed to match that of the actual hardware proposed for transport. Based on LS-DYNA drop simulations (DAC-EA-801699-A001 and DAC-EA-801699-A002) the six test units with their associated test weights represent the worst drop orientations for the ES-3100 package. TU-5 used a near replicate of the lightest weight contents for its mock-up component. NCT free-drop, 9-m (30-ft) free drop, 9-m (30-ft) crush and puncture tests were made as specified in 10 CFR 71.71(c)(1), and 73(c)(1) through (c)(3) on all six full-scale test packages prior to thermal testing. The results of this testing are discussed in Sects. 2.7.1, 2.7.2, and 2.7.3. The 1.2-m (4-ft), 9-m (30-ft) drop and crush test orientations were as follows: two tests with the long axis of drum at an oblique angle of 12° to impact surface; a center of gravity over the corner of the drum lid; a drop with the long axis of drum parallel with the impact surface; and a vertical drop on to the drum lid. The subsequent 40-in. puncture drops were made at various orientations as shown in Table 2.19.

Prior to the thermal test, each test unit was preheated to the maximum temperature extreme in accordance with 10 CFR 71.73(b). Since the containment vessels were initially assembled at ~101.35 kPa (14.7 psia) at 25°C (77°F), the initial internal containment vessel pressure was ~105.70 kPa (15.33 psia) at 38°C (100°F) using the ideal gas law. In accordance with 10 CFR 71.73(b)(1), the internal pressure should be that calculated for the maximum normal operating pressure or the adjusted calculated value of 210.29 kPa (30.50 psia). This slight pressure differential has little or no effect on the thermal test results. The maximum decay heat load of the contents is calculated to be 5 W based on 35.2 kg of HEU. Analysis of the ES-3100 package after thermal HAC tests both with and without the decay heat load has been performed. The average projected temperature increase during HAC due to a 5 W heat source

without insolation for Kaolite 1600 or Packcrete , as calculated in DAC M801940-0002, would be ~5.17°C (9.30°F) at the CV top (node Y), ~5.18°C (9.33°F) at the CV O-ring (node W), ~8.05°C (14.49°F) at the CV mid body (node V), and ~6.55°C (11.78°F) at the CV bottom (node T). This decay heat adjustment as well as the various other adjustments like applying solar insolation prior to and following the thermal test are discussed and evaluated in Sect. 3.4.2.

3.4.2 Fire Test Conditions

Full-scale testing in accordance with 10 CFR 71.73 for HAC was conducted on prototypical packages. Therefore, no analyses were conducted to show compliance with the HAC thermal test. However, analyses were conducted and are discussed in Sect. 3.4.3 to determine the thermal impacts of an internal 5W heat source, application of insolation prior to the thermal test, application of insolation during cool down, location of crush plate impact on test unit, thermal capacitance differences between test hardware and proposed shipping hardware and the substitution of Kaolite 1600 with Packcrete.

Full-scale testing of six ES-3100 test units was conducted in accordance with 10 CFR 71.73(c)(4) for HAC. A single full-scale ES-3100 test unit (TU-4) was assembled and subjected to both NCT and to the sequential tests specified in 10 CFR 71.73(c). The furnace used for thermal testing was the No. 3 Furnace at Timken Steel Company in Latrobe, Penn., which is a gas-fired furnace. Oxygen content in stack gases from the furnace were not monitored because it was not anticipated that any of the package's materials of construction were combustible. There was some burning of the silicone pads which are placed between the inner liners and the top plugs of the packages. However, it should be noted that this furnace employs "pulsed" fire burners. This type of burner is unique in that the natural gas flow rate is varied based on furnace controller demands, but the flow of air through the burners is constant, even when no gas is flowing, thereby ensuring a very rich furnace atmosphere capable of supporting any combustion of package materials of construction.

The most significant change to the definition of the HAC thermal test in the current 10 CFR 71 is the requirement for calculation purposes to base convective heat input on "that value which may be demonstrated to exist if the package was exposed to the fire specified." This is not especially significant for this package because it was tested in the gas-fired furnace with burners placed in an attitude which produced a strong convective swirl. Careful examination of the thermal test data indicates that the total heat imparted to the packages was significantly greater than the required total heat specified in 10 CFR 71.73(c)(4). Compliance with ASTM E 2230, *Standard Practice for Thermal Qualification of Type B Packages for Radioactive Material*, was accomplished by the method described in Sect. 7.3 of this standard. This standard is in general agreement with Paragraph 2.2.1 ("Steady-state Method of Compliance") of SG 140.1 entitled *Combination Test/Analysis Method Used to Demonstrate Compliance to DOE Type B Packaging Thermal Test Requirements (30 Minute Fire Test)*.

Prior to the beginning of the thermal test, the furnace was characterized for temperature and heat recovery times. The support stand was welded to a large steel plate which had been placed on the floor of the furnace prior to heating. This steel plate acted as the radiating surface at the bottom of the furnace, as well as providing the ability to hold the test stand rigidly in place. Before heating the furnace, workers practiced loading and unloading test packages from the cold furnace to ensure that the furnace door would not remain open >90 s during each loading. In fact, the maximum time the door was open during any loading was 64 s. As discussed in *Test Report of the ES-3100 Package* (ORNL/NTRC-013), six thermocouples were affixed to the drum assembly's exterior surface. Metal retainer clips were welded to the exterior surface to hold the thermocouples in place. The thermocouple tips were inserted underneath the metal clips, and the wire was wrapped around the metal clip. To eliminate any radiant heat exchange between the thermocouples and the furnace walls, the tips and metal clips were covered with a ceramic coating. Three thermocouples were mounted on each of the walls of the furnace, as well as on the furnace floor, on the furnace door, and three thermocouples were mounted on the test stand.

A minimum of 24 h prior to the beginning of all testing, the furnace was turned on with a set-point temperature of 871°C (1600°F). Following each test, the furnace set point was adjusted to 871°C (1600°F) for at least 45 min prior to the beginning of the next test. The furnace control data recorder ran continuously for the entire duration of the preheat cycle test. TU-1 through TU-5 were preheated to >38°C (100°F) by placing the packages in an environmental chamber, which was heated by a torpedo-type kerosene space heater controlled by a mechanical bulb thermostat with a control range of 38 to 93°C (100 to 200°F). The environmental chambers were similar: a welded steel frame with fiberglass insulation panels. Figure 3.8 shows the chamber used for TU-1 through TU-5, which was heated from the bottom with four floor register vents located around the perimeter and a 20.32-cm (8-in.)–diam manual dampened center venting stove pipe.

The set point temperature of the environmental chamber was monitored and adjusted for the duration of the preheat cycle. Initially, the thermostat was set to 66°C (150°F) for ~23 h. The thermostat set point was then reduced to 43°C (110°F) for the remainder of the preheat cycle (24 h). All packages were preheated for at least 47 h. No test package was loaded into the furnace until 15 of the 18 thermocouples monitoring the furnace had a reading of 800°C (1475°F) or higher. All packages were placed in the preheated furnace on the support stand with the long axis positioned horizontally, and the package lid facing toward a furnace side wall (Fig. 3.9). These packages were exposed to the radiation environment for a minimum of 30 min after all functioning furnace thermocouples and at least four of the six test package exterior surface thermocouples reached a temperature of 800°C (1475°F). During the testing of each package, the thermocouple temperature data recorder was set to record every 15 s.

After each test, the furnace was allowed to reheat for a minimum of 45 min after obtaining the set point temperature before testing the next unit. The furnace control temperature data recorder ran continuously for the duration of the preheat. No test package was loaded into the furnace until all functioning thermocouples on the furnace walls and support stand had again reached a temperature of 800°C (1475°F) or higher.

All units were tested in a horizontal attitude with the top end of the package facing to the right side wall of the furnace and the 0° mark on the drum facing the floor of the furnace. The data from each of the thermal tests, as shown in the test report, show that at least four of the six external drum thermocouples reached temperatures well in excess of 800°C (1475°F) and remained above 800°C (1475°F) during the 30-min thermal testing. Similarly, all other surfaces of the furnace, including the support stand, exceeded 800°C (1475°F) during the timed portion of the thermal test. For the test specified in the regulations, regardless of the amount of heat input by convection, radiation, or conduction, the maximum temperature the skin of the package could reach would be 800°C (1475°F). That is, the source of the heat in the regulatory specified test is at 800°C (1475°F). Heat can only be transferred from a hotter source to a colder source. Thus, regardless of the mode of heat transfer, the greatest temperature a specimen exposed to the 10 CFR 71.73(c)(4) thermal test can attain is 800°C (1475°F). Therefore, the fact that these test packages attained temperatures well in excess of 800°C (1475°F) is an excellent indication that the thermal tests performed not only met the requirements of 10 CFR 71.73(c)(4) but actually exceeded them markedly. The results of these tests are provided in the test report (ORNL/NTRC-013).

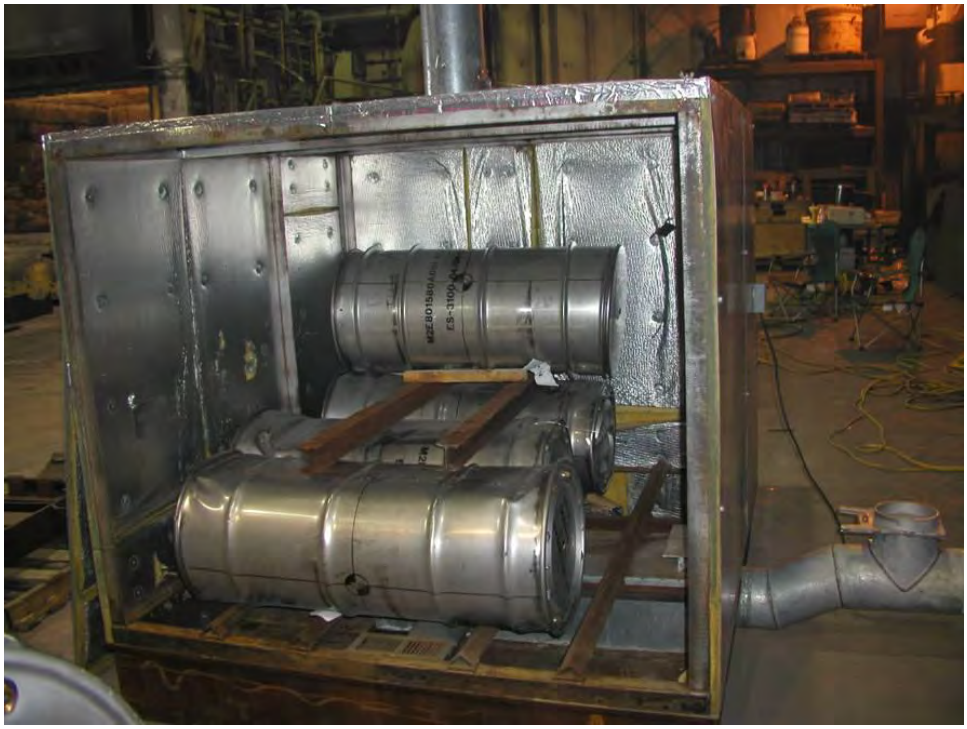

Fig. 3.8. TU-1 through TU-5 preheat arrangement.

Fig. 3.9. Test unit insertion into furnace.

Each test package was removed from the furnace and placed in an area where it was not exposed to artificial cooling (Figs. 3.10 and 3.11). As the furnace door was opened for each test unit, flaming or smoking was visible at the tamper-indicating device (TID) holes in the drum/lid interface. Flaming continued on some of the packages for a short duration; the longest flame duration was 22 min after removal from the furnace. Smoke was also visible from each of the packages and continued after flames were no longer visible. The packages continued to smoke between 12 and 60 min after removal from the furnace. All the packages were allowed to cool naturally to room temperature. The post-thermal testing weights of each unit are summarized in Table 3.17. The drums were disassembled, and the damage was photographed. Each package was visually inspected, and the condition of the package and any observations were recorded.

3.4.3 Maximum Temperatures and Pressure

The six test units previously subjected to both NCT and HAC drop testing were thermally tested in accordance with 10 CFR 71.73(c)(4). To determine the maximum temperatures reached during thermal testing, temperature-indicating patches were placed at various locations throughout the test package at assembly. The temperature range for each patch used is identified in Table 3.18. When the temperature of an indicator was reached, the color would change to black (i.e., blackout temperature). The range of possible blackout temperatures of the patches was from 51.67 to 260°C (125 to 500°F). For TU-1 through TU-5, Table 3.18 defines the number and location of the temperature-indicating patches. A temperature adjustment was evaluated to compensate for conducting the HAC compliance tests with BoroBond4 and substituting Cat 277-4 for the production shipping containers. This adjustment was determined by using an undamaged package and subjecting it to a thermal environment representative of that required by 10 CFR 71.73(c)(4). Based on the analytical results shown in DAC-PKG-801699-A001 and DAC-PKG-801940-A001, the containment vessel in a package using Cat 277-4 would be from 2.5 to 8°F cooler than a package with BoroBond4. Therefore, the results from TU-5 are used without further adjustment for substitution of 277-4 in the final production hardware.

Since the structural and thermal interface between the various mock-ups and containment vessels is the same as the actual hardware, the use of steel mock-ups to simulate the contents is not expected to affect the results of the thermal test significantly. The total maximum weight of the test packages ranged from 157.4 kg (347 lb) to 203.7 kg (449 lb). The ES-3100 package has a nominal gross shipping weight that ranges from 146.88 kg (323.79 lb) to 187.81 kg (414.05 lb) for the minimum and maximum weight containment vessel configurations shown in Table 2.8, respectively. However, the effect on temperature is evaluated in the following paragraphs due to thermal capacitance differences between the mock-up and the actual contents.

Fig. 3.10. Test unit removal from furnace.

Fig. 3.11. Test unit cool down and monitoring arrangement.

Test mock-up components		6 (B)	"B" 77–127 (171–261)	5.26 & 5.27

[a] ORNL/NTRC-013.

In order to predict the maximum temperature for the packaging components during HAC with Kaolite 1600 or Packcrete, transient thermal analyses were performed on the finite element model of the ES-3100 shipping container (undamaged configuration) to simulate HAC as prescribed by 10 CFR 71.73(c)(4) [DAC M801940-0002]. A 30-min fire of 800°C (1475°F) was simulated by applying natural convection and radiant exchange boundary conditions to all external surfaces of the drum (assuming the drum is in a horizontal orientation) with various content heat loads up to 5 W. There are heat flux boundary conditions simulating insolation applied to the model before and after the 30-minute fire. The initial temperature distribution within the package having content heat loads as previously stated is obtained from their respective quasi steady-state (with solar insolation) analyses when the maximum O-ring temperature is reached. The initial temperature distribution within the package having no content heat load (0 W) is assumed to be at a uniform temperature equal to the ambient temperature of 38°C (100°F). The content heat load is then simulated by applying a uniform heat flux to the internal surfaces of the elements representing the containment vessel. This is further discussed in DAC M801940-0002.

Following the 30-min fire transient analyses, 48-h cool-down transient thermal analyses are performed using the temperature distribution at the end of the fire as the initial temperature distribution. During post-fire cool-down, natural convection and radiant exchange boundary conditions are applied to all external surfaces of the drum (assuming the drum is in a horizontal orientation). Additionally, cases are analyzed in which insolation is included during the post-fire cool-down. For the cases in which insolation is applied to the model during cool-down, insolation is applied during the first 12-h period following the 30-min fire, and then alternated (off, then on) as was done for NCT. These simulations are compared to determine the impact of applying solation insolation during the cool-down phase.

Based on the previous analysis of the ES-3100 package using BoroBond4 (DAC-PKG-801699-A001), it was noted that using the low-end density of Kaolite 1600 results in higher containment vessel temperatures than using the high-end density of Kaolite 1600. For this reason, the NCT and HAC thermal analyses with Kaolite 1600 were run using a density of 19.4 lb/ft^3. Similarly, the low-end density of the Cat 277-4 material (100 lb/ft^3) was also used in these analyses (DAC M801940-0002). The Packcrete insulation material has been further evaluated with numerous thermal properties as a function of temperature recorded in RP 802282-0002. The maximum temperatures calculated for the ES-3100 shipping container for HAC are summarized in Tables 3.19 through 3.26 for the analyses using Packcrete with various thermal properties combinations. The maximum temperatures calculated for the ES-3100 shipping container during HAC using Kaolite 1600 with a density of 19.4 lb/ft^3 and Cat 277-4 with a density of 100 lb/ft^3 are summarized in Table 3.27. The acronyms for various material properties shown in Tables 3.19 through 3.27 are identified as follows:

ASH – average specific heat for Packcrete;
LSH – low specific heat for Packcrete;
HSH – high specific heat for Packcrete;
LTC – low thermal conductivity for Packcrete;
HTC – high thermal conductivity for Packcrete;
LD – low density for Packcrete;
HD – high density for Packcrete;
277LD – 277-4 material low density;
277HD – 277-4 material high density; and
Kaolite LD – Kaolite low material density.

As previously stated, temperature indicators (patches) were placed on the surface of each containment vessel, inner liner, and mock-up component in TU-1 through TU-5. The blackout temperatures that occurred during thermal testing are recorded for each test unit; the maximum blackout temperatures are listed in Table 3.4. A maximum blackout temperature of 116°C (241°F) was recorded in the vicinity of the O-rings on the containment vessel of TU-5. As discussed below, this temperature will be conservatively adjusted to correlate the test conditions to shipping conditions with decay heat and solar insolation. The blackout temperatures are increased to account for (1) the temperature interval between blackout dots; (2) the temperature increase due to the effects of applying solar insolation prior to the HAC thermal test; (3) the temperature increase due to the decay heat load of the actual contents being shipped; (4) the temperature increase due to effects of applying solar insolation during cool-down; (5) effects of crushing at different locations along the body of the shipping package; (6) thermal capacitance difference in the proposed contents and hardware used during testing; and (7) temperature difference occurring when using Packcrete vs Kaolite 1600.

The initial adjustment for the blackout readings is an increase of 6.11°C (11.0°F) from the patch that blacked out. The highest blackout reading indicates that the actual temperature is somewhere between the highest temperature indicated and the next higher temperature.

The second adjustment compensates for applying solar insolation in accordance with 10 CFR 71.71(c)(2) prior to the thermal test. The temperature profile of the package that is used prior to analytical thermal test is the temperature distribution when the maximum inner O-ring temperature location is achieved. Averaging the individual change at each node of interest for all runs shown in Tables 3.18 through 3.26, the temperature increase at Node Y is 31.14°C (56.06°F); at Node W is 31.11°C (56.00°F); at Node V is 26.67°C (48.00°F); and at Node T is 24.74°C (44.54°F).

The third temperature adjustment considered is the temperature increase due to the decay heat load of the actual contents being shipped. Averaging the individual change at each node of interest for all runs shown in Tables 3.18 through 3.26 due to 5W decay heat load, the temperature increase at Node Y is 5.28°C (9.51°F); at Node W is 5.30°C (9.54°F); at Node V is 8.25°C (14.85°F); and at Node T is 6.75°C (12.15°F).

The fourth adjustment is a temperature increase to represent the effect of insolation heat flux on the package immediately following the conclusion of the thermal HAC test. Averaging the individual change at each node of interest for all runs shown in Tables 3.18 through 3.26 due to insolation during cool-down, the temperature increase at Node Y is 5.47°C (9.85°F); at Node W is 5.32°C (9.57°F); at Node V is 7.23°C (13.01°F); and at Node T is 5.52°C (9.94°F).

The fifth temperature adjustment considered is the temperature increase to the containment vessel based on the location of impact from the 500 kg (1100 lb) crush plate. Based on the differences in location of the crush plate between TU-1 and TU-2, crushing the shipping package with the center of gravity of the plate directly above the containment vessel flange increases the containment vessel temperature on average ~6.11°C (11°F).

[b] Insolation conditions in accordance with DAC M801940-0002, Sect. 6.6.1.3.
SB = solar heat flux applied before the HAC fire.
SA = solar heat flux applied after the HAC fire.

The sixth adjustment compensates for the shipment of very small quantities of HEU, rather than the steel mock-ups, and removes the requirement for a minimum content weight. The higher content weight was used for testing to cover the possibility of shipping larger components without retesting. The larger content weight gave conservative structural deformation test results to the drum assembly than would the actual shipping weight. One effect, however, of using the larger test mass could be to reduce the containment vessel's temperature rise during the thermal test because the mock-up acts like a heat sink. In order to evaluate this temperature adjustment, a mock-up of the originally lightest proposed shipment was used in TU-5. The structural and thermal interface between the mock-up components and the containment vessel was designed to match that of the actual shipping hardware, thereby providing the same conductive heat path for thermal testing. As shown by the test results, both the containment vessel and mock-up components of TU-5 recorded higher temperatures than the other test units. This supports the theory that the heavier mock-ups act as heat sinks for the containment vessel. Since the earlier compliance testing, even lower amounts of material are proposed for shipment in the ES-3100. In order to quantify the magnitude of this adjustment, a heat transfer balance is conducted below. This method represents a conservative approach to estimating the adjustment and is not intended to reflect the actual temperature difference. Since the blackouts were recorded on the surface of the mock-up component, adjusted temperatures of 64°C (219°F), 99°C (210°F), and 93°C (199°F) for the top can, middle can, and bottom can are assumed for the following heat transfer equations. The amount of heat absorbed by the mock-up components during the thermal test of TU-5 is calculated as follows:

$$Q = C_{pi} \times (T_{maxi} - T_{mini}) \times W_{Mi}$$

The mockup components for TU-5 consisted of three 10-in.–high steel cans. Two of the upper cans were empty. The bottom can contained 5.9 lb of steel grit. Each individual can weighed ~0.70 lb. Two temperature-indicating patches were placed around the external mid height diameter of each can ~180° apart. The blackout readings on the top, mid, and bottom cans were 99°C (210°F), 93°C (199°F), and 88°C (190°F), respectively. Each of these readings is increased by either 5 or 6°C (9 or 11°F) due to the accuracy of the patches. Therefore, the top can, middle can, and bottom can and steel grit reached an adjusted temperature of 104°C (219°F), 99°C (210°F), and 93°C (199°F), respectively. Therefore, the mockup contents absorbed ~ 9.476×10^4 J as calculated below:

$$\begin{aligned} Q_A &= \sum C_{pi} \times (T_{maxi} - T_{mini}) \times W_{Mi}, \\ &= 460.5 \times (104 - 37.78) \times (0.318) + 460.5 \times (99 - 37.78) \times (0.318) + 460.5 \\ &\quad \times (93 - 37.78) \times (2.99), \\ &= 94760.2 \text{ J}, \end{aligned}$$

where

Q_A = absorbed heat by mockup contents,
C_{pi} = specific heat of the steel cans and grit,
= 460.5 J/kg-°C (0.11 Btu/lb-°F),

T_{maxi} = recorded mock-up can temperatures,
= 104°C (219°F), (top can)
= 99°C (210°F), (middle can)
= 93°C (199°F), (bottom can and steel grit)

T_{mini} = temperature of preheated test units,
= 37.78°C (100°F),

W_{MI} = mock-up component weights for TU-5,
= 0.318 kg (0.70 lb), (top can)
= 0.318 kg (0.70 lb), (middle can)
= 2.99 kg (6.60 lb). (bottom can and steel grit)

The sixth temperature adjustment caused by adding this 9.476×10^4 J (89.81Btu) of heat from the mockup contents into the containment vessel can then be calculated by using the following equation:

$$\begin{aligned} dT &= Q_A / (C_{pcv} \times W_{cv}), \\ &= 9.476 \times 10^4 \text{ J} / (502.36 \text{ J/kg-°C} \times 14.97 \text{ kg}), \\ &= 12.60°C \text{ (22.68°F)}, \end{aligned}$$

where

C_{pcv} = specific heat of the stainless steel containment vessel,
= 502.36 J/kg-°C,

W_{cv} = mass of the empty stainless steel containment vessel,
= 14.97 kg.

The sixth temperature adjustment is 12.60°C (22.68°F).

The seventh temperature adjustment compensates for conducting the HAC compliance tests with Kaolite 1600 vs Packcrete. From the results shown in the last column of Table 3.27 for Kaolite 1600 and the last column of Table 3.26 for Packcrete (material properties that caused the highest temperature increase), the temperature increase at Node Y is 4.10°C (7.38°F); at Node W is 4.13°C (7.44°F); at Node V is 3.75°C (6.75°F); and at Node T is 5.33°C (9.59°F).

Table 3.28 summarizes the numerous temperature adjustments needed for the containment vessel.

Table 3.28. Predicted temperature adjustments (°F) for containment vessel due to HAC

Node ID [a]	Analytical temperature adjustments							Total temp adjustment
	1	2	3	4	5	6	7	
Y	11.00	56.06	9.51	9.85	11.00	22.68	7.38	127.48
W	11.00	56.00	9.54	9.57	11.00	22.68	7.44	127.23
V	11.00	48.00	14.85	13.01	11.00	22.68	6.75	127.29
T	11.00	44.54	12.157	9.94	11.00	22.68	9.59	120.90

[a] See Fig. 3.7 for details of node locations.

Table 3.29 shows the results of adding the seven temperature adjustments previously discussed to the black-out temperatures for the containment vessel with the 3.6-kg (8-lb) mock-up (TU-5). These adjusted temperatures would not adversely affect the stainless-steel components of the containment vessel. EPDM O-rings are rated for reliable service for a continuous 1000 h at −40 to 150°C (−40 to 302°F) [Table 3.11]. As shown in Fig. 2-28 of the *Parker O-Ring Handbook*, these O-ring materials can survive at the predicted temperature shown in Table 3.29 (368.23°F) for ~five hours. Based on the O-ring temperature curve shown in Fig. 7-24 of DAC M801940-0002, the O-ring temperature would have fallen ~40°F to 328°F over that 5 hour period. At ~328°F, the O-ring should be able to survive ~20 hours. The total length of time above the continuous service temperature of 150°C (302°F) for the EPDM O-ring is ~11 hours. Based on the predicted data and the curves from *Parker O-Ring Handbook*, the thermally tested packages with all the conservative adjustments would remain below the acceptable time at temperature limits. Therefore, these adjusted temperatures would not adversely affect the containment vessel O-rings.

Table 3.29. Predicted temperatures of the containment vessel due to HAC

Node ID [a]	Analytical temperature adjustments (°F)	Maximum blackout temperature on TU-5 (°F)	Final predicted temperature (°F)
Y	127.48	261	388.48
W [b]	127.23	241	368.23
V	127.29	199	326.29
T	120.90	210	330.90

[a] See Fig. 3.7 for node locations.
[b] This is the nodal location nearest the inner O-ring location.

To determine the maximum pressure inside the containment vessel as a result of thermal testing, the average adjusted gas temperature must be calculated based on the above results. The approach used is to divide the containment vessel volume into three distinct equal regions and then average the three together. The first volume is represented by the gas adjacent to the containment vessel lid and flange region and the top convenience can. Based on the temperature recorded near the O-rings [116.11°C (241°F)] and the temperature recorded on the external surface of the convenience can [98.89°C (210°F)], the average temperature of the gas in this region is 107.50°C (225.50°F). Using the temperature adjustment of 70.67°C (127.23°F) for this region, the adjusted average temperature in the first region is 178.17°C (352.73°F). The second volume is represented by the gas adjacent to the second convenience can from the top. Based on the temperature recorded on the containment vessel wall and convenience can [92.78°C (199°F)], the average temperature of gas in this region is 92.78°C (199°F). Using the temperature adjustment of 70.72°C (127.29°F) for this region, the adjusted average temperature in the second region is 163.50°C (326.29°F). The third and final volume is represented by the gas adjacent to the bottom convenience can. Again based on the convenience can temperature [87.78°C (190°F)] and the containment vessel end cap temperature [98.89°C (210°F)], the average temperature of gas in this region is 93.33°C (200°F). Using the temperature adjustment of 67.17°C (120.90°F) for this region, the adjusted average temperature in the third region is 160.50°C (320.90°F). Averaging these three temperatures, an average adjusted gas temperature of 167.39°C (333.31°F) is determined for the containment vessel.

As shown in Appendix 3.5.2, the maximum adjusted average gas temperature and pressure in the containment vessel during accident conditions was calculated to be 167.39°C (333.31°F), and 1206.24 kPa (174.95 psia), respectively. For conservatism and for use in Chaps. 2 and 4, the maximum adjusted average gas temperature and pressure in the containment vessel during accident conditions are rounded up to 167.78°C (334°F) and 1206.58 kPa (175.00 psia), respectively.

The maximum adjusted temperature on the surface of the containment vessel, adjacent to the O-rings, was 186.79°C (368.23°F). This is well within the design range for the packaging. The full body helium leak test on all test units following thermal testing meets the “leaktight” criteria in accordance with ANSI N14.5-1997. Visual inspection following testing and unloading indicated that no distortion or damage occurred in the containment vessel wall, sealing lid, closure nut, O-rings, or sealing surfaces. No water was visible inside the containment vessel following the 0.9-m (3-ft) water immersion test or the 15-m (50-ft) water immersion test on TU-6.

The ES-3100 package satisfies the requirements of 10 CFR 71.73 for transport of the 35.2-kg (77.60-lb) arrangements shown in Table 2.8. Section 2.7 has additional details to support this conclusion.

3.4.4 Maximum Thermal Stresses

The maximum adjusted HAC temperature of the ES-3100 containment vessel was based upon the thermal testing results in the vicinity of the O-rings. The maximum temperature recorded in the vicinity of the ES-3100 O-rings (241°F) is shown in Table 3.4. As shown in Sect. 3.4.3, the maximum temperature for the containment vessel at the O-ring location was adjusted for the ES-3100 package to 186.79°C (368.23°F). As previously discussed and as shown in Fig. 2-28 of the *Parker O-Ring Handbook*, this O-ring material can survive at the predicted temperature shown in Table 3.29 (368.23°F) for ~five hours. Based on the O-ring temperature curve shown in Fig. 7-24 of DAC M801940-0002, the O-ring temperature would have fallen ~40°F to 328°F over that 5 hour period. At ~328°F, the O-ring should be able to survive ~20 hours. The total length of time above the continuous service temperature of 150°C (302°F) for the EPDM O-ring is ~11 hours. Based on the predicted data and the curves from *Parker O-Ring Handbook*, the thermally tested packages with all the conservative adjustments would remain below the acceptable time at temperature limits. Hence, no damage would be expected to the O-rings during HAC.

The test packages were all preheated to >38°C (100°F) prior to being placed in the furnace, which was heated to >800°C (1475°F). As noted in the test report (ORNL/NTRC-013), the temperatures recorded on the containment vessels of TU-1 through TU-5 were fairly uniform, both vertically and circumferentially. The maximum temperature variation on the containment vessels was ~50°F (from the test temperatures reported in Table 3.4). No damage would be expected on the containment vessel from thermal stresses resulting from a temperature differential of this magnitude. This conclusion is based on the guidelines given in *ASME Boiler and Pressure Vessel Code*, Sect. III. Thermal stress is defined as a self-balancing stress produced by a non-uniform distribution of temperature (*ASME Boiler and Pressure Vessel Code*, Sect. III, NB-3213.13). This paragraph further states that there are two types of thermal stresses: general thermal stress and local thermal stress. An example of a general stress is that produced by an axial temperature distribution in a cylindrical shell (NB-3213.9). This general stress is further classified (NB-3213.9) as a secondary stress (that is, a normal stress or a shear stress developed by the constraint of adjacent materials or by self-constraint of the structure). NB-3213.9 further states that the basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions that cause the stress to occur, and failure from a single application would not be expected. An example of a local thermal stress is a small hot spot in the wall of a pressure vessel (NB-3213.13). Local thermal stress is associated with almost complete suppression of the differential expansion and thus produces no significant distortion. Such stresses are considered only from a fatigue standpoint. Fatigue will not result from a one-time cyclic event such as an accidental fire.

Following the thermal test, the volume between the O-rings on the five containment vessels (Sect. 2.7.4) was then leak tested and met the air leak-rate criterion of 10^{-4} ref-cm^3/s. Following the O-ring leak check, the six containment vessels were drilled and tapped for full body helium leak testing. All six containment vessels passed the leak rate criteria for leaktightness per ANSI N14.5-1997. The containment vessels were then submerged under a pressure equivalent to 0.9 m (3 ft) of water for 8 h, with no leakage noted (Sect. 2.7.5). Visual inspection following testing and disassembly also indicated that no distortion or damage occurred in the containment vessel wall, sealing lid, closure nut, O-rings, or sealing surfaces. These tests and observations demonstrate that thermal stresses produced during testing did not affect the containment capability of the containment vessel.

3.4.5 Accident Conditions for Fissile Material Packages for Air Transport

The expanded fire test conditions specified in 10 CFR 71.55(f)(1)(iv) for fissile material package designs for air transportation was not conducted. The issue of subcriticality is addressed in Chap. 6 with content mass limits as addressed in Chap. 1 for air transport.

Appendix 3.5.1
Containment Vessel Pressure due to Normal Conditions of Transport for the Proposed Contents

The following calculations determine the pressure of the containment vessel when subjected to the tests and conditions of Normal Condition of Transport per 10 CFR 71.71 for the most restrictive convenience can arrangements shipped in the ES-3100. The following packaging arrangements are evaluated for shipment:

1. one shipment will contain six cans with external dimensions of 4.25-in. diam by 4.875-in. high;
2. one shipment will contain five cans with external dimensions of 4.25-in. diam by 4.875-in. high and three can spacers, top can will be empty;
3. one shipment will contain three cans with external dimension of 4.25-in. diam by 8.75-in. high and two can spacers;
4. one shipment will contain three cans with external dimension of 4.25-in. diam by 10-in. high;
5. one shipment will contain six cans with external dimension of 3.00-in. diam by 4.75-in. high;
6. one shipment will contain three polyethylene bottles with external dimensions of 4.94-in. diam by 8.7-in. high;
7. one shipment will contain three Teflon FEP bottles with external dimensions of 4.69-in. diam by 9.4-in. high;
8. one shipment will contain a brazed assembly of two cans with final external dimensions of 4.25-in. diam by 17.50-in. high. An empty can with external dimensions of 4.25-in. diam by 8.75-in. high will be placed on top or bottom of the 17.50-in.–high can;
9. one shipment will contain fuel rods, or tubes, or plates greater than 17.00 in. in length. These items are bundled together and protected on both ends with an open-ended can with external dimensions of ≤5.0-in. diam by ≤ 8.75-in. high. Total assembly height will be ≤30.5 in. If space is available inside the containment vessel, stainless-steel metal scrubbers will be added on the bottom and top of this assembly or an empty convenience can will be placed on the top or bottom of the assembly;
10. one shipment will contain three cans brazed together with external dimensions of 4.25-in. diam by ~30-in. high; and
11. one shipment will contain closed cans with diameters >4.25 in. In this situation, the void volume inside the loaded containment vessel must be ≥42.779 $in.^3$ in order to not exceed the previously high pressure prediction for containment vessel arrangement (CVA) 7.

To determine this pressure, the following assumptions have been made:

1. The highly enriched uranium (HEU) contents are loaded into convenience cans which are placed inside the ES-3100 containment vessel at standard temperature (T_{amb}) and pressure (P_t) [25°C (77°F) and 101.35 kPa (14.7 psia)] with air at a maximum relative humidity of 100% for all configurations except for CVA 7. CVA 7 assumes the air is 100% dry.

2. The convenience cans are assumed to not be sealed.

3. Convenience can and bottle geometry does not change during pressure increase inside containment vessel.

4. If metal convenience cans are used, the total amount of polyethylene, nylon, or Teflon bagging and lifting slings is limited to 500 g per containment vessel shipping arrangement.

5. The mass of offgassing material (polyethylene, nylon, or Teflon bagging , Teflon bottles, silicone pads, lifting slings) is assumed to be 1490 g for the offgassing evaluation of CVA 7.

6. CVA 11 uses metal cans and, therefore, is limited to 500 g of polyethylene, nylon, or Teflon bagging and lifting slings.

The offgassing material limits identified in assumptions 4 and 5 have been established based on the needs of shippers. All configurations are limited to 500 g of polyethylene, nylon, or Teflon in the form of bags, slings, and/or polyethylene bottles. When the requirement to ship material in Teflon bottles arose, the upper limit of 1490 g of offgassing material was established. This limit is a combination of three Teflon bottles (330 g per bottle) and the original 500 g allowance for polyethylene, nylon, or Teflon bagging material. These offgassing material limits have been used in calculations pertaining to containment vessel pressure, radioactive material leakage criteria, and criticality control. Therefore, portions of the safety basis for this shipping package have been based on these material limits.

Applying Dalton's law concerning a mixture of gases, the properties of each component are considered as though each component exists separately at the volume and temperature of the mixture. Therefore, the molar quantities of each constituent inside the containment vessel (i.e., dry air, water vapor, polyethylene, nylon, or Teflon bagging, and silicone rubber) must be calculated individually.

To calculate these molar properties, the void volume of the containment vessel must be determined. The volume inside an empty ES-3100 containment vessel was determined from ALGOR finite element software to be 623.38 $in.^3$ (10,215.36 cm^3).

I. Molar quantity determination for dry air and water vapor

According to *Fundamentals of Classical Thermodynamics* (Van Wylen), "Relative humidity (Φ) is defined as the ratio of the mole fraction in the mixture to the mole fraction of vapor in a saturated mixture at the same temperature and total pressure."

Since the vapor is considered an ideal gas, the definition reduces to the ratio of the partial pressure of the vapor (P_v) as it exists in the mixture to the saturation pressure of the vapor (P_g) at the same temperature.

Therefore,

$$\Phi = P_v / P_g .$$

From the above equation and interpolating the values given in Table A.1.1 of *Fundamentals of Classical Thermodynamics* (Van Wylen), the partial pressure of the water vapor at saturation is:

$$\begin{aligned} P_v &= 1.0\ (0.464)\ \text{psia}, \\ &= 0.464\ \text{psia}. \end{aligned}$$

The partial pressure of the dry air (P_a) in the volume:

$$\begin{aligned} P_a &= P_t - P_v , \\ &= 14.7 - 0.464, \\ &= 14.236\ \text{psia}. \end{aligned}$$

From the ideal gas law, the number of water vapor moles and dry air moles in the void volume (V_V) for each CVA is calculated as follows:

$$n_v = \frac{P_v \times V_v}{R_u \times T_{amb} \times 12}, \quad n_a = \frac{P_a \times V_v}{R_u \times T_{amb} \times 12}.$$

To determine the number of moles, the void volume of the air mixture must be determined. The void volume (V_V) in the containment vessel for each CVA is calculated as follows:

$$V_V = V_{ECV} - V_{SP} - V_{PB} - V_{SCC} - V_{CS} - V_{CH},$$

where

V_{ECV} = volume inside an empty containment vessel,
V_{SP} = silicone pad volume,
V_{PB} = polyethylene, nylon, or Teflon bagging or lifting sling volume,
V_{SCC} = structural volume of the convenience cans or bottles,
V_{CS} = external volume of the can spacers,
V_{CH} = external volume of the convenience can handles.

A summary for each CVA is shown in Table 1.

The bounding case for oxide material contained in 4.25-in–diam cans based on the volumes listed in Table 1 is CVA 1 at 588.46 in.^{3} CVA 1's void volume is the lowest of the volumes shown in Table 1 for configurations that are used to transport the materials in the form of oxide. CVA 2 and CVA 3 have smaller volumes primarily due to the use of can spacers. Can spacers are not required when transporting oxides. To determine the minimum volume for this configuration, the mass limit of 15.13 kg of oxides is used in conjunction with the lowest density oxide of 7.3 kg/L (UO_3). The resulting volume is 15.13 kg / 7.3 kg/L × 1 ft^3 / 28.32 L × 1728 in.^{3} / ft^3 = 126.464 in.^{3} Therefore, the bounding volume for CVA 1 is 574.66 in.^{3} − 126.464 in.^{3} = 448.20 in.^{3}

Table 1. Containment vessel void volume for each CVA

	CVA	V_{ECV} (in.^{3})	V_{SP} [a] (in.^{3})	V_{PB} (in.^{3})	V_{SCC} (in.^{3})	V_{CS} (in.^{3})	V_{CH} (in.^{3})	V_V (in.^{3})
1	Six 4.875-in.–high cans Seven silicone pads Six can handles	623.38	9.35	30.51	7.84	0.00	1.02	574.66
2	Five 4.875-high cans Nine silicone pads Three Cat 277-4 spacers Eight can handles	623.38	12.03	30.51	6.47	60.60	1.36	512.41
3	Three 8.75-in.–high cans Two Cat 277-4 spacers Six silicone pads Five can handles	623.38	8.02	30.51	5.14	40.40	0.85	538.46
4	Three 10-in.–high cans Four silicone pads Three can handles	623.38	5.35	30.51	5.56	0.00	0.51	581.45
5	Six 4.75-in.–high nickel cans	623.38	0.00	30.51	12.64	0.00	1.02	579.21
6	Three 4.94-in.–OD polyethylene bottles	623.38	0.00	9.46	21.05	0.00	0.00	592.87
7	Three 4.69-in.–OD Teflon FEP bottles	623.38	0.00	30.51	27.95	0.00	0.00	564.92
8	One 17.5-in.–high can loaded One 8.75-in.–high can empty Three silicone pads Two can handles	This configuration is bounded by CVA 3						
9	Two open-ended cans One empty convenience can with height ≤ 8.75-in. Three silicone pads Two can handles	This configuration is bounded by CVA 4 [b]						
10	Three 10-in. cans brazed together Two silicone pads One can handle	This configuration is bounded by CVA 4						
11	Closed convenience cans with diameters greater or equal to 4.25-in. Seven silicone pads							42.779 (min.)

[a] This assumes that the internal convenience cans, polyethylene or Teflon FEP bottles, and Cat 277-4 spacer cans are not sealed.
[b] Although CVA 9 may slightly exceed the height of the combined three 25.4 cm (10 in.) can height (CVA 4), the open-ended cans and contents produce a larger void volume and thereby lower overall pressure inside the containment vessel.

Only CVA 7 can accommodate the uranyl nitrate crystals (UNX) held in the Teflon bottles. CVA 7 is limited to 9.17 kg of the uranyl nitrate hexahydrate crystals and 11.9 kg of uranyl nitrate trihydrate crystals (see Appendix 3.5.4). For the bounding pressure calculation, the smallest resulting free volume in CVA 7 is then 564.92 − 11.9 kg / 2.81 kg/L × 1 ft^3 / 28.32 L × 1728 in.^{3} / ft^3 = 564.92 in.^{3} − 258.4 in.^{3} = 306.52 in.^{3}. The bounding case for all materials contained in cans with a diameter >4.25 in. is determined by not exceeding the maximum predicted HAC pressure previously determined for CVAs 1 and 7. A minimum void volume of 42.779 in.^{3} in the containment vessel has been calculated. This value is conservatively rounded up to 43 in.^{3}

Using the above molar equations and bounding volumes, the number of moles for water vapor and dry air in the vessel for CVAs 1, 7, and 11 are summarized in Table 2.

Table 2. Water vapor and dry air molar summary for each CVA

CVA	P_a (psia)	P_v (psia)	V_V (in.^{3})	R_u (ft-lb/lb-mol·R)	T_{amb} (R)	n_v (lb-mol)	n_a (lb-mol)
1	14.236	0.464	448.20	1545.32	537	2.0884E-05	6.4075E-04
7	14.700 [a]	0.000 [a]	306.52	1545.32	537	0.0000E+00	4.5248E-04
11	14.236	0.464	42.779	1545.32	537	1.9933E-06	6.1157E-05

[a] This represents a worst case set of conditions due to the later addition of water vapor from efflorescence of the UNX crystals.

II. Molar quantity determination due to offgassing for each containment vessel arrangement

The maximum temperature calculated for the containment vessel is 89.60°C (193.28°F). This temperature is assumed to be constant throughout the containment vessel and contents. Therefore, the polyethylene, nylon, or Teflon bags, polyethylene bottles, Teflon FEP bottles, and silicone rubber can pads are assumed to be at this temperature.

Using the above calculated results and the specific gas generation of polyethylene, nylon, or Teflon bags and silicone rubber pad measurements at temperatures up to 170°C (338°F) conducted by the Y-12 Development Division, the amount of gas (V_{bo} and V_{po}) generated due to offgassing of the polyethylene, nylon, or Teflon bags and/or polyethylene bottles, and silicone rubber can pads at any temperature is estimated by first determining the offgassing volume per unit mass at temperature and multiplying that by the total mass of the bags and can supports inside the containment vessel. Based on testing at a temperature of 93.33°C (200°F), no recordable offgassing occurred in the polyethylene, nylon, or Teflon bags and/or polyethylene bottles, or silicone rubber pad material as documented in Y/DZ-2585. The data showed that the Teflon FEP material offgassing volume per unit mass (V_{tf}) was conservatively assumed to be 0.25 cm^3/g@STP (Y/DZ-2720). These values are used to determine the offgassing volumes as shown below:

$V_{po} = W_p \times 0.0 / 16.387$ (in.^{3}) (offgassing volume of silicone rubber pads)

$V_{bo} = W_b \times 0.0 / 16.387$ (in.^{3}) (offgassing volume of polyethylene, nylon, or Teflon bags and/or polyethylene bottles or lifting sling)

$V_{tf} = W_{tf} \times 0.25 / 16.387$ (in.^{3}) (offgassing volume of Teflon bottles)

From the ideal gas law, the number of gas moles in the volume at standard temperature and pressure is as follows:

$$n_{io} = \frac{P_v \times V_i}{R_u \times T_{amb} \times 12}.$$

A summary of the results obtained using the above equations for the bounding CVA is presented in Tables 3, 4, and 5.

Table 3. Molar quantity of gas generated due to the silicone rubber pad offgassing [a]

CVA	W_p (g)	V_{po} (in.^{3})	P_V (psia)	R_u (ft-lb/lb-mol·R)	T_{amb} (R)	n_{po} (lb-mol)

7	990.00	15.10	14.7	1545.32	537	2.2296E-05

III. Gas generation due to radiolysis of water

Buildup of hydrogen gas (H_2) and oxygen gas (O_2) in the ES-3100 containment vessel due to radiolysis is incorporated into the pressure calculation by assuming that 5 mol % of the free volume is hydrogen gas. Since each mole of H_2 generated is accompanied by 0.5 mol of O_2, the concentration of H_2 will reach 5 mol % when volume of H_2 is 0.05405 times the initial void volume (see Sect. 3.5.4.8 of Appendix 3.5.4). Using the ideal gas law, the number of gas moles of hydrogen in the volume at standard temperature and pressure is:

$$n_r = \frac{P_v \times V_r}{R_u \times T_{amb} \times 12},$$

where

n_r = individual molar quantity for hydrogen and oxygen gas;
V_r = volume of gas assumed generated by radiolysis.

A summary of the results for hydrogen and oxygen generation due to radiolysis using the above equation is presented in Table 6.

Table 6. Molar quantity of oxygen and hydrogen gas generation due to radiolysis

CVA	V_v (in.^{3})	V_h (in.^{3})	P_v (psia)	R_u (ft-lb/lb-mol·R)	T_{amb} (R)	n_{r-H2} (lb-mol)	n_{r-O2} (lb-mol)
1	448.20	24.23	14.7	1545.32	537.0	3.5761E-05	1.7881E-05
7	306.52	16.57	14.7	1545.32	537.0	2.4457E-05	1.2228E-05
11	42.779	2.31	14.7	1545.32	537.0	3.4133E-06	1.7066E-06

IV. Molar quantity of gas generated due to the efflorescence nature of the uranyl nitrate crystals

The UNX crystals in any hydrated state will decompose and lose water molecules at the temperature shown in Table 3.3 [193.28°F (89.60°C)]. The partial pressure of water vapor in this mixture is conservatively estimated to be the saturated vapor pressure (P_{sv}) of water at 193.28°F or 10.062 psia. Using the ideal gas law, the molar quantity of water vapor (n_v) in this volume at the maximum containment vessel temperature and the saturated vapor pressure is:

$$n_v = \frac{P_{sv} \times V_v}{R_u \times T_{cv} \times 12},$$

$$= (10.062 \times 306.52) / (1545.32 \times 12 \times 653.28),$$
$$= 2.5459 \times 10^{-4} \text{ lb-mol},$$

where

n_v = molar quantity for water vapor;
V_v = void volume of containment vessel;
T_{cv} = maximum temperature of containment vessel; and
P_{sv} = interpolated saturated vapor pressure of water at temperature from *Fundamental of Classical Thermodynamic* (Van Wylen), Table A.1.1, p. 650.

V. Total pressure due to offgassing and NCT temperatures inside the containment vessel

The total pressure of the mixture at 89.60°C (193.28°F), P_T, for the bounding CVA is the sum of each of the previously calculated molar quantities. Table 7 summarizes the molar constituents and total pressure of each bounding CVA. The following equation is used to calculated the final containment vessel pressure:

$$P_{89.60°C} = (\sum n_i \times R \times T \times 12) / V_{GMV},$$

where

n_i = individual molar quantity for each gas,

T = average gas temperature,
= 89.60°C (193.28°F),

V_{GMV} = V_v = gas mixture volume.

Table 7. Total pressure inside the containment vessel at 89.60°C (193.28°F)

CVA [a]	n_a [b] (lb-mol)	n_v [b] (lb-mol)	n_{po} [b] (lb-mol)	n_{bo} [b] (lb-mol)	n_{tf} [b] (lb-mol)	n_{H2} [b] (lb-mol)	n_{O2} [b] (lb-mol)	n_T [b] (lb-mol)	P_T (psia)
1	6.4075E-04	2.0884E-05	0.0000E+00	0.0000E+00	0.0000E+00	3.5761E-05	17881E-05	7.1428E-04	19.333
7	4.5248E-04	2.5459E-04 [c]	0.0000E+00	0.0000E+00	2.2296E-05	2.4457E-05	1.2228E-05	7.6605E-04	30.276
11	6.1157E-05	1.9933E-06	0.0000E+00	0.0000E+00	0.0000E+00	3.4133E-06	1.7066E-06	6.8270E-05	19.333

[a] This assumes that the internal convenience cans, polyethylene or Teflon FEP bottles, and Cat 277-4 spacer cans are not sealed.
[b] n_a—molar quantity of dry air in the gas mixture;
n_v—molar quantity of water vapor in the gas mixture;
n_{po}—molar quantity of gas due to offgassing of the silicone rubber pads;
n_{bo}—molar quantity of gas due to offgassing of the polyethylene, nylon, or Teflon bags, polyethylene bottles, and lifting sling;
n_{tf}—molar quantity of gas due to offgassing of the Teflon bottles;
n_{H2}—molar quantity of hydrogen gas due to radiolysis of water;
n_{O2}—molar quantity of oxygen gas due to radiolysis of water; and
n_T—total molar quantity in the gas mixture.
[c] This value is the molar quantity of water vapor generated from the efflorescence of UNX crystals.

VI. Total pressure at −40°C (−40°F)

At −40°C (−40°F), the partial pressure of the water vapor is conservatively assumed to be zero. Therefore, the final pressure of the mixture at −40°C (−40°F) is calculated according to the ideal gas law based solely on the partial pressure of the air.

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2},$$

where

P_1 = 14.236 psi,
T_1 = 77°F = 536.67 R,
T_2 = −40°F = 419.67 R,
V_1 = V_2.

Rearranging and solving for P_2,

P_2 = $P_1 (T_2 / T_1)$,
= (14.236)(419.67 / 536.67),
= 11.13 psia.

VII. Maximum containment vessel pressure differential in accordance with air transport guidance

The methodology used to determine the maximum pressure differential for air transport in accordance with IAEA SSR-6, paragraphs 620 and 621 incorporate the following assumptions.

1. The three containment vessel arrangements previously discussed in this appendix will be evaluated.
2. Evaluation will be conducted at the maximum containment vessel temperature shown in Table 3.15 for air transport.
3. Maximum containment vessel temperature was determined using an ambient temperature of 55°C, self-heating of the package contents, and no insolation.
4. Maximum pressure differential is the maximum normal operating pressure (MNOP) plus 95 kPa.

A value of 147.99°F was determined and documented in DAC M801940-0002 and is used as an average temperature of the containment vessel. The molar quantity results shown in Table 8 will be evaluated at this temperature as shown in Table 9. UNX crystals will not be transported by air. Therefore, there is no longer a need to evaluate CVA 7.

Table 8. Total molar quantities inside the containment vessel

CVA [a]	n_a [b] (lb-mol)	n_v [b] (lb-mol)	n_{po} [b] (lb-mol)	n_{bo} [b] (lb-mol)	n_{tf} [b] (lb-mol)	n_{H2} [b] (lb-mol)	n_{O2} [b] (lb-mol)	n_T [b] (lb-mol)
1	6.4075E-04	2.0884E-05	0.0000E+00	0.0000E+00	0.0000E+00	3.5761E-05	1.7881E-05	7.1528E-04
11	6.1157E-05	1.9933E-06	0.0000E+00	0.0000E+00	0.0000E+00	3.4133E-06	1.7066E-06	6.8270E-05

[a] This assumes that the internal convenience cans, polyethylene or Teflon FEP bottles, and Cat 277-4 spacer cans are not sealed.
[b] n_a—molar quantity of dry air in the gas mixture;
n_v—molar quantity of water vapor in the gas mixture;
n_{po}—molar quantity of gas due to offgassing of the silicone rubber pads;
n_{bo}—molar quantity of gas due to offgassing of the polyethylene, nylon, or Teflon bags, polyethylene bottles, and lifting sling;
n_{tf}—molar quantity of gas due to offgassing of the Teflon bottles;
n_{H2}—molar quantity of hydrogen gas due to radiolysis of water;
n_{O2}—molar quantity of oxygen gas due to radiolysis of water; and
n_T—total molar quantity in the gas mixture.
[c] This value is the molar quantity of water vapor generated from the efflorescence of UNX crystals.

In accordance with IAEA SSR-6, para. 621, the maximum differential pressure (P_{DIFF}) generated under air transport conditions is the maximum normal operating pressure calculated in Table 9 plus 95 kPa (13.78 psi). This pressure differential will be used in Table 2.21a to evaluate the containment vessel structural integrity for air transport.

Table 9. Containment vessel MNOP at 64.44°C (147.99°F)

CVA	n_T (lb-mol)	P_{MNOP} (psia)	P_{DIFF} (psig)
1	7.1528E-04	3.29	17.07
11	6.8270E-05	3.29	17.07

Appendix 3.5.2
Containment Vessel Pressure due to Hypothetical Accident Conditions for the Proposed Contents

The following calculations determine the pressure of the containment vessel when subjected to the tests and conditions of Hypothetical Accident Conditions per 10 CFR 71.73 for the most restrictive convenience can arrangements shipped in the ES-3100 package. The following packaging arrangements are evaluated for shipment:

1. one shipment will contain six cans with external dimensions of 4.25-in. diam by 4.875-in. high;
2. one shipment will contain five cans with external dimensions of 4.25-in. diam by 4.875-in. high and three can spacers, the top can is empty;
3. one shipment will contain three cans with external dimensions of 4.25-in. diam by 8.75-in. high and two can spacers;
4. one shipment will contain three cans with external dimensions of 4.25-in. diam by 10-in. high;
5. one shipment will contain six nickel cans with external dimensions of 3.00-in. diam by 4.75-in. high;
6. one shipment will contain three polyethylene bottles with external dimensions of 4.94-in. diam by 8.7-in. high;
7. one shipment will contain three Teflon FEP bottles with external dimensions of 4.69-in. diam by 9.4-in. high;
8. one shipment will contain a brazed assembly of two cans with final external dimensions of 4.25-in. diam by 17.50-in. high. An empty can with external dimensions of 4.25-in. diam by 8.75-in. high will be placed on top or bottom of the 17.50-in.–high can;
9. one shipment will contain fuel rods, or tubes, or plates greater than 17.00 in. in length. These items are bundled together and protected on both ends with an open-ended can with external dimensions of ≤5.0-in. diam by ≤ 8.75-in. high. Total assembly height will be ≤30.5 in. If space is available inside the containment vessel, stainless-steel metal scrubbers will be added on the bottom and top of this assembly or an empty convenience can will be placed on the top or bottom of the assembly;
10. one shipment will contain three cans brazed together with external dimensions of 4.25-in. diam by ~30-in. high; and
11. one shipment will contain closed cans with diameters >4.25 in. In this situation, the void volume inside the loaded containment vessel must be ≥42.779 $in.^3$ in order to not exceed the previously high pressure prediction for containment vessel arrangement (CVA) 7.

To determine this pressure, the following assumptions have been made.

1. The highly enriched uranium (HEU) contents are loaded into convenience cans and placed inside the ES-3100 containment vessel at standard temperature [25°C (77°F)] and at the maximum normal operating pressure (see Table 7 of Appendix 3.5.1).
2. The convenience cans are assumed to not be sealed.
3. Convenience can and bottle geometry does not change during pressure increase inside containment vessel.
4. If metal convenience cans are used, the total amount of polyethylene, nylon, or Teflon bagging and lifting slings is limited to 500 g per containment vessel shipping arrangement.
5. The mass of offgassing material (polyethylene, nylon, or Teflon bagging , Teflon bottles, silicone pads, lifting slings) is assumed to be 1490 g for the offgassing evaluation of CVA 7.
6. Hydrogen and oxygen molar quantities calculated in Appendix 3.5.1 are conservatively added to the gas mixture for HAC.
7. The contribution in pressure generated by the efflorescence of uranyl nitrate crystals (UNX) is incorporated into the results for CVA 7.
8. CVA 11 uses metal cans and, therefore, is limited to 500 g of polyethylene, nylon, or Teflon bagging and lifting slings.

The offgassing material limits identified in assumptions 4 and 5 have been established based on the needs of shippers. All configurations are limited to 500 g of polyethylene, nylon, or Teflon in the form of bags, slings, and/or polyethylene bottles. When the requirements to ship material in Teflon bottles arose, the upper limit of 1490 g of offgassing material was established. This limit is a combination of three Teflon bottles (990 g) and the original 500 g allowance for polyethylene, nylon, or Teflon bagging material. These offgassing material limits have been used in calculations pertaining to containment vessel pressure, radioactive material leakage criteria, and criticality control. Therefore, portions of the safety basis for this shipping package have been based on these material limits.

Applying Dalton's law concerning a mixture of gases, the properties of each component are considered as though each component exists separately at the volume and temperature of the mixture. Therefore, the molar quantities of each constituent inside the containment vessel (i.e., dry air, water vapor, polyethylene, nylon, or Teflon bagging and/or polyethylene bottles, silicone rubber pads, and Teflon bottles) must be calculated individually.

To calculate these molar properties, the void volume of the containment vessel must be determined. The volume inside an empty ES-3100 containment vessel was determined from ALGOR finite element software to be 623.38 $in.^3$ (10,215.36 cm^3).

I. Molar quantity determination based on MNOP

To use the maximum normal operating pressure at standard temperature, the number of lb-mol of gas needs to be increased using the following equation:

$$n_{MNOP} = \frac{P_T \times V_v}{R_u \times T_{amb} \times 12} \ (molar\ equation)\ .$$

Using P_T from Table 1 and the molar equation, the total number of moles is summarized in Table 2.

Table 1. Total pressure inside the containment vessel at 89.60°C (193.28°F) [a]

CVA	n_a [b] (lb-mol)	n_v [b] (lb-mol)	n_{po} [b] (lb-mol)	n_{bo} [b] (lb-mol)	n_{tf} [b] (lb-mol)	n_{H2} [b] (lb-mol)	n_{O2} [b] (lb-mol)	n_T [b] (lb-mol)	P_T (psia)

7	30.276	306.52	1545.32	537	9.3193E-04
11	19.333	42.779	1545.32	537	8.3054E-05

II. Molar quantity determination due to offgassing for each containment vessel arrangement

To determine the maximum pressure inside the containment vessel as a result of thermal testing, the average adjusted gas temperature must be calculated based on the above results. The approach used is to divide the containment vessel volume into three distinct equal regions and then average the three together. The first volume is represented by the gas adjacent to the containment vessel lid and flange region and the top convenience can. Based on the temperature recorded near the O-rings [116.11°C (241°F)] and the temperature recorded on the external surface of the convenience can [98.89°C (210°F)], the average temperature of the gas in this region is 107.50°C (225.50°F). Using the temperature adjustment of 70.67°C (127.23°F) for this region (Sect. 3.4.3), the adjusted average temperature in the first region is 178.17°C (352.73°F). The second volume is represented by the gas adjacent to the second convenience can from the top. Based on the temperature recorded on the containment vessel wall and convenience can [92.78°C (199°F)], the average temperature of gas in this region is 92.78°C (199°F). Using the temperature adjustment of 70.72°C (127.29°F) for this region (Sect. 3.4.3), the adjusted average temperature in the second region is 163.50°C (326.29°F). The third and final volume is represented by the gas adjacent to the bottom convenience can. Again based on the convenience can temperature [87.78°C (190°F)] and the containment vessel end cap temperature [98.89°C (210°F)], the average temperature of gas in this region is 93.33°C (200°F). Using the temperature adjustment of 67.17°C (120.90°F) for this region (Sect. 3.4.3), the adjusted average temperature in the third region is 160.50°C (320.90°F). Averaging these three temperatures, an average adjusted gas temperature of 167.39°C (333.31°F) is determined for the containment vessel.

Using the above calculated results and the specific gas generation of polyethylene, nylon, or Teflon bags and silicone rubber pads measurements at temperatures up to 170°C (338°F) conducted by the Y-12 Development Division (Y/DZ-2585), the amount of gas generated due to offgassing of the silicone rubber can pads, the polyethylene, nylon, or Teflon bags and/or polyethylene bottles, and the Teflon FEP bottles at 167.39°C (333.31°F), (V_{po}, V_{bo}, and V_{tf}) is estimated by first determining the offgassing volume per unit mass at temperature and multiplying that by the total mass of the bags, bottles, slings, and silicone rubber can supports inside the containment vessel. Based on testing at an approximate temperature of 170°C (338°F), values of ~9.0 and ~0.98 cm^3/g @STP for the polyethylene, nylon, or Teflon bagging and/or polyethylene bottles, and silicone rubber pads, respectively, were taken from the curves for the offgassing volume per unit mass as documented in Y/DZ-2585. The data showed that the Teflon FEP material offgassing volume per unit mass (V_{tf}) was conservatively assumed to be 0.25 cm^3/g@STP (Y/DZ-2720). These values are used to determine the offgassing volume as shown below:

$V_{po} = W_p \times 0.98 / 16.387\ (in.^3)$ (offgassing volume of silicone rubber pads)

$V_{bo} = W_b \times 9.0 / 16.387\ (in.^3)$ (offgassing volume of polyethylene, nylon, or Teflon bags, polyethylene bottles, and lifting sling)

$V_{tf} = W_{tf} \times 0.25 / 16.387\ (in.^3)$ (offgassing bottles of Teflon FEP bottles)

From the ideal gas law, the number of gas moles in the volume is as follows:

$$n_i = \frac{P_v \times V_i}{R_u \times T_{amb} \times 12}.$$

A summary of the results obtained using the above equations for CVAs 1, 7, and 11 is presented in Tables 3, 4, and 5.

III. Gas generation due to radiolysis of water

Buildup of hydrogen gas (H_2) and oxygen gas (O_2) in the ES-3100 containment vessel due to radiolysis is incorporated into the pressure calculation by assuming that 5 mol % of the free volume is hydrogen gas. Since each mole of H_2 generated is accompanied by 0.5 mol of O_2, the concentration of H_2 will reach 5 mol % when volume of H_2 is 0.05405 times the initial void volume (see Sect. 3.5.4.8 of Appendix 3.5.4). Using the ideal gas law, the number of gas moles of hydrogen in the volume at standard temperature and pressure is:

$$n_r = \frac{P_v \times V_r}{R_u \times T_{amb} \times 12},$$

where

n_r = individual molar quantity for hydrogen and oxygen gas,
V_r = volume of gas assumed generated by radiolysis.

A summary of the results for hydrogen and oxygen generation due to radiolysis using the above equation is presented in Table 6.

Table 6. Molar quantity of oxygen and hydrogen gas generation due to radiolysis

CVA	V_v (in.^{3})	V_h (in.^{3})	P_v (psia)	R_u (ft-lb/lb-mol·R)	T_{amb} (R)	n_{r-H2} (lb-mol)	n_{r-O2} (lb-mol)

IV. Molar quantity of gas generated due to the efflorescence nature of the uranyl nitrate crystals

The UNX crystals in any hydrated state will decompose and lose water molecules at the average gas temperature shown in Sect. 3.4.3 [167.39°F (333.31°C)]. The partial pressure of water vapor in this mixture is conservatively estimated to be the saturated vapor pressure (P_{sv}) of water at 333.31°F or 107.94 psia. Using the ideal gas law, the molar quantity of water vapor (n_v) in this volume at the maximum containment vessel temperature and the saturated vapor pressure is:

$$\begin{aligned} n_v &= (P_{sv} \times V_v) / (R_u \times T_{cv} \times 12); \\ &= (107.94)(306.52) / (1545.32 \times 12 \times 793.31); \\ &= 2.2490 \times 10^{-3} \text{ lb-mol}; \end{aligned}$$

where

n_v = individual molar quantity for water vapor;
V_v = void volume of containment vessel;
T_{cv} = average gas temperature inside the containment vessel = 460 + 333.31 R; and
P_{sv} = interpolated saturated vapor pressure of water at temperature from *Fundamental of Classical Thermodynamic* (Van Wylen), Table A.1.1, p. 650.

V. Total pressure due to offgassing and HAC temperatures inside the containment vessel with efflorescence of uranyl nitrate crystals

The total pressure of the mixture at 167.39°C (333.31°F), P_T, for each CVA is the sum of each of the previously calculated molar quantities. Table 7 summarizes the molar constituents and total pressure of each CVA. The following equation is used to calculate the final containment vessel pressure:

$$P_{167.39°C} = (\sum n_i \times R \times T \times 12) / V_{GMV},$$

where

n_i = individual molar quantity for each gas,

T = average gas temperature,
= 167.39°C (333.31°F),

V_{GMV} = V_v,
= gas mixture volume.

Appendix 3.5.3
Silicone Rubber Thermal Properties from Therm 1.2 Database

The thermal properties for silicone rubber used in the thermal analyses of the ES-3100 shipping container were obtained from the Therm 1.2 Thermal Properties Database by R. A. Bailey. Since Therm 1.2 is not a publicly available program, screen captures from Therm 1.2 of the data for silicone rubber are presented in Figs. 1 and 2 in English and SI units, respectively.

Appendix 3.5.4
Estimates of Hydrogen Buildup in the ES-3100 Package Containing Highly Enriched Uranium

3.5.4.0 Summary

Table 3.5.4.1 below indicates that the ES-3100 package with Containment Vessel Arrangement 1 (CVA 1, see Appendix 3.5.1) and a 15.13-kg load of uranium oxide with 3 wt % water, will generate 5 mol % of hydrogen in the void space of the containment vessel in ~1.44 years (17 months). With CVA 7, a load of 4.75 kg of uranyl nitrate hexahydrate crystals [$UO_2(NO_3)_2 \cdot XH_2O$, X = 6, 21.6 wt % water] or a load of 6.70 kg of uranyl nitrate trihydrate crystals (X=3, 12.1 wt % water) will generate 5 mol % of hydrogen in ~1.16 years (14 months). With CVA 7, a load of 9.17 kg of hexahydrate crystals will generate 5 mol % in ~0.45 years (5.3 months) while a load of 11.90 kg of trihydrate crystals will generate 5 mol % in ~0.46 years (5.5 months).

Table 3.5.4.1 Summary of load weights and shipment durations

Weight (kg)	Water		Time to 5 mol % hydrogen (y/month) [c]
	X	wt %	
Oxides [CVA 1] [a]			
15.13	UO_2	3.0	1.47/17.6
15.13	U_3O_8	3.0	1.46/17.5
15.13	UO_3	3.0	1.44/17.3
$UO_2(NO_3)_2 \cdot XH_2O$ [CVA 7] [b]			
4.75	6	21.64	1.16/13.9
6.70	3	12.13	1.17/14.0
9.17	6	21.64	0.445/5.3
11.90	3	12.13	0.463/5.5

[a] CVA 1 consists of six steel cans (see Sect. 3.1.4.1).
[b] CVA 7 consists of three Teflon bottles (see Sect. 3.1.4.1).
[c] The values have been rounded down for conservatism.

3.5.4.1 Introduction

There is a concern that hydrogen gas (H_2) could build up to dangerous levels in the ES-3100 package. Consequently, it is necessary to estimate the combination of shipping weight and transit time that limits the H_2 concentration in the package to 5 mol % (established as a limit for the purposes of this analysis). The H_2 can be generated by radiolysis and/or chemical reaction involving any material containing hydrogen. Of the anticipated materials to be shipped, the only chemical reaction would be metal reacting with water (or water vapor) to form H_2 and a metal oxide. It will be shown that radiolysis of water is the major source of H_2 for uranium oxides and uranyl nitrate crystals.

The materials that may be shipped in the ES-3100 include highly enriched uranium (HEU) in the form of uranium oxide (UO_3, U_3O_8, and UO_2) and uranyl nitrate crystals [UNX or $UO_2(NO_3)_2 \cdot XH_2O$]. The water associated with oxides ranges from 0 to 3 wt % (Sect. 1.2.2). The water in UNX ranges from X = 0 to X = 6 (0 to 21.6 wt %). The molecular weights of uranyl nitrate [$UO_2(NO_3)_2$] and H_2O are 391 and 18 g/mol, respectively, so the fraction of water in UN6 is $6 \times 18 / (391 + 6 \times 18) = 0.216$. There is no liquid water (sorbed or interstitial) associated with any of the other contents. However, the air in the void

spaces of the package contains water vapor (humidity). It will be shown that the maximum amount of H_2 from humidity is below 5 mol %.

3.5.4.2 Initial hydrogen in convenience containers

It was suggested that convenience containers stored for a long period of time could accumulate significant amounts of H_2 in the containers before being placed in the ES-3100. The convenience containers are Teflon bottles for UNX, and cans or polyethylene bottles for other materials. An estimate of the accumulated H_2 is given in this section.

The ES-3100 has several containment vessel arrangements (CVAs, see Appendix 3.5.1, Table 1) for the convenience containers. CVA 7 consists of three Teflon bottles and is the only arrangement for UNX. CVAs 5 (nickel alloy cans) and 6 (polyethylene bottles) can only be used for oxides while the remaining CVAs (steel cans) may be used for oxides or metal. The bounding arrangement for oxides is CVA 1 (6 steel cans) because it has the smallest free volume [574.66 in.^{3} (Appendix 3.5.1, Table 1)].

The H_2 generated in a container can leak out through tiny spaces in imperfect lids and by permeation or diffusion through the walls of the container. The largest leaks are through the lids but these are difficult to characterize. Consequently, this calculation conservatively considers only permeation and diffusion through the cylindrical surfaces. Because permeation is usually a faster mechanism than diffusion and is more likely with plastics, the permeation model was used for the Teflon bottles. Since metals are not very permeable, the diffusion model was used for the cans.

The rate of gas loss through permeation is based on an equation in *Perry's Chemical Engineers' Handbook* (p. 6-39, Eq. 6-170). The resulting expression is

$$d(n_P) / dt = -P_T \times \Delta P \times A_T / \tau_T \times \rho_G \times (1 + \Delta P / P_0),$$

where

n_P = the amount of gas in the three Teflon bottles, mol;
t = time, y;
P_T = the permeability of H_2 through Teflon, $cm^2/y \cdot Pa$;
ΔP = the pressure increase over the initial value, Pa;
A_T = the cylindrical area of three Teflon bottles (each is 4.69-in. diam × 9.4-in. tall) 2682.8 cm^2 (Y/HDPO/03-43);
τ_T = the thickness of each bottle, 0.13 cm (Y/HDPO/03-43);
ρ_G = the molar density of an ideal gas at 25°C and 1 atm, 4.087×10^{-5} mol/cm^3;
P_0 = the initial pressure in the bottles, 101,325 Pa (1 atm); and

$1 + \Delta P / P_0$ corrects the gas density for the pressure increase.

The permeability of H_2 through Teflon at 25°C is 3.12×10^{-5} $cm^2/y \cdot Pa$, which is equivalent to 9.89×10^{-8} $cm^2/s \cdot Bar$ (*Parker O-Ring Handbook*, Table 3-24, p.3-30).

At steady state, the permeation rate is balanced by the gas generation rate.

$$1.5 \times d(n_{H2}) / dt = P_T \times \Delta P \times A_T / \tau_T \times \rho_G \times (1 + \Delta P / P_0),$$

$$\rightarrow \Delta P \times (1 + \Delta P / P_0) = [1.5 \times d(n_{H2}) / dt] / [P_T \times A_T / \tau_T \times \rho_G],$$

where

$d(n_{H2}) / dt$ = the H_2 generation rate, 0.01379 mol/y for 4750 g of $UO_2(NO_3)_2 \cdot 6H_2O$ (see Sect. 3.5.4.7);
1.5 = a factor to account for the oxygen released with the hydrogen.

As an example for 4750 g of $UO_2(NO_3)_2 \cdot 6H_2O$, the above expression for ΔP with the above parameters is $\Delta P = \{[1.5 \times 0.01379 \text{ mol/y}] / [3.12 \times 10^{-5} \text{ cm}^2/\text{y} \cdot \text{Pa} \times (2682.8 \text{ cm}^2 / 0.13 \text{ cm}) \times 4.087 \times 10^{-5} \text{ mol/cm}^3]\} / (1 + \Delta P / 101{,}325 \text{ Pa})$. $\Delta P = 779.5$ Pa satisfies the above expression.

The steady-state mole fraction and H_2 amount are

$$f_{H2B} = (2 / 3) \times \Delta P / (P_0 + \Delta P),$$
$$n_{H2B} = f_{H2B} \times V_B \times \rho_G \times (1 + \Delta P / P_0) = V_B \times \rho_G \times (2 / 3) \times \Delta P / P_0,$$
$$V_B = 6840 - Wt_{UNX} / \rho_{UN6},$$

where

f_{H2B} = the mole fraction of H_2 in the bottles;
n_{H2B} = the amount of H_2 in the three bottles, mol;
2 / 3 = a factor to account for the fact that 1 / 3 of the pressure increase is due to oxygen;
V_B = the free volume of the 3 bottles, cm^3 [5149.6 cm^3 for 4750 g of $UO_2(NO_3)_2 \cdot 6H_2O$];
6840 = the empty void volume of three Teflon bottles, 6840 cm^3 (Y/HDPO/03-43);
Wt_{UNX} = the total weight of UNX in the containers, g;
ρ_{UN6} = the theoretical density of UN6 and, lacking data for other UNX hydrates, is also applied to all the hydrates, 2.81 g/cm^3 (CRC Handbook, p. 4-94).

For the example of 4750 g of $UO_2(NO_3)_2 \cdot 6H_2O$, the above equation becomes

$$n_{H2B} = 5149.6 \text{ cm}^3 \times 4.087 \times 10^{-5} \text{ mol/cm}^3 \times (2 / 3) \times 779.5 \text{ Pa} / 101{,}325 \text{ Pa},$$
$$= 0.001079 \text{ mol.}$$

The rate of H_2 loss through diffusion is based on an equation in *Perry's Chemical Engineers' Handbook* (p. 5-47, Eq. 5-189). The resulting expression is

$$d(n_{H2C}) / dt = -D \times \Delta C \times A_D / \tau_D,$$

where

n_{H2C} = the amount of H_2 in the 6 cans, mol;
$d(n_{H2C}) / dt$ = the rate of H_2 lost through diffusion from the 6 cans, mol/y;
D = the diffusivity, cm^2/y;
ΔC = the H_2 concentration increase over the initial value, mol/cm^3;
A_D = the cylindrical area of six steel cans, (each is 4.25-in. diam × 4.88-in. tall, see Sect. 1, Fig. 1.4), 2522.2 cm^2;
τ_D = the thickness of the can (assumed to be 0.012 in.), 0.0305 cm.

At steady state, the diffusion rate is balanced by the H_2 generation rate.

$$d(n_{H2}) / dt = D \times \Delta C \times A_D / \tau_D \rightarrow \Delta C$$
$$= [d(n_{H2}) / dt] / [D \times A_D / \tau_D]$$

The steady-state H_2 amount and mole fraction are

$$n_{H2C} = V_C \times \Delta C,$$
$$f_{H2C} = (V_C \times \Delta C) / (V_C \times \rho_G) = \Delta C / \rho_G,$$
$$V_C = V_0 - Wt_{OX} / \rho_{OX},$$

where

f_{H2C} = the mole fraction of H_2 in the cans;
V_C = the free volume in 6 cans, cm^3 (5001.3 cm^3 for 15,130 g of U_3O_8);
V_0 = the free volume of the 6 empty cans, 6806.8 cm^3;
Wt_{OX} = the total weight of uranium oxides in the containers, g;
ρ_{OX} = the theoretical density of uranium oxides, 7.3 g/cm^3 for UO_3, 8.38 for U_3O_8, and 10.97 for UO_2 (CRC Handbook, p. 4-94).

H_2 diffusion is discussed at http://www1.eere.energy.gov/hydrogenandfuelcells/pdfs/03_babu_transfer.pdf, p. 42 (Sudarsanam 2005). There is a wide range of values for diffusivity at room temperatures and a suggested value of ~5×10^{-7} cm^2/s (15.8 cm^2/y) is probably a low number for plain steel without welds or rough surfaces. This is the value used for calculating the diffusion loss rate of H_2 from the cans.

For 15,130 g of U_3O_8, the value of $d(n_{H2}) / dt$ is 0.01185 mol/y (see Sect. 3.5.4.7). ΔC = 0.01185 mol/y / [15.8 cm^2/y × 2522.2 cm^2 / 0.0305 cm] = 9.078E-09 mol/cm^3. The amount of H_2 in the 6 cans is n_{H2C} = 5001.3 cm^3 × 9.078E-09 mol/cm^3 = 4.540E-05 mol.

The above analysis assumed the material to be shipped is distributed equally to the maximum number of convenience containers for the specified CVAs (3 bottles for CVA 7 and 6 cans for CVA 1). If the material can be packed into fewer convenience containers, the amount of initial H_2 would be less. The expressions for C and n_{H2C} indicate that n_{H2C} is proportional to $V_C / A_D = (V_0 - Wt_{OX} / \rho_{OX}) / A_D$. If the empty volume and surface area of a single can is v and a, respectively, the above proportionality becomes $(Nc \times v - Wt_{OX} / \rho_{OX}) / (Nc \times a) = v / a - Wt_{OX} / (Nc \times a \times \rho_{OX})$ where Nc is the number of cans (1 to 6). As Nc increases, $Wt_{OX} / (Nc \times a \times \rho_{OX})$ decreases so that less is subtracted from v / a. The result is increasing n_{H2C}.

3.5.4.3 Hydrogen generation by chemical reaction with water

Metals can combine with the oxygen in water to release H_2. The only source of water for metals is the humidity of the air in the void spaces of the package. The air is assumed to be at 25°C, 1 atm (101.325 kPa) and 100% relative humidity. The vapor pressure of water at 25°C is 3.1690 kPa (CRC Handbook, p. 6-8), so the initial concentration of water vapor is 3.1690 / 101.325 = 0.031 mol fraction. Since 1 mol of water vapor produces 1 mol of H_2 and the oxygen is bound up as solid metal oxides, this reaction does not change the total gas pressure. Therefore, if all the water vapor reacts with the metal, the maximum concentration of H_2 is also 0.031 mol fraction, which is below the 5 mol % limit.

3.5.4.4 Radiation energy calculations

The radiation energy that drives radiolysis can be estimated from the decay rate and maximum decay energy of each radionuclide that makes up the HEU compounds (oxides and crystals). The bounding information to calculate these terms and the results are given in Table 3.5.4.2. It should be noted that the transuranic concentration can be much higher for HEU metal. As shown in Chap. 1, some Thorium (^{232}Th) compounds or oxides mixed with uranium are proposed for transport. Shipping of ^{232}Th is bounded by the analysis using uranium for the hydrogen gas generation due to the following: (1) the A_2 value of ^{232}Th is unlimited; (2) the decay energy of ^{232}Th is less than all other uranium isotopes; and (3) the half-life of ^{232}Th is significantly longer than the uranium isotopes. Therefore, the radiation energy is less for ^{232}Th compounds or oxides.

Table 3.5.4.2. Radiation energy calculations

Nuclide	$Wt\%_n$ [a]	MW_n [b] (g/mol)	T_{Hn} [b] (y)	α_{Mn} [b] (MeV)	D_{Rn} [c] [atms/(g y)]	Nuclide contr [c] [MeV/(gU y)]

^{237}Np	2.50E+00	237.0482	2.14E+06	4.957	8.23E+14	1.02E+14
Total	1.00E+02					1.395E+15

[a] Wt % from Appendix 4.5.1 (Table 1). Maximum transuranic for compounds is 40 µg/gU and 0.60 MBq/gU activity.
[b] MW is molecular weight; T_H is half life; and α is the maximum energy emitted (*CRC Handbook of Chemistry and Physics*, pp. 11-140 and 11-141).
[c] D_R is decay rate, and Nuclide Contr is the contribution of each nuclide to the total rate of decay energy.
[d] Transuranic α assumed to be equal to ^{246}Cm.

The decay rate per gram of the n^{th} radionuclide is

$$D_{Rn} = [\ln(2) / T_{Hn}] \times A_N / MW_n;$$
$$= \text{the decay rate of the } n^{th} \text{ radionuclide, atoms/y;}$$

T_{Hn} = half life of the n^{th} radionuclide, y;
A_N = Avogadro's number, 6.022×10^{23} molecules/mol;
MW_n = the molecular (atomic) weight of the n^{th} radionuclide, g/mol.

All the radionuclides in Table 3.5.4.2 are primarily α emitters, and the total rate of radiation dose is given as

$$D_E = \sum_{n=1}^{N} \frac{Wt\%_n \times D_{Rn} \times \alpha_{Mn}}{100},$$

where

D_E = the total rate of decay energy per gram of uranium, Mev/(gU y);
$Wt\%_n$ = the weight percent of the n^{th} radionuclide in the uranium;
α_{Mn} = the α energy emitted in the decay of the n^{th} radionuclide, MeV; and
N = the total number of radionuclides.

The above calculation of D_E for HEU is 1.395×10^{15} MeV/(gU y).

3.5.4.5 Hydrogen generation by radiolysis of polyethylene

Almost all the radiation energy from HEU is due to alpha particles with energies of 4–5 MeV (Table 3.5.4.2). These particles are not very penetrating and will only deposit their energy into materials that are in intimate contact with the uranium atoms (i.e., the water of hydration in uranyl nitrate crystals and the water associated with the oxides). The polyethylene, nylon, or Teflon is in the form of bottles and

bags that surround the uranium and the only alpha particles that reach the polyethylene, nylon, or Teflon come from the outer range of alpha particle penetration within the HEU.

Equations 1.9 and 1.10 on p. 9 in *Handbook of Radioactivity Analysis* approximate the range of alpha particle penetration in air, and other materials for α energy in the range of 4 to 7 MeV. These are combined to give the following expression for calculating the range in HEU (metal, oxide, or crystals).

$$R = 9.6 \times 10^{-7} \times \alpha_{MA}^{3/2} \times (MW_A)^{1/2} / \rho,$$

where

R = the range of alpha particle penetration in the HEU, m;
α_{MA} = the average α energy emitted by the HEU, ~4.9 MeV (Table 3.5.4.2);
MW_A = the average molecular weight of the HEU, ~235.5 g/mol (Table 3.5.4.2); and
ρ = the density of the HEU, g/cm^3.

The range increases with decreasing ρ, and the smallest value for ρ is ~1.5 g/cm^3. {The smallest approximate bulk density of HEU oxide, *Cost-Effectiveness of Utilizing Surplus Depleted Uranium (DU)*, [WM-4009]}. The resulting range is 1.07×10^{-4} m.

The radius of a polyethylene bottle is 0.0627 m [4.94-in. diam (Table 2.10), configuration designated as CVA 6]. If the HEU oxide fills the bottle, the alpha particles generated in the outer range come from the HEU between 0.0627 and $(0.0627 - 1.07 \times 10^{-4}$ m). For an infinite cylinder, the fraction of the total radiation within this range is $[(0.0627)^2 - (0.0627 - 1.07 \times 10^{-4})^2] / (0.0627)^2 = 0.00339$. Half of this radiation would be directed toward the center of the cylinder, and much of the outward-directed portion would be absorbed passing through the HEU. Consequently, the radiation absorbed by the polyethylene would be much less than 1% of that absorbed by the water, and the H_2 generated in the polyethylene would be correspondingly less than that generated in the water.

3.5.4.6 Hydrogen generation by radiolysis of water

Assuming an infinite amount of water is available, the radiolytic hydrogen generation rate is given by the following expression (based on NUREG/CR-6673, p. 31, Eq. 4.7):

$$d(n_{H2}) / dt = (D_H / 100) \times [G(H_2) / A_N],$$

where

n_{H2} = the amount of hydrogen generated, mol;
t = time, y;
D_H = the decay energy absorbed by the water, eV/y; and
$G(H_2)$ = a radiolytic hydrogen generation factor for alpha radiation in water, molecules H_2/100 eV absorbed by water.

3.5.4.7 Radiolytic hydrogen generation factors for alpha radiation in water

A bounding value for $G(H_2)$ with alpha radiation is 1.6 molecules H_2/100 eV absorbed by water (NUREG/CR-6673, p. 12, Table 3.1). However, 2003 experimental data from Oak Ridge National Laboratory suggest lower $G(H_2)$ values [*Alpha Radiolysis of Sorbed Water on Uranium Oxides and Uranium Oxyfluorides* (ORNL/TM-2003/172) and *Water Sorption and Radiolysis Studies for Neptunium Oxides* (ORNL/TM-2003/194)]. Table 3.5.4.3 lists the $G(H_2)$ values derived from these experiments. The largest of the ORNL values (1.02) is used for the hydrogen generation calculations.

Table 3.5.4.3. $G(H_2)$ values derived from alpha radiolysis experiments

[a] G'(gas) for ORNL/TM-2003/172 is based on a measured slope in Fig. 3.3 or 3.5. For ORNL/TM-2003/194, the values are listed on Figs. 4.11–4.14.

The G'(gas) value is the initial slope of the gas yield (mmol/g material) versus the decay energy (MGy) converted to units of molecules of gas per 100 eV. G'(gas) for ORNL/TM-2003/172 is based on a measured slope in Fig. 3.3 or 3.5 while the values for ORNL/TM-2003/194 are listed on Figs. 4.11 through 4.14. Figure 3.5.4.1 is from ORNL/TM-2003/172 (p. 9, Fig. 3.5) with lines added to outline the initial slope and facilitate reading values. From Fig. 3.5.4.1, the gas yield difference along the slope is $0.023 - (-0.0005) = 0.0235$ millimol/g or $0.0235 \times A_N / 1000 = 1.42 \times 10^{19}$ molecules/g. The decay energy difference along the slope is 20.0 MGy or $20.0 \times 6.24 \times 10^{21} = 1.25 \times 10^{23}$ eV (6.24×10^{21} eV/g = 1 MGy). Therefore, G'(gas) is $1.42 \times 10^{19} / 1.25 \times 10^{23}) \times 100 = 0.0113$ molecules gas/100 eV. It is assumed the gas is due to the decomposition of H_2O and has a molar composition of 2/3 H_2 and 1/3 oxygen (O_2). The derived G'(H_2) is 2/3 of the G'(gas) value or 0.00756 molecules H_2/100 eV decay energy.

The radiation calculated in Table 3.5.4.2 is the decay energy rather than the energy absorbed by the water associated with the material. The energy absorbed by the associated water, D_H, is approximately equal to the decay energy, D_E, multiplied by the fraction of electrons associated with the water or

$$Gf = e^-(H_2O) / e^-(mat),$$

where

$$e^-(mat) = \sum_{i=1}^{I} e^-(mat_i);$$

Gf = the fraction of electrons associated with the water;
$e^-(H_2O)$ = the number of electrons associated with the water, electrons/molecule;
e^-(mat) = the total number of electrons associated with the molecular species; electrons/molecule;
$e^-(mat_i)$ = the contribution of the i^{th} molecular species to e^-(mat); and
I = the total number of molecular species.

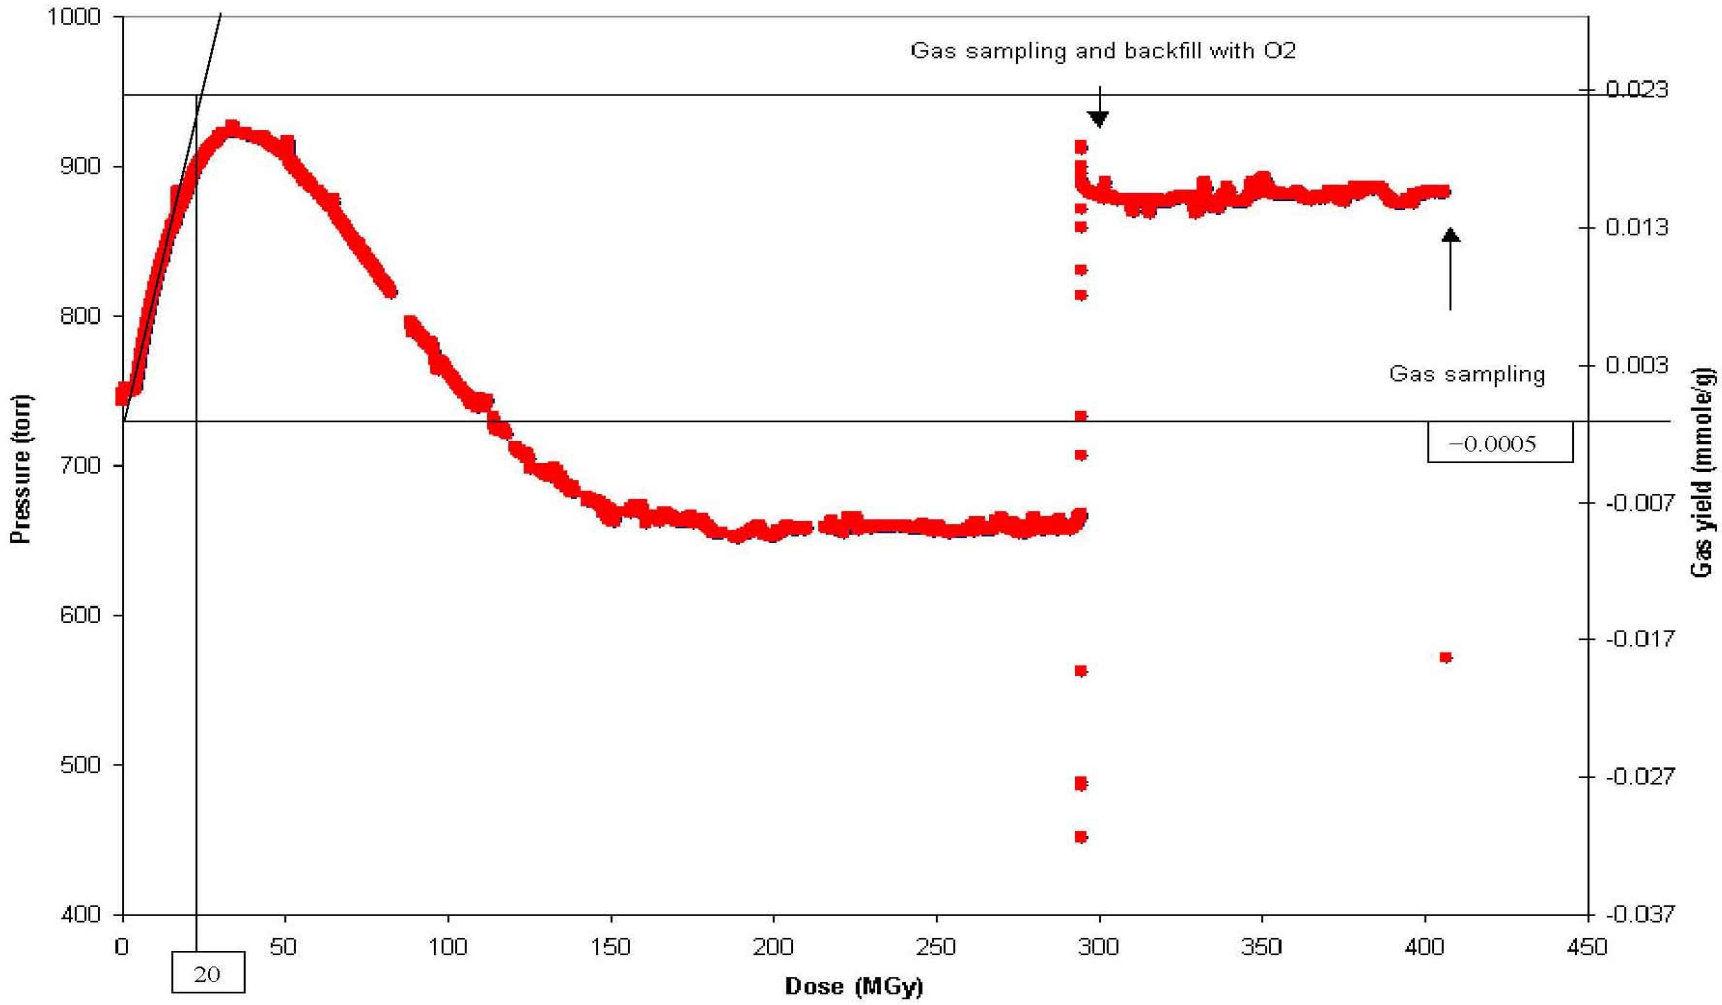

Fig. 3.5.4.1. Pressure and gas yield as a function of dose.

Note: Based on Fig. 3.5 in *Alpha Radiolysis of Sorbed Water on Uranium Oxides and Uranium Oxyfluorides* (ORNL/TM-2003/172), Sample A-4-1 (5.64 g U_3O_8 with 2 wt % H_2O, spiked with 0.0249 g ^{244}Cm).

The energy absorbed by the water is

$$D_H = Gf \times D_E,$$

and

$$G'(H_2) = Gf \times G(H_2) \rightarrow G(H_2) = G'(H_2) / Gf.$$

Two methods to calculate Gf are reported in *Calculation of Hydrogen Generation Rates for Storage of Post-KIS Oxide in 9975 Shipping Containers* (Calculation No. N-CLC-K-00219, p. 9 and 10). In the more rigorous of the two methods, Gf is estimated from the material stoichiometry and molecular weights. Using this more rigorous method, $e^-(mat_i)$ is calculated as

$$e^-(mat_i) = f_i \times \sum_{i=1}^{J} \frac{n_{i,j} \times Z_{i,j}}{MW_i},$$

where

f_i = the weight fraction of the i^{th} molecular species,
MW_i = the molecular weight of the i^{th} species,
$n_{i,j}$ = the number of moles of the j^{th} element in the i^{th} species,
J = the total number of elements in the i^{th} species, and
$Z_{i,j}$ = the atomic number of the j^{th} element in the i^{th} species.

According to the preceding equation, the expression for the number of electrons associated with the water is

$$e^-(H_2O) = f_{H2O} \times 10 / (16 + 2) = f_{H2O} \times 0.5556.$$

A mixture of water and U_3O_8 (assuming all the uranium is ^{235}U) is

$$e^-(mat) = f_{H2O} \times 0.5556 + f_{U3O8} \times (3 \times 92 + 8 \times 8) / (3 \times 235 + 8 \times 16) = f_{H2O} \times 0.5556 + f_{U3O8} \times 0.4082$$

where

f_{H2O} = the weight fraction of water and

f_{U3O8} = the weight fraction of U_3O_8
= $1 - f_{H2O}$ if no other material is present.

A $G'(H_2)$ value of 0.00756 molecules H_2/100 eV decay energy is derived from the experiment by Icenhour and Toth with a U_3O_8 sample (5.64 g) containing 2% water and spiked with 0.0249 g ^{244}Cm (ORNL/TM-2003/172, p. 7, Table 3.1). The mass of ^{244}Cm can be neglected, so the calculation of $G(H_2)$ for this sample is $e^-(H_2O) = 0.02 \times 0.5556 = 0.0111$; $e^-(mat) = 0.0111 + 0.98 \times 0.4082 = 0.4111$; $Gf = 0.0111 / 0.4111 = 0.0270$; and $G(H_2) = 0.00756 / 0.0270 = 0.280$ molecules H_2/100 eV absorbed by the water. Since the largest of the ORNL values (1.02) is used for the hydrogen generation calculations, the $G'(H_2)$ value for any other water content is the corresponding value of $Gf \times 1.02$.

To calculate Gf for $UO_2(NO_3)_2 \cdot XH_2O$, the two components are $UO_2(NO_3)_2$ and H_2O, where f_{H2O} is

$$f_{H2O} = X \times (2 + 16) / [235 + 2 \times 16 + 2 \times (14 + 3 \times 16) + X \times (2 + 16)],$$
$$= 1 / [1 + 391 / (X \times 18)],$$

$$e^-(mat) = f_{H2O} \times 0.5556 + f_{UN2O8} \times (92 + 8 \times 8 + 2 \times 7) / (391),$$
$$= f_{H2O} \times 0.5556 + f_{UN2O8} \times 0.4348,$$

f_{UN2O8} = the weight fraction of $UO_2(NO_3)_2 = 1 - f_{H2O}$.

The following example calculations are for U_3O_8 with 3% H_2O and $UO_2(NO_3)_2 \cdot XH_2O$ with X = 6 (f_{H2O} = 0.2164, Sect. 3.5.4.1). The $e^-(H_2O)$ and e^-(mat) values for the U_3O_8 are 0.0300 × 0.5556 = 0.0167 and 0.0167 + 0.9700 × 0.4082 = 0.4126, respectively. The resulting Gf and G'(H_2) values for the U_3O_8 are 0.0167 / 0.4126 = 0.0404 and 0.0404 × 1.02 = 0.0412, respectively. The corresponding values for $UO_2(NO_3)_2 \cdot 6H_2O$ are $e^-(H_2O)$ = 0.2164 × 0.5556 = 0.1202, e^-(mat) = 0.1202 + 0.7836 × 0.4348 = 0.4609, Gf = 0.1202 / 0.4609 = 0.2608, and G'(H_2) = 0.2608 × 1.02 = 0.2661.

The equation for the H_2 generation rate ($d(n_{H2})/dt$, mol H_2/y) is given in Sect. 3.5.4.6. The emitted radiation rate is 1.395×10^{21} eV/[GU Y] (1.395E+15 MeV/[gU y], Table 3.5.4.2). The uranium content of U_3O_8 with 3% H_2O is (1 − 0.0300) × 3 × 235 / (3 × 235 + 8 × 16) = 0.8209 gU/g and $UO_2(NO_3)_2 \cdot 6H_2O$ is 235 / (235 + 2 × 16 + 2 × [14 + 3 × 16] + 6 × (2 + 16) = 0.4709 gU/g. For 15,130 g of U_3O_8 with 3% H_2O, $d(n_{H2}) / dt = 15{,}130 \times 0.8209 \times 1.39 \times 10^{21} \times 0.0412 / (100 \times 6.022 \times 10^{23}) = 0.01185$ mol H_2/y. For 4750 g of $UO_2(NO_3)_2 \cdot 6H_2O$, $d(n_{H2}) / dt = 4750 \times 0.4709 \times 1.39 \times 10^{21} \times 0.2661 / (100 \times 6.022 \times 10^{23}) = 0.0137$ mol H_2/y.

3.5.4.8 Time to reach 5 mol %

The time at which the H_2 concentration in the void space of the package reaches 5 mol % depends on the H_2 generation rate and the initial amount of gas in the void space. This void space includes the internal void space within the convenience containers and the void space in the containment vessel outside the convenience containers. It is assumed that the convenience containers are open to the containment vessel and all the gases initially present, and subsequently generated, are mixed in this void space.

The initial amount of gas in the void space is given by

$$n_I = V_{VT} \times \rho_G,$$
$$V_{VT} = V_{BT} - Wt / \rho,$$

where

n_I = the initial amount of gas in the containment vessel void space, mol;
V_{VT} = the void volume of the loaded containment vessel, cm^3;
V_{BT} = the void volume of the containment vessel with empty convenience containers, 9417.0 cm^3 (574.66 $in.^3$) and 9,257.3 cm^3 (564.92 $in.^3$) for CVA 1 and CVA 7, respectively (Appendix 3.5.1, Table 1);
Wt = the total load weight (Wt_{UNX} or Wt_{OX}), g;
ρ = the density of the load material (ρ_{UNX} or ρ_{OX}).

Since each mole of H_2 generated is accompanied by 0.5 mol of O_2, the concentration of H_2 will reach 5 mol % when

$$(n_{H2GN} + n_{H2I}) / (1.5 \times n_{H2GN} + n_I) = 0.05 \text{ or } n_{H2GN} = 0.05405 \times n_I - 1.08108 \times n_{H2I},$$

where

n_{H2GN} = the amount of H_2 generated after the containment vessel is loaded, mol,
n_{H2I} = the initial amount of H_2 in the convenience containers when the containment vessel is loaded (= n_{H2B} or n_{H2C}), mol.

As an example, 15,130 g of U_3O_8 (ρ is 8.38 g/cm^3) in a CVA 1 configuration will result in a loaded void volume (V_{VT}) of 9417.0 − 15130 / 8.38 = 7611.5 cm^3. The initial amount of gas (n_I) is 7611.5 cm^3 × 4.087 × 10^{-5} mol/cm^3 = 0.31108 mol. The initial amount of H_2 in the convenience containers (n_{H2I}) is 4.5402E-05 mol (Sect. 3.5.4.2) so n_{H2GN} = 0.05405 × 0.31108 − 1.08108 × 4.54E-05 = 0.016765 mol.

3.5.4.9 Hydrogen buildup

The buildup of H_2 in the containment vessel can be expressed as

$$\frac{d(n_{H2GN})}{dt} = \frac{d(n_{H2})}{dt} - L_{MH2},$$

where

L_{MH2} = the permeation loss rate of H_2 through the main O-ring of the containment vessel, mol /y.

Parker O-Ring Handbook (Sect. 3.12.1, p. 3-21) gives the following expression for the permeation loss of H_2 through an O-ring:

L_{VH2} = $0.7 \times F \times D \times P \times Q \times (1 - S)^2$;
= the permeation loss rate of H_2 through the O-ring, std cm^3 H_2/s;

F = the permeability of hydrogen through the O-ring material (ethylene propylene, Table 3.10) at 38°C, 28.9E-08 std cm^3 H_2/(cm s bar) [*Parker O-Ring Handbook*, Table 3-24, p. 3-29];
D = the inside diameter of the O-ring, 5.359 in. (Drawing M2E801580A013, Appendix 1.3.7);
P = the pressure differential across the seal, psi;
S = the fraction of the O-ring cross-section reduced by squeezing the ring in the gland, 0.15 to 0.21 (Sect. 4.1.1), 0.21 conservatively selected;
Q = a factor depending on S (ring is lubricated, Table 3.10), 0.72 (*Parker O-Ring Handbook*, Fig. 3-11, p. 3-21);
L_{MH2} = L_{VH2} multiplied by (3600 s/h × 24 h/d × 365.25 d/y) and divided by 22,414 std cm^3/mol.

The pressure increase in the containment vessel is given by

P = $1.5 \times n_{H2GN} / n_I \times P_i$,
P_i = the initial pressure of the gas in the containment vessel, 14.7 psia.

If the initial pressure is equal to the ambient pressure (the usual situation), the pressure differential across the seal is equal to P.

If all of the above terms are combined, the expression for $d(n_{H2GN}) / dt$ becomes

$$\frac{d(n_{H2GN})}{dt} = \frac{d(n_{H2})}{dt} - \frac{k \times n_{H2GN}}{n_I},$$

$$\begin{aligned} k &= 0.7 \times F \times D \times 1.5 \times P_i \times Q \times (1 - S)^2 \times (3600 \times 24 \times 365.25) / 22414, \\ &= 0.01512 \text{ mol/y}. \end{aligned}$$

The solution to the above differential equation is

$$n_{H2GN} = [d(n_{H2}) / dt] \times n_I / k \times [1.0 - \exp(-k \times t / n_I)],$$

and the time when n_{H2GN} reaches $0.05405 \times n_I - 1.08108 \times n_{H2I}$ is

$$t = -\text{Ln}(1.0 - [0.05405 \times n_I - 1.08108 \times n_{H2I}] \times k / [d(n_{H2}) / dt \times n_I]) \times n_I / k.$$

As an example, the time for the 15,130 g of U_3O_8 is $-\text{Ln}(1.0 - 0.016765 \text{ mol} \times 0.01512 \text{ mol/y} / [0.01185 \text{ mol/y} \times 0.31108 \text{ mol}]) \times 0.31108 \text{ mol} / 0.01512 \text{ mol/y} = 1.465$ y.

As shown in Table 3.5.4.2, the bounding value of the decay energy (D_E) is 1.39×10^{15} MeV/(gU y). The energy per gram of material is the product of $D_E \times$ the fraction of uranium in the material. The fraction of uranium in UO_2 with $f_{H2O} = 0.03$ (3% water) is $(1 - 0.03) \times 235 / (235 + 2 \times 16) = 0.85375$ gU/g material. Similarly, the fractions in U_3O_8 and UO_3 are 0.82095 and 0.80548, respectively. The corresponding fraction in crystals is $235 / [235 + 2 \times 16 + 2 \times (14 + 3 \times 16) + X \times (2 + 16)] = 0.47094$ gU/g material for X = 6 $[UO_2(NO_3)_2 \cdot 6H_2O]$ and 0.52809 for X = 3 $[UO_2(NO_3)_2 \cdot 3H_2O]$. The decay energies are 1.19×10^{15} MeV/y g material for UO_2 with 3% H_2O, 1.15×10^{15} for U_3O_8, 1.12×10^{15} for UO_3, 6.57×10^{14} for $UO_2(NO_3)_2 \cdot 6H_2O$, and 7.37×10^{14} for $UO_2(NO_3)_2 \cdot 3H_2O$.

Table 3.5.4.4 summarizes the calculations for the time to reach 5 mol % H_2 in the void space of the containment vessel, as a function of the total weight of the material in the containers (Wt). The total amount of H_2 in the void space is the sum of the initial H_2 plus the added H_2 while the total gas in the void space is the sum of the initial gas plus 1.5 times the added H_2. The 1.5 factor accounts for the O_2 generated with the H_2. For 15.13 kg of U_3O_8 with 3% H_2O, the time to reach 5 mol % H_2 in the void space is 1.5 years or 18.2 months. At that time, the total amount of H_2 in the void space is 0.00005 + 0.01820 = 0.01825 mol while the total gas in the void space is 0.33777 + 1.5 × 0.01820 = 0.36507 mol.

Table 3.5.4.4. Summary of calculation results

4. CONTAINMENT

Design analysis, full-scale testing, and similarity of the ES-3100 prototypes have been used to demonstrate that the ES-3100 package with highly enriched uranium (HEU) is in compliance with the applicable containment requirements of Title 10 Code of Federal Regulations, Part 71 (10 CFR 71). The containment requirements of 10 CFR 71.51 are shown in Table 4.1. A bounding load case has been established for the ES-3100 package, and it assumes that the maximum HEU content is 35.2 kg (Sect. 1.2.2.6) with a decay heat load of 5 W (Sect. 3.1.2). This decay heat load and the volumes established for the convenience cans, polyethylene, nylon or Teflon bagging, spacers, silicone rubber pads, and the containment vessel void volume are discussed in Sect. 3.1.2 and Appendix 3.5.1. Chapters 2 and 3 of this safety analysis report for packaging (SARP) also examine the effects of the lightest weight HEU content [2.77 kg (6.11 lb)]. Section 3.4.3 also examines the conservative effects of shipping no contents inside the containment vessel but including the maximum decay heat load for the proposed contents. The evaluations in Chapters 2, 3, and 4 have demonstrated that the ES-3100 shipping package with HEU content weight ranging from 0 kg (0 lb) to 35.2 kg (77.60 lb) meets the containment requirements specified in 10 CFR 71 for all conditions of transport. As shown in Chap. 1, some Thorium (^{232}Th) compounds or oxides mixed with uranium are proposed for transport. Shipping of ^{232}Th is bounded by the containment analyses using uranium due to the following: (1) the A_2 of ^{232}Th is unlimited; (2) the decay energy of ^{232}Th is less than all other uranium isotopes; and (3) the half-life of ^{232}Th is significantly longer than the uranium isotopes. A summary of the containment boundary design and fabrication acceptance basis is given in Table 4.2. No credit is taken for the ability of the various convenience cans to protect the HEU contents from being released.

The analysis documented in Appendix 4.5.1 was conducted to establish the upper limit for the total activity and the maximum number of A_2s proposed for transport in the ES-3100 package. The maximum activity [7.2554×10^{-1} TBq (19.6092 Ci)] of the contents occurs 10 years after initial fabrication. When the maximum activity-to-A_2 value (4.7528×10^{3}) is reached at ~70 years from material fabrication, the corresponding activity is 7.2456×10^{-1} TBq (19.5827 Ci). These values have been determined using a maximum of 35.2 kg of HEU with isotopic weight percents as shown in Table 4.3. By applying the maximum weight percents of isotopes ^{233}U, ^{234}U, ^{236}U and by incorporating the traces of ^{232}U and the transuranic isotopes, the maximum activity, minimum A_2 value, and the minimum leakage requirements were determined for the proposed contents and are summarized in Tables 4.4, 4.5, 4.6, and 4.8. Containment vessel design verification tests for NCT and HAC are shown in Tables 4.7 and 4.9, respectively. Table 4.6 summarizes the results of evaluating the International Atomic Energy Agency (IAEA) requirements for air transportation of fissile uranium in accordance with 10 CFR 71.51(a)(1). The ANSI N14.5 leaktight criterion achieved by compliance testing is substantially below the results shown in Table 4.6 for air transport. Therefore, the IAEA SSR-6 requirements of no loss or dispersal of radioactive contents from the containment system is satisfied. The mass and isotopic concentrations used for the proposed content do not take into consideration limits based on shielding and subcriticality.

Table 4.1. Containment requirements of transport for Type B packages

Condition	Allowable release rate [a]
Normal Conditions of Transport (NCT)	$R_N = 10^{-6}$ A_2 per hour = 2.78×10^{-10} A_2 per second
Hypothetical Accident Conditions (HAC)	$R_A = A_2$ in 1 week = 1.65×10^{-6} A_2 per second For ^{85}Kr, a value of 10 A_2 in 1 week is used

[a] From ANSI N14.5-1997, Sects. 5.4.1 and 5.4.2, and 10 CFR 71.51(a)(1) and (a)(2).

Table 4.2. Summary of the containment vessel design and fabrication acceptance basis

Weight (empty, nominal)	15.10 kg (33.29 lb)
Temperature at loading (air fill, average)	25°C (77°F)
Pressure at loading (air fill, average)	101.35 kPa (14.70 psia)
Hydrostatic pressure test	1034 ± 34 kPa (150 ± 5) gauge
Leakage rate testing [a]	
Acceptance leakage rate test, air (or equivalent)	
Containment boundary [b]	$L_T \leq 1 \times 10^{-7}$ ref-cm^3/s
Fabrication verification of O-ring seal [c]	$L_T \leq 1 \times 10^{-4}$ ref-cm^3/s
Preshipment, air [d]	$L_T \leq L_R$ or no detected leakage when tested to a sensitivity of 1×10^{-3} ref-cm^3/s

[a] L_T is the maximum allowable test leakage rate for a set of testing conditions.
[b] Acceptance leakage testing of the containment boundary includes fabrication, periodic (within 12 months of use), and maintenance testing. According to Subclause 2.1 of ANSI N14.5-1997, *leaktight* is defined as an air leakage rate of 1×10^{-7} ref-cm^3/s; under the same conditions, this air leakage rate is ~ equal to a helium leakage rate of 2×10^{-7} cm^3/s.
[c] Performed at initial fabrication on the fully assembled containment vessel with both O-rings installed to demonstrate the functionality of the leak-test port and sealing capability of the outer O-ring (Appendix 1.3.3).
[d] L_R as defined in ANSI N14.5-1997, Subclause 6.2, is the more restrictive reference air leakage rate based on the allowable leakage rate for both NCT and HAC.

Table 4.3. Isotopic mass and weight percent for the HEU contents

Nuclide	Weight percent [a]	Mass (g)
U-232	0.000004	0.001408
U-233	0.600000	211.200000
U-234	2.000000	704.000000
U-235	54.819996	19,296.638592
U-236	40.000000	14,080.000000
U-238	0.000000	0.000000
Transuranic	0.080000 [b]	28.160000
Np-237	2.500000	880.000000
Total	**100.000000**	**35,200.000000**

[a] Weight percent values of individual isotopes are those that generate the largest activity within the allowable ranges presented in Sect. 1.2.2.
[b] The transuranic weight percent of 0.080000 applies to ground transport only. The maximum transuranic weight percent in contents transported by air will be 0.004000.

Table 4.4. Activity, A_2 value, and number of A_2 proposed for transport

Year	Fast absorption			Medium absorption			Slow absorption		
	Activity (TBq)	A_2 (TBq)	Act / A_2	Activity (TBq)	A_2 (TBq)	Act / A_2	Activity (TBq)	A_2 (TBq)	Act / A_2

70	7.246E-01	1.5385E-04	4.710E+03	7.2456E-01	1.5349E-04	4.7206E+03	7.246E-01	1.5245E-04	4.7528E+03

Table 4.5. Regulatory leakage criteria for NCT

Verification activity	Fast absorption		Medium absorption		Slow absorption	
	$L_{RN\text{ - air}}$ (ref-cm^3/s)	$L_{RN\text{ - He}}$ (cm^3/s)	$L_{RN\text{ - air}}$ (ref-cm^3/s)	$L_{RN\text{ - He}}$ (cm^3/s)	$L_{RN\text{ - air}}$ (ref-cm^3/s)	$L_{RN\text{ - He}}$ (cm^3/s)
Design [a]	1.4151E-04	1.7416E-04	1.4119E-04	1.7378E-04	1.4025E-04	1.7269E-04

[a] The procedure used to calculate the above criteria is shown in Appendix 4.5.2. This data has been extracted from Table 1 in Appendix 4.5.2.

Table 4.6. 10 CFR 71.51(a)(1) leakage criteria for air transport in accordance with IAEA environmental conditions

Temperature	Slow absorption [a, b, c]	
	$L_{RN\text{ - air}}$ (ref-cm^3/s)	$L_{RN\text{ - He}}$ (cm^3/s)
Lower limit (-40°C)	1.7184E-04	2.0938E-04
Upper limit (64.44°C)	2.1611E-04	2.6031E-04

[a] The procedure used to calculate the above criteria is shown in Appendix 4.5.2.
[b] Slow absorption criteria has been shown to produce the lowest leakage criteria.
[c] The IAEA SSR-6 requirement is no loss or dispersal of radioactive contents from the containment system. This condition is satisfied based on the leaktight criterion achieved by compliance test units.

Table 4.7. Containment vessel verification tests criteria for NCT

Test type	Test values	Leakage test procedure
Design and compliance leakage testing		
Design verification of O-ring seal (air)	$L_T \leq 1.0 \times 10^{-4}$ ref-cm^3/s	See ORNL/NTRC-013
Design verification of containment vessel boundary (helium)	$L_T \leq 2.0 \times 10^{-7}$ cm^3/s	See ORNL/NTRC-013
Verification leakage testing		
Fabrication, periodic, and maintenance (helium)	$L_T \leq 2.0 \times 10^{-7}$ cm^3/s	Y51-01-B2-R-140 (Appendix 8.3.1) or equivalent
Fabrication verification of O-ring seal (air)	$L_T \leq 1.0 \times 10^{-4}$ ref-cm^3/s	Tested at initial fabrication in accordance with the supplier's approved procedure as required by Appendix 1.3.3
Preshipment (air)	$L_T \leq L_R$ or no detected leakage when tested to a sensitivity of 1×10^{-3} ref-cm^3/s	Y51-01-B2-R-074 (Appendix 7.5.2) or equivalent

The initial composition of the content contains several isotopes of uranium (Sect. 1.2.2). As a result of radioactive decay, the ingrowth of uranium daughter products occurs, and these concentrations of daughter products will vary with time. The uranium isotopes and daughter products are considered a mixture of radionuclides, and the method for determining the mixture's A_2 value in Section IV, Appendix A, 10 CFR 71 is applied. The A_2 value for the most conservative set of contents defined in Sect. 1.2.2 has been calculated in Appendix 4.5.1. Since the HEU can be in the form of oxides (U_3O_8-Al, UO_2-Mg, UO_2-ZrO_2, UO_2, UO_3, U_3O_8, UO_2-Th, or UO_2-ThO_2), uranyl nitrate crystals (UNX), metal or alloy, research reactor fuel elements and components, or compounds, the calculation of the mixture's A_2 used the various uranium isotopic A_2 values for fast, medium, and slow lung absorption criteria shown in Table A-1 of Appendix A of 10 CFR 71. As previously stated, ^{232}Th is bounded by the use of uranium isotopes and is subsequently neglected in further analyses.

The mass and material compositions analyzed in this section of the SARP are not limited by the combustible gas requirements stated in NUREG-1609, Sect. 4.5.2.3, which requires the applicant to demonstrate that any combustible gases generated in the package during a period of one year do not exceed 5% (by volume) of the free gas volume in any confined region of the package. No credit should be taken for getters, catalysts, or other recombination devices. The analysis conducted in Appendix 3.5.4 evaluates the different packaging arrangements for the generation of hydrogen gas due to the radiolysis of water vapor, free water, interstitial water, polyurethane bags, and polyurethane or Teflon bottles. By limiting the mass and the material distribution as shown in Appendix 3.5.4, the combustible gas concentration limit stated in NUREG-1609 is not exceeded. These limits are further shown in Tables 1.3 and 1.3a. Getters, catalysts, or other recombination devices are not employed in any of the containment vessel packaging arrangements. The analysis conducted in Appendix 3.5.1 predicts the maximum normal operating pressure (MNOP) inside the containment vessel for the various packaging arrangements and masses discussed previously. This appendix also includes the hydrogen gas generation predicted by Appendix 3.5.4.

4.1 DESCRIPTION OF THE CONTAINMENT SYSTEM

As shown in Table 4.4, the number of A_2s proposed for shipping exceeds 3000. In accordance with NUREG-1609, the containment vessel is a Category I vessel. Therefore, the containment vessel is designed (using nominal dimensions for each component), fabricated, and inspected in accordance with the American Society of Mechanical Engineers (ASME) *Boiler and Pressure Vessel Code*, Sect. III, Div. 1, Subsection NB and Sect. IX.

4.1.1 Containment Boundary

The containment boundary consists of the vessel's body, lid assembly, and inner O-ring (Sect. 1.2.1.5, Fig. 1.3). Only the inner O-ring is considered part of the boundary. The outer O-ring is provided to allow a post-assembly verification leak check. Two methods of fabrication may be used to fabricate the containment vessel body as shown on Drawing M2E801580A012 (Appendix 1.3.7). The first method uses a standard 5-in., schedule 40 stainless-steel pipe per ASME SA-312 Type TP304L, a machined flat-head bottom forging per ASME SA-182 Type F304L, and a machined top flange forging per ASME SA-182 Type F304L. The nominal outside diameter of the 5-in. schedule 40 pipe is machined to match the nominal wall thickness of 0.254 cm (0.100 in.). Each of these pieces is joined with full-penetration circumferential weld as shown on sheet 2 of Drawing M2E801580A012 (Appendix 1.3.7). The weld filler material conforms to Sect. II, Part C, of the *ASME Boiler and Pressure Vessel Code*. All full-penetration welds are dye penetrant and radiographically inspected in accordance with Sect. III, Div. 1, Subsection NB-5000, of the *ASME Boiler and Pressure Vessel Code*. The top flange is machined to match the schedule 40 stainless-steel 5-in. pipe, to provide two concentric half-dovetailed O-ring grooves in the flat face, to provide locations for two 18-8 stainless-steel dowel pins, and to provide the threaded portion for closure using the lid assembly. The second method of fabrication uses flow forming to create the complete body (flat bottom, cylindrical body, and flange) from a single forged billet or bar with final material properties in accordance with ASME SA-182 Type F304L. Final machining of the top flange area is identical to that of the welded forging method. The lid assembly, which completes the containment boundary structure, consists of a sealing lid, closure nut, and external retaining ring (Drawing M2E801580A014, Appendix 1.3.7). The containment vessel sealing lid (Drawing M2E801580A015, Appendix 1.3.7) is machined from Type 304 stainless-steel bar with final material properties in accordance with ASME SA-479. The containment vessel closure nut is machined from a Nitronic 60 stainless-steel bar with material properties in accordance with ASME SA-479. These two components are held together using an external retaining ring made from Type 302 stainless steel. A weld is used to seal around a plug that is inserted inside the hole used for machining the pathway for leak testing between the O-rings. Since this plug and weld are outside the containment boundary, the weld is not important to safety. However, it is important to operation because its sealing capability is needed to properly conduct the preshipment leak test. This weld is addressed in Paragraph 3.4 of the containment vessel equipment specification (JS-YMN3-801580-A001, Appendix 1.3.3). In this specification, the weld is inspected visually and using dye penetrant. The requirements of NB-5110 and NB-5350 of the *ASME Boiler and Pressure Vessel Code* also apply. The sealing lid is further machined to accept a ⅜-in.-16 swivel hoist ring bolt, to provide a leak-check port between the elastomeric O-rings, and notched along the perimeter to engage two dowel pins. The lid assembly, with the O-rings in place on the body, are joined together by torquing the closure nut and sealing lid assembly to 162.7 ± 6.78 N·m (120 ± 5 ft-lb). The sealing lid portion of the assembly is restrained from rotating during this torquing operation by the two dowel pins installed in the body flange. This torquing of the closure nut represents the positive fastening device used to satisfy the requirements of 10 CFR 71.43(c). The effectiveness of this closure system has been demonstrated by the NCT and HAC tests, which show that the complete containment system, including welds and O-ring seals, meet the leaktight criterion as defined in ANSI N14.5-1997 after the conclusion of the test series documented in ORNL/NTRC-013.

10 CFR 71.73(c) requires that the package containment vessel be immersed in 15 m (50 ft) of water, which is equivalent to an external pressure differential of 150 kPa (21.7 psi). The design analyses (DAC-M900000-0002) show that this vessel is conservatively rated for the 150 kPa (21.7 psi) external pressure differential requirement, as well as for an internal pressure differential of 1378.95 kPa (200 psig). A summary of the containment boundary design and acceptance basis is given in Table 4.2.

The ES-3100 package has no connections, fittings, valves, tapped holes, or other devices that penetrate the containment boundary; therefore, the package does not allow continuous venting during transport. The leak test port on the containment vessel lid accesses the annulus between the two O-rings. Since the outer O-ring is not considered to be part of the containment boundary, this leak test port does not penetrate the containment boundary. Therefore, the requirements of 10 CFR 71.43(e) and (h) are not applicable.

The containment vessel O-rings (Drawing M2E801580A013, Appendix 1.3.7) are manufactured from ethylene propylene diene monomer (EPDM) in accordance with Equipment Specification SPC M801580-0002 (Appendix 1.3.9).

The EPDM O-rings are rated for continuous service as a static face seal in the temperature range of −40 to 150°C (−40 to 302°F) [*Parker O-Ring Handbook*, Fig. 2-24]. Tests conducted by Los Alamos National Laboratory (LANL) on a similar compound used as a static face seal, are documented in *SAFKEG 2863B Tests for Verification of O-ring Performance* (TR 96/12/20). The material compound for the LANL tests was certified to ASTM D 2000 as M3BA610A14B13F17. The ES-3100 package O-rings are also certified to ASTM D 2000 as M3BA712A14B13F17. The class of material in the LANL test is identical except that the durometer and tensile strengths are somewhat less than those of the ES-3100 package. Each material was tested in accordance with ASTM D 2137 for brittleness at −40°C (−40°F) without failure. The leak test fixture, as reported in TR 96/12/20, provided a maximum compression of 25.7% in a static face seal configuration. The compression range provided by the flange and lid design of the ES-3100 package is 14.8 to 20.8% or 0.051 to 0.076 cm (0.020 to 0.030 in.) compression due to the half-dovetail design. Furthermore, *Parker O-Ring Handbook* states that the minimum squeeze for all seals, regardless of cross-section, should be ~0.018 cm (0.007 in.). Since the minimum compression is 0.051 cm (0.020 in.) and the flange and lid with the closure nut have nearly identical coefficient of thermal expansion, the sealing performance at −40°C (−40°F) should not be degraded. Therefore, the performance of the ES-3100 O-rings should be representative of those documented in TR 96/12/20. These tests demonstrated that the O-rings were leaktight over the temperature range of −40 to 205°C (−40 to 401°F), which is greater than the operating temperature range of −40 to 186.79°C (−40 to 368.23°F) of the ES-3100 containment vessel (Table 3.5). In addition to component testing, an ES-3100 full-scale test unit [Test Unit (TU)-2] was chilled to ≤ −40°C and later subjected to an NCT drop test and the entire HAC test battery. The containment vessel was leak tested and achieved “leaktight” status. Therefore, the continuous service temperature rating of the EPDM O-ring has been verified by testing.

4.1.2 Special Requirements for Plutonium

The HEU contents have only trace amounts of the transuranic isotopes. Therefore, the requirements in 10 CFR 71.63 and 71.74 are not applicable.

4.2 CONTAINMENT UNDER NORMAL CONDITIONS OF TRANSPORT

Title 10 CFR 71.51(a)(1) specifies that there shall be no loss or dispersal of radioactive contents as demonstrated to a sensitivity of 10^{-6} A_2 per hour, no significant increase in external radiation levels, and no substantial reduction in the effectiveness of the packaging. The initial composition of the HEU contains several isotopes of uranium and transuranic contributors (Table 4.3). As a result of radioactive

decay, uranium, transuranics, and daughter product isotopes are present in the HEU contents at varying concentrations depending on the length of decay time. The HEU, with its isotopes and daughter isotopes and contributions from unknown transuranic isotopes, qualifies as a mixture for A_2 determination (Appendix A of 10 CFR 71). The A_2 value and the maximum content activity-to-A_2 value ratio for this mixture have been calculated for several different decay times (Table 4.4). As calculated in Appendix 4.5.1, the A_2 value [1.5245×10^{-4} TBq (4.1203×10^{-3} Ci)] and the maximum content activity-to-A_2 ratio (4.7528×10^{3}) used to qualify this package occurs at ~70 years of decay. As previously stated, these values have been determined using a bounding case maximum of 35.2 kg of HEU with isotopic weight percent values as shown in Table 4.3. The specified composition is a very conservative upper bound achieved by using the maximum weight percent values for the higher specific activity isotopes (^{232}U, ^{233}U, ^{234}U, and ^{236}U), including contributions from other transuranics and ^{237}Np.

The maximum activity, minimum A_2, and minimum leakage requirements were determined for this worst case scenario and are presented in Tables 4.4 and 4.5. These masses and isotopic concentrations were used for the proposed contents without regard to limits established based on shielding and subcriticality considerations. The actual mass limits affirmed for this shipping package are established in Chap. 1 (Tables 1.3, 1.3a, and 1.3b). The analyses conducted in Appendix 4.5.2 assume that the total mass of uranium for each component is available for release as an aerosol (worst case). From experimental tests, the maximum aerosol density containing uranium particulate was reported in "Leakage of Radioactive Powders from Containers" (Curren and Bond) to be 9.0×10^{-6} g/cm^3. This aerosol density is used to calculate the total activity concentration in ANSI N14.5-1997, Sect. B.15, Examples 13, 27, and 29.

The containment criteria for the ES-3100 package will be leaktight (defined in paragraph 2.1 of ANSI N14.5-1997 as having a leakage rate $\leq 1 \times 10^{-7}$ ref-cm^3/s) during the prototype tests. This leaktight criterion satisfies the design verification requirement stipulated in paragraph 7.2.4 of ANSI N14.5-1997. The requirements of ANSI N14.5-1997 are used for the design and fabrication containment verification of the ES-3100 leakage rate testing.

The design, fabrication, maintenance, and periodic leakage rate limit is 1×10^{-7} ref-cm^3/s air (or equivalent). Preshipment leakage rate testing, which demonstrates correct assembly of the containment vessel, shall be performed to the acceptance criterion of either (1) a leakage rate of not more than the reference air leakage rate, L_R, or (2) no detected leakage when tested to a sensitivity of at least 10^{-3} ref-cm^3/s (ANSI N14.5-1997, Subclause 7.6.4). The preshipment, fabrication, and maintenance leakage rate tests are required to be conducted on each containment vessel in accordance with ANSI N14.5-1997 and are specified in Chapters 7 and 8. In addition to these leakage tests, Subclause 7.5.2 of ANSI N14.5-1997 states that the periodic leakage rate testing shall be conducted within 12 months prior to each shipment. Testing of the ES-3100 and EPDM O-rings, documented in RP 801580-0022, *ES-3100 Containment Vessel (CV) O-rings Life Extension Testing*, provides the justification to extend the periodic leakage rate testing frequency to 24 months. Therefore, the periodic leakage rate testing specified in Chapter 8 shall be conducted in accordance with ANSI N14.5-1997 except for the frequency. These leakage rates are not dependent on filters or mechanical cooling.

The complete design verification testing of the ES-3100 package for NCT was conducted on test unit TU-4. Since the containment vessel was assembled at ambient conditions, the pressure was nominally 101.35 kPa (14.70 psia) at 25°C (77°F). In accordance with 10 CFR 71.71(b), the initial pressure inside each containment vessel should be the maximum normal operating pressure (MNOP). As calculated in Appendix 3.5.1 and rounded up, the bounding case MNOP is 108.94 kPa (15.8 psig). The stresses at the MNOP are insignificant compared to the allowable stresses (Tables 2.21 and 2.21a). O-ring grooves are designed and fabricated in accordance with guidance from the *Parker O-Ring Handbook*. In accordance with Fig. 3-2 of the *Parker O-Ring Handbook*, the durometer of the O-ring, and the tolerance gap from the production drawings, the O-ring should be able to withstand ~800 psig

before anti-extrusion devices are required. Therefore, conducting a compliance test with the MNOP in the containment vessel will have little, if any, effect on the results.

Following the design verification testing of paragraphs 10 CFR 71.71(c)(5) through 71.71(c)(10) excluding 71.71(c)(8), TU-4 was subjected to the sequential testing of paragraphs 10 CFR 71.73(c)(1) through (c)(4). Upon removal of the containment vessel from the drum assembly, the cavity between the O-rings was leak checked. This unit recorded a leak rate between the O-rings of 2.4773×10^{-5} ref-cm^3/s (ORNL/NTRC-013).

Following the O-ring leak test, the entire containment boundary of TU-4 was helium leak tested to a value $\leq 2 \times 10^{-7}$ cm^3/s, thereby verifying a leak-tight boundary. The leak-test procedure followed to verify this criterion is documented in the ES-3100 test report (ORNL/NTRC-013). The maximum recorded helium leakage rate for this containment vessel was 2.0×10^{-7} cm^3/s after 20 min of testing. Visual inspection following the testing indicated that neither the vessel body, the O-rings, the seal areas, nor the vessel lid assembly were damaged during the tests. Pictures taken of the containment vessel top following testing showed that the closure nut had rotated a maximum of 0.15 cm (0.060 in.) from its original radial position obtained during assembly. Based on the pitch of the closure nut, this rotation translates into only 0.0013 cm (0.0005 in.) decompression of the O-rings. This compares to the original nominal compression of 0.064 cm (0.025 in.). Therefore, O-ring compression was maintained during compliance testing. Based on these results, the ES-3100 package meets and exceeds the containment criteria specified in 10 CFR 71.51 for NCT when used to ship the contents described in Sect. 1.2.2.

Following fabrication, the containment vessel undergoes hydrostatic pressure testing to 1034 kPa (150 psi) gauge. The hydrostatic test is conducted before the final leakage test. Following the hydrostatic pressure test, and prior to conducting the leakage test, the containment vessel and O-ring cavity must be thoroughly dried. Each vessel is then leak tested with helium to 2×10^{-7} cm^3/s. In accordance with *ASME Boiler and Pressure Vessel Code*, Sect. V, Subsection A, Article 10, Appendix IX, "Helium Mass Spectrometer Test—Hood Technique," a system response time must be established to determine the helium leak testing duration. The fabricators of this package used the *ASME Boiler and Pressure Vessel Code* approach and determined that the system response time for their setup of this containment vessel was ~15 s. To ensure that the leak detector steady-state (equilibrium) response is reached, the helium leak test duration was established at 2 min (8 × system response time). This test ensures the containment vessel's integrity (walls, welds, inner O-ring seal) as delivered for use in accordance with paragraph 6.3.2 of ANSI N14.5-1997.

Following placement of the HEU content inside the containment vessel and joining the body and lid assembly, the volume between the containment vessel's O-ring seals is typically evacuated and leak checked using the pressure rise air leak test prescribed in Sect. 7.1.2.1. The acceptance criterion for preshipment leakage rate testing shall be either (1) a leakage rate of not more than the reference air leakage rate, L_R, or (2) no detected leakage rate when tested to a sensitivity of at least 10^{-3} ref-cm^3/s. This ensures that each containment vessel has been properly assembled in accordance with paragraph 7.6.4 of ANSI N14.5-1997.

The design verification tests were conducted following compliance tests in accordance with 10 CFR 71.71 and 71.73. The effectiveness of this closure system has been demonstrated by the NCT and HAC tests, which show that the complete containment system, including welds and O-ring seals, meet the leaktight criterion as defined in ANSI N14.5-1997 after the conclusion of the test series documented in ORNL/NTRC-013.

4.3 CONTAINMENT UNDER HYPOTHETICAL ACCIDENT CONDITIONS

Requirements. A Type B package, in addition to satisfying the requirements of paragraphs 10 CFR 71.41 through 71.47, must be designed, constructed, and prepared for shipment so under the tests specified in Sect. 71.73 ("Hypothetical Accident Conditions"), there would be no escape of ^{85}Kr exceeding 10 A_2 in one week, no escape of other radioactive material exceeding a total amount A_2 in one week, and no external radiation dose rate exceeding 10 mSv/h (1 rem/h) at 1 m (40 in.) from the external surface of the package.

Analysis. Calculations have been conducted in Appendix 4.5.2 to determine the regulatory leakage criteria to satisfy the above requirements. The results are shown in Table 4.8. These analyses assume that the total mass of uranium for each component is available for release as an aerosol (worst case). From experimental tests, the maximum aerosol density containing uranium particulate was reported by Curren and Bond to be 9.0×10^{-6} g/cm^3. This aerosol density is used to calculate the total activity concentration in ANSI N14.5-1997, Sect. B.15, Examples 13, 27, and 29. Design leakage rate verification testing of the containment boundary (Table 4.9) was conducted on TU-1 through TU-6 and documented in the test report (ORNL/NTRC-013). Since each containment vessel was assembled at ambient conditions, the pressure was nominally 101.35 kPa (14.70 psi) at 25°C (77°F). In accordance with 10 CFR 71.73(b), for these tests, the initial pressure inside each containment vessel should be the maximum normal operating pressure. As shown in Tables 2.21 and 2.21a, the stresses at the maximum normal operating pressure are insignificant compared to the allowable stresses. Therefore, conducting compliance testing with nominal pressure in the containment vessel would have little, if any, effect on the results. During the structural and thermal tests conducted on the ES-3100 for HAC, the drum experienced plastic deformation, and the insulation and impact limiter material experienced some deterioration, as anticipated (Sect. 2.7). The containment vessels did not exhibit any signs of damage and passed post-test leak tests and the subsequent 10 CFR 71.73(c)(5)–specified 0.9-m (3-ft) water immersion tests except for TU-6. TU-6 was subjected to the test specified in 10 CFR 71.73(c)(6). After completion of this test, the containment vessel was removed and the lid was drilled and tapped for a helium leak-check port. The entire containment boundary was then helium leak checked and passed the leaktight criteria. Also, no visible water was seen inside the inner O-ring groove of TU-6 and no water was observed inside any of the other test units.

To verify the entire containment boundary to the leaktight criteria, the containment vessels of TU-1 through TU-5 were helium leak tested using the procedure shown in the test report (ORNL/NTRC-013). These test units had previously been subjected to the drop test stipulated in 10 CFR 71.71 (c)(6) and the sequential tests stipulated in 10 CFR 71.73 except for TU-4, which had been first subjected to the testing in accordance with 10 CFR 71.71. The maximum recorded helium leak rate for any of these containment vessels was 2.0×10^{-7} cm^3/s after 21 min of testing on TU-4 as documented in Sect. 5.2.2 of ORNL/NTRC-013. TU-2 and TU-5 displayed some unusual pulsing action during leak testing. The root cause of these oscillatory leak rates has not been determined. However, it is postulated that the seal around the machined port in the lid that is used for helium leak checking the test units was the cause of this unusual pattern. In accordance with the *ASME Boiler and Pressure Vessel Code*, Sect. V, Subsection A, Article 10, Appendix IX, "Helium Mass Spectrometer Test – Hood Technique," a system response time must be established to determine the helium leak testing duration. The fabricators of this package used this *ASME Boiler and Pressure Vessel Code* approach and determined that the system response time for their leak test setup with this containment vessel was ~15 s. To ensure that the leak detector steady-state (equilibrium) response is reached, the helium leak test duration was established at 2 min (8 × system response time). Since the helium leakage rates observed at NTRC (ORNL/NTRC-013), using a configuration similar to the fabricator's test arrangement, remained below the ANSI N14.5-1997 leak tight value for ~10 min, it was determined that the test duration was adequate and the units were leaktight. The peak amplitude changed after adding helium in a manner expected

for diffusion through the O-rings rather than a rise immediately following the addition of helium that would indicate a leak to the outside of the containment vessel. This is further discussed and graphically presented in Sect. 5.2.2 of ORNL/NTRC-013. These measured leakage rates verify that the containment vessels are leaktight in accordance with ANSI N14.5-1997. Therefore, the containment boundary of the ES-3100 package was maintained during the HAC testing.

The 35.2 kg of HEU content is unirradiated; therefore, only very small quantities of fission gas products will be produced from spontaneous fission and subcritical neutron induced fission. Fission gas products are produced in such small quantities that they have no measurable effect on the releasable content source term or containment vessel pressurization. Fission gas products will not be considered further in this SARP.

Table 4.8. Regulatory leakage criteria for HAC

Verification activity	Fast absorption		Medium absorption		Slow absorption	
	$L_{RA\text{ - air}}$ (ref-cm^3/s)	$L_{RA\text{ - He}}$ (cm^3/s)	$L_{RA\text{ - air}}$ (ref-cm^3/s)	$L_{RA\text{ - He}}$ (cm^3/s)	$L_{RA\text{ - air}}$ (ref-cm^3/s)	$L_{RA\text{ - He}}$ (cm^3/s)

[a] The procedure used to calculate the above criteria is shown in Appendix 4.5.2. This data has been extracted from Table 1 in Appendix 4.5.2.

Table 4.9. Containment vessel design verification tests for HAC

Test type	Test values	Leakage test procedure
Design and compliance leakage testing		
Design verification of O-ring seal (air)	$L_T \leq 1.0 \times 10^{-4}$ ref-cm^3/s	See ORNL/NTRC-013
Design verification of CV boundary (helium)	$L_T \leq 2.0 \times 10^{-7}$ cm^3/s	See ORNL/NTRC-013

4.4 LEAKAGE RATE TESTS FOR TYPE B PACKAGES

The maximum allowable release of radioactive material allowed by 10 CFR 71.51(a)(2) under HAC is A_2 in one week. Title 10 CFR 71.51(a)(2) also specifies that there be no escape of ^{85}Kr exceeding 10 A_2 in one week. ANSI N14.5-1997 specifies the leakage test methods and leakage rates that are accepted in NRC Regulatory Guide 7.4 as demonstrating that a package meets the 10 CFR 71.51(a)(2) requirements for containment. The containment criteria for the ES-3100 package will be leaktight, defined in ANSI N14.5 paragraph 2.1 as having a leakage rate $\leq 1 \times 10^{-7}$ ref-cm^3/s, during the prototype tests. This leaktight criterion satisfies the design verification requirement stipulated in paragraph 7.2.4 of ANSI N14.5-1997. With the exception of the periodic leakage rate testing frequency discussed below, the requirements of ANSI N14.5-1997 are used for all stages of containment demonstration for the ES-3100 leakage rate testing (i.e., design, fabrication, maintenance, periodic and preshipment). The design, fabrication, maintenance, and periodic leakage rate limit is 1×10^{-7} ref-cm^3/s air (or equivalent). Preshipment leakage rate testing, which demonstrates correct assembly of the containment vessel, shall be performed to the acceptance criterion of either (1) a leakage rate of not more than the reference air leakage rate, L_R, or (2) no detected leakage when tested to a sensitivity of at least 10^{-3} ref-cm^3/s (ANSI N14.5-1997, Subclause 7.6.4). The preshipment, fabrication, and maintenance leakage rate tests are required to be conducted on each containment vessel in accordance with ANSI N14.5-1997 and are specified in Chapters 7 and 8. In addition to these leakage tests, Subclause 7.5.2 of ANSI N14.5-1997 states that the periodic leakage rate testing shall be conducted within 12 months prior to each shipment. Testing of the ES-3100 and EPDM O-rings, documented in RP 801580-0022, provides the justification to extend the periodic leakage rate testing frequency to 24 months. Therefore, the periodic leakage rate testing specified in Chapter 8 shall be conducted in accordance with ANSI N14.5-1997 except for the frequency. These leakage rates are not dependent on filters or mechanical cooling.

The requirements of ANSI N14.5-1997 are used for all stages of containment verification for the ES-3100; the design (HAC test) leakage rate limit is 1×10^{-7} ref-cm^3/s (which is defined as leaktight in ANSI N14.5-1997). The packaging has been shown to maintain containment before and after prototype testing by leakage tests performed for containment verification to the requirements of ANSI N14.5-1997. TU-4's containment vessel was subjected to both the NCT and HAC tests. TU-1 through TU-5 were subjected to the free drop stipulated in 10 CFR 71.71(c)(7) and to the sequential HAC test stipulated in 10 CFR 71.73. Following these tests, each containment vessel was helium leak tested in accordance with the test plan. Again, the test results verified that the containment vessels were leaktight. Thus, there could be no release of radioactive materials from the containment vessels. These leakage rates are not dependent on filters or mechanical cooling. These measured leakage rates verify that the containment vessels are leaktight in accordance with ANSI N14.5-1997.

Therefore, the ES-3100 package meets the containment criteria as specified in 10 CFR 71.73 for HAC when shipping the proposed 35.2 kg of HEU in the containment vessel.

Appendix 4.5.1
Determination of A_2 for the ES-3100 Package with HEU Contents

Introduction

The containment criteria for radioactive, fissile material packages are given in 10 CFR 71.51(a)(1) for Normal Conditions of Transport (NCT) [$\leq 10^{-6}$ A_2/h] and in 71.51(a)(2) for Hypothetical Accident Conditions (HAC) [$\leq A_2$ in a week]. The A_2 value for this mixture of radioisotopes must be determined to establish the content containment criteria and to determine the maximum release quantity that is allowed by the regulations. These values for a mixture of isotopes are determined by the methodology given in 10 CFR 71, Appendix A, "Determination of A_1 and A_2," Sect. IV. The results of these analyses are used to demonstrate compliance of the ES-3100 package with the containment requirements of 10 CFR 71.

Scope

The A_2 value of the highly enriched uranium (HEU) content to be shipped is evaluated based on the mass and weight percents of HEU shown in Table 1 and defined in Sect. 1.2.2. The weight percents shown in Table 1 are the ones that generate the largest activity within the allowable ranges presented in Sect. 1.2.2. Incorporating the new 10 CFR 71 A_2 values for the uranium isotopes, three different categories have been established based on the absorption rate of the uranium isotopes. The fast lung absorption, medium lung absorption, and slow lung absorption categories are addressed in subsequent sections. By applying the maximum weight percents of isotopes ^{232}U, ^{233}U, ^{234}U, ^{236}U and by incorporating the traces of ^{237}Np and the transuranic isotopes, the maximum activity, minimum A_2 value, and the minimum leakage requirements were determined for each category of absorption for the HEU contents. The mass and isotopic concentrations used for the proposed content do not take into consideration limits based on shielding and subcriticality.

Table 1. Isotopic mass and weight percent for the HEU contents [a]

Nuclide	Weight percent	Mass (g)
U-232	0.000004	0.001408
U-233	0.600000	211.200000
U-234	2.000000	704.000000
U-235	54.819996	19,296.638592
U-236	40.000000	14,080.000000
U-238	0.000000	0.000000
Transuranic	0.080000 [b]	28.160000
Np-237	2.500000	880.000000
Total	**100.000000**	**35,200.000000**

[a] Weight percents values of individual isotopes are those that generate the largest activity within the allowable ranges presented in Sect. 1.2.2.

[b] The transuranic weight percent of 0.080000 applies to ground transport only. The maximum transuranic weight percent in contents transported by air will be 0.004000.

According to 10 CFR 71, Appendix A, parent and daughter nuclides are considered to be a mixture of different nuclides than those of the parent nuclide. The radioactive decay of uranium [refer to

the decay chains presented by Dr. David C. Kocher, *Radioactive Decay Data Tables* (DOE/TIC-11026)] creates isotopes that will accumulate enough activity to exceed their respective criteria for limited quantities (49 CFR 173.425, Table 4, "Activity Limits for Limited Quantities, Instruments, and Articles") and for Type A quantities of radionuclides (10 CFR 71, Table A-1, "A_1 and A_2 Values for Radionuclides"). Furthermore, the A_2 value for the mixture will change over time as a result of radioactive decay. The analysis below shows that the A_2 value for this mixture reaches a minimum at initial fabrication, increases to the 10^{th} year, and declines through the 70^{th} year.

Analysis

Mass Tables. The mass and weight fractions for HEU isotopes used in the containment calculations are presented in Table 1. For conservatism, a small quantity of ^{232}U is assumed in this material at fabrication.

ORIGEN-S Results. The source terms of the isotopes in the mixtures were evaluated using the ORIGEN-S computer program (NUREG/CR-0200). The mass values for the parent and daughter products are presented in Table 2 for the time interval of 0–70 years. Contributions from the transuranics and ^{237}Np are held constant at each time interval during the 70-year evaluation.

The A_2 value of each mixture was calculated using the procedure shown in Tables 3, 4, and 5 for the above time intervals. The 70^{th} year of decay represents the smallest value of A_2 and the maximum activity-to-A_2 value ratio (the smallest maximum allowable leakage rate within the time interval examined). A summary of the content activity and the A_2 value of the various configurations for the above time interval is given in Table 6.

From Sect. 1.2.2, the activity and mass concentrations for the transuranics are 1.2×10^{7} Bq/gU and 800 µg/gU (ground transport only), respectively. Using a maximum uranium mass of 35.2 kg, the mass of transuranics is calculated to be 28.160 g and the activity is calculated to be 4.2240×10^{-1} TBq. Dividing this activity by the mass results in a specific activity of 1.5×10^{-2} TBq/g. In accordance with 10 CFR 71, Appendix A, Table A-3 for "contents with no relevant data," an A_2 value of 9.0×10^{-5} TBq is obtained.

Section 1.2.2 gives a maximum concentration for Np-237 of 0.025 g/gU. Using a maximum uranium mass of 35.2 kg, the mass of Np-237 is calculated to be 880 g. This value is used in Tables 3, 4, and 5 for the Np-237 contents.

Results

The containment criteria analysis indicates that the HEU contents must be shipped in a Type B material package since their activities are greater than the A_2 value. The smallest A_2 value of 1.5245×10^{-4} TBq (4.1203×10^{-3} Ci) in conjunction with the maximum activity-to-A_2 value ratio of 4,752.8 occurs after ~70 years of decay for the assumed maximum 35.2 kg of HEU.

Appendix 4.5.2
Calculation of the ES-3100 CV Regulatory Reference Air Leakage Rates

Introduction

The ES-3100 leak-testing requirements of the containment boundary are based on the smallest maximum allowable leakage rate generated from the maximum uranium content defined in Table 4.3. Section 5 of ANSI N14.5-1997 defines the maximum allowable leakage rate based on the maximum allowable release rate. These leakage rates, L_N and L_A, are the maximum allowable O-ring seal leakage rates for Normal Conditions of Transport (NCT) and Hypothetical Accident Conditions (HAC). The worst-case maximum allowable leakage rates are used to calculate an equivalent leakage hole diameter following ANSI N14.5-1997, Appendix B, for each condition of transport. This leakage hole diameter is used to calculate a reference air and a helium leakage rate for leak testing. A bounding mass for the highly enriched uranium (HEU) content of 35.2 kg is used in this calculation to certify the ES-3100 package for shipment. The maximum allowable leakage rates are calculated using this maximum content mass in a much more dispersive form (oxide powder) at the highest calculated pressures and temperatures. This appendix shows the procedure used to calculate the leak criteria for the uranium constituents in the "slow lung absorption" group. Table 1 shows the results of using this procedure for fast, medium, and slow absorption uranium constituents as a function of decay time.

HEU Content

Calculate R_N and R_A: (Table 4.1)

The maximum allowable release rate is based on using A_2.

$A_2 = 1.5245 \times 10^{-4}$ TBq, (4.1203×10^{-3} Ci). [Table 6 (Appendix 4.5.1)]

The containment requirements for NCT and HAC are:

$R_N = A_2 \times 10^{-6}$ TBq/h,
$= A_2 \times 2.78 \times 10^{-10}$ TBq/s, [ANSI N14.5-1997 (Eq. 1)]
$= 1.5245 \times 10^{-4} \times 2.78 \times 10^{-10}$ TBq/s,
$= 4.2382 \times 10^{-14}$ TBq/s, (1.1455×10^{-12} Ci/s).

$R_A = A_2$ (TBq/week),
$= A_2 \times 1.65 \times 10^{-6}$ (TBq/s), [ANSI N14.5-1997 (Eq. 2)]
$= 1.5245 \times 10^{-4} \times 1.65 \times 10^{-6}$ TBq/s,
$= 2.5155 \times 10^{-10}$ TBq/s, (6.7986×10^{-9} Ci/s). (or limited to 10 A_2/week of ^{85}Kr)

Following ANSI N14.5-1997, the medium aerosol activity must be calculated to determine the leakage rates.

m = total nuclide mass in the package available for release (g),
TotA = total activity in the package available for release (TBq),
TSA = total specific activity in the package available for release (TBq/g).

Table 1. Regulatory leakage criteria for 35.2 kg of HEU

Years from fabrication		NCT		HAC	
		$L_{RN - air}$ (ref-cm^3/s)	$L_{RN - He}$ (cm^3/s)	$L_{RA - air}$ (ref-cm^3/s)	$L_{RA - He}$ (cm^3/s)

	70	1.4025E-04	1.7269E-04	1.5836E-01	1.5706E-01

For HEU content:

$$\begin{aligned} TSA &= TotA / m, \\ &= 7.2456 \times 10^{-1}\ (TBq) / 35{,}200\ (g), && \text{[Table 6 (Appendix 4.5.1)]} \\ &= 2.0584 \times 10^{-5}\ TBq/g, \\ \rho_P &= 9 \times 10^{-6}\ g/cm^3. && \text{(The maximum density of powder aerosols in the fill gas)} \end{aligned}$$

For any packaging arrangement:

$$\begin{aligned} C_N &= \text{activity per unit volume of medium that could escape from the containment system } (TBq/cm^3), \\ &= TSA \times \rho_P, \\ &= 2.0584 \times 10^{-5}\ (TBq/g) \times 9 \times 10^{-6}\ (g/cm^3), \\ &= 1.8526 \times 10^{-10}\ TBq/cm^3. \end{aligned}$$

Using Curren's maximum aerosol density, $C_A = C_N$:

$$\begin{aligned} C_A &= \text{activity per unit volume of exiting gas } (TBq/cm^3), && \text{(HAC)} \\ &= 1.8526 \times 10^{-10}\ TBq/cm^3. \end{aligned}$$

Section 6.1 of ANSI N14.5-1997 calculates L_N with (Eq. 3) and L_A with (Eq. 4). L_N and L_A are the maximum allowable leakage rates for the containment vessel fill gas aerosol during NCT and HAC, respectively.

$$\begin{aligned} L_N &= \text{maximum allowable leakage rate for the medium for NCT } (TBq/cm^3), \\ &= R_N / C_N, && \text{[ANSI N14.5-1997 (Eq. 3)]} \\ &= 4.2382 \times 10^{-14}\ (TBq/s) / 1.8526 \times 10^{-10}\ (TBq/cm^3), \\ &= 2.2878 \times 10^{-4}\ cm^3/s, \end{aligned}$$

$$\begin{aligned} L_A &= \text{maximum allowable leakage rate for the medium for HAC } (TBq/cm^3), \\ &= R_A / C_A, \\ &= 2.5155 \times 10^{-10}\ (TBq/s) / 1.8526 \times 10^{-10}\ (TBq/cm^3), \\ &= 1.3578\ cm^3/s. \end{aligned}$$

L_N and L_A correspond to the upstream volumetric leakage rate (L_u) at the upstream pressure (P_u) in the ANSI N14.5-1997 formulas for use later in this appendix. The reference air leakage rates $L_{R,N}$ and $L_{R,A}$ for NCT and HAC, based on the L_N and L_A, are then calculated using the maximum temperatures and pressure combinations from Table 7 in Appendix 3.5.1 (NCT) and from Table 7 in Appendix 3.5.2 (HAC) as the basis. For conservatism, the latter values have been rounded up to compensate for numerical tolerance issues. Therefore, the following analyses will use a pressure of 30.50 psia at a temperature of 194°F for the NCT evaluation and a pressure of 175.0 psia at a temperature of 334°F for the HAC evaluation.

Determination of the Leakage Test Procedure Requirements for the HEU Content

This calculation will examine the most conservative effects of a fully loaded containment vessel with an HEU mass of 35.2 kg. The smallest allowable leakage values are shown in Tables 4.5 and 4.8. The A_2 value and the maximum content activity-to-A_2 value ratio for this mixture were calculated for several different decay times (Table 6, Appendix 4.5.1). As calculated in Appendix 4.5.1, the A_2 value

and the maximum content activity-to-A_2 ratio used to qualify this package occur at ~70 years of decay and are 1.5245×10^{-4} TBq (4.1203×10^{-3} Ci) and 4,752.8 respectively. These values are used to determine the leakage test procedural requirements when packaging any convenience cans/contents arrangements in the ES-3100 package. The convenience cans/contents are sealed inside the containment vessel in an environmentally controlled area.

The following analysis determines the maximum allowable O-ring seal air reference leakage rate for both NCT and HAC. The ANSI N14.5-1997 recommended method using a straight circular tube to model the leakage path is applied. Using this "standard" leakage hole model permits the calculation of equivalent reference leakage rates from which leak-test requirements can be established. Viscosity data for air and helium used in the following analyses were obtained from curve fitting routines at specific temperatures based on viscosity data for air (*CRC Handbook of Chemistry and Physics*) and helium (NBS Technical Note 631).

L_N and L_A correspond to the upstream volumetric leakage rate (L_u) at the upstream pressure (P_u).

$$L_N = 2.2878 \times 10^{-4} \text{ cm}^3/\text{s},$$
$$L_A = 1.3578 \text{ cm}^3/\text{s}.$$

Find the maximum pressure and temperature in the containment vessel:

Converting the temperature to degrees Kelvin:

$$T = 273.15 + T\ (°C),$$
$$= 273.15 + 5 / 9\ (°F - 32)\ (K),$$

$$T_N = 273.15 + 5 / 9\ (194°F - 32)\ (K), \quad (T = 194°F)$$
$$= 363.15 \text{ K}, \quad (NCT)$$

$$T_A = 273.15 + 5 / 9\ (334°F - 32)\ (K), \quad (T = 334°F)$$
$$= 440.93 \text{ K}. \quad (HAC)$$

Converting the pressures from psia to atmospheres:

$$P_N = P\ (psia) / 14.696\ (psia/atm), \quad (\text{where P is the pressure in Sect. } 3.3.2)$$
$$= 30.5\ (psia) / 14.696\ (psia/atm), \quad (\text{rounded up for NCT})$$
$$= 2.0754 \text{ atm},$$

$$P_A = P\ (psia) / 14.696\ (psia/atm), \quad (\text{where P is the pressure in Sect. } 3.4.2)$$
$$= 175.0\ (psia) / 14.696\ (psia/atm), \quad (\text{rounded up for HAC})$$
$$= 11.9080 \text{ atm}.$$

NCT Leakage Hole Diameter for the HEU Content

The following calculations determine the leakage hole diameter that generates the maximum allowable leakage rate during NCT. To keep these calculations conservative, the maximum values for temperature and pressure were used as steady-state conditions for NCT.

Input data for NCT with air fill gas:

$L_N = 2.2878 \times 10^{-4}$ cm^3/s, (Maximum upstream leakage)
$P_u = 2.0754$ atm, (Upstream pressure = 30.5 psia)
$P_d = 0.2382$ atm, [Downstream pressure = 3.5 psia, per 10 CFR 71.71(3)]
$a = 0.3531$ cm, (Leak path length, 0.139-in. O-ring section diameter)
$T = 363.15$ K, (Fill gas temperature = 194°F)
$\mu = 0.02150$ cP, (Viscosity at temperature)
$M = 29$ g/g-mol. (Molecular weight of fill gas)

The average pressure is:

$$P_a = (P_u + P_d) / 2,$$
$$= (2.0754 + 0.2382) / 2,$$
$$= 1.1568 \text{ atm.} \quad \text{(Average pressure during NCT)}$$

According to ANSI N14.5-1997, the flow leakage hole diameter is unknown. Therefore, the mass-like leakage flow rate must be calculated to calculate the average leakage flow rate.

Q is the mass-like leakage for flow using the upstream leakage, L_u, and pressure, P_u:

$$Q = P_u L_u, \quad \text{(Eq. B1)}$$
$$L_u = L_N, \quad \text{(NCT leakage)}$$

$$Q = (2.0754)(\text{atm})\ (2.2878 \times 10^{-4})(\text{cm}^3/\text{s}),$$
$$= 4.7481 \times 10^{-4} \text{ atm-cm}^3/\text{s}, \quad \text{(NCT mass-like leakage rate)}$$

$$Q = P_a L_a, \quad \text{(Eq. B1)}$$

$$L_a = Q / P_a,$$
$$= 4.7481 \times 10^{-4} \text{ (atm-cm}^3/\text{s)} / (1.1568) \text{ (atm)},$$
$$= 4.1045 \times 10^{-4} \text{ cm}^3/\text{s}. \quad \text{(NCT average leakage rate)}$$

Solve equations B2–B4 from ANSI N14.5-1997:

$$L_a = (F_c + F_m)(P_u - P_d) \text{ cm}^3/\text{s}, \quad \text{(Eq. B2)}$$
$$= (F_c + F_m)(2.0754 - 0.2382),$$
$$= (1.8372)(F_c + F_m) \text{ cm}^3/\text{s},$$

$$F_c = (2.49 \times 10^6) D^4 / (a \mu) \text{ (cm}^3/\text{atm-s)}, \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6) D^4 / [(0.3531)(0.02150)],$$
$$= (3.2795 \times 10^8) D^4 \text{ cm}^3/\text{atm-s},$$

$$F_m = (3.81 \times 10^3) D^3 (T / M)^{.5} / (a P_a) \text{ (cm}^3/\text{atm-s)}, \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3) D^3 (363.15 / 29)^{.5} / [(0.3531)(1.1568)],$$
$$= (3.3012 \times 10^4) D^3 \text{ cm}^3/\text{atm-s}.$$

From the mass-like leakage calculation:

$L_a = 4.1045 \times 10^{-4}$ cm^3/s. (NCT average leakage rate)

Find the leakage hole diameter that sets:

$L_2 = L_a$.

Using the equations:

$L_2 = (1.8372)\ (F_c + F_m)$ cm^3/s,
$F_c = (3.2795 \times 10^8)\ D^4$ cm^3/atm-s,
$F_m = (3.3012 \times 10^4)\ D^3$ cm^3/atm-s.

To get a better guess on a new D, use:

$D = D_2\ (L_a / L_2)^{0.252}$.

Now a guess must be made for D_2 to solve Eq. B2 for NCT:

D_2 = 0.001 cm, and solve for $L_a = 4.1045 \times 10^{-4}$ cm^3/s. (NCT average leakage rate)

Diameter	F_c	F_m	L_2	L_a / L_2
1.0000E-03	3.2795E-04	3.3012E-05	6.6318E-04	0.61891
8.8612E-04	2.0220E-04	2.2969E-05	4.1368E-04	0.99218
8.8437E-04	2.0060E-04	2.2833E-05	4.1051E-04	0.99986
8.8433E-04	2.0058E-04	2.2831E-05	4.1045E-04	1.00000

The NCT leakage hole diameter for the HEU oxide content:

$D = 8.8433 \times 10^{-4}$ cm. (NCT diameter)

NCT Reference Air Leakage Rate for HEU Content

The leakage hole diameter found for the maximum allowable leakage rate for NCT will be used to determine the reference air leakage rate. O-ring seal leakage testing must ensure that no leakage is greater than the leakage generated by the hole diameter $D = 8.8433 \times 10^{-4}$ cm. Therefore, the NCT reference leakage flow rate ($L_{R, N}$) must be calculated to determine the allowable test leakage rate.

Input data for NCT reference air leakage rate:

$D = 8.8433 \times 10^{-4}$ cm, (From NCT)
$a = 0.3531$ cm, (Leak path length, 0.139-in. O-ring section diameter)
$P_u = 1.0$ atm, (Upstream pressure)
$P_d = 0.01$ atm, (Downstream pressure)
$T = 298$ K, (Fill gas temperature, 77°F)

$M = 29$ g/g-mol, (Molecular weight of air)

$\mu = 0.0185$ cP, (Viscosity of air at reference temperature)

Calculate P_a:

$$P_a = (P_u + P_d) / 2,$$
$$= (1.0 + 0.01) /2,$$
$$= 0.505 \text{ atm}, \quad \text{(NCT average pressure)}$$

$$F_c = (2.49 \times 10^6) D^4 / (a \mu) \text{ (cm}^3\text{/atm-s)}, \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6) (8.8433 \times 10^{-4})^4 / [(0.3531) (0.0185)],$$
$$= (3.8122 \times 10^8) (8.8433 \times 10^{-4})^4,$$
$$= 2.3316 \times 10^{-4} \text{ cm}^3\text{/atm-s},$$

$$F_m = (3.81 \times 10^3) D^3 (T / M)^{.5} / (a P_a) \text{ (cm}^3\text{/atm-s)}, \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3) (8.8433 \times 10^{-4})^3 (298 / 29)^{.5} / [(0.3531) (0.505)],$$
$$= (6.8501 \times 10^4) (8.8433 \times 10^{-4})^3,$$
$$= 4.7374 \times 10^{-5} \text{ cm}^3\text{/atm-s},$$

$$L_u = (F_c + F_m) (P_u - P_d) (P_a / P_u) \text{ (cm}^3\text{/s)}, \quad \text{(Eq. B5)}$$
$$= (2.3316 \times 10^{-4} + 4.7374 \times 10^{-5})(\text{cm}^3\text{/atm-s}) (1.0 - 0.01)(\text{atm}) (0.505 / 1.0),$$
$$= (2.8053 \times 10^{-4})(\text{cm}^3\text{/atm-s}) (0.49995)(\text{atm}),$$
$$= 1.4025 \times 10^{-4} \text{ cm}^3\text{/s}.$$

The reference air leakage rate as defined in ANSI N14.5-1997, Sect. B.3, is the upstream leakage in air.

$L_{RN,Air} = 1.4025 \times 10^{-4}$ ref-cm^3/s. (For HEU oxide content)

The same equations can be used to calculate an allowable leakage rate using helium for leak testing.

$M = 4$ g/g-mol, (Molecular weight of helium)

$\mu = 0.0198$ cP, (Viscosity of helium at temperature)

$$F_c = (2.49 \times 10^6) D^4 / (a \mu) \text{ (cm}^3\text{/atm-s)}, \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6) (8.8433\times 10^{-4})^4 / [(0.3531) (0.0198)],$$
$$= (3.5619 \times 10^8) (8.8433 \times 10^{-4})^4,$$
$$= 2.1785 \times 10^{-4} \text{ cm}^3\text{/atm-s},$$

$$F_m = (3.81 \times 10^3) D^3 (T / M)^{.5} / (a P_a) \text{ (cm}^3\text{/atm-s)}, \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3) (8.8433 \times 10^{-4})^3 (298 / 4)^{.5} / [(0.3531) (0.505)],$$
$$= (1.8444 \times 10^5) (8.8433 \times 10^{-4})^3,$$
$$= 1.2756 \times 10^{-4} \text{ cm}^3\text{/atm-s},$$

$$L_u = (F_c + F_m) (P_u - P_d) (P_a / P_u) \text{ (cm}^3\text{/s)}, \quad \text{(Eq. B5)}$$
$$= (2.1785 \times 10^{-4} + 1.2756 \times 10^{-4})(\text{cm}^3\text{/atm-s}) (1.0 - 0.01)(\text{atm}) (0.505 / 1.0),$$
$$= (3.4541 \times 10^{-4})(\text{cm}^3\text{/atm-s}) (0.49995)(\text{atm}),$$
$$= 1.7269 \times 10^{-4} \text{ cm}^3\text{/s}.$$

The allowable leakage rate using helium for leak testing is:

$L_{RN,\,He} = 1.7269 \times 10^{-4}$ cm^3/s. (NCT helium test value)

HAC Leakage Hole Diameter for HEU Content

The calculation of a maximum allowable leakage rate hole diameter is based on the temperature and pressure of the fill gas aerosol for HAC, assuming the content is in an oxide powder form. Keeping this calculation conservative, the maximum values for temperature and pressure were used as steady-state conditions for a week. The maximum values were generated during the 30-min burn test for HAC.

Input data for HAC:

$L_A = 1.3578$ cm^3/s, (Maximum exit leakage)
$P_u = 11.9080$ atm, (Upstream pressure = 175.0 psia)
$P_d = 1.0$ atm, (Downstream pressure)
$T = 440.93$ K, (Fill gas temperature = 334°F)
$\mu = 0.02479$ cP, (Viscosity of air at temperature)
$M = 29$ g/g-mol, (Molecular weight of air)
$a = 0.3531$ cm, (Leak path length, 0.139-in. O-ring section diameter)

$P_a = (P_u + P_d) / 2,$
$= (11.9080 + 1.0) / 2,$ (HAC average pressure)
$= 6.4540$ atm.

Q is the mass-like leakage for flow using the upstream leakage, L_u, and pressure, P_u:

$Q = P_u L_u,$ (Eq. B1)
$L_u = L_A.$ (HAC leakage)

$Q = (11.9080)(\text{atm})\ (1.3578)(\text{cm}^3/\text{s}),$
$= 16.1691$ atm-cm^3/s, (HAC mass-like leakage rate)

$Q = P_a L_a,$ (Eq. B1)

$L_a = Q / P_a,$
$= 16.1691$ (atm-cm^3/s) / (6.4540) (atm),
$= 2.5053$ cm^3/s. (HAC average leakage rate)

Solve equations B2–B4 from ANSI N14.5-1997:

$L_a = (F_c + F_m)\ (P_u - P_d)$ (cm^3/s), (Eq. B2)
$= (F_c + F_m)\ (11.9080 - 1.0),$
$= 10.9080\ (F_c + F_m)$ cm^3/s,

$F_c = (2.49 \times 10^6)\ D^4 / (a\ \mu)$ (cm^3/atm-s), (Eq. B3)
$= (2.49 \times 10^6)\ D^4 / [(0.3531)\ (0.02479)],$
$= (2.8435 \times 10^8)\ D^4$ cm^3/atm-s,

$$F_m = (3.81 \times 10^3)\, D^3\, (T / M)^{.5} / (a\, P_a)\ (cm^3/atm\text{-}s), \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3)\, D^3\, (440.93 / 29)^{.5} / [(0.3531)\,(6.4540)],$$
$$= (6.5198 \times 10^3)\, D^3\ cm^3/atm\text{-}s.$$

From the mass-like leakage calculation:

$$L_a = 2.5053\ cm^3/s. \quad \text{(HAC average leakage rate)}$$

Find the leakage hole diameter that sets:

$$L_2 = L_a.$$

Using the equations:

$$L_2 = 10.9080\,(F_c + F_m)\ cm^3/s,$$
$$F_c = (2.8435 \times 10^8)\, D^4\ cm^3/atm\text{-}s,$$
$$F_m = (6.5198 \times 10^3)\, D^3\ cm^3/atm\text{-}s.$$

To get a better guess on a new D, use:

$$D = D_2\,(L_a / L_2)^{0.252}.$$

Now a guess must be made for D_2 to solve Eq. B2 for HAC:

D_2 = 0.01 (cm), and solve for $L_a = 2.5053\ (cm^3/s)$. (HAC average leakage rate)

Diameter	F_c	F_m	L_2	L_a / L_2
1.0000E-02	2.8453E+00	6.5198E-03	3.1108E+01	0.08054
5.3004E-03	2.2458E-01	9.7087E-04	2.4603E+00	1.01829
5.3247E-03	2.2872E-01	9.8426E-04	2.5056E+00	0.99987
5.3245E-03	2.2869E-01	9.8417E-04	2.5053E+00	1.00000

The HAC leakage hole diameter for the HEU oxide content is:

$$D = 5.3245 \times 10^{-3}\ cm. \quad \text{(HAC diameter)}$$

HAC Reference Air Leakage Rate for HEU Content

The leakage hole diameter found for the maximum allowable leakage rate for HAC will be used to determine the reference air leakage rate. O-ring seal leakage testing must assure that no leakage is greater than the leakage generated by the hole diameter $D = 5.3245 \times 10^{-3}$ cm. Therefore, the HAC reference air leakage rate ($L_{R,A}$) must be calculated to determine the acceptable test leakage rate for post-HAC leakage testing.

Input data for HAC reference air leakage rate:

$D = 5.3245 \times 10^{-3}$ cm, (From the HAC of transport)
$a = 0.3531$ cm, (Leak path length, 0.139-in. O-ring section diameter)
$P_u = 1.0$ atm, (Upstream pressure)
$P_d = 0.01$ atm, (Downstream pressure)
$T = 298$ K, (Fill gas temperature, 77°F)
$M = 29$ g/g-mol, (Molecular weight of air)
$\mu = 0.0185$ cP. (Viscosity at temperature)

Calculate P_a:

$$P_a = (P_u + P_d) / 2,$$
$$= 0.505 \text{ atm,} \quad \text{(HAC average pressure)}$$

$$F_c = (2.49 \times 10^6)\, D^4 / (a\, \mu) \text{ (cm}^3\text{/atm-s),} \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6)\, (5.3245 \times 10^{-3})^4 / [(0.3531)\, (0.0185)],$$
$$= (3.8122 \times 10^8)\, (5.3245 \times 10^{-3})^4,$$
$$= 3.0641 \times 10^{-1} \text{ cm}^3\text{/atm-s,}$$

$$F_m = (3.81 \times 10^3)\, D^3\, (T / M)^{.5} / (a\, P_a) \text{ (cm}^3\text{/atm-s),} \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3)\, (5.3245 \times 10^{-3})^3\, (298 / 29)^{.5} / [(0.3531)\, (0.505)],$$
$$= (6.8501 \times 10^4)\, (5.3245 \times 10^{-3})^3,$$
$$= 1.0340 \times 10^{-2} \text{ cm}^3\text{/atm-s,}$$

$$L_u = (F_c + F_m)\, (P_u - P_d)\, (P_a / P_u) \text{ (cm}^3\text{/s),} \quad \text{(Eq. B5)}$$
$$= (3.0641 \times 10^{-1} + 1.0340 \times 10^{-2}) \text{(cm}^3\text{/atm-s)}\, (1.0 - 0.01) \text{(atm)}\, (0.505 / 1.0),$$
$$= (3.1675 \times 10^{-1}) \text{(cm}^3\text{/atm-s)}\, (0.49995) \text{(atm)},$$
$$= 1.5836 \times 10^{-1} \text{ cm}^3\text{/s.}$$

The HAC reference air leakage rate as defined in ANSI N14.5-1997, Sect. B.3, is the upstream leakage in air.

$L_{RA,Air} = 1.5836 \times 10^{-1}$ ref-cm^3/s. (for HEU oxide content)

The same equations can be used to calculate an allowable leakage rate using helium for leak testing.

$M = 4$ g/g-mol, (Molecular weight of helium)
$\mu = 0.0198$ cP, (Viscosity of helium at temperature)

$$F_c = (2.49 \times 10^6)\, D^4 / (a\, \mu) \text{ (cm}^3\text{/atm-s),} \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6)\, (5.3245 \times 10^{-3} \text{ cm})^4 / [(0.3531)\, (0.0198)],$$
$$= (3.5619 \times 10^8)\, (5.3245 \times 10^{-3} \text{ cm})^4,$$
$$= 2.8629 \times 10^{-1} \text{ cm}^3\text{/atm-s,}$$

$$F_m = (3.81 \times 10^3)\, D^3\, (T / M)^{0.5} / (a\, P_a)\ (cm^3/atm\text{-}s), \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3)\, (5.3245 \times 10^{-3}\ cm)^3\, (298 / 4)^{.5} / [(0.3531)\, (0.505)],$$
$$= (1.8444 \times 10^5)\, (5.3245 \times 10^{-3}\ cm)^3,$$
$$= 2.7842 \times 10^{-2}\ cm^3/atm\text{-}s,$$

$$L_u = (F_c + F_m)\, (P_u - P_d)\, (P_a / P_u)\ (cm^3/s), \quad \text{(Eq. B5)}$$
$$= (2.8629 \times 10^{-1} + 2.7842 \times 10^{-2})(cm^3/atm\text{-}s)\, (1.0 - 0.01)(atm)\, (0.505 / 1.0),$$
$$= (3.1413 \times 10^{-1})(cm^3/atm\text{-}s)\, (0.49995)(atm),$$
$$= 1.5705 \times 10^{-1}\ cm^3/s.$$

The allowable leakage rate using helium for leak testing for HAC is:

$$L_{RA,\,He} = 1.5705 \times 10^{-1}\ cm^3/s. \quad \text{(HAC helium test value)}$$

Determination of the Leakage Test Procedure Requirements for the HEU Content Transported by Air

The IAEA SSR-6, para. 621, states: "Packages containing radioactive material, to be transported by air, shall be capable of withstanding, without loss or dispersal of radioactive contents from the containment system, an internal pressure that produces a pressure differential of not less than the maximum normal operating pressure plus 95 kPa." As shown in Table 2.20, the maximum normal operating pressure (MNOP) for CVA 1 or CVA 11 was predicted to be 31.943 kPa (4.633 psi) gauge [133.30 kPa (19.333 psi) absolute] for ground transportation. As shown in Appendix 3.5.1, Table 9, the maximum pressure differential for both containment vessel arrangements determined for air transport is the MNOP plus 95 kPa (13.78 psi) or 117.69 kPa (17.07 psi). The following calculations will examine the most conservative effects of a fully loaded containment vessel with an HEU mass of 35.2 kg and this pressure differential. The smallest allowable leakage values are shown in Table 4.6. The A_2 value and the maximum content activity-to-A_2 value ratio for this mixture were calculated for several different decay times (Table 6, Appendix 4.5.1). As calculated in Appendix 4.5.1, the A_2 value and the maximum content activity-to-A_2 ratio used to qualify this package occur at ~70 years of decay and are 1.5245×10^{-4} TBq (4.1203×10^{-3} Ci) and 4,752.8, respectively. These values are used to determine the leakage test procedural requirements when packaging any convenience cans/contents arrangements in the ES-3100 package. The convenience cans/contents are sealed inside the containment vessel in an environmentally controlled area.

The following analysis determines the maximum allowable O-ring seal air reference leakage rate for NCT during air transport. The ANSI N14.5-1997 recommended method using a straight circular tube to model the leakage path is applied. Using this "standard" leakage hole model permits the calculation of equivalent reference leakage rates from which leak-test requirements can be established. Viscosity data for air and helium used in the following analyses were obtained from curve fitting routines at specific temperatures based on viscosity data for air (*CRC Handbook of Chemistry and Physics*) and helium (NBS Technical Note 631). To also comply with 49 CFR 173.410(i)(2), the range of temperature evaluated will be from −40 to 55°C (ambient temperature). According to IAEA SSG-26, para. 621.3, the evaluation at an ambient temperature of 55°C does not consider insolation; however, self-heating of the package is taken into account. An analysis has been conducted, and results for these conditions are shown in Table 3.14. The maximum temperature predicted for the containment vessel was 64.44°C (147.99°F). This temperature will be used in the following analysis as the maximum gas temperature (T_{NL}).

L_N and L_A correspond to the upstream volumetric leakage rate (L_u) at the upstream pressure (P_u).

$$L_N = 2.2878 \times 10^{-4} \text{ cm}^3/\text{s},$$
$$L_A = 1.3578 \text{ cm}^3/\text{s}.$$

Find the maximum pressure and a temperature in the containment vessel from -40 to 55°C:

Converting the temperature to Kelvin:

$$T = 273.15 + T\ (°C),$$
$$= 273.15 + 5 / 9\ (°F - 32)\ (K),$$

$$T_{NL} = 273.15 + 5 / 9\ (-40°F - 32)\ (K), \quad [T = -40°F\ (-40°C)]$$
$$= 233.15 \text{ K}, \quad \text{(NCT low limit)}$$

$$T_{NH} = 273.15 + 5 / 9\ (147.99°F - 32)\ (K), \quad [T = 147.99°F\ (64.44°C)]$$
$$= 337.59 \text{ K}, \quad \text{(NCT high limit)}$$

Converting the pressures from psia to atmospheres:

$$P_N = P\ (\text{psia}) / 14.696\ (\text{psia/atm}), \quad [\text{where P is the pressure in Sect. 3.3.2 plus 13.78 psia (95 kPa)}]$$
$$= 17.07\ (\text{psia}) / 14.696\ (\text{psia/atm}), \quad \text{(rounded up for NCT)}$$
$$= 1.1615 \text{ atm},$$

NCT Leakage Hole Diameter for the HEU Content during Air Transport at the Lower Temperature Limit of IAEA SSG-26

The following calculations determine the leakage hole diameter that generates the maximum allowable leakage rate during NCT. To keep these calculations conservative, the maximum values for temperature and pressure were used as steady-state conditions for NCT as dictated for air transport.

Input data for NCT at the lower temperature limit with air fill gas:

$L_N = 2.2878 \times 10^{-4} \text{ cm}^3/\text{s}$, (Maximum upstream leakage)
$P_u = 1.1615 \text{ atm}$, (Upstream pressure = 17.07 psia)
$P_d = 0 \text{ atm}$, [Downstream pressure = 0 psia, per 10 CFR 71.71(3)]
$a = 0.3531 \text{ cm}$, (Leak path length, 0.139-in. O-ring section diameter)
$T = 233.15 \text{ K}$, (Fill gas temperature = −40°F)
$\mu = 0.01518 \text{ cP}$, (Viscosity at temperature)
$M = 29 \text{ g/g-mol}$. (Molecular weight of fill gas)

The average pressure is:

$$P_a = (P_u + P_d) / 2,$$
$$= (1.1615 + 0) / 2,$$
$$= 0.5808 \text{ atm}. \quad \text{(Average pressure during NCT)}$$

According to ANSI N14.5-1997, the flow leakage hole diameter is unknown. Therefore, the mass-like leakage flow rate must be calculated to calculate the average leakage flow rate.

Q is the mass-like leakage for flow using the upstream leakage, L_u, and pressure, P_u:

$$Q = P_u L_u, \quad \text{(Eq. B1)}$$
$$L_u = L_N, \quad \text{(NCT leakage)}$$

$$Q = (1.1615)(\text{atm})\ (2.2878 \times 10^{-4})(\text{cm}^3/\text{s}),$$
$$= 2.6573 \times 10^{-4}\ \text{atm-cm}^3/\text{s}, \quad \text{(NCT mass-like leakage rate)}$$

$$Q = P_a L_a, \quad \text{(Eq. B1)}$$

$$L_a = Q / P_a,$$
$$= 2.6573 \times 10^{-4}\ (\text{atm-cm}^3/\text{s}) / (0.5808)\ (\text{atm}),$$
$$= 4.5755 \times 10^{-4}\ \text{cm}^3/\text{s}. \quad \text{(NCT average leakage rate)}$$

Solve equations B2–B4 from ANSI N14.5-1997:

$$L_a = (F_c + F_m)\ (P_u - P_d)\ \text{cm}^3/\text{s}, \quad \text{(Eq. B2)}$$
$$= (F_c + F_m)\ (1.1615 - 0.0000),$$
$$= (1.16153.0641)\ (F_c + F_m)\ \text{cm}^3/\text{s},$$

$$F_c = (2.49 \times 10^6)\ D^4 / (a\ \mu)\ (\text{cm}^3/\text{atm-s}), \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6)\ D^4 / [(0.3531)\ (0.01518)],$$
$$= (4.6459 \times 10^8)\ D^4\ \text{cm}^3/\text{atm-s},$$

$$F_m = (3.81 \times 10^3)\ D^3\ (T / M)^{.5} / (a\ P_a)\ (\text{cm}^3/\text{atm-s}), \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3)\ D^3\ (233.15 / 29)^{.5} / [(0.3531)\ (0.5808)],$$
$$= (5.2685 \times 10^4)\ D^3\ \text{cm}^3/\text{atm-s}.$$

From the mass-like leakage calculation:

$$L_a = 4.5755 \times 10^{-4}\ \text{cm}^3/\text{s}. \quad \text{(NCT average leakage rate)}$$

Find the leakage hole diameter that sets:

$$L_2 = L_a.$$

Using the equations:

$$L_2 = (1.1615)\ (F_c + F_m)\ \text{cm}^3/\text{s},$$
$$F_c = (4.6459 \times 10^8)\ D^4\ \text{cm}^3/\text{atm-s},$$
$$F_m = (5.2685 \times 10^4)\ D^3\ \text{cm}^3/\text{atm-s}.$$

To get a better guess on a new D, use:

$$D = D_2\ (L_a / L_2)^{0.252}.$$

Now a guess must be made for D_2 to solve Eq. B2 for NCT:

D_2 = 0.001 cm, and solve for $L_a = 4.5755 \times 10^{-4}$ cm^3/s. (NCT average leakage rate)

Diameter	F_c	F_m	L_2	L_a / L_2
1.0000E-03	4.6459E-04	5.2685E-05	6.0083E-04	0.76153
9.3365E-04	3.5303E-04	4.2879E-05	4.5986E-04	0.99498
9.3247E-04	3.5124E-04	4.2716E-05	4.5759E-04	0.99990
9.3245E-04	3.5120E-04	4.2713E-05	4.5755E-04	1.00000

The NCT leakage hole diameter for the HEU oxide content:

$D = 9.3245 \times 10^{-4}$ cm. (NCT diameter)

NCT Reference Air Leakage Rate for HEU Content Transported by Air

The leakage hole diameter found for the maximum allowable leakage rate for NCT will be used to determine the reference air leakage rate. O-ring seal leakage testing must ensure that no leakage is greater than the leakage generated by the hole diameter $D = 9.3245 \times 10^{-4}$ cm. Therefore, the NCT reference leakage flow rate ($L_{R, N}$) must be calculated to determine the allowable test leakage rate.

Input data for NCT reference air leakage rate:

$D = 9.3245 \times 10^{-4}$ cm, (From NCT)
$a = 0.3531$ cm, (Leak path length, 0.139-in. O-ring section diameter)
$P_u = 1.0$ atm, (Upstream pressure)
$P_d = 0.01$ atm, (Downstream pressure)
$T = 298$ K, (Fill gas temperature, 77°F)
$M = 29$ g/g-mol, (Molecular weight of air)
$\mu = 0.0185$ cP, (Viscosity of air at reference temperature)

Calculate P_a:

$$P_a = (P_u + P_d) / 2,$$
$$= (1.0 + 0.01) /2,$$
$$= 0.505 \text{ atm,} \quad \text{(NCT average pressure)}$$

$$F_c = (2.49 \times 10^6) D^4 / (a \mu) \text{ (cm}^3\text{/atm-s),} \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6) (9.3245 \times 10^{-4})^4 / [(0.3531) (0.0185)],$$
$$= (3.8122 \times 10^8) (9.3245 \times 10^{-4})^4,$$
$$= 2.8819 \times 10^{-4} \text{ cm}^3\text{/atm-s,}$$

$$F_m = (3.81 \times 10^3) D^3 (T / M)^{.5} / (a P_a) \text{ (cm}^3\text{/atm-s),} \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3) (9.3245 \times 10^{-4})^3 (298 / 29)^{.5} / [(0.3531) (0.505)],$$
$$= (6.8501 \times 10^4) (9.3245 \times 10^{-4})^3,$$
$$= 5.5535 \times 10^{-5} \text{ cm}^3\text{/atm-s,}$$

$L_u = (F_c + F_m)(P_u - P_d)(P_a / P_u)$ (cm^3/s), (Eq. B5)
$= (2.8819 \times 10^{-4} + 5.5535 \times 10^{-5})$ (cm^3/atm-s) (1.0 − 0.01) (atm) (0.505 / 1.0),
$= (3.4372 \times 10^{-4})$ (cm^3/atm-s) (0.49995) (atm),
$= 1.7184 \times 10^{-4}\ 2 \times 10^{-5}$ cm^3/s.

The reference air leakage rate as defined in ANSI N14.5-1997, Sect. B.3, is the upstream leakage in air.

$L_{RN,Air} = 1.7184 \times 10^{-4}$ ref-cm^3/s. (For HEU oxide content)

The same equations can be used to calculate an allowable leakage rate using helium for leak testing.

$M = 4$ g/g-mol, (Molecular weight of helium)
$\mu = 0.0198$ cP, (Viscosity of helium at temperature)

$F_c = (2.49 \times 10^6)\ D^4 / (a\ \mu)$ (cm^3/atm-s), (Eq. B3)
$= (2.49 \times 10^6)\ (9.3245 \times 10^{-4})^4 / [(0.3531)\ (0.0198)]$,
$= (3.5619 \times 10^8)\ (9.3245 \times 10^{-4})^4$,
$= 2.6926 \times 10^{-4}$ cm^3/atm-s,

$F_m = (3.81 \times 10^3)\ D^3\ (T / M)^{.5} / (a\ P_a)$ (cm^3/atm-s), (Eq. B4)
$= (3.81 \times 10^3)\ (9.3245 \times 10^{-4})^3\ (298 / 4)^{.5} / [(0.3531)\ (0.505)]$,
$= (1.8444 \times 10^5)\ (9.3245 \times 10^{-4})^3$,
$= 1.4953 \times 10^{-4}$ cm^3/atm-s,

$L_u = (F_c + F_m)(P_u - P_d)(P_a / P_u)$ (cm^3/s), (Eq. B5)
$= (2.6926 \times 10^{-4} + 1.4953 \times 10^{-4})$ (cm^3/atm-s) (1.0 − 0.01) (atm) (0.505 / 1.0),
$= (4.1880 \times 10^{-4})$ (cm^3/atm-s) (0.49995) (atm),
$= 2.0938 \times 10^{-4}$ cm^3/s.

The allowable leakage rate using helium for leak testing is:

$L_{RN,\,He} = 2.0938 \times 10^{-4}$ cm^3/s.

NCT Leakage Hole Diameter for the HEU Content during Air Transport at the Upper Temperature Limit [147.99°F (64.44°C)] per IAEA SSG-26

The following calculations determine the leakage hole diameter that generates the maximum allowable leakage rate during NCT. To keep these calculations conservative, the maximum values for temperature and pressure were used as steady-state conditions for NCT.

Input data for NCT at the upper temperature limit with air fill gas:

$L_N = 2.2878 \times 10^{-4}$ cm^3/s, (Maximum upstream leakage)
$P_u = 1.1615$ atm, (Upstream pressure = 17.07 psia)
$P_d = 0$ atm, [Downstream pressure = 0 psia, per 10 CFR 71.71(3)]
$a = 0.3531$ cm, (Leak path length, 0.139-in. O-ring section diameter)
$T = 337.59$ K, [Fill gas temperature = 147.44°F (64.44°C)]
$\mu = 0.02036$ cP, (Viscosity at temperature)
$M = 29$ g/g-mol. (Molecular weight of fill gas)

The average pressure is:

$$P_a = (P_u + P_d) / 2,$$
$$= (1.1615 + 0.0000) / 2,$$
$$= 0.5808 \text{ atm.} \quad \text{(Average pressure during NCT)}$$

According to ANSI N14.5-1997, the flow leakage hole diameter is unknown. Therefore, the mass-like leakage flow rate must be calculated to calculate the average leakage flow rate.

Q is the mass-like leakage for flow using the upstream leakage, L_u, and pressure, P_u:

$$Q = P_u L_u, \quad \text{(Eq. B1)}$$
$$L_u = L_N, \quad \text{(NCT leakage)}$$

$$Q = (1.1615) \text{ (atm) } (2.2878 \times 10^{-4}) \text{ (cm}^3\text{/s)},$$
$$= 2.6573 \times 10^{-4} \text{ atm-cm}^3\text{/s}, \quad \text{(NCT mass-like leakage rate)}$$

$$Q = P_a L_a, \quad \text{(Eq. B1)}$$

$$L_a = Q / P_a,$$
$$= 2.6573 \times 10^{-4} \text{ (atm-cm}^3\text{/s) / (0.5808) (atm)},$$
$$= 4.5755 \times 10^{-4} \text{ cm}^3\text{/s}. \quad \text{(NCT average leakage rate)}$$

Solve Eqs. B2–B4 from ANSI N14.5-1997:

$$L_a = (F_c + F_m) (P_u - P_d) \text{ cm}^3\text{/s}, \quad \text{(Eq. B2)}$$
$$= (F_c + F_m) (1.1615 - 0),$$
$$= (1.1615) (F_c + F_m) \text{ cm}^3\text{/s},$$

$$F_c = (2.49 \times 10^6) D^4 / (a \mu) \text{ (cm}^3\text{/atm-s)}, \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6) D^4 / [(0.3531) (0.02036)],$$
$$= (3.4642 \times 10^8) D^4 \text{ cm}^3\text{/atm-s},$$

$$F_m = (3.81 \times 10^3) D^3 (T / M)^{.5} / (a P_a) \text{ (cm}^3\text{/atm-s)}, \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3) D^3 (337.59 / 29)^{.5} / [(0.3531) (0.5808)],$$
$$= (6.3397 \times 10^4) D^3 \text{ cm}^3\text{/atm-s}.$$

From the mass-like leakage calculation:

$$L_a = 4.5755 \times 10^{-4} \text{ cm}^3\text{/s}. \quad \text{(NCT average leakage rate)}$$

Find the leakage hole diameter that sets:

$$L_2 = L_a.$$

Using the equations:

$$L_2 = (1.1615) (F_c + F_m) \text{ cm}^3\text{/s},$$
$$F_c = (3.4642 \times 10^8) D^4 \text{ cm}^3\text{/atm-s},$$
$$F_m = (6.3397 \times 10^4) D^3 \text{ cm}^3\text{/atm-s}.$$

To get a better guess on a new D, use:

$$D = D_2 (L_a / L_2)^{0.252}.$$

Now a guess must be made for D_2 to solve Eq. B2 for NCT:

D_2 = 0.001 cm, and solve for $L_a = 4.5755 \times 10^{-4}$ cm^3/s. (NCT average leakage rate)

Diameter	F_c	F_m	L_2	L_a / L_2
1.0000E-03	3.4642E-04	6.3397E-05	4.7602E-04	0.96120

The NCT leakage hole diameter for the HEU oxide content:

$D = 9.8976 \times 10^{-4}$ cm. (NCT diameter)

NCT Reference Air Leakage Rate for HEU Content Transported by Air

The leakage hole diameter found for the maximum allowable leakage rate for NCT will be used to determine the reference air leakage rate. O-ring seal leakage testing must ensure that no leakage is greater than the leakage generated by the hole diameter $D = 9.8976 \times 10^{-4}$ cm. Therefore, the NCT reference leakage flow rate ($L_{R, N}$) must be calculated to determine the allowable test leakage rate.

Input data for NCT reference air leakage rate:

$D = 9.8976 \times 10^{-4}$ cm, (From NCT)
$a = 0.3531$ cm, (Leak path length, 0.139-in. O-ring section diameter)
$P_u = 1.0$ atm, (Upstream pressure)
$P_d = 0.01$ atm, (Downstream pressure)
$T = 298$ K, (Fill gas temperature, 77°F)
$M = 29$ g/g-mol, (Molecular weight of air)
$\mu = 0.0185$ cP, (Viscosity of air at reference temperature)

Calculate P_a:

$$P_a = (P_u + P_d) / 2,$$
$$= (1.0 + 0.01) /2,$$
$$= 0.505 \text{ atm,} \quad \text{(NCT average pressure)}$$

$$F_c = (2.49 \times 10^6) D^4 / (a \mu) \text{ (cm}^3\text{/atm-s),} \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6) (9.8976\times 10^{-4})^4 / [(0.3531) (0.0185)],$$
$$= (3.8122 \times 10^8) (9.8976\times 10^{-4})^4,$$
$$= 3.6585 \times 10^{-4} \text{ cm}^3\text{/atm-s,}$$

$$F_m = (3.81 \times 10^3)\, D^3\, (T / M)^{.5} / (a\, P_a)\ (cm^3/atm\text{-}s), \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3)\, (9.8976 \times 10^{-4})^3\, (298 / 29)^{.5} / [(0.3531)\, (0.505)],$$
$$= (6.8501 \times 10^4)\, (9.8976 \times 10^{-4})^3,$$
$$= 6.6418 \times 10^{-5}\ cm^3/atm\text{-}s,$$

$$L_u = (F_c + F_m)\, (P_u - P_d)\, (P_a / P_u)\ (cm^3/s), \quad \text{(Eq. B5)}$$
$$= (3.6585 \times 10^{-4} + 6.6418 \times 10^{-5})\ (cm^3/atm\text{-}s)\ (1.0 - 0.01)\ (atm)\ (0.505 / 1.0),$$
$$= (4.3227 \times 10^{-4})\ (cm^3/atm\text{-}s)\ (0.49995)\ (atm),$$
$$= 2.1611 \times 10^{-4}\ cm^3/s.$$

The reference air leakage rate as defined in ANSI N14.5-1997, Sect. B.3, is the upstream leakage in air.

$$L_{RN,Air} = 2.1611 \times 10^{-4}\ ref\text{-}cm^3/s. \quad \text{(For HEU oxide content)}$$

The same equations can be used to calculate an allowable leakage rate using helium for leak testing.

$$M = 4\ g/g\text{-}mol, \quad \text{(Molecular weight of helium)}$$
$$\mu = 0.0198\ cP, \quad \text{(Viscosity of helium at temperature)}$$

$$F_c = (2.49 \times 10^6)\, D^4 / (a\, \mu)\ (cm^3/atm\text{-}s), \quad \text{(Eq. B3)}$$
$$= (2.49 \times 10^6)\, (9.8976 \times 10^{-4})^4 / [(0.3531)\, (0.0198)],$$
$$= (3.5619 \times 10^8)\, (9.8976 \times 10^{-4})^4,$$
$$= 3.4183 \times 10^{-4}\ cm^3/atm\text{-}s,$$

$$F_m = (3.81 \times 10^3)\, D^3\, (T / M)^{.5} / (a\, P_a)\ (cm^3/atm\text{-}s), \quad \text{(Eq. B4)}$$
$$= (3.81 \times 10^3)\, (9.8976 \times 10^{-4})^3\, (298 / 4)^{.5} / [(0.3531)\, (0.505)],$$
$$= (1.8444 \times 10^5)\, (9.8976 \times 10^{-4})^3,$$
$$= 1.7884 \times 10^{-4}\ cm^3/atm\text{-}s,$$

$$L_u = (F_c + F_m)\, (P_u - P_d)\, (P_a / P_u)\ (cm^3/s), \quad \text{(Eq. B5)}$$
$$= (3.4183 \times 10^{-4} + 1.7884 \times 10^{-4})\ (cm^3/atm\text{-}s)\ (1.0 - 0.01)\ (atm)\ (0.505 / 1.0),$$
$$= (5.2066 \times 10^{-4})\ (cm^3/atm\text{-}s)\ (0.49995)\ (atm),$$
$$= 2.6031 \times 10^{-4}\ cm^3/s.$$

The allowable leakage rate using helium for leak testing is:

$$L_{RN,\,He} = 2.6031 \times 10^{-4}\ cm^3/s.$$

The design verification tests were conducted following compliance tests in accordance with 10 CFR 71.71 and 71.73. The effectiveness of this closure system has been demonstrated by the NCT and HAC tests, which show that the complete containment system, including welds and O-ring seals, meet the leaktight criterion as defined in ANSI N14.5-1997 after the conclusion of the test series documented in ORNL/NTRC-013. This leaktight criterion is substantially below the above calculated results for air transport. Therefore, the requirements of 10 CFR Part 71.51(a)(1) are satisfied as well as the IAEA SSR-6 requirement of no loss or dispersal of radioactive contents from the containment system.

5. SHIELDING EVALUATION

This section describes the shielding evaluation performed for the shipment of up to 36 kg of highly enriched uranium (HEU) metal or 24 kg of HEU oxide powder in the ES-3100 shipping package. The objective of this evaluation is to demonstrate—for both normal conditions of transport (NCT) and hypothetical accident conditions (HAC)—compliance of this package with the performance requirements specified in Title 10, Part 71, of the Code of Federal Regulations (CFR) [10 CFR 71] and U.S. Department of Transportation (DOT) regulations for packaging and shipment of hazardous materials given in Title 49 CFR.

5.1 DESCRIPTION OF SHIELDING DESIGN

5.1.1 Design Features

The ES-3100 package for NCT consists of stainless-steel convenience cans loaded with HEU material, can spacer assemblies to support and position the convenience cans, the ES-3100 containment vessel (CV), and an insulation-filled drum as shown in Appendix 1.3.1. Calculations presented in Appendix 5.5.3 demonstrate from a shielding evaluation standpoint that there are minor statistical differences among the calculated dose rates for different source configurations using either the Kaolite or Packcrete impact-absorbing and thermal-insulating materials. Thus, the Kaolite shielding calculations in this chapter are considered to bound packages with Packcrete. None of the package materials are specifically designed for shielding gamma rays (photons), the primary contributor to external package dose rates for the specified source configurations. For NCT and HAC shielding calculations, the packing materials inside the CV are conservatively not modeled. It is assumed that the CV remains intact during HAC, but all the packaging materials external to the CV are removed. The geometry of the shielding analysis model is a conservative, cylindrical representation of the package.

Two sets of contents have been investigated for the shielding analysis. These are 36 kg of HEU metal and 24 kg of HEU oxide powder. The analyses of these models have been performed such that the results and conclusions cover other proposed contents in an equivalent or conservative manner. For the source calculation, the uranium is enriched at 92 wt % ^{235}U and is assumed to contain 0.6 wt % ^{233}U, 2.0 wt % ^{234}U, 1.0 wt % ^{236}U, 4.4 wt % ^{238}U, 2.5 wt % ^{237}Np, 40 parts per billion (ppb) ^{232}U, and 800 parts per million (ppm) weapons-grade plutonium to represent all other transuranic trace elements. The value of 800 ppm weapons-grade plutonium applies to ground transport only. Contents for air transport are limited to 40 ppm weapons-grade plutonium. There are two sources of the transuranic contamination in this HEU. First, much of this uranium originated from recycled material. Second, some uranium had plutonium components removed by machining or other processes, but left contamination. This contamination became mixed with the uranium as it was recast and used for other purposes.

5.1.2 Summary Table of Maximum Radiation Levels

The results of the shielding model evaluations, summarized in Tables 5.1 and 5.2, are the calculated dose rates at the locations indicated for the uranium metal and uranium oxide contents. These dose rates are based on the conservative assumption there is no packaging material except the content inside the CV. The side dose rates in Table 5.1 for the HEU metal content are maximized by assuming the content in the hemi-shell configuration. The top and bottom dose rates for the HEU metal content are maximized by assuming the content in the form of a cylinder at the top or at the bottom of the CV, respectively. For the HEU oxide content, the side drum surface photon dose rate presented in Table 5.2 is from the solid cylindrical configuration of 47.365 cm height and density of 4.0 g/cm^3. The 1 m from the side surface photon dose rates for the NCT and HAC are from the cylindrical shell configuration of 2.6275 cm inner radius, 6.35 cm outer radius, 76.2 cm height, and density of 3.0 g/cm^3. The neutron side dose rates are from the solid cylinder at the top of the CV configuration with a density of 10.96 g/cm^3. The top and bottom dose rates are from the cylinder type configuration with a density of 10.96 g/cm^3 at the top and bottom of the CV configurations, respectively. The uncertainty associated with the results is one standard deviation of the mean (i.e., one sigma uncertainty expressed as a percentage of the mean) calculated using the MCNP Monte Carlo code (LA-UR-03-1987). The shielding evaluation demonstrates the package with HEU metal or HEU oxide content meets all dose-rate limits as specified in 10 CFR 71.47(a) and 49 CFR 173.441(a) for NCT and 10 CFR 71.51(a)(2) for HAC, as shown by the dose rates in Tables 5.1 and 5.2 and the information in Sect. 5.3. The maximum radiation level at the package surface is measured when it is presented for transport. The maximum radiation level at 1 m from the external surface will also be measured to establish the transport index (TI) for the package. The calculated TI values are 6.2 and 5.1 for the HEU metal and HEU oxide contents, respectively. The measured dose rates are expected to be much lower than the calculated dose rates due to conservatism and bounding nature of the calculations. The measured radiation levels are evaluated against the allowable radiation levels prescribed in 10 CFR 71.47 and 49 CFR 173.441.

5.2 SOURCE SPECIFICATION

The principal source for the calculated dose rates is the decay of the radioactive isotopes. There is also neutron and photon production from spontaneous and neutron-induced fissions, secondary photon generation, and [alpha (α), n] reactions in trace element impurities. The isotopic content used in the shielding calculations is shown in Table 5.3. ^{237}Np and transuranic (2.58 wt % combined in Table 5.3) are conservatively added to the source term without increasing the content mass. A trace amount of ^{232}U (40 ppb), which significantly increases the dose rate, is also added to the source term. This composition was chosen to represent all proposed package contents described in Sect. 1.2.2. The uranium metal source is assumed to be the same as that for the oxides per unit HEU mass. Details of the source specifications and their use in the dose-rate calculations are provided in Appendix 5.5.1.

Table 5.1. Calculated external dose rates for the ES-3100 package with 36 kg of HEU metal contents

[a] Side drum surface photon dose rate is from the solid cylindrical configuration (height = 47.365 cm and density = 4.0 g/cm^3 sitting at the bottom of the CV). The 1 m from the side surface photon dose rates for the NCT and HAC are from the cylindrical shell configuration (inner radius = 2.6275 cm, outer radius = 6.35 cm, height = 76.2 cm, and density 3.0 g/cm^3). The neutron side dose rates are from the solid cylinder (density = 10.96 g/cm^3) at the top of the CV configuration. The top and bottom photon and neutron dose rates are from the cylinder-type configurations (density = 10.96 g/cm^3) at the top and bottom of the CV, respectively.

[b] MCNP5 Monte Carlo code results (LA-UR-03-1987). The uncertainty associated with the results is one standard deviation of the mean (i.e., one sigma uncertainty expressed as a percentage of the mean) calculated using MCNP5.

[c] One meter from the drum for NCT and one meter from the CV for HAC.

[d] Includes secondary photon dose rate (<1% of neutron dose rates).

[e] The radiation shielding transport index is 5.1.

[f] Nonexclusive use radiation dose limit in accordance with 10 CFR 71.47(a) and 49 CFR 173.441(a).

[g] Not applicable.

[h] Radiation dose limit in accordance with 10 CFR 71.51(a)(2).

Table 5.3. Radioisotope composition for all ES-3100 package analysis source calculations with HEU content and other nuclides per HEU unit weight

Isotope	wt % [a]
^{232}U	0.000004
^{233}U	0.600000
^{234}U	2.000000
^{235}U	92.000000
^{236}U	1.000000
^{238}U	4.399996
^{237}Np	2.500000
Transuranic [b]	0.080000
Total	102.58

[a] ^{237}Np and transuranic are added to the uranium source composition without adding their weights in the source mass calculations.

[b] The transuranic contents are: 1.60×10^{-5} wt % ^{238}Pu, 7.41×10^{-2} wt % ^{239}Pu, 5.20×10^{-3} wt % ^{240}Pu, 4.48×10^{-4} wt % ^{241}Pu, 3.20×10^{-5} wt % ^{242}Pu, and 2.40×10^{-4} wt % ^{241}Am. ^{237}Np and transuranic are added to the uranium source composition without adding their weights.

5.2.1 Gamma Source

The photon source is calculated by the Standardized Computer Analysis for Licensing Evaluation (SCALE) module of ORIGEN-S (NUREG/CR-0200, Vol. II, Sect. F7) as a function of the 47 energy group photon spectrum and decay time. Additional information about ORIGEN-S methodology and input is available in Appendix 5.5.1. It is shown that the photon spectrum around 10.5 years decay time provides maximum photon dose rates, and the spectra are given in Table 5.4. Figure 5.1 shows the photon spectrum for ^{232}U and the total source composition including ^{232}U. In Table 5.4, the photon source for the 38th energy group (2.6 – 2.7 MeV) is 1.062×10^4 photons/s/g. Figure 5.1 shows that this photon source comes from ^{232}U and this phenomenon is a result of the ^{232}U daughter product (i.e., ^{208}Tl) decaying to ^{208}Pb. This 38th energy group photon source contributes most of the calculated photon dose rates presented in Tables 5.1 and 5.2. The photon spectrum computed by ORIGEN-S includes photons arising from X-rays, gamma-rays, internal bremsstrahlung, spontaneous fission gamma-rays, and gamma-ray accompanying (α, n) reactions.

Table 5.4. Photon source for 1 g of HEU for all contents

Group number	Energy range (MeV)	Source [a] (photons/s)

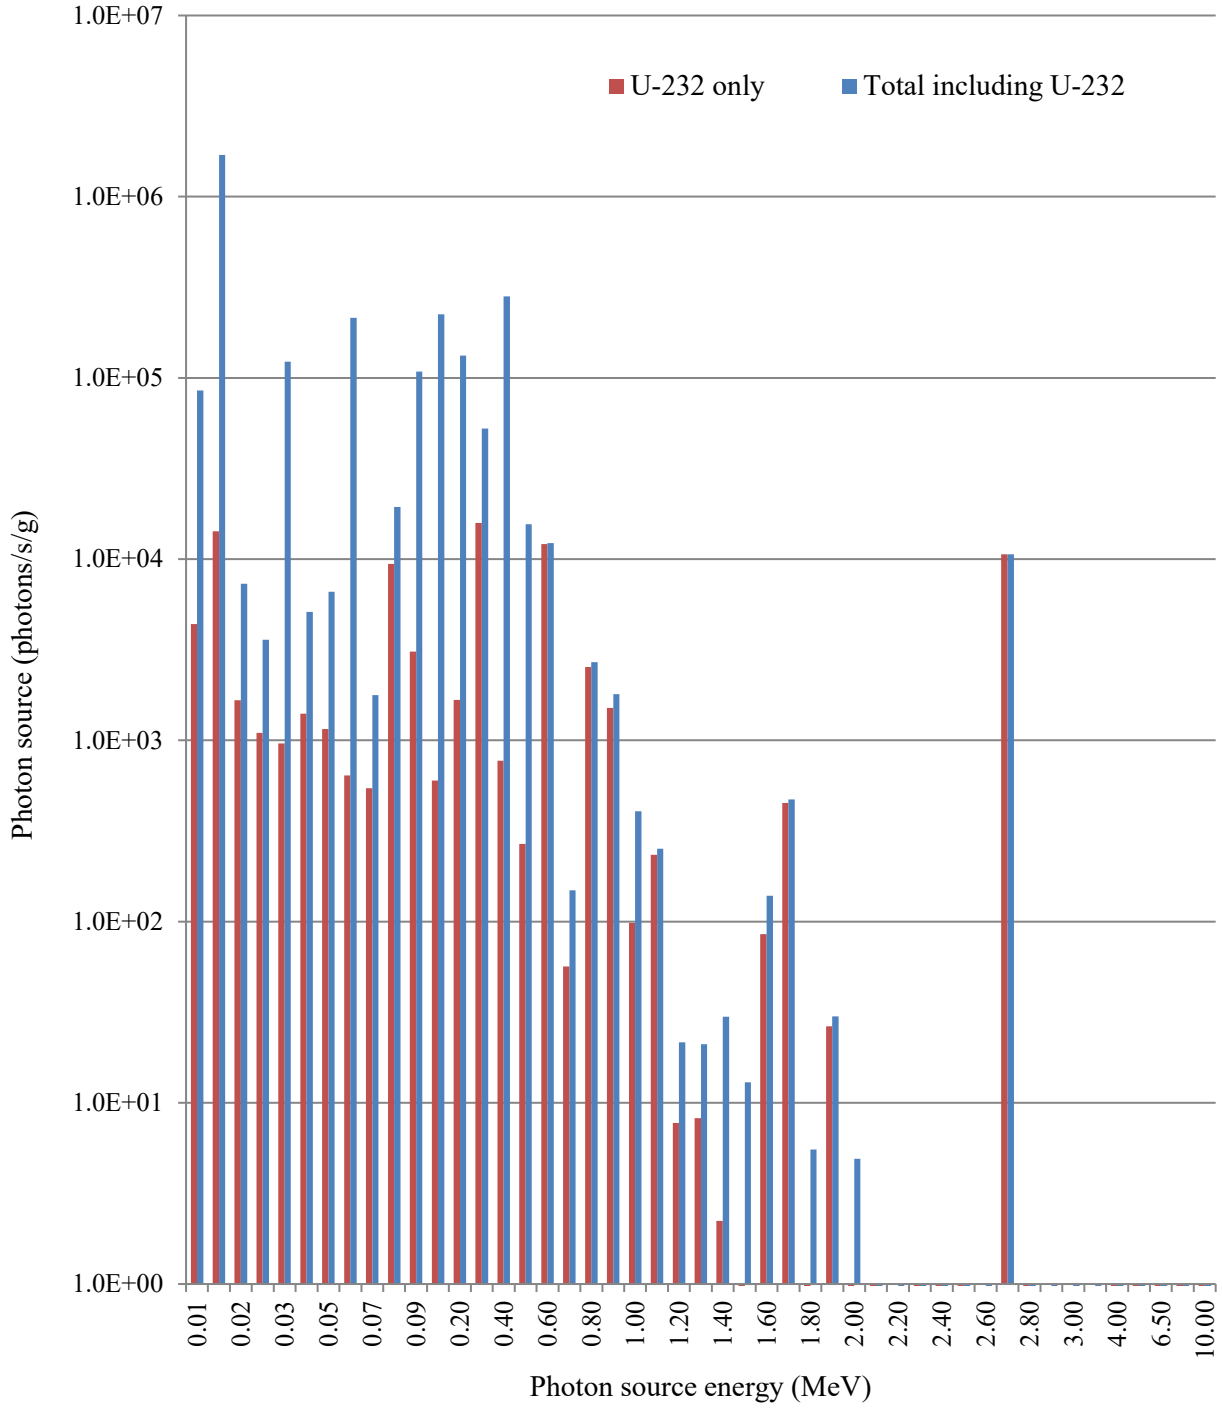

Fig. 5.1. Photon spectrum for ^{232}U only and HEU content including ^{232}U.

5.2.2 Neutron Source

The neutron source given in Table 5.5 is generated using ORIGEN-S as a function of the 27 energy group neutron spectrum and decay time. It is shown that the neutron spectrum around 50 years decay time provide maximum neutron dose rates. Figure 5.2 shows the neutron spectrum for different neutron source constituents. Figure 5.2 shows transuranic components contribute most of the neutron source spectrum, particularly at higher energy intervals. Neutron source from the spontaneous fission, (α, n), and delayed neutrons are included in Table 5.5 spectrum. Induced fission neutrons and secondary photons are included in the dose rate calculations. Oxygen was not included in the uranium oxide source calculation, but the neutron source includes (α, n) neutrons from the UO_2 default option in the ORIGEN-S code (NUREG/CR-0200, Vol. II, Sect. F7). The production of neutrons from subcritical multiplication is calculated as part of the shielding evaluation by using the default option (i.e., no NONU card in the MCNP input file). If the NONU card is not used, all cells are given their regular treatment of real fission. The neutrons are captured by the fissile and fissionable materials producing neutron-induced fissions.

Table 5.5. Neutron source for 1 g of HEU for all contents

Group number	Energy range (MeV)	Source [a] (neutrons/s)
1–17	$1.00 \times 10^{-11} – 5.83 \times 10^{-4}$	0 [b]
18	$5.83 \times 10^{-4} – 3.04 \times 10^{-3}$	7.034×10^{-6}
19	$3.04 \times 10^{-3} – 1.50 \times 10^{-2}$	8.280×10^{-5}

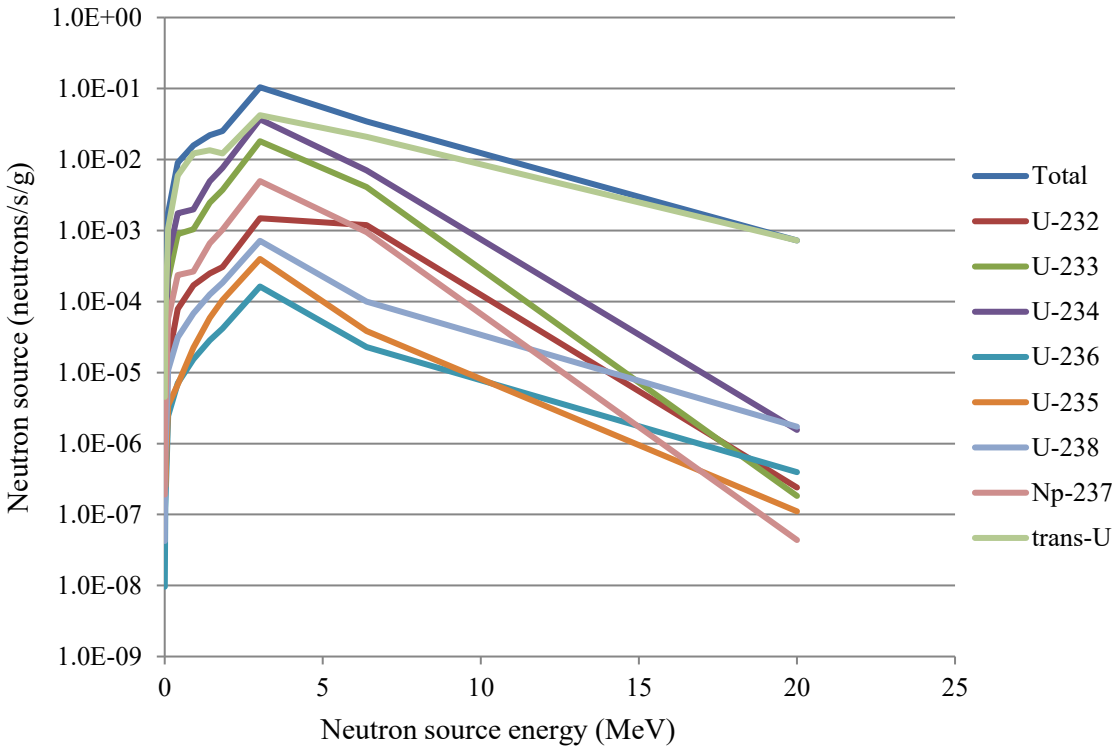

Fig. 5.2. Neutron spectrum for HEU source composition.

5.3 SHIELDING MODEL

The geometry of the shielding analysis model inside the CV is conservative because no packing materials besides the content are included in the model. The analyzed package contents are (a) 36 kg of HEU metal and (b) 24 kg of HEU oxide. The 36 kg of HEU metal analyzed are in the form of a solid cylinder, cylindrical shell, vertical plate, cylindrical hemi-shell, single solid rod, and cylindrical segment. The HEU metal in the form of a cylinder with the same radius as the CV is moved to the bottom and top of the CV for the maximum bottom and top dose rate configurations. The HEU metal in all configurations mentioned are analyzed for the maximum side dose rates. The 24 kg of HEU oxide powder analyzed are in cylindrical and cylindrical-shell forms of varying height and density. The material with maximum density in cylindrical shape and with the same radius as the CV is moved to the bottom and top of the CV for the maximum bottom and top dose rate configurations for the HEU oxide. The worst cases at the bottom, side, and top dose rates for the HEU metal and oxide are presented in Tables 5.1 and 5.2, and are assumed to bound any possible source configuration for the container.

Three-dimensional detailed geometric models are created to calculate the dose rates external to the ES-3100 shipping package when loaded with each of the configurations outlined in Sect. 5.3.1. Figure 5.3 presents the packaging without any content. The details of several sections of the packaging are shown in Figs. 5.4, 5.5, and 5.6. The shielding model of the ES-3100 package is represented in the MCNP Monte Carlo radiation transport code to perform the photon and neutron transport and dose rate calculations (LA-UR-03-1987) for these configurations. Dose rates are calculated in by converting the photon and neutron fluxes using the American National Standards Institute and American Nuclear Society conversion factors (ANSI/ANS-6.1.1).

5.3.1 Configuration of Source and Shielding

The photon and neutron sources from the radioactive contents described in the previous section and listed in Tables 5.4 and 5.5, are input to the MCNP code to calculate the ES-3100 external package dose rates given in Tables 5.1, 5.2, and 5.7.

The packaging component drawings are shown in Appendix 1.3.1. The package contents analyzed are (a) 36 kg of HEU metal and (b) 24 kg of HEU oxide. The analyses of these models have been performed in a manner covering all other proposed contents identified in Sect. 1.2.2 in an equivalent or conservative manner. Figure 5.7 shows the NCT and HAC calculation models in MCNP for cylinder type HEU metal source configuration. Figure 5.8 shows the NCT calculation model for UO_2 source configuration.

There are no radiation streaming paths from the source toward the package exterior. The models are analyzed for both photon and neutron sources, and for both NCT and HAC. Table 5.6 lists the locations of the external dose-rate detectors for the NCT and HAC models. For NCT, dose rates are calculated at detector locations that are identified by their distance from the external surface of the drum (1 mm and 1 m from the external surface of the drum). All components outside the CV are removed for HAC shielding models and the detector locations are modeled as if they were 1 m from the external surface of the CV. Additional information on the models is presented in Appendices 5.5.1 and 5.5.2.

The dose rates presented in Tables 5.1 and 5.2 should bound the dose rates for all proposed content loadings in the ES-3100. In some cases, it is not possible or practical to find an exact maximum dose rate geometric configuration due to the statistical uncertainty of the calculation method, variations in model radius vs. height, variable densities, source configuration, etc. The presence of 800-ppm transuranic trace elements has no effect on the photon dose rates. Although it has significant effects on the neutron dose rates, the neutron dose rates constitute only 2.0% or less of the total dose rates.

[c] Locations are relative to the drum for NCT and relative to the containment vessel for HAC.
[d] Surface side location is at the axial mid-point of the content height.

5.3.1.1 Photon model for 36-kg HEU metal content

The HEU metal content in the ES-3100 may be many small, irregularly shaped pieces, each placed at some arbitrary orientation inside the convenience cans. Several conservative, regular geometry models have been devised to cover these and other proposed loadings. The convenience cans and can spacers are omitted from the models and these assumptions are conservative.

Six geometric models inside the CV are analyzed to calculate the liming dose rates for HEU metal content. The geometric configurations are solid cylinder (Fig. 5.9), cylindrical hemi-shell (Fig. 5.10), cylindrical shell (Fig. 5.11), plate (Fig. 5.12), single rod (Fig. 5.13), and cylindrical segment (Fig. 5.14). The figures show the sectional views of these configurations. The 1 mm and 1 m from the drum side surface and 1 m from the CV side surface dose rates with uncertainty for these configurations are presented in Table 5.7. The cylindrical hemi-shell configuration produces the maximum NCT and HAC side photon dose rates, which are presented in Table 5.1. Brief descriptions of the six configurations are discussed below.

Solid cylinder configuration: A solid uranium metal cylinder of 6.35 cm radius and 15.1003 cm height is placed either at the top or at the bottom of the CV. The solid cylinder at the top configuration produces the maximum photon dose rates at the: (1) 1 mm and 1 m from the top surface for NCT and (2) 1 m from the top CV surface for HAC. This top configuration also produces the maximum neutron dose rates at the: (1) 1 mm and 1 m from the drum top and side surface for NCT and (2) 1 m from the CV top and side surface for HAC. The solid cylinder at the bottom configuration produces the maximum photon dose rates at the: (1) 1 mm and 1 m from the drum bottom surface for NCT and (2) 1 m from bottom CV surface for HAC. This bottom configuration also produces the maximum neutron dose rates at the: (1) 1 mm and 1 m from the drum bottom surface for NCT and (2) 1 m from CV bottom surface for HAC. These maximum dose rates are presented in Table 5.1. The side and top sections of the solid cylinder configuration are shown in Fig. 5.9.

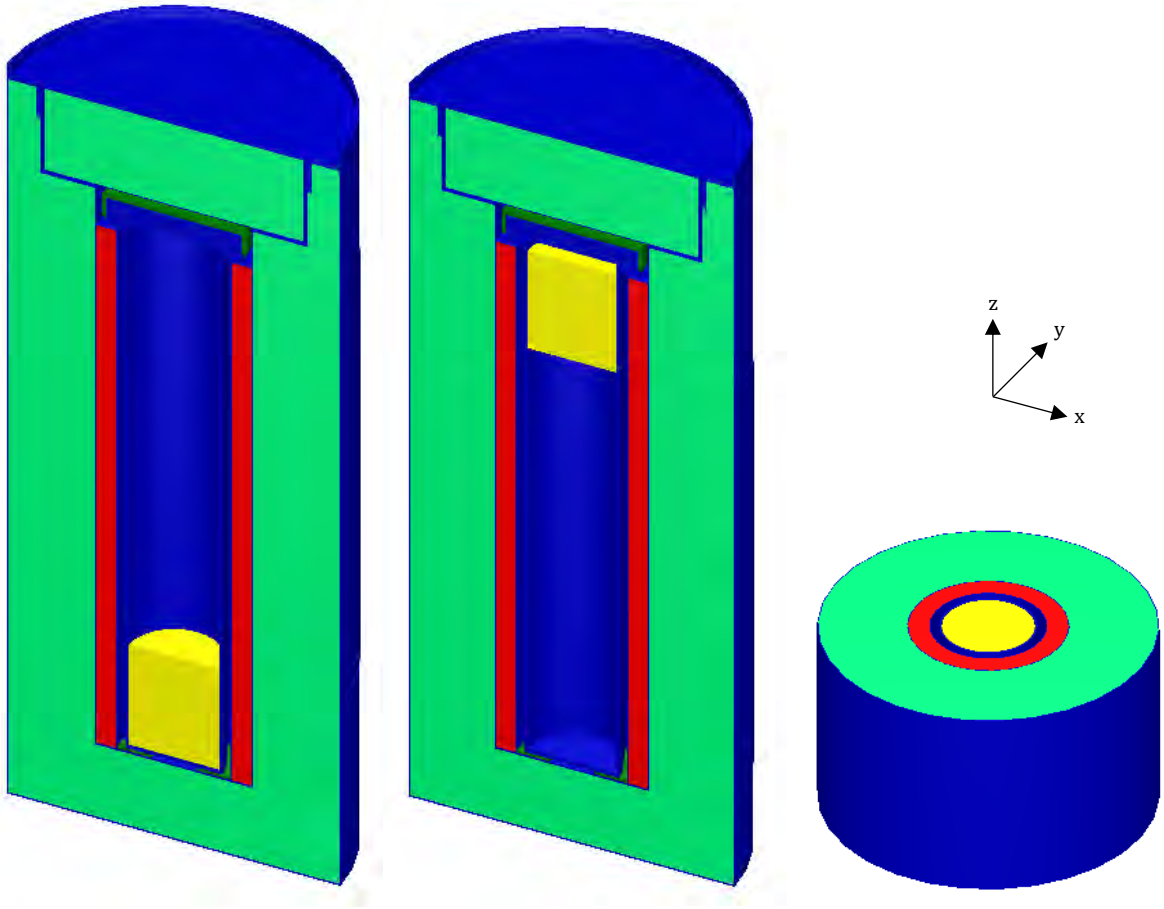

Fig. 5.9. Calculation model of the ES-3100 shipping package for NCT with cylinder type source configuration shown in yellow (x-z side and x-y top sections).

Cylindrical hemi-shell configuration: A cylindrical hemi-shell of 4.9337 cm inner radius, 6.35 cm outer radius, and 76.2 cm height with interior opening inward is placed inside the CV along +x axis. This configuration produces the maximum photon dose rates at the: (1) 1 mm and 1 m from the drum side for NCT, and (2) 1 m from the CV side surface for HAC. These dose rates are presented in Table 5.1. The side and top sections of the cylindrical hemi-shell calculation model are shown in Fig. 5.10.

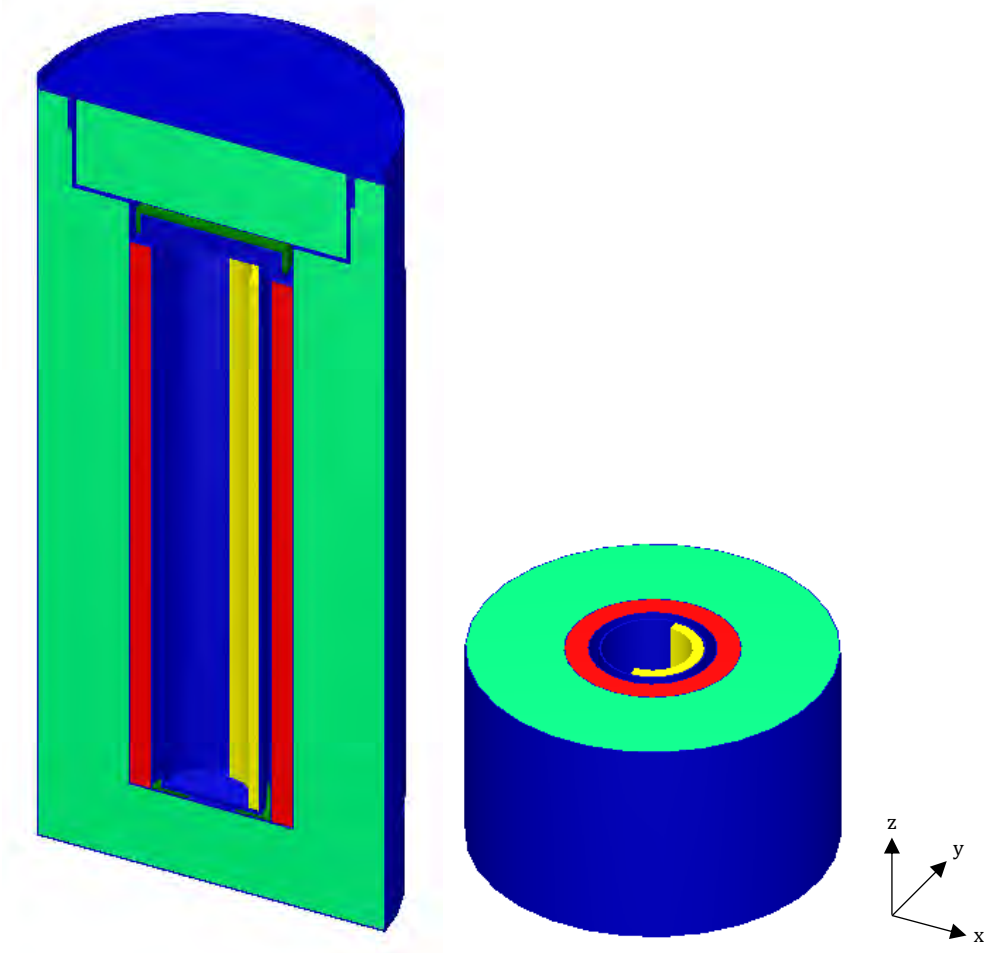

Fig. 5.10. Calculation model of the ES-3100 shipping package for NCT with cylindrical hemi-shell source configuration shown in yellow (x-z side and x-y top sections).

Cylindrical shell configuration: A cylindrical shell of variable inner radius and height with 6.35 cm outer radius is placed inside the CV for investigating side surface dose rates. The shell of 5.6861 cm inner radius and 76.2 cm height produces the maximum NCT dose rates at 1 mm and 1 m from the drum side surface and the HAC dose rates at 1 m from the CV surface for the cylindrical shell configuration. The side and top sections of the cylindrical shell calculation model are shown in Fig. 5.11.

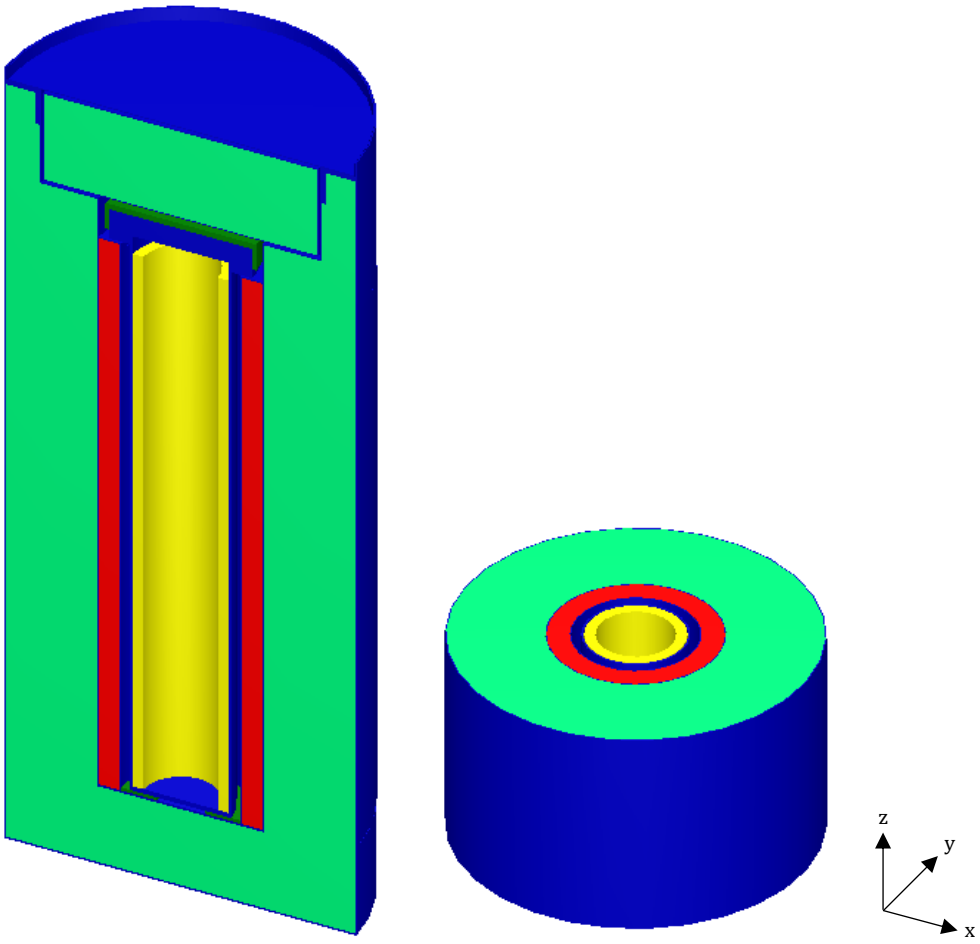

Fig. 5.11. Calculation model of the ES-3100 shipping package for NCT with cylindrical shell source configuration shown in yellow (x-z side and x-y top sections).

Rectangular plate configuration: A rectangular plate of 1.9829 cm width, 12.66 cm length, and 76.2 cm height is placed along the centerline on the y-axis. The NCT 1 mm and 1 m from the drum side surface, and the HAC 1 m from the CV side surface dose rates are calculated and presented in Table 5.7. The side and top sections of the plate calculation model are shown in Fig. 5.12.

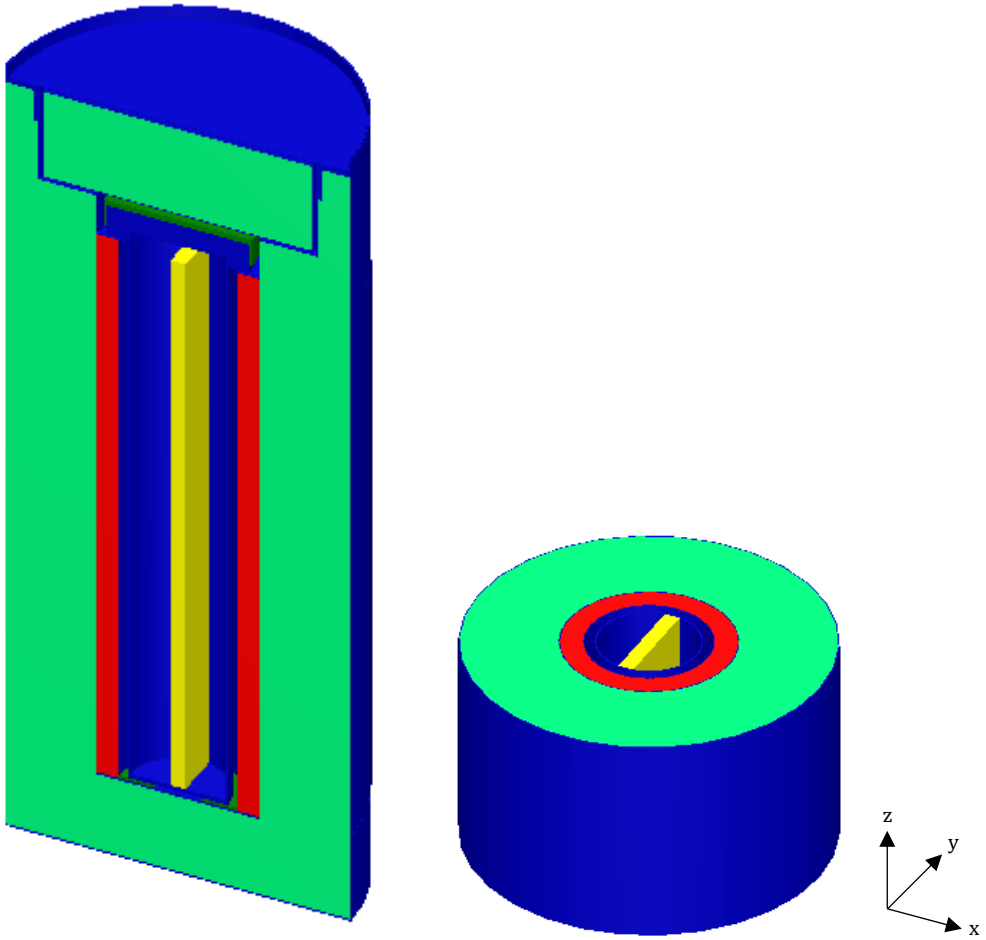

Fig. 5.12. Calculation model of the ES-3100 shipping package for NCT with plate type source configuration shown in yellow (x-z side and x-y top section).

Cylindrical rod configuration: A cylindrical rod of 2.82675 cm radius and 76.2 cm length is placed along x-axis close to the CV. The NCT 1 mm and 1 m from the drum side surface, and the HAC 1 m from the CV side surface dose rates are presented in Table 5.7. The side and top sections of the cylindrical rod calculation model are shown in Fig. 5.13.

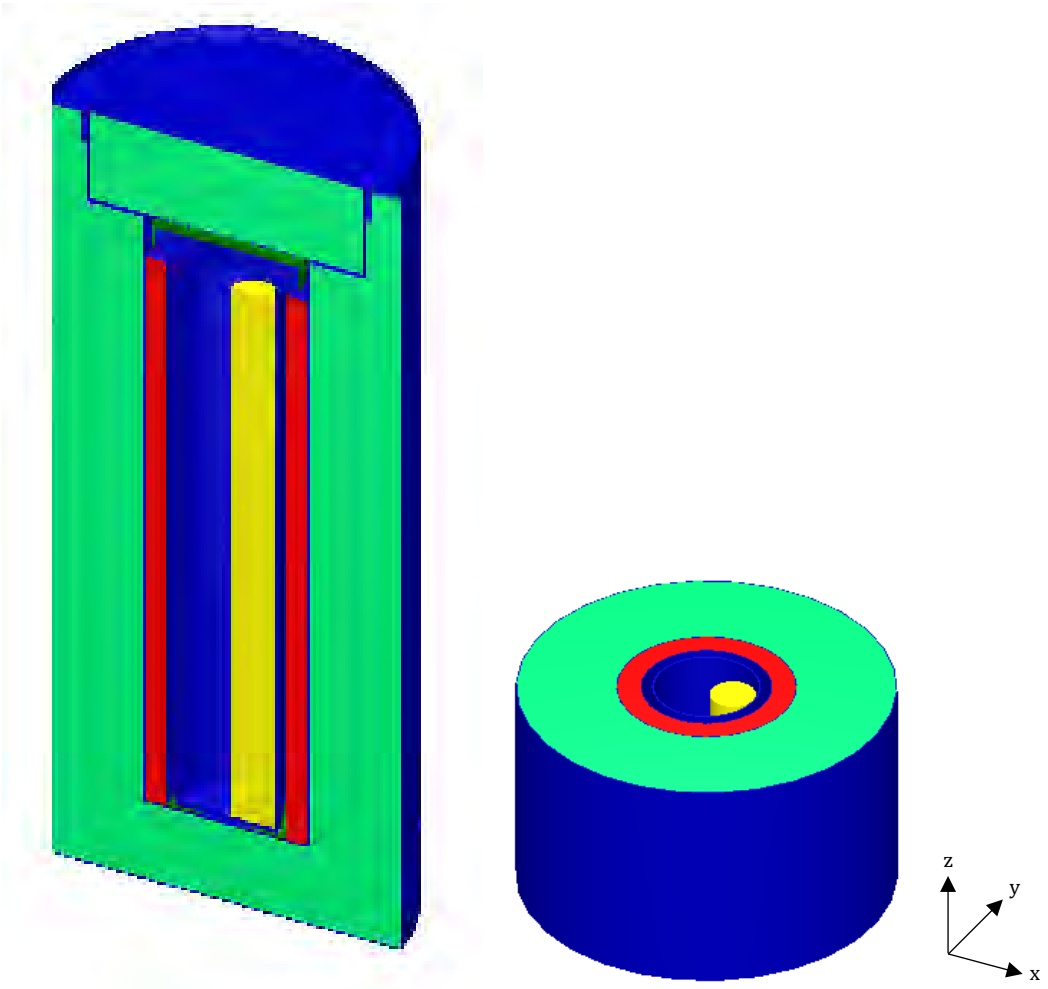

Fig. 5.13. Calculation model of the ES-3100 shipping package for NCT with single rod source configuration shown in yellow (x-z side and x-y top sections).

Cylindrical segment configuration: A cylindrical segment of 6.35 cm radius and 76.2 cm height, which is 3.1442 cm off from the center, is placed along x-axis close to the CV. The NCT 1 mm and 1 m from the drum side surface, and the HAC 1 m from the CV side surface dose rates are presented in Table 5.7. The side and top sections of the cylindrical segment calculation model are shown in Fig. 5.14.

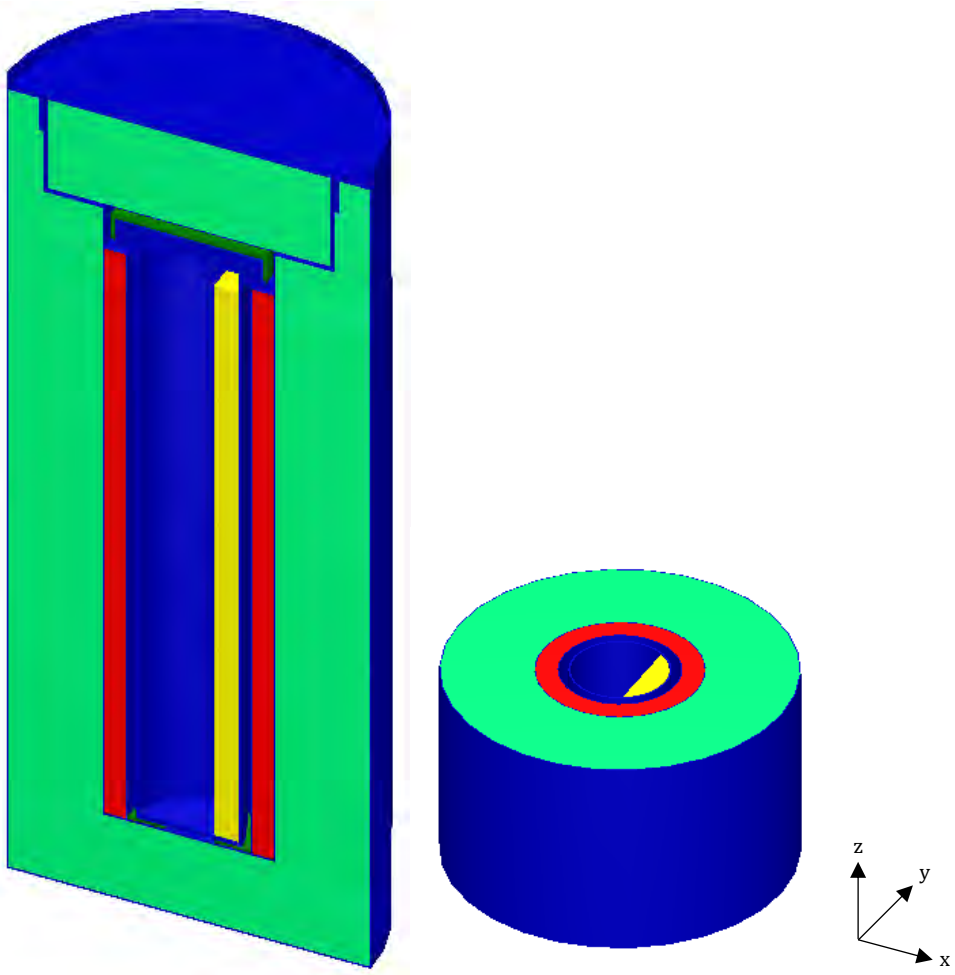

Fig. 5.14. Calculation model of the ES-3100 shipping package for NCT with cylindrical segment source configuration shown in yellow (x-z side and x-y top sections).

[a] MCNP5 Monte Carlo code results (LA-UR-03-1987). The uncertainty associated with the results is one standard deviation of the mean (i.e., one sigma uncertainty expressed as a percentage of the mean) calculated using MCNP5.
[b] Height is 76.2 cm for all configurations except solid cylinders at the top or bottom of CV.
[c] Includes secondary photon.

Table 5.7 shows the cylindrical hemi-shell configuration produces the maximum NCT and HAC side dose rates. The variations in dose rates described here are due to the variations in source-detector point geometry and the self-absorption of photons in the source material. Figures 5.15, 5.16, and 5.17 show photon dose rate and the associated absolute uncertainty contours for the cylindrical hemi-shell source configuration. The photon dose contours for the cylinder source configurations at the top and bottom of the cylinder are shown in Figs. 5.18 and 5.19. The photon dose rate contours for the rectangular plate source configuration in the x-z and y-z planes are shown in Figs. 5.20 and 5.21. The calculated dose rates for 36-kg HEU metal or 24-kg HEU oxide content defined in Table 5.3 are not close to the regulatory limits.

5.3.1.2 Neutron model for 36-kg HEU metal content

For the NCT and HAC neutron top and bottom dose rate calculations for the 36-kg HEU contents, it was assumed all the uranium was a solid cylinder (i.e., radius = 6.35 cm, height = 15.1003 cm, and density = 18.82 g/cm^3) at the bottom or at the top of the CV. These configurations produce the maximum neutron top and bottom dose rates for both NCT and HAC. The results are presented in Table 5.1. The NCT and HAC neutron side dose rates are calculated for six different geometric configurations: solid cylinder (Fig. 5.9), cylindrical hemi-shell (Fig. 5.10), cylindrical shell (Fig. 5.11), plate (Fig. 5.12), single rod (Fig. 5.13), and cylindrical segment (Fig. 5.14). The side neutron dose rates for these configurations are presented in Table 5.7. The neutron dose rate and the associated absolute uncertainty contours for the cylindrical hemi-shell source configuration are shown in Figs. 5.22 and 5.23. The combined neutron and photon side dose rates for these configurations are also presented in Table 5.7. The combined side dose rates for NCT and HAC are the highest for the cylindrical hemi-shell configuration and is presented in Table 5.1.

5.3.1.3 Photon model for 24-kg HEU oxide content

The photon dose rate calculation model was developed to apply to 24 kg of HEU oxide content for all three common uranium oxides (i.e., UO_2, UO_3, and U_3O_8). The theoretical densities for these oxides are 10.96 g/cm^3, 7.29 g/cm^3, and 8.30 g/cm^3, respectively. In the package loading models, the convenience can locations are completely filled with oxide powder, and the actual densities, always less than theoretical values, will be the oxide mass divided by the model can volume. The dose rate model excludes the convenience cans, and it is represented by a solid cylinder of oxide resting on the CV interior base. The cylinder radius is 6.35 cm, and the height is variable. The density is adjusted for each calculation to preserve the 24-kg oxide mass. The HEU mass is 21.126 kg for UO_2, the largest uranium mass of the three oxides for 24 kg of HEU oxide. For side dose rate calculations, cylindrical shell with varying shell thickness and height with different UO_2 density from 2.5 to 10.96 g/cm^3 while maintaining the oxide mass of 24 kg have also been analyzed. Different configurations are analyzed to get the maximum dose rates that are presented in Table 5.2. The dose rates presented in Table 5.2 will also bound the dose rates from lower density oxides (i.e., <2.5 g/cm^3) and the oxide mass will be lower than 24 kg due to volumetric limitations inside the CV.

The photon NCT side dose rate is for a UO_2 cylinder of 47.365 cm height and 4.0 g/cm^3 density. The 1-m side NCT and side HAC photon dose rates are from the cylindrical shell configuration of 2.6275 cm inner radius, 6.35 cm outer radius, 76.2 cm height, and density of 3.0 g/cm^3. The top and bottom NCT and HAC photon dose rates are from the UO_2 solid cylinder configuration of density 10.96 g/cm^3 at the top and bottom of the CV, respectively. Figure 5.24 shows the photon dose-rate contours for the UO_2 cylinder of 75.785 cm height, 6.35 cm radius, and 2.5 g/cm^3 density.

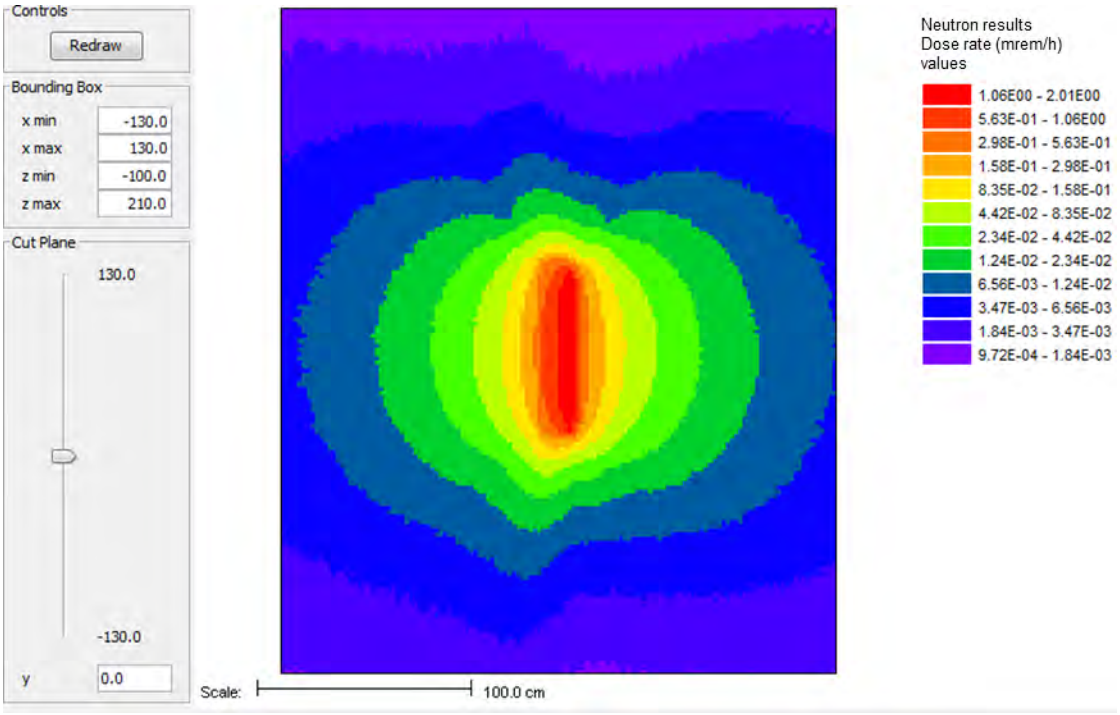

Fig. 5.22. Neutron dose rate contours for the cylindrical hemi-shell configuration (x-z plane).

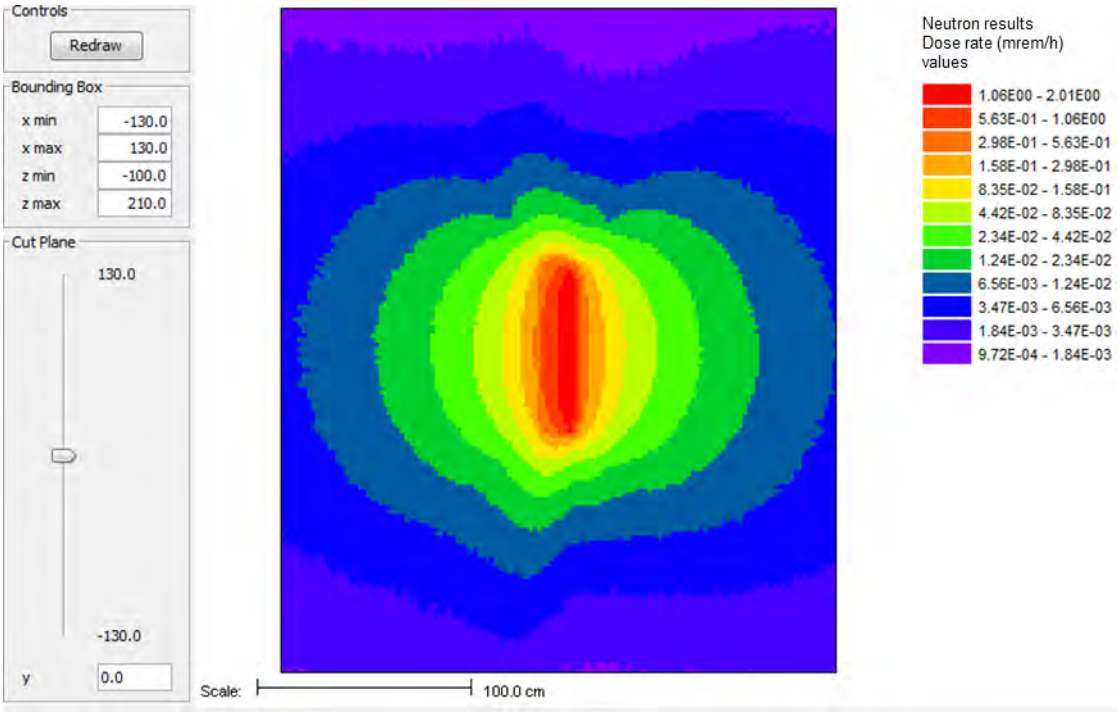

Fig. 5.23. Neutron dose rate absolute uncertainty contours for the cylindrical hemi-shell configuration (x-z plane).

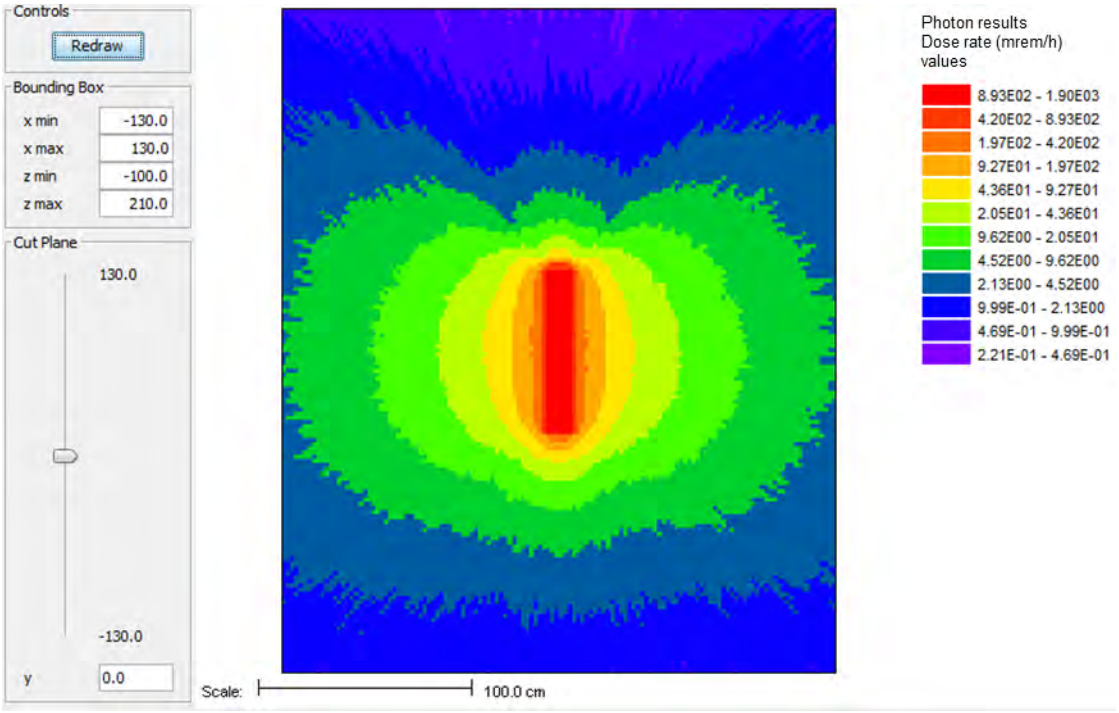

Fig. 5.24. Photon dose rate contours for the UO_2 cylindrical powder configuration of 75.785 cm height and 6.35 cm radius (x-z plane).

5.3.1.4 Neutron model for 24-kg HEU oxide content

The neutron model for the calculated dose rate is a solid cylinder of UO_2 of 6.35 cm radius either at the bottom or at the top of the CV. The density of UO_2 used in the model is 10.96 g/cm^3 and the height is 17.286 cm. The top and bottom NCT and HAC neutron dose rates are calculated by placing the UO_2 cylinder at the top and bottom of the CV, respectively. The side NCT and HAC neutron dose rates are from the UO_2 solid cylinder of density at the top of the CV. The oxide mass in a cylindrical shape is the only analyzed configuration for neutron dose rate contribution since the uranium oxides are in powder form and the contribution of neutron dose rate is <1% of the combined (photon and neutron) dose rate.

5.3.1.5 Containment vessel O-rings dose rate

The dose rate at the location of the CV O-rings is calculated for HEU metal case with cylindrical type fuel configuration at the top of the CV. Figure 5.25 shows the location of the O-rings. The radial and height locations of the point detector calculation point are 6.8 cm and 91.20 cm, respectively. The calculated photon dose rate is 483.92 mrem/h, and the neutron and secondary photon dose rate combined is 16.33 mrem/h. The calculated combined dose rate with 3σ uncertainty at the O-ring is 506.5 mrem/h. Using a 1-rad/rem conversion factor, which is applied to the photon dose rate and conservatively applied to the relatively low neutron dose rate, the maximum total calculated dose rate at the O-ring location is ~0.5 rad/h. The O-ring location dose rate for the HEU metal case bounds that for the HEU oxide case.

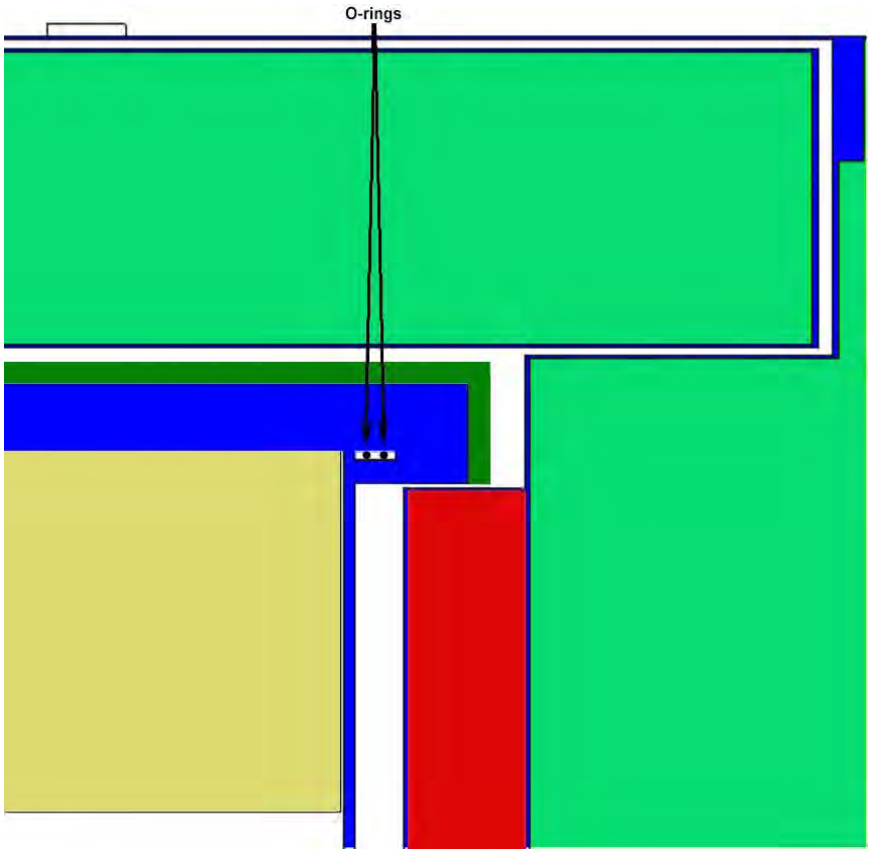

Fig. 5.25. Calculation model of the ES-3100 shipping package for NCT with cylinder type configuration at the top of CV for dose rate calculations at O-rings (x-z side section).

5.3.1.6 Effects of impurities

The content may contain radioactive and nonradioactive material as impurities. The presence of ^{232}U, ^{233}U, ^{234}U, ^{236}U, ^{237}Np, and plutonium contents is conservatively included in the source-term calculations (Table 5.3). The nonradioactive impurities, if any are present, do not affect the photon source term. The neutron dose rate is negligible in comparison to the total dose rate presented in Tables 5.1 and 5.2. Therefore, it can be concluded that the presence of nonradioactive impurities does not significantly affect the total dose rates presented in Tables 5.1 and 5.2.

5.3.1.7 Conservative features of the packaging model

Several conservative features are included in the model. All dimensions and densities of the packaging materials are modeled as equal to or less than specified or nominal values. The content is modeled conservatively to calculate the side, top, and bottom dose rates (Sect. 5.3.1). All packaging materials inside the CV are neglected. The convenience cans, can spacers, content wrappings, covers, supports, etc., are omitted. The CV model, therefore, contains HEU material content only. For HEU oxide cases, all contents are modeled as cylinders or cylindrical shells with the base resting on the lower CV surface with a maximum specified radius of 6.35 cm (the maximum allowable convenience can diameter is 5 in.) and with a height, inner radius (if any), and density adjusted for each specific model to preserve the content mass. In this conservative manner, it is possible to cover all specified combinations of can loadings and can and spacer placements with a minimum number of calculations. The geometric configuration of some of the cases investigated represents a situation where the maximum

possible mass loading for a convenience can would be exceeded if the cans had been included in the model. The calculated dose rates from the models used, however, will always exceed those from a model where the geometry is expanded so the can mass loadings are not exceeded and the internal CV hardware is included.

5.3.2 Material Properties

The material properties for the ES-3100 package shielding models are shown in Table 5.8. Kaolite and Packcrete are impact-absorbing and thermal-insulating materials and Cat 277-4 is a neutron-attenuating material used in the ES-3100 package. Additional information on these materials can be found in Chapters 1, 2, and 6.

[b] Comparative analyses for Kaolite and Packcrete are provided in Appendix 5.5.3.

5.4 SHIELDING EVALUATION

5.4.1 Methods

Two computer programs were used in the shielding evaluation: ORIGEN-S and MCNP5. Both are stand-alone codes. Brief descriptions of the programs are presented below.

1. ORIGEN-S (NUREG/CR-0200, Vol. II, Sect. F7) is a general depletion and decay code. Given an initial isotopic distribution, materials are decayed to provide time-dependent, energy-grouped photon and neutron sources.

2. MCNP5 (LA-UR-03-1987) is a general-purpose Monte Carlo transport code that treats multidimensional neutron, photon, and coupled problems. MCNP5 and the cross section library used for the materials in this analysis are based on Evaluated Nuclear Data Files VII cross sections for neutrons and MCPLIB04 for photons.

A Type 5 point detector tally was used for calculating the photon and neutron dose rates for NCT and HAC. These dose rates are reported in Tables 5.1, 5.2, and 5.7. Type 4 tally dose rates (segmented volume detectors) for neutrons and photons are also calculated from tally cells, each of 1 cm height, arranged around the package surface and at 1 m from the external surface of the drum for NCT and HAC side doses for symmetrical source distribution cases. Volume detectors are also used at the top and bottom surfaces and at 1m from the external top and bottom surfaces for symmetrical source distribution cases. The volume detector tallies are used only to compare the Type 5 point detector tally dose rates.

5.4.2 Input and Output Data

Sample input files are shown in Appendices 5.5.1 and 5.5.2. The limiting output dose rates are shown in Tables 5.1 and 5.2. Point detectors are used for all dose-rate calculations. A large number of particle histories were used to assemble reliable statistics. The results are judged to be acceptable from the tally fluctuation chart, and the relative error (fractional standard deviation) is lower than the criterion (0.05 for point detectors).

5.4.3 Flux-to-Dose-Rate Conversion

Dose rates were calculated at the detector locations by converting the calculated photon and neutron fluxes using the ANSI/ANS conversion factors (ANSI/ANS-6.1.1). These factors for the energy groups used in the shielding evaluation are shown in Tables 5.9 and 5.10.

5.4.4 External Radiation Levels

The calculated maximum side, top, and bottom external dose rates for the HEU metal and oxide contents are presented in Tables 5.1 and 5.2, respectively. The dose rates were calculated by the computer code MCNP. Comparison of dose rates calculated at the detector locations to the requirements of 10 CFR 71 demonstrates compliance of the package. The calculated total dose rates are well within the NCT limits of 200 mrem/h and 10 mrem/h on the drum surface and 1 m from the drum surface, respectively. Calculated HAC dose rates at 1 m from the CV surface are well within the limit of 1000 mrem/h. The shielding analyses were done in a conservative manner applicable to all proposed ES-3100 package contents listed in Sect. 1.2.2. The MCNP calculated dose rates for the HEU metal contents were compared against the Monaco (ORNL/TM-2005/39) calculated dose rates in a journal paper (Paul 2019) and were found to be in general agreement.

In addition to the required external package dose rate calculations, auxiliary calculations were performed to give an upper bound estimate for the dose rate at the location of the CV O-rings. The maximum calculated combined dose rate with 3σ uncertainty at the O-ring was 506.5 mrem/h. Using a 1-rad/rem conversion factor, which was applied to the photon dose rate and conservatively applied to the relatively low neutron dose rate, the maximum total calculated dose rate at the O-ring location was ~0.5 rad/h. The O-ring location dose rate for the HEU metal case bounds that for the HEU oxide case.

Table 5.9. ANSI/ANS-1977 photon flux-to-dose-rate conversion factors

Appendix 5.5.1
Origen-S Input Data

The ORIGEN-S (NUREG/CR-0200) input file used for the Table 5.1 and 5.2 calculated dose rates is provided. The input file in Appendix 5.5.1.1 is for the source term based on the radionuclides in Table 5.3. The concentration of each isotope is based on 1 g of highly enriched uranium (HEU). This is a conservative assumption because the uranium mass is not compensated (reduced) due to the addition of the radionuclide impurity masses of ^{237}Np and Pu. This file has generated the photon and neutron spectrum in Tables 5.4 and 5.5, respectively, which are used to calculate the HEU metal and oxide results in Tables 5.1 and 5.2.

Appendix 5.5.2
MCNP Input Data

Included here are some of the input files used for the dose rate calculations that provide results listed in Tables 5.1 and 5.2. For the normal conditions of transport (NCT) cases, the detectors are set at 1 mm and 1 m from the drum side, top, and bottom surfaces. For the hypothetical accident conditions (HAC) cases, all cells and surfaces external to the containment vessel (CV) are eliminated, and the detectors are set at 1 m from the external surface of the CV. For photon dose-rate calculations for both NCT and HAC cases, the 47 energy group photon spectrum in Table 5.4 are used. For neutron and secondary photon dose-rate calculations for both NCT and HAC cases, the 18–27 energy group neutron spectra in Table 5.5 are used. The contribution of low energy spectra (Groups 1-17) to the neutron dose rate is neglected because the contribution to the dose rate from these groups is minimal. The secondary photon dose rates are less than 1% of the neutron dose rates and the contribution from the secondary photon dose rates are shown as part of the neutron dose rates in Tables 5.1 and 5.2.

Representative input files used for the dose rates calculations are listed below.

Section **Description**

5.5.2.1 NCT for 36-kg uranium metal photon side dose-rate calculations (cylindrical hemi-shell configuration source moved towards x-axis in CV) 5-45
5.5.2.2 NCT for 36-kg uranium metal photon top dose-rate calculations (cylinder configuration source moved to the top of CV) 5-56
5.5.2.3 NCT for 36-kg uranium metal neutron and secondary photon top and side dose-rate calculations (cylinder configuration source moved to the top of CV) 5-68
5.5.2.4 HAC for 36-kg uranium metal neutron and secondary photon side dose-rate calculations (cylindrical hemi-shell configuration source moved towards x-axis in CV) 5-82
5.5.2.5 NCT for 24-kg uranium oxide photon side dose-rate calculations (cylinder configuration source) 5-95

5.5.2.2 NCT for 36-kg uranium metal photon top dose-rate calculations (cylinder configuration source moved to the top of CV)

```
photon_top.inp - ES-3100: 2015 HEU detailed mmodel (primary photons)
c
c    NCT configuration
c    (top dose rate calculations)
c    source in cylindrical form sitting at the top of CV for
c    top dose rate calculations for 2015 Revision
c
c    mcnp geometry model (CV and outside) is identical to criticality model
c    (KENO Model).
c    47 energy groups are used for the photon spectrum.  In the older version,
c    18 energy groups were used.
c    surface detectors are placed 0.1 cm and 100 cm way from the surfaces
c    and detectors are placed on the side, top, and bottom.
c    point detectors are used for dose rate calculations (used for results).
c    segmented volume detectors are used for side dose rate calculations (for checking).
```

```
c    volume detectors are used to check bottom and top dose rate calculations.
c    ANSI/ANS-6.1.1-1977 Dose conversion factors are used,
c    multiplied by 1000 to convert from rem to mrem
c

```

5.5.2.3 NCT for 36-kg uranium metal neutron and secondary photon top and side dose-rate calculations (cylinder configuration source moved to the top of CV)

```
neutron_top.inp - ES-3100: 2015 HEU model (neutrons and secondary photons)
c
c    NCT configuration
c    (top dose rate calculations)
c    source in cylindrical form sitting at the top of CV for
c    top dose rate calculations for 2015 calculation Revision
c
c    mcnp geometry model (CV and outside) is identical to criticality model
c    (KENO Model).
c    47 energy groups are used for the photon spectrum.  In the older version,
c    18 energy groups were used.
c    surface detectors are placed 0.1 cm and 100 cm way from the surfaces
c    and detectors are placed on the side, top, and bottom.
c    point detectors are used for dose rate calculations (used for results).
c    segmented volume detectors are used for side dose rate calculations (for checking).
```

```
c    volume detectors are used to check bottom and top dose rate calculations.
c    ANSI/ANS-6.1.1-1977 Dose conversion factors are used,
c    multiplied by 1000 to convert from rem to mrem

5.5.2.4 HAC for 36-kg uranium metal neutron and secondary photon side dose-rate calculations (cylindrical hemi-shell configuration source moved towards x-axis in CV)

```
neutron_hemishell.inp - ES-3100: 2015 HEU detailed model
c                 (neutrons & sec photons)
c                 U-metal case (76.2 cm ht cylindrical hemishell
c                 density = 18.82 g/cc; IR=4.9337 cm; OR=6.35 cm)
c    configuration
c    (side dose rate calculations)
c    source in cylindrical hemishell form sitting at the bottom of CV for
c    side dose rate calculations for 2015 Revision
c
c    mcnp geometry model (CV and outside) is identical to criticality model
c    (KENO Model).
c    47 energy groups are used for the photon spectrum.  In the older version,
c    18 energy groups were used.
c    surface detectors are placed 0.1 cm and 100 cm way from the surfaces
c    and detectors are placed on the side, top, and bottom.
c    point detectors are used for dose rate calculations (used for results).
c    segmented volume detectors are used for side dose rate calculations (for checking).
c    volume detectors are used to check bottom and top dose rate calculations.
c    ANSI/ANS-6.1.1-1977 Dose conversion factors are used,
c    multiplied by 1000 to convert from rem to mrem

```

5.5.2.5 NCT for 24-kg uranium oxide photon side dose-rate calculations (cylinder configuration source)

```
photon_side8.inp- ES-3100: 2015 HEU detailed model (primary photons)
c                 UO2 case (47.365 cm ht cylindrical
c                 density = 4.0 g/cc; OR=6.35 cm)
c    configuration
c    (bottom dose rate calculations)
c    source in cylindricalshell form sitting at the bottom of CV for
c    side dose rate calculations for 2015 Revision
c
c    mcnp geometry model (CV and outside) is identical to criticality model
c    (KENO Model).
c    47 energy groups are used for the photon spectrum.  In the older version,
c    18 energy groups were used.
c    surface detectors are placed 0.1 cm and 100 cm way from the surfaces
c    and detectors are placed on the side, top, and bottom.
c    point detectors are used for dose rate calculations (used for results).
c    segmented volume detectors are used for side dose rate calculations (for checking).
c    volume detectors are used to check bottom and top dose rate calculations.
c    ANSI/ANS-6.1.1-1977 Dose conversion factors are used,
c    multiplied by 1000 to convert from rem to mrem
c
c    segmented volume detectors are placed

Appendix 5.5.3
Comparative NCT Dose Rates for Kaolite and Packcrete

The material properties of the impact-limiting and thermal-insulating materials, Kaolite and Packcrete, used in the ES-3100 shielding models for the comparative dose rate calculations are shown in Table 5.5.3.1. In this comparative study, Packcrete with a density of 0.31076 g/cm^3 (19.4 lb/ft^3) [Table1, RP 802282-0002 000 02] is used for dose rate calculations instead of Kaolite with a density of 0.321 g/cm^3. The properties of the other packaging materials remain invariant in the dose rate calculations. Dose rates are calculated at 1 mm and 1 m from the side, top, and bottom surfaces for the 36 kg solid cylinder at the top of the CV, bottom of the CV, cylindrical hemi-shell, cylindrical shell, rectangular plate, cylindrical rod, and cylindrical segment configurations. The same source configurations are used in Table 5.7 for side dose rates for the various highly enriched uranium metal source configurations. In addition, dose rates are also compared for the 24 kg UO_2 powder source configuration. The calculated dose rates are presented in Tables 5.5.3.2–5.5.3.7. There are minor statistical differences among the calculated dose rates for different source configurations using either Kaolite or Packcrete as the impact-limiting and thermal-insulating material. Therefore, it can be concluded that the shielding evaluation for the ES-3100 package with Kaolite validates the use of the ES-3100 package with Packcrete as the impact-limiting and thermal-insulating material.

6. CRITICALITY EVALUATION

This chapter describes the criticality safety evaluation of the Y-12 National Security Complex (Y-12) Model ES-3100 package with solid highly enriched uranium (HEU) metal or alloys (specific information for alloys are addressed in Sects. 6.2.1, 6.2.4, 6.3.2, 6.4, 6.4.1, and 6.6.1), or HEU oxide, or highly enriched uranyl nitrate crystals (UNX). HEU metal or alloy may be in the form of solid shapes (cylinders, bars, buttons, billets, slugs, unirradiated TRIGA fuel), broken metal, turnings, fines, powder, or content of an unspecified geometric shape and characterized as broken metal. Distinguished from TRIGA contents, the research reactor related contents covered under this criticality evaluation are fuel elements or fuel components, broken metal, U alloys, or oxides.

A variety of similar materials from various reactor programs were added under a subsequent revision of the criticality safety evaluation (Appendix 6.9.8). These additional contents include bare, clad or canned uranium metal alloy or oxide in various shapes as pellets, rods, plates, bundled components and fuel assemblies. Compounds of uranium include uranium tetrafluoride, uranyl fluoride, uranium carbide, and uranium nitride. The physical form of these uranium compounds is described as powder, beads, and ash. Both content moisture and content uniformity are not defined. The criticality evaluation has been updated as discussed in Appendices 6.9.9, 6.9.10, and 6.9.11.

Physical testing of Type-B fissile material packages for surface transportation conducted in accordance with the physical testing requirements of 10 CFR 71 is limited to the ES-3100 packaging and non-fissile dummy contents. Consequently, analytic methods are used to demonstrate compliance of the ES-3100 package with the applicable performance requirements in 10 CFR 71. The specific requirements investigated for compliance in this evaluation are contained in 10 CFR 71.55, "General Requirements of all Fissile Material Packages," and 10 CFR 71.59, "Standards for Arrays of Fissile Material Packages." Physical testing of Type-B fissile material packages transported by air is not conducted for the ES-3100. Analytic methods are also used to demonstrate compliance of the ES-3100 package with the requirements of 10 CFR 71.55(f). This is accomplished by demonstrating compliance of the package with the more stringent requirements of the International Atomic Energy Agency (IAEA) for situations where the conditions of the fissile material package following the tests cannot be demonstrated (IAEA SSG-26, Para. 683.2).

6.1 DESCRIPTION OF THE CRITICALITY DESIGN

6.1.1 Design Features

The principal design feature of interest in the criticality evaluation of the Model ES-3100 package is the containment/outer drum system (Drawing M2E801580A031, Appendix 1.3.7). The ES-3100 package uses a single containment system (Drawing M2E801580A011, Appendix 1.3.7) to contain the HEU contents. The containment is a high-integrity, watertight, post-load leak-testable, stainless-steel vessel (Fig. 1.3). The outer drum system (Drawing M2E801580A001, Appendix 1.3.7) is a recessed, double-compartment body with a removable top for insertion and removal of the containment vessel (CV). The body weldment liner outer cavity and the top plug weldment contain Kaolite 1600 (Kaolite), a thermal insulation material that protects the CV from thermal absorption, shock and impact. The body weldment liner inner cavity contains a neutron poison, "277-4," which serves as a strong neutron absorber. Other chapters of this report (Chaps. 2, 3, and 4) demonstrate the integrity of the ES-3100 package [i.e., that this single CV remains intact and watertight under the Normal Conditions of Transport (NCT) and Hypothetical Accident Conditions (HAC)].

Typical shipping configurations inside the ES-3100 containment vessel are illustrated in Fig. 1.4. The 277-4 canned spacers will only be used for contents shipped in metal convenience cans. Three 4.25-in.-diam × 10.0-in.-tall or six 4.25-in.-diam × 4.88-in.-tall convenience cans separated by can pads may be placed inside the 31-in.-tall cavity of the ES-3100 containment vessel (Fig. 1.4). Other can arrangements fit inside the containment vessel, such as three 4.25-in.-diam × 8.75-in.-tall or five 4.25-in.-diam × 4.88-in.-tall convenience cans. Both of these can arrangements include can pads and 277-4 canned spacers with overall dimensions of 4.25-in. diam × 1.82-in. height (Drawing M2E801580A043, Appendix 1.3.7). Nickel alloy cans are ~3-in. diam × 4.75-in. tall. Up to three Teflon bottles (4.69-in. diam × 9.4-in. tall) or three polyethylene bottles (4.94-in. diam × 8.7-in. tall) will fit inside the containment vessel; however, 277-4 canned spacers are not used with these configurations. If closed convenience cans with an outer diameter >4.25 in. are used, at least 43 $in.^3$ of free or void volume must exist inside the containment vessel to allow for gas expansion and offgassing of material at temperatures associated with NCT or HAC.

A modified convenience can may be used to package the TRIGA and research reactor related contents that do not fit inside these containers. A 17.5-in.- or 30-in.-tall convenience can is constructed from two 4.25-in.-diam × 8.75-in.-tall or three 10-in. cans brazed together. The research reactor fuel elements and fuel components that cannot be packaged in these convenience cans due to their overall dimensions will be bundled together and protected on each end with an open-ended convenience can having an outer diameter ≤ 5 in. Solid form HEU contents (i.e., spheres, cylinders, bars, slugs, etc.) that will not fit in a 4.25-in. convenience can may be bagged only with no convenience can required around the content. For contents that are bagged only, stainless-steel metal scrubbers may be placed on the top and bottom of this assembly inside the CV. For these bagged contents, the void volume requirement stated in Sect. 1.2.2.8, *Loading restrictions*, Item 8 must still be satisfied.

Credit is not taken in this criticality analysis for fissile material spacing provided by the presence of the convenience cans or bottles inside the CV. These containers are not manufactured to the American Society of Mechanical Engineers *Boiler and Pressure Vessel Code*, Sect. III, Subsection NG, or better.

6.1.2 Codes and Standards

Testing conducted in accordance with the physical testing requirements of 10 CFR 71 demonstrated that water leakage into the containment is not a credible event under the NCT and HAC. As directed, credit for the high-integrity, watertight containment is not taken in this criticality evaluation per discussions held at public meetings at the U.S. Nuclear Regulatory Commission (Docket 71-9315).

Liquid HEU is not being shipped in the ES-3100. With the exception of UNX crystals, the other uranium contents being shipped are not soluble in water and do not form solutions. The hypothetical occurrence of uranyl nitrate solution is evaluated as a consequence of evaluating the presence of water inside the CV. Thus, uranyl nitrate solution is evaluated even though it is not shipped as an approved package content in the ES-3100.

10 CFR 71.55(b) requires the evaluation of water leakage into the CV or leakage of liquid contents out of the CV and other conditions that produce maximum reactivity in the single package. For solid uranium contents, water leakage conditions are simulated by flooding all regions outside and inside of the CV, including the sealed convenience cans. For liquid uranium "contents," water leakage conditions are simulated by flooding all regions outside the CV except the CV well. The uranyl nitrate (UN) solution resides inside both the CV well and the CV, including the Teflon bottles. Per 10 CFR 71.55(b), a flooded CV under full water reflection is also evaluated. Under such leakage conditions, the calculated neutron multiplication factor ($k_{eff} + 2\sigma$) for the ES-3100 package with HEU contents is lower than the upper subcritical limit (USL) for a subcritical system. Water inleakage into the CV or liquid content leakage out of the CV will not produce a criticality in the CV of a disassembled

package or an assembled single package. Therefore, the Model ES-3100 shipping package complies with all of the requirements of 10 CFR 71.55(b) and (d).

While the loss of containment is deemed incredible by merit of the results of the physical tests performed under 10 CFR 71.71 and 10 CFR 71.73, credit for the high-integrity, watertight containment is not taken in the single package analysis [10 CFR 71.55(d) and (e)]. Only partial credit is taken in the package array analysis (10 CFR 71.59). In both the single package and package array analyses, the CV is flooded with water. This fictitious "evaluation" water provides moderation to such an extent as to cause maximum reactivity of the content consistent with the chemical and physical form of the material present. While UN crystals are soluble in water, leakage of UN solution out of the CV for undamaged packages under 10 CFR 71.59 (a)(1) or damaged packages under 10 CFR 71.59 (a)(2) is not considered credible during NCT or HAC based on results for tests specified in 10 CFR 71.71 and 10 CFR 71.73. Because credit for the high-integrity, watertight containment is not fully taken in the criticality evaluation, the fissile mass loading limits are very conservative.

The NCT tests under 10 CFR 71.71 and the HAC tests under 10 CFR 71.73 demonstrate that containment is not breached. Nevertheless, CV flooding is assumed in the criticality calculations performed for the derivation of fissile material loading limits. The 7.1–10.1 kg quantities of evaluation water in both the NCT and HAC criticality calculations are not actually present in the CV. Simulation of this condition in the criticality calculations produces fissile material content that is more reactive than actual.

The 7.1–10.1 kg quantity of evaluation water does not necessarily bound reasonable amounts of hydrogenous packing material present inside the CV when the fissile material is in particulate form (primarily HEU oxides and UNX crystals) or must be evaluated as particulate matter (broken metal). Packing materials include can pads; polyethylene, nylon, and Teflon bags; vinyl tape; and polyethylene or Teflon bottles, if used. An administrative criticality control is used to restrict the amount of hydrogenous packing material normally present inside the CV (Item 7 in Sect. 6.2.4).

Under NCT and HAC, three parameters that affect criticality and may vary during transport of the Model ES-3100 package are the number of packages transported, the amount of water present in the package, and the volatile (organic material) contents of the package. The number of packages transported is limited by the criticality safety index (CSI) established by this criticality evaluation. Both the amount of water present in the package and the volatile (organic material) contents of the package are parameters for the following reasons. First, volatile materials can be driven off at the high temperatures of HAC. Second, the inherent water content of the Kaolite in NCT and the water absorption by the Kaolite in HAC are unknowns. These parameters determine a variety of competing effects that govern the fission process, including, but not limited to, mass, moderation, absorption, and reflection. To ensure that all effects are adequately included in this criticality evaluation, the range of these parameters is evaluated.

It is possible for accidents to be significantly more severe in the air transport mode than in the surface transport mode. Thus, the performance requirements for packages designed to be transported by air are more stringent. These requirements address separate aspects of the accident assessment and apply only to the criticality evaluation of an individual package under isolation (IAEA SSG-26). For a fissile material package designed to be transported by air, 10 CFR 71.55(f) requires that the criticality evaluation demonstrate that the package be subcritical assuming reflection by 20 cm (7.9 in.) of water but no water inleakage when subjected to the sequential application of the HAC free drop and crush tests of 10 CFR 71.73(c)(1 and 2) and the modified puncture and thermal tests of 10 CFR 71.55(f)(1)(iii and iv). 10 CFR 71.55(f)(2) requires the criticality evaluation demonstrate that the package be subcritical, assuming reflection by 20 cm (7.9 in.) of water but no water inleakage, when subjected to an impact on an unyielding surface of 90 m/s normal to the surface.

The ES-3100 package was not subjected to physical testing of Type-C fissile material packages transported by air as specified in IAEA SSR-6, Para. 683. Instead, analytic methods are used to demonstrate compliance of the ES-3100 package with the requirements of 10 CFR 71.55(f). This is accomplished by demonstrating compliance of the package with the more stringent requirements imposed by the IAEA for situations where the conditions of the fissile material package following the tests cannot be demonstrated (IAEA SSG-26, Para. 683.2). Paragraph 683.2 of IAEA SSG-26 states that worst-case assumptions regarding the geometric arrangement of the package and contents should be made in the criticality evaluation taking into account all moderating and structural components of the packaging. The assumptions should be in conformity with the potential worst-case effects of the mechanical and thermal tests, and all package orientations should be considered for the analysis. Subcriticality must be demonstrated after due consideration of such aspects as the efficiency of the moderator, loss of neutron absorbers, rearrangement of packaging components and contents, geometry changes, and temperature effects. Given that the requirements of 10 CFR 71.55(f) mirror the IAEA requirements of SSR-6, Para. 683, for Type B(U) fissile material packages, this approach is considered an acceptable one.

6.1.3 Summary of the Criticality Evaluation

The following criticality evaluation shows that the Model ES-3100 package with designated content satisfies the requirements of 10 CFR 71.55 and 71.59 for surface transport, and of 10 CFR 71.55(f) for air transport. Designated contents are **solid** HEU metal or alloy of specified shape (cylinders, bars, buttons, billets, slugs, and unirradiated TRIGA fuel), broken metal, turnings, fines, or powder; **solid** HEU metal or alloy of unspecified geometric shape and characterized as broken metal; HEU product or skull oxides; or UNX crystals. HEU skull oxides are distinguished from product oxides (UO_2, U_3O_8, or UO_3) as being a residue of graphite and oxidized uranium (U_3O_8) recovered in the casting process. The criticality evaluation of these contents is addressed in the main subsections of this chapter. The criticality evaluation of the contents not covered under the initial evaluation is addressed in Appendices 6.9.8, 6.9.9, and 6.9.11 as explained therein.

Tables 6.1a–6.1f pertain to surface-only modes of transportation. The column headings across the tables identify content and 277-4 canned spacer configurations. The tables are organized into groups of rows, which identify the defining calculations for addressing the performance requirements of 10 CFR 71.55(b), 71.55(d), 71.55(e), or 71.59 (see "Conditions" column). The defining calculations are also discussed in Sects. 6.4, 6.5, or 6.6, as appropriate. The KENO V.a input listings for the calculations are provided in Appendix 6.9.7. The rows within the groups cite the specific requirements stated in the CFR paragraphs and provide details regarding how these conditions are addressed or treated in the defining calculations for each content and 277-4 canned spacer configuration listed in a table column. Results of the criticality evaluation are summarized in Tables 6.1a and 6.1b for **solid** HEU metal in the form of specified shape (cylinders, bars, buttons, billets, and slugs); Table 6.1c for HEU broken metal or **solid** HEU metal of unspecified geometric shape and characterized as broken metal; Table 6.1d for HEU metal in the form of turnings, fines, or powder; Table 6.1e for HEU product and skull oxide; and Table 6.1f for UNX crystals and unirradiated TRIGA reactor fuel elements. In some cases, studies were performed to determine which is more reactive — no polyethylene or 500 g of polyethylene. The most reactive cases of these evaluations are cited in Tables 6.1a–6.1f.

Table 6.1a. Summary of criticality evaluation for solid HEU metal cylinders and bars

Conditions	Cylinders (d ≤ 3.24 in.) no can spacers	Cylinders (d ≤ 3.24 in.) with can spacers	Square bars (l,w ≤ 2.29 in.) no can spacers	Cylinders (3.24 < d ≤ 4.25 in.) no can spacers	Cylinders (3.24 < d ≤ 4.25 in.) with can spacers
General requirements for each fissile package (§71.55)					
"A package used for shipment of fissile material must be so designed and constructed and its contents so limited that it would be subcritical if water were to leak into the containment system, . . . so that under the following conditions, maximum reactivity of the fissile material would be attained:" (Paragraph "b")	$k_{eff} + 2\sigma \leq 0.9228$ cvcrcyt11_21_1	$k_{eff} + 2\sigma \leq 0.8866$ cvcrcyt11_36_2	$k_{eff} + 2\sigma \leq 0.8787$ cvcrsqt11_36_1	$k_{eff} + 2\sigma \leq 0.9215$ cvcrcyct11_17_1	$k_{eff} + 2\sigma \leq 0.9202$ cvcrcyct11_32_2
(1) the most reactive credible configuration consistent with the chemical and physical form of the material,	3 stacked cylinders (d = 3.24 in.) 1 cylinder per convenience can, no can spacers, 21,000-g ^{235}U	3 stacked cylinders (d = 3.24 in.) 1 cylinder per convenience can, with can spacers, 36,000-g ^{235}U	3 stacked bars (l,w = 2.29 in.) 1 bar per convenience can, no can spacers, 36,000-g ^{235}U	3 stacked cylinders (d = 4.25 in.) 1 cylinder per convenience can, no can spacers, 17,000-g ^{235}U	3 stacked cylinders (d = 4.25 in.) 1 cylinder per convenience can, with can spacers, 32,000-g ^{235}U
(2) moderation by water to the most reactive credible extent,	Flooding of the CV	Same	Same	Same	Same
(3) close full reflection of the containment system by water on all sides, or such greater reflection of the containment system as may be provided by the surrounding material of the packaging.	30.48-cm H_2O surrounding the CV	Same	Same	Same	Same

Table 6.1a. Summary of criticality evaluation for solid HEU metal cylinders and bars

Conditions	Cylinders ($d \leq 3.24$ in.) no can spacers	Cylinders ($d \leq 3.24$ in.) with can spacers	Square bars ($l,w \leq 2.29$ in.) no can spacers	Cylinders ($3.24 < d \leq 4.25$ in.) no can spacers	Cylinders ($3.24 < d \leq 4.25$ in.) with can spacers
"A package used for shipment of fissile material must be so designed and constructed and its contents so limited under the tests specified in §71.71 (Normal Conditions of Transport) . . ." (Paragraph "d")					
(1) the contents would be subcritical,	$k_{eff} + 2\sigma \leq 0.9035$ ncsrcyt11_21_1_15	$k_{eff} + 2\sigma \leq 0.8731$ ncsrcyt11_36_2_15	$k_{eff} + 2\sigma \leq 0.8652$ ncsrsqt11_36_1_15	$k_{eff} + 2\sigma \leq 0.8941$ ncsrcyct11_17_1_15	$k_{eff} + 2\sigma \leq 0.8946$ ncsrcyct11_32_2_15
(2) the geometric form of the package contents would not be substantially altered,	3 stacked cylinders (d = 3.24 in.) 1 cylinder per convenience can, no can spacers, 21,000-g ^{235}U	3 stacked cylinders (d = 3.24 in.) 1 cylinder per convenience can, with can spacers, 36,000-g ^{235}U	3 stacked bars (l,w = 2.29 in.) 1 bar per convenience can, no can spacers, 36,000-g ^{235}U	3 stacked cylinders (d = 4.25 in.) 1 cylinder per convenience can, no can spacers, 17,000-g ^{235}U	3 stacked cylinders (d = 4.25 in.) 1 cylinder per convenience can, with can spacers, 32,000-g ^{235}U
(3) there would be no leakage of water into the containment system unless, in the evaluation of undamaged packages under §71.59(a)(1), it has been assumed that moderation is present to such an extent as to cause maximum reactivity consistent with the chemical and physical form of the material,	Moderation is present to such an extent as to cause maximum reactivity	Same	Same	Same	Same
(4) there will be no substantial reduction in the effectiveness of the packaging	30.48-cm H_2O surrounding the drum (d=18.37 in., h=43.5 in.)	Same	Same	Same	Same

Table 6.1a. Summary of criticality evaluation for solid HEU metal cylinders and bars

Conditions	Cylinders (d ≤ 3.24 in.) no can spacers	Cylinders (d ≤ 3.24 in.) with can spacers	Square bars (l,w ≤ 2.29 in.) no can spacers	Cylinders (3.24 < d ≤ 4.25 in.) no can spacers	Cylinders (3.24 < d ≤ 4.25 in.) with can spacers
"A package used for shipment of fissile material must be so designed and constructed and its contents so limited that under the tests specified in §71.73 (Hypothetical Accident Conditions) the package would be subcritical. For this determination, it must be assumed that:" (Paragraph "e")	$k_{eff} + 2\sigma \leq 0.9044$ hcsrcyt12_21_1_15	$k_{eff} + 2\sigma \leq 0.8734$ hcsrcyt12_36_2_15	$k_{eff} + 2\sigma \leq 0.8642$ hcsrsqt12_36_1_15	$k_{eff} + 2\sigma \leq 0.8979$ hcsrcyct12_17_1_15	$k_{eff} + 2\sigma \leq 0.8977$ hcsrcyct12_32_2_15
(1) the fissile material is in the most reactive credible configuration consistent with the chemical and physical form of the contents,	3 stacked cylinders (d = 3.24 in.) 1 cylinder per convenience can, no can spacers, 21,000-g ^{235}U	3 stacked cylinders (d = 3.24 in.) 1 cylinder per convenience can, with can spacers, 36,000-g ^{235}U	3 stacked bars (l,w = 2.29 in.) 1 bar per convenience can, no can spacers, 36,000-g ^{235}U	3 stacked cylinders (d = 4.25 in.) 1 cylinder per convenience can, no can spacers, 17,000-g ^{235}U	3 stacked cylinders (d = 4.25 in.) 1 cylinder per convenience can, with can spacers, 32,000-g ^{235}U
(2) water moderation occurs to the most reactive credible extent consistent with the chemical and physical form of content,	Flooding of the package	Same	Same	Same	Same
(3) there is full reflection by water on all sides, as close as is consistent with the damage condition of the package.	30.48-cm H_2O surrounding the reduced diameter drum (d=17.20 in., h=43.5 in.)	Same	Same	Same	Same

Table 6.1a. Summary of criticality evaluation for solid HEU metal cylinders and bars

Standards for arrays of fissile material packages (§71.59)						
" . . . the designer of a fissile material package shall derive a number "N" based on all the following conditions being satisfied, assuming packages are stacked together in any arrangement and with close reflection on all sides of the stack by water: " (Paragraph "a")						
Transport index based on nuclear criticality control, CSI = 0.0	**Load-limited to 2,600-g ^{235}U, no can spacers**	**Load-limited to 2,755-g ^{235}U, no can spacers**	**Load-limited to 2,880-g U, no can spacers**	**Load-limited to 3,200-g ^{235}U, no can spacers**	**Load-limited to 3,570-g ^{235}U, no can spacers**	**Load-limited to 7,200-g U, no can spacers**
(1) five times "N" undamaged packages with nothing between the packages would be subcritical,	$k_{eff} + 2\sigma \leq 0.93426$ nciabmt11p_5_1_6_3	$k_{eff} + 2\sigma \leq 0.93464$ nciabmt11p_8_1_5_3	$k_{eff} + 2\sigma \leq 0.93549$ nciabmt11p_11_1_4_3	$k_{eff} + 2\sigma \leq 0.93490$ nciabmt11p_18_1_3_3	$k_{eff} + 2\sigma \leq 0.93377$ nciabmt11p_27_1_2_3	$k_{eff} + 2\sigma \leq 0.93629$ nciabmt11p_39_1_1_3
(2) two times "N" damaged packages, if each package were subject to the tests specified in §71.73 (Hypothetical Accident Conditions) would be subcritical with optimum interspersed hydrogenous moderation,	$k_{eff} + 2\sigma \leq 0.93447$ hciabmt12p_5_1_6_3	$k_{eff} + 2\sigma \leq 0.93569$ hciabmt12p_8_1_5_3	$k_{eff} + 2\sigma \leq 0.93594$ hciabmt12p_11_1_4_3	$k_{eff} + 2\sigma \leq 0.93612$ hciabmt12p_18_1_3_3	$k_{eff} + 2\sigma \leq 0.93602$ hciabmt12p_27_1_2_3	$k_{eff} + 2\sigma \leq 0.93648$ hciabmt12p_39_1_1_3
(3) the value of "N" cannot be <0.5.	$N(1,2) = \infty$	Same	Same	Same	Same	Same

(3) the value of "N"	N(1,2) = 16/24	Same	Same	Same	Same	Same

[a] Neutron multiplication factors and "N" are shown for an NCT array size of 7×7×3 and an HAC array size of 5×5×2; both arrays are nearly cubic arrangements. An HAC array size is not available for CSI=1.8; therefore, CSI for NCT at 1.8 is rounded up to 2.0 as shown.

[b] Neutron multiplication factors and "N" are shown for an NCT array size of 27×3 and an HAC array size of 16×3; where packages in the planar dimension are in explicit triangular-pitch arrangement and stacked three high in the vertical direction. An NCT array size of 81 packages gives a CSI value of 3.12 (50 / 16), while an HAC array size of 48 packages gives a CSI value of 2.08 (50 / 24). The specified CSI value of 3.2 is the larger of the two numbers rounded up to the nearest tenth decimal place as shown.

(1) five times "N" undamaged packages	$k_{eff} + 2\sigma \leq 0.93479$ nctf5bmt11p_5_1_6_3	$k_{eff} + 2\sigma \leq 0.93508$ nctf5bmt11p_14_1_5_3	$k_{eff} + 2\sigma \leq 0.93367$ nctf5bmt11p_27_1_4_3	$k_{eff} + 2\sigma \leq 0.92826$ nctf5bmt11p_42_1_3_3	$k_{eff} + 2\sigma \leq 0.90345$ nctf5bmt11p_42_1_2_3	$k_{eff} + 2\sigma \leq 0.87716$ nctf5bmt11p_42_1_1_3
(2) two times "N" damaged packages, ...	$k_{eff} + 2\sigma \leq 0.91484$ hctf5bmt12p_5_1_6_3	$k_{eff} + 2\sigma \leq 0.91688$ hctf5bmt12p_14_1_5_3	$k_{eff} + 2\sigma \leq 0.91496$ hctf5bmt12p_27_1_4_3	$k_{eff} + 2\sigma \leq 0.90875$ hctf5bmt12p_42_1_3_3	$k_{eff} + 2\sigma \leq 0.88319$ hctf5bmt12p_42_1_2_3	$k_{eff} + 2\sigma \leq 0.85772$ hctf5bmt12p_42_1_1_3
(3) the value of "N"	N(1,2) = 16/24	Same	Same	Same	Same	Same

[a] Neutron multiplication factors and "N" are shown for an NCT array size of 7×7×3 and an HAC array size of 5×5×2; both arrays are nearly cubic arrangements. An HAC array size is not available for CSI=1.8; therefore, CSI for NCT at 1.8 is rounded up to 2.0 as shown.

[b] Neutron multiplication factors and "N" are shown for an NCT array size of 27×3 and an HAC array size of 16×3; where packages in the planar dimension are in explicit triangular-pitch arrangement and stacked three high in the vertical direction. An NCT array size of 81 packages gives a CSI value of 3.12 (50 / 16), while an HAC array size of 48 packages gives a CSI value of 2.08 (50 / 24). The specified CSI value of 3.2 is the larger of the two numbers rounded up to the nearest tenth decimal place as shown.

Table 6.1e. Summary of criticality evaluation for HEU product oxide

Conditions	HEU product oxide 2.0-6.54 g/cm^3 ≤ 21,125-g ^{235}U	HEU product oxide ≥ 1.75 g/cm^3 ≤ 14,083-g ^{235}U	HEU product oxide ≥ 1.5 g/cm^3 ≤ 12,323-g ^{235}U	HEU product oxide ≥ 1.25 g/cm^3 ≤ 10,562-g ^{235}U
General requirements for each fissile package (§71.55)				
"A package used for shipment of fissile material must be so designed and constructed and its contents so limited that it would be subcritical if water were to leak into the containment system, . . . so that under the following conditions, maximum reactivity of the fissile material would be attained:" (Paragraph "b")	$k_{eff} + 2\sigma \leq 0.9143$ cvcrpdoxt11_1_3_24_15	$k_{eff} + 2\sigma \leq 0.9196$ cvcrldoxt11_1_20_15	$k_{eff} + 2\sigma \leq 0.9154$ cvcrldoxt11_2_18_15	$k_{eff} + 2\sigma \leq 0.9208$ cvcrldoxt11_3_16_15
(1) the most reactive credible configuration consistent with the chemical and physical form of the material,	HEU oxide at the bulk density is assumed dispersed in the CV, where the oxide fills the CV to a height determined by the oxide mass. The oxide is saturated with water. Water fills the void region above the oxide content, but this amount of water is reduced by an amount equivalent to the volume occupied by can spacers. The can pads, spacer can, and convenience can steel are replaced by water. See Sect. 6.9.3.1 for justification of the content model.			
(2) moderation by water to the most reactive credible extent,	Flooding of the CV			
(3) close full reflection of the containment system by water on all sides, or such greater reflection of the containment system as may be provided by the surrounding material of the packaging.	30.48-cm H_2O surrounding the CV			
"A package used for shipment of fissile material must be so designed and constructed and its contents so limited under the tests specified in §71.71 (Normal Conditions of Transport) . . ." (Paragraph "d")				
(1) the contents would be subcritical,	$k_{eff} + 2\sigma \leq 0.8166$ ncsrpdoxt11_1_3_24	$k_{eff} + 2\sigma \leq 0.8123$ ncsrldoxt11_1_20	$k_{eff} + 2\sigma \leq 0.8110$ ncsrldoxt11_2_28	$k_{eff} + 2\sigma \leq 0.8092$ ncsrldoxt11_3_16
(2) the geometric form of the package contents would not be substantially altered,	HEU oxide at the bulk density is assumed dispersed in the CV, where the oxide fills the CV to a height determined by the oxide mass. The oxide is saturated with water. Water fills the void region above the oxide content, but this amount of water is reduced by an amount equivalent to the volume occupied by can spacers. The can pads, spacer can, and convenience can steel are replaced by water.

[a] See Appendix 6.9.11 for removal of the carbon limit.

[b] For HEU product oxides with a bulk density ranging from ≥ 2.0 g/cm^3 to 6.54 g/cm^3 at a CSI of 0.4, the maximum ^{235}U per ES-3100 package is 12,323 g as discussed in Appendix 6.9.9.

Table 6.1e. Summary of criticality evaluation for HEU product and skull oxide

Conditions	HEU product oxide ≥ 1.75 g/cm^3 ≤ 14,083-g ^{235}U	HEU product oxide ≥ 1.5 g/cm^3 ≤ 12,323-g ^{235}U	HEU product oxide ≥ 1.25 g/cm^3 ≤ 10,562-g ^{235}U
General requirements for each fissile package (§71.55)			
"A package used for shipment of fissile material must be so designed and constructed and its contents so limited that it would be subcritical if water were to leak into the containment system, . . . so that under the following conditions, maximum reactivity of the fissile material would be attained:" (Paragraph "b")	$k_{eff} + 2\sigma \leq 0.9111$ cvcrldoxt11_4_13_15	$k_{eff} + 2\sigma \leq 0.9060$ cvcrldoxt11_5_11_15	$k_{eff} + 2\sigma \leq 0.8943$ cvcrldoxt11_6_8_15
(4) the most reactive credible configuration consistent with the chemical and physical form of the material,	HEU oxide at the bulk density is assumed dispersed in the CV, where the oxide fills the CV to a height determined by the oxide mass. The oxide is saturated with water. Water fills the void region above the oxide content, but this amount of water is reduced by an amount equivalent to the volume occupied by can spacers. The can pads, spacer can, and convenience can steel are replaced by water. See Sect. 6.9.3.1 for justification of the content model.		
(5) moderation by water to the most reactive credible extent,	Flooding of the CV		
(6) close full reflection of the containment system by water on all sides, or such greater reflection of the containment system as may be provided by the surrounding material of the packaging.	30.48-cm H_2O surrounding the CV		
"A package used for shipment of fissile material must be so designed and constructed and its contents so limited under the tests specified in §71.71 (Normal Conditions of Transport) . . ." (Paragraph "d")			
(7) the contents would be subcritical,	$k_{eff} + 2\sigma \leq 0.8052$ ncsrldoxt11_4_13	$k_{eff} + 2\sigma \leq 0.7984$ ncsrldoxt11_5_11	$k_{eff} + 2\sigma \leq 0.7871$ ncsrldoxt11_6_8
(8) the geometric form of the package contents would not be substantially altered,	HEU oxide at the bulk density is assumed dispersed in the CV, where the oxide fills the CV to a height determined by the oxide mass. The oxide is saturated with water. Water fills the void region above the oxide content, but this amount of water is reduced by an amount equivalent to the volume occupied by can spacers. The can pads, spacer can, and convenience can steel are replaced by water.		

Table 6.1e. Summary of criticality evaluation for HEU product and skull oxide

Conditions	HEU product oxide ≥ 1.75 g/cm^3 ≤ 14,083-g ^{235}U	HEU product oxide ≥ 1.5 g/cm^3 ≤ 12,323-g ^{235}U	HEU product oxide ≥ 1.25 g/cm^3 ≤ 10,562-g ^{235}U
(9) there would be no leakage of water into the containment system unless, in the evaluation of undamaged packages under §71.59(a)(1), it has been assumed that moderation is present to such an extent as to cause maximum reactivity consistent with the chemical and physical form of the material,	Moderation is present to such an extent as to cause maximum reactivity		
(10) there will be no substantial reduction in the effectiveness of the packaging	30.48-cm H_2O surrounding the drum (d = 18.37 in., h = 43.5 in.)		
"A package used for shipment of fissile material must be so designed and constructed and its contents so limited that under the tests specified in §71.73 (Hypothetical Accident Conditions) the package would be subcritical. For this determination, it must be assumed that:" (Paragraph "e")	$k_{eff} + 2\sigma \leq 0.8063$ hcsrldoxt12_4_13	$k_{eff} + 2\sigma \leq 0.7997$ hcsrldoxt12_5_11	$k_{eff} + 2\sigma \leq 0.7890$ hcsrldoxt12_6_8
(11) the fissile material is in the most reactive credible configuration consistent with the chemical and physical form of the contents,	HEU oxide at the bulk density is assumed dispersed in the CV, where the oxide fills the CV to a height determined by the oxide mass. The oxide is saturated with water. Water fills the void region above the oxide content, but this amount of water is reduced by an amount equivalent to the volume occupied by can spacers. The can pads, spacer can, and convenience can steel are replaced by water.		
(12) water moderation occurs to the most reactive credible extent consistent with the chemical and physical form of content,	Flooding of the package		
(13) there is full reflection by water on all sides, as close as is consistent with the damage condition of the package.	30.48-cm H_2O surrounding the reduced diameter drum (d = 17.20 in., h = 43.5 in.)		

Table 6.1e. Summary of criticality evaluation for HEU product and skull oxide

The evaluation limits for solid HEU metal shapes are listed in the column headings appearing to the right of the "Conditions" column of Table 6.1a. Limits expressed in terms of the diameter for a cylinder and the length-width of the geometric cross section for a square bar are established by the size of the convenience can opening through which these contents are inserted. Potential fissile (^{235}U) mass loading limits for these contents are given in the information blocks where a description of the content appears for the fissile material "in the most reactive credible configuration."

The fissile (^{235}U) or uranium masses listed in the column headings of Tables 6.1b–6.1f indicate evaluation limits for the associated content configurations. In the case of slugs (Table 6.1b), the ^{235}U evaluation limits represent the fissile content contained in the slugs with maximum tolerances applied. In the case of broken metal (Table 6.1c), the ^{235}U evaluation limits represent the maximum amount of ^{235}U adequately subcritical in a flooded, reflected CV as conservatively applied over the indicated range of enrichment. For HEU enrichments ≤ 60%, the 35.32-kg package limit on the amount of HEU to be shipped in an ES-3100 becomes the evaluation limit. Relative to the broken metal limits specified in Table 6.1c, the ^{235}U evaluation limit permissible for HEU metal in the form of turnings, fines, or powder is reduced at the higher enrichments (Table 6.1d). For HEU oxide and UNX crystals (Tables 6.1e and 6.1f), the ^{235}U evaluation limits correspond to the 24-kg package limit on the amount of HEU oxide or UNX crystals to be shipped. For HEU skull oxide (Table 6.1e), the ^{235}U evaluation limit represents a maximum derived from the evaluation of an inventory at Y-12. For unirradiated TRIGA reactor fuel elements (Table 6.1f), the ^{235}U evaluation limit represents a maximum for the fuel manufacturer's product line.

The NCT and HAC array analyses [10 CFR 71.59(a)(1) and (a)(2)] may reveal reductions in the potential loading limits for content and 277-4 canned spacer configurations initially identified in the single package calculations [10 CFR 71.55(b), (d), and (e)] of Tables 6.1a–6.1f. This occurs in order to achieve fissile material loadings which are at or below the subcritical safety limit. These reduced loading limits are identified as "**load-limited to**" values in the "CSI" rows.

Table 6.2a summarizes the fissile loading limits derived from Tables 6.1a–6.1f for surface-only transport mode. In establishing compliance with the fissile loading limit indicated in Table 6.2a for uranium alloys of aluminum, molybdenum, zirconium, stainless steel, titanium, tungsten, niobium, silicon, or vanadium, the content mass of ^{235}U includes the mass of the non-uranium alloy constituents. The fissile loading limits pertaining to the air-transport mode summarized in Table 6.2b are derived from the air-transport analysis addressed in Sect. 6.7. Packages transported by air involve both surface and air modes of transportation. The loading limit for packages under mixed-mode transportation is taken as the most restrictive limit for either mode (surface or air transport).

The "no water inleakage" condition of 10 CFR 71.55(f)(1) and (f)(2) signifies that the hydrogenous material present in the package during air transport is limited to the amount present in the package when it is loaded on the aircraft for transport. The dry-baked Kaolite in the drum body weldment and drum top plug consists of vermiculite-cement constituents and 2,204.7 g of bound water. Potential sources of additional hydrogen moderator are the hydrogenous packing materials present inside the CV, moisture inside the CV well, and the moisture inside the Kaolite region of the package.

For establishing the loading limits for air transport, the total **free** water in wet Kaolite was conservatively evaluated up to 15 lb (6,803.8 g). Based on this evaluation, **free** water must be limited to 12 lb (5,443.1 g) for maintaining the required margin of subcriticality when shipping under the air transport loading limits specified in Table 6.2b. This requirement is specific to the Kaolite region of the ES-3100 package for two reasons. First, the hydrogenous packing material inside the CV is limited to 500 g per the air transport evaluation. Second, the use of a drum covering and administrative controls (Sects. 7 and 7.1.3.1) will ensure dryness of the CV well. Package operational controls and acceptance limits (Chaps. 7 and 8) will ensure that a package to be used for air transport is qualified.

				20% enr.	**70% enr.**
CSI = 0.0	9,682-g ^{235}U hciapdoxt12_1_1_11_3	15,673-g ^{235}U and 921-g C [i] nciask_9_15	3,297-g ^{235}U nciapunhct11_7_3	921-g ^{235}U nciatrigap_1_15_3	408-g ^{235}U nciatriga70p_1_15_3
CSI = 0.4	12,323-g ^{235}U [j] 5ncf1pdoxt11_1_1_14_3	–	11,303-g ^{235}U ncf1punhct11_24_3	–	–

[a] Uranium alloys (uranium with aluminum, thorium, molybdenum, zirconium, stainless steel, titanium, tungsten, niobium, silicon, or vanadium) may be loaded to the appropriate mass limit as discussed in Appendix 6.9.11.

[b] When can spacers **are not** used, the mass limit = 17,374-g ^{235}U.

[c] When can spacers are used, a greater fissile mass limit is permissible based on enrichment. For CSI=0 and enrichments >80 wt %, the fissile mass must be reduced below the volumetric limit. For CSI=0.4, fissile mass is volumetrically limited by the size of the slugs. Note that within a fixed volume, the HEU mass increases slightly with decreasing enrichment.

[d] Case ncf5bmt11p_14_1_5_3 (with a mass of 23.560 kg ^{235}U) establishes the CSI value of 3.2. The more restrictive mass of 23.370 kg ^{235}U is from Case **cvr3lhap_18_1_5_15** (Table 6.1c).

[e] Case ncf5bmt11p_22_2_6_3 (with a mass of 27.400 kg ^{235}U) establishes the CSI value of 3.2. The more restrictive mass of 22.400 kg ^{235}U is from Case cvr3lhap_9_1_6_15 (Table 6.1c).

[f] Samples and small quantities (≤ 50 g) of HEU metal or alloy turnings, fines, or powder can be shipped under the parent form mass limits (e.g., broken metal, reactor fuel, etc.).

[g] Case ncf5bmt11p_34_2_5_3 (with a mass of 30.970 kg ^{235}U) establishes the CSI value of 3.2. The more restrictive mass of 23.370 kg ^{235}U is from Case cvr3lhap_18_1_5_15 (Table 6.1c).

[h] For ground transport, TRIGA reactor fuel element content will be limited to three fuel sections ("meats") per loaded convenience can and up to three loaded cans per package. The TRIGA fuel content may also be configured as clad fuel rods, each rod derived from a single TRIGA fuel element. A ~15-in.-long rod consists of the three fuel pellets and an exterior sheath of clad, where protruding clad at each end has been crimped in. Clad fuel rods will be packed into convenience cans, with a maximum of three fuel rods per loaded convenience can and one loaded can per containment vessel.

[i] Removal of the carbon limit (i.e., 921-g C) is addressed in Appendix 6.9.11.

[j] See Appendix 6.9.9.

[k] Case ncf5bmt11p_42_2_4_3 (with a mass of 32.400 kg ^{235}U) establishes the CSI value of 3.2. The more restrictive mass of 27.990 kg ^{235}U is from Case cvr3lhap_28_1_4_15 (Table 6.1c).

[l] Case ncf4bmt11p_5_1_6_3 (with a mass of 10.700 kg ^{235}U) establishes the CSI value of 2.0. The more restrictive mass of 10.500 kg ^{235}U is from Case cvr3chap_5_1_6_15 (Table 6.1d).

[m] Case nctf5bmt11p_5_1_6_3 (with a mass of 19.100 kg ^{235}U) establishes the CSI value of 3.2. The more restrictive mass of 10.500 kg ^{235}U is from Case cvr3chap_6_1_6_15 (Table 6.1d).

[n] Case nctf5bmt11p_14_1_5_3 (with a mass of 23.560 kg ^{235}U) establishes the CSI value of 3.2. The more restrictive mass of 15.295 kg ^{235}U is from Case cvr3lhap_14_1_5_15 (Table 6.1d).

[o] Case nctf5bmt11p_27_1_4_3 (with a mass of 26.100 kg ^{235}U) establishes the CSI value of 3.2. The more restrictive mass of 19.800 kg ^{235}U is from Case cvr3lhap_23_1_4_15 (Table 6.1d).

[p] Case nctf5bmt11p_42_1_3_3 (with a mass of 28.800 kg ^{235}U) establishes the CSI value of 3.2. The more restrictive mass of 26.400 kg ^{235}U is from Case cvr3lhap_34_1_3_15 (Table 6.1d).

[a] The loading limit for mixed mode transportation is taken as the most restrictive limit for either the surface or the air mode of transportation, Tables 6.2a or 6.2b.

[b] For air transport, TRIGA reactor fuel element content will be limited to fuel sections or clad fuel rods as described for surface-only modes of transportation in footnote "c" of Table 6.2a and the fissile mass limit specified herein, whichever is more limiting.

[c] Research reactor related contents of uranium metal or U-Al alloy are packaged for air transport under these specified limits.

[d] Research reactor related contents of U_3O_8-Al, UO_2, or UO_2-Mg are packaged for air transport under limits specified for unirradiated TRIGA fuel elements. Per package limits for these items are a maximum of 921-g ^{235}U at enrichments not exceeding 20 wt % and a maximum of 408-g ^{235}U for content enrichments greater than 20 wt %.

[e] Appendix 6.9.10 details air transport evaluation of HEU oxide and compounds.

Research reactor fuel elements or fuel components are composed of U-Al, U_3O_8-Al, UO_2, or UO_2-Mg. Related materials are broken uranium metal, U-Al alloy, or oxides of U_3O_8, U_3O_8-Al, or UO_2-Mg. With the exception of the oxide and compounds, research reactor related contents are packaged for air transport under limits specified in Table 6.2b for HEU broken metal, solid HEU metal of unspecified geometric shape and characterized as broken metal, turnings, fines, or powder. The oxide and compounds are packaged for air transport under limits specified in Table 6.2b for unirradiated TRIGA fuel elements. Per package limits for these items are a maximum of 921-g ^{235}U at enrichments not exceeding 20 wt % and a maximum of 408-g ^{235}U for content enrichments greater than 20 wt %.

Table 6.9.8.1-2 (Appendix 6.9.8) summarizes the fissile material load limits for the contents not covered in Table 6.2a. The loading limits from Tables 6.2a and 6.9.8.1-2 are consolidated in Tables 1.3 and 1.3a.

The criticality evaluation demonstrates that the ES-3100 packaging with the HEU content satisfies the requirements for single packages and for arrays of fissile material packages when the packages are load-limited as specified in Tables 6.2a, 6.2b, and 6.9.8.1-2 (reproduced in Tables 1.3, 1.3a, and 1.3b) under the conditions identified in Sect. 6.2.4.

6.1.4 Criticality Safety Index

A CSI is assigned to the Model ES-3100 package on the basis of an adequate margin of subcriticality for the single package and arrays of packages for both NCT and HAC. Values for the CSI given in Tables 6.2a and 6.2b are based on the uranium and the ^{235}U mass of the content and on the presence of 277-4 canned spacers as defined in Sect. 6.2.2.

The CSI is determined from bounding calculations using KENO V.a models of the CV, the single package, and arrays of packages (NUREG/CR-0200, Rev. 6). It is a dimensionless number used to limit the number of packages in a conveyance for nuclear criticality safety control. The CSI is the larger of the CSI values for NCT and for HAC. For NCT, the CSI is equal to 50 divided by the allowable number of packages "N" that can be shipped, where the allowable number of packages is one-fifth of the maximum array size that is calculated to be subcritical. For HAC, the CSI is equal to 50 divided by the allowable number of packages "N" that can be shipped, where the allowable number of packages is one-half of the maximum array size that is calculated to be subcritical. The CSI is a calculated number rounded up to the nearest first decimal.

The array sizes examined in this evaluation are infinite, 13×13×6, 9×9×4, 7×7×3, 5×5×2, explicit triangular pitch (ETP) 27×3 for NCT, ETP 16×3 for HAC, and the degenerate single unit. For NCT, the "N" and corresponding CSI values for arrays determined to be adequately subcritical are as follows: N = ∞, CSI = 0; N = 202, CSI = 0.3; N = 64, CSI = 0.8; N = 29, CSI = 1.8; N = 10, CSI = 5.0; and N = 16, CSI = 3.2. For HAC, the "N" and corresponding CSI values for arrays determined to be adequately subcritical are as follows: N = ∞, CSI = 0; N = 507, CSI = 0.1; N =162, CSI = 0.4; N = 73, CSI = 0.7; N = 25, CSI = 2.0; and N = 24, CSI = 2.1. Absent an exact correspondence of CSI values for the NCT and HAC, the following arrays results were selected for rounded CSI values as indicated in Tables 6.1a–6.1f:

- infinite arrays evaluated for both NCT and HAC [designated as "(1,2)"], where N(1,2) = for a CSI = 0;
- 13×13×6 evaluated for NCT and 9×9×4 evaluated for HAC where N(1,2) = (202,162) for a CSI = 0.4;
- 9×9×4 evaluated for NCT and 7×7×3 evaluated for HAC where N(1,2) = (64,73) for a CSI = 0.8;

- 7×7×3 evaluated for NCT and 5×5×2 evaluated for HAC where N(1,2) = (29,25) for a CSI = 2.0; and
- 27×3 evaluated for NCT and 16×3 evaluated for HAC where N(1,2) = (16,24) for a CSI = 3.2.

6.2 PACKAGE CONTENTS

The **package content** is defined as the HEU fissile material, bottles, convenience cans, canned spacers, can pads, and the associated packing materials (polyethylene, nylon, and Teflon bags; pads; tape; etc.) inside the ES-3100 CV.

6.2.1 Fissile Material Contents

The per-package HEU mass loadings considered in the criticality evaluation range from 1000 to 36,000 g for uranium metal and from 1000 to 24,000 g for uranium oxide and UNX crystals. The HEU mass may include nonradioactive contaminants and trace elements or materials in the HEU.

The bounding types of HEU content evaluated in this criticality analysis are 4.25-in.- and 3.24-in.-diam cylinders; 2.29-in.-square bars; 1.5-in.-diam × 2-in.-tall slugs; cubes ranging from 0.25 to 1 in. on a side; broken metal pieces of unspecified geometric shapes; skull oxide; uranium oxide; UNX crystals; and unirradiated TRIGA reactor fuel elements.

The terms “broken metal” and “turnings, fines, or powder” are used to describe an HEU content without restrictions on shape or size other than a minimum size limit (spontaneous ignition), a maximum mass limit (criticality control), a minimum enrichment (the lower limit for HEU at 19 wt % ^{235}U in uranium), and the capacity limits of the convenience cans. The content geometry envelope encompasses regular, uniform shapes and sizes as well as irregular shapes and sizes. Broken metal pieces are distinguished from turnings, fines, or powder as having a surface-area-to-mass ratio of not greater than 1 cm^2/g or must not pass through a 3/8-in. mesh sieve (or equivalent size-grading method). By this definition, turnings, fines, or powder are packed in cans that are sealed and the cans’ atmosphere is inerted for pyrophoric considerations.

HEU in the form of oxide with residual metallic particles is referred to as Clinkers and Screenings. This material results from metal casting operations where uranium metal is melted in a graphite crucible. After the metal is poured into casting molds, the crucibles are cleaned of residual material. The residual are bits of scrap metal and oxide debris. This residual material is passed through a sieve, where finer oxide passes through the sieve and is considered to be skull oxide. The material that does not pass through the sieve is considered to be Clinkers and Screenings. This material is predominantly oxide, but often will have small particles of metal. From a criticality safety standpoint, the HEU metal or alloy turnings, fines, and powders model is more conservative than the HEU oxide model, and thus Clinkers and Screenings will be conservatively loaded under the mass loading limits for HEU metal or alloy turnings, fines, and powders.

The density of HEU metal ranges from 18.811 to 19.003 g/cm^3 for HEU metal, corresponding to enrichments ranging from 100 to 19 wt % ^{235}U. Theoretical (crystalline) densities for HEU oxide are 10.96 g/cm^3, 8.30 g/cm^3, and 7.29 g/cm^3 for UO_2, U_3O_8, and UO_3, respectively. However, bulk densities of product oxide are typically on the order of 2.0 to 6.54 g/cm^3. With increased moderation of fissile mass possible at these lower densities, only “less-than-theoretical” mass loadings would actually be achieved. Skull oxides are a mixture of U_3O_8 and graphite, having densities on the order of 2.44 g/cm^3 for poured material and 2.78 g/cm^3 for tamped (packed) material. Combined water saturation and crystallization of the HEU oxide is not expected in the HAC because UO_2 is non-hygroscopic, and

both UO_3 and U_3O_8 are only mildly hygroscopic. The density of UNX crystals varies depending on the degree of hydration. The most reactive form of UNX crystals considered for shipment in the ES-3100 is $UO_2(NO_3)\cdot xH_2O$ with 6 molecules of hydration, having a density of 2.79 g/cm3. UNX crystals are highly soluble in nitric acid and mildly soluble in water. Dissolution of UNX crystals in water is assumed in this criticality evaluation. The content geometry envelope encompasses both regular, uniform clumps and densities, and irregular clumps and densities.

The ~40 stock items of TRIGA fuel are cataloged as one of the four basic types: a standard element, an instrumented element, a fuel follower control rod, or a cluster assembly. The active region of TRIGA element consists of three 5-in long sections "fuel meats" of uranium zirconium hydride ($UZrH_x$). The "x" in $UZrH_x$ equals 1.6 in all cases except for two stock items where x = equals 1.0 and the fissile content is < 40-g ^{235}U. The clad thickness is ~0.02 in. for a TRIGA fuel element with stainless steel cladding and ~0.03 in. for an element with aluminum cladding.

Solid form TRIGA fuel is either 20 or 70 wt % enriched in ^{235}U and has specific dimensional characteristics for its designed function. For the 20 wt % enriched TRIGA elements, the active fuel diameters are 1.44 in., 1.41 in., 1.40 in., 1.37 in., 1.34 in., or 1.31 in. The uranium weight fractions are 45 wt %, 30 wt %, 20 wt %, 12 wt %, and 8.5 wt %. The TRIGA element with a maximum fissile content of 307-g ^{235}U in 1,560-g U is 45 wt % U in $UZrH_x$ and has a computed density of ~8.6 g/cm^3 (Appendix 6.9.3.1). For the 70 wt % enriched TRIGA fuel, the active fuel diameter is 1.44 in. in the standard element and instrumented element, and 1.31 in. in the fuel follower control rod. Both the standard element and instrumented elements contain ~136-g ^{235}U in 194-g U, while the fuel follower control rod contains ~113-g ^{235}U in 162-g U. The 70 wt % enriched TRIGA fuel is 8.5 wt % U in $UZrH_x$ and has a computed density of ~5.7 g/cm^3 (Appendix 6.9.3.1).

In preparation for shipment in the ES-3100, the unirradiated TRIGA fuel elements may be disassembled and the fuel sections removed from the thin-wall cladding. The TRIGA fuel may also be configured as clad fuel rods. Each clad fuel rod will be derived from a single TRIGA fuel element by removal of the stainless steel or aluminum clad beyond the plenum adjacent to the axial ends of the active fuel section. Each ~15-in.-long rod consists of the 3 fuel pellets and an exterior sheath of clad, where the protruding clad at each end has been crimped in.

The 0.02-in.-thick sheath of stainless steel clad adds ~179 g to the mass of the active fuel for the standard element or instrumented element with 1.48 in. overall diameter, and ~163 g to active fuel mass for the fuel follower control rod with 1.35 in. overall diameter. Allowance for 0.5 in. of residual stainless steel crimped on each end of the clad fuel rod adds ~11 to 12 g stainless steel to these amounts. Likewise, the 0.03-in.-thick sheath of aluminum clad adds ~90 g to the mass of the active fuel for the 1.47-in.-diam standard element or instrumented element. Allowance for 0.5 in. of residual aluminum crimped on each end of the clad fuel rod adds ~6 g aluminum.

Research reactor fuel elements or fuel components are composed of U-Al, U_3O_8-Al, UO_2, UO_2-Zr, UO_2-ZrO_2, or UO_2-Mg. Related materials include broken uranium metal, U-Al alloy, or oxides (UO_2, UO_3, U_3O_8, U_3O_8-Al, UO_2-ZrO_2, or UO_2-Mg). These items contain small quantities of fissile uranium typically ranging from 4.2-g ^{235}U to 2000-g ^{235}U. The maximum enrichment is ~93%. Components are of various solid shapes (rods, square bars, plates, or tubes).

HEU oxide fuel coated with carbon is allowed with no additional limits or controls as presented in Appendix 6.9.11. Since the CV was conservatively modeled as fully flooded, adding carbon results in a less reactive system because any carbon added would displace water, which is a much better moderator.

Skull oxides, uranium alloys of aluminum, molybdenum, or zirconium and unirradiated TRIGA reactor fuel elements are evaluated where composition data is for material in the as-manufactured condition. A maximum enrichment of 100 wt % is used for HEU metal, oxide and UNX crystals in the criticality calculations strictly for the purpose of maximizing reactivity, even though HEU enrichment ranges from 19 to 97.7 wt % ^{235}U. Although mass loading limits for oxide and crystals are based on 100% enrichment, the actual enrichment is expected to be less than the stated maximum, with the remainder of the uranium being primarily ^{238}U. The HEU mass may also include nonradioactive contaminants and trace elements or materials in the HEU.

No intact weapon part or component will be shipped in this package. Weapon parts or components that have been reduced to "broken metal pieces" or processed into HEU oxide and meet the additional content requirements identified in Sect. 6.2.4 may be shipped in this package.

6.2.2 Convenience Cans, Teflon and Polyethylene Bottles, and 277-4 Canned Spacers

HEU fissile material to be shipped in the ES-3100 package will be placed in stainless steel, tin-plated carbon steel, aluminum, or nickel alloy convenience cans, polyethylene or Teflon bottles, or polyethylene bagging. Can lids may be welded, press fit, slip lid, or crimp seal types; bottle lids are screw cap type. Convenience cans and bottles are used to hold the HEU for shipment in the ES-3100 package and to assure that the inside of the CV does not become contaminated with HEU under NCT. The HEU metal or oxide content may be wrapped or bagged in polyethylene, and the convenience cans may also be wrapped in polyethylene to further reduce the possibility of radioactive contamination of the packaging. Nylon straps may be used for handling the nickel alloy cans. Masses of the convenience cans and packing materials are in addition to the fissile material mass.

Three 4.25-in.-diam × 10.0-in.-tall or six 4.25-in.-diam × 4.88-in.-tall convenience cans, separated by can pads, may be placed inside the 31-in.-tall cavity of the ES-3100 CV (Fig. 1.4). The convenience cans may have press-fit or crimp-seal lids. The size of solid content placed inside a convenience can is physically limited by both the can opening and the usable height of the convenience can. Other can arrangements fit inside the CV, such as three 4.25-in.-diam × 8.75-in.-tall convenience cans or five 4.25-in.-diam × 4.88-in.-tall convenience cans. Both of these can arrangements include can pads and 277-4 canned spacers. Nickel alloy cans to be used exclusively for HEU oxide content are ~3-in. diam × 4.75-in. tall. Three Teflon bottles (4.69-in. diam × 9.4-in. tall) or three polyethylene bottles (4.94-in. diam × 8.76-in. tall) fit inside the CV; however, 277-4 canned spacers are not used with these configurations.

A modified convenience can may be used to package the TRIGA and research reactor fuel element and fuel components that do not fit inside these containers. A 17.5 in. or 30 in.-tall convenience can is constructed from two 4.25-in.-diam × 8.75-in.-tall or three 10-in. cans brazed together. The research reactor fuel elements and fuel components that cannot be packaged in these convenience cans due to their overall dimensions will be bundled together and protected on each end with an open-ended convenience can having an outer diameter ≤ 5 in.

The can pad and 277-4 canned spacer have overall dimensions of 4.25-in. diam × 1.82-in. height (Drawing M2E801580A043, Appendix 1.3.7). A stainless-steel spacer can with a lid has a usable cavity with dimensions of 4.13-in. diam × 1.37-in. height, which nominally allows for ~510 g of neutron poison material. If closed convenience cans with an outer diameter >4.25 in. are used, at least 43 $in.^3$ of free or void volume must exist inside the CV to allow for gas expansion and offgassing of material at temperatures associated with NCT or HAC.

6.2.3 Packing Materials

Polyethylene, nylon, or Teflon bags may be used for contamination control to hold the HEU material that is packed into a convenience can. Realistically, the number of bags used to bag content and wrap a convenience can would be six bags at most. Given that each bag weighs ~28 g, this results in a maximum of ~510 g of bagging per ES-3100 package. Possible additional sources of hydrogenous material inside the CV include can pads and vinyl tape. Nylon ($C_{12}H_{22}N_2O_2$) and Teflon (C_2F_4) have a lower hydrogen density than water and polyethylene and are bounded by the polyethylene evaluations.

Polyethylene bottles (~85 g) may be used to pack HEU oxide; however, polyethylene bags are not used for packing HEU oxide. While polyethylene bags may be used to bag the 85 g polyethylene bottles, the amount of hydrogenous packing material inside the CV is limited to an equivalent 500 g polyethylene. Non-metallic containers such as polyethylene or Teflon (~303 g) may be used to pack UNX crystals. Likewise, polyethylene bags are not used for packing the UNX crystals and the amount of hydrogenous packing material inside the CV is limited to an equivalent 500 g polyethylene.

Normally, the H/X ratio inside the CV is specified as an administrative control used to restrict both the amount of hydrogenous packing material normally used inside the CV and other sources of moisture present in the fissile content. The total amount of hydrogen inside the CV is used in the determination of package H/X ratio (i.e., the ratio of the number of hydrogen atoms "H" to the number of fissile atoms "X," where the hydrogen atoms are those of the content, including absorbed moisture and of the packing material both inside and outside of the convenience cans). However, CV flooding is assumed in calculations performed for the derivation of fissile material loading limits. This simulated condition produces fissile material content that is more reactive than actual.

The 7.1–10.1 kg quantity of evaluation water required in both the NCT and HAC criticality calculations bounds reasonable amounts of hydrogenous packing material present inside the ES-3100 CV for solid HEU metal content (cylinders, bars, buttons, slugs, unirradiated TRIGA fuel, and research-related fuel components fissile material). The hydrogenous packing material encompasses the solid fissile material but is not interspersed within it.

However, the 7.1–10.1 kg quantity of evaluation water does not necessarily bound reasonable amounts of hydrogenous packing material present inside the CV when the fissile material is in particulate form (primarily HEU oxides and UNX crystals) or must be evaluated in particulate form (broken metal). An administrative criticality control is used to restrict the amount of hydrogenous packing material normally present inside the CV (see Sect. 6.2.4, Item 7).

6.2.4 Package Content Loading Restrictions

Loading restrictions based upon the results of the criticality safety calculations presented in Sects. 6.4 and 6.5 are as follows:

1. HEU fissile material to be shipped in the ES-3100 package must be placed in stainless steel, tin-plated carbon steel, aluminum, or nickel alloy convenience cans, polyethylene or Teflon bottles, or polyethylene bagging. Enriched uranium oxide in the form of UO_2-Mg will be shipped in glass bottles inside a metal convenience can. Any closure is allowed on the convenience can.

2. The content shall not exceed the "per package" fissile material mass loading limits specified in Tables 6.2a and 6.2b, and 277-4 canned spacers shall be used as indicated for criticality control. Research reactor related contents of uranium metal or U-Al alloy may be packaged for air transport under limits specified in Table 6.2b for HEU broken metal, solid HEU metal of unspecified geometric

shape and characterized as broken metal, turnings, fines, or powder. Research reactor fuel elements and components may be packaged for air transport under limits specified in Table 6.2b for unirradiated TRIGA fuel elements. Per package limits for these items are a maximum of 921-g ^{235}U for content at enrichments not exceeding 20 wt % and a maximum of 408-g ^{235}U for content enrichments greater than 20 wt %.

3. Where 277-4 canned spacers are required, not greater than one-third of the permissible package content for that category indicated in Tables 6.2a or 6.2b shall be loaded in any vacancy between or adjacent to canned spacers inside the CV. The content mass loading may be further restricted based on structural, mechanical, and practical considerations (see Chaps. 1 and 2).

4. As shown in Fig. 1.4, the ES-3100 package may carry up to six loaded convenience cans. In situations where the plan for loading the CV calls for the use of empty convenience cans to fill the CV, empty cans and/or stainless-steel scrubbers may be used to fill the void space in the CV. If empty cans are shipped, a minimum 0.32-cm (0.125-in.)-diam hole must be placed through the lid to prevent over-pressurization of the can in the event of a thermal accident. These empty cans may be placed above or below the loaded cans.

5. The presence of uranium isotopes is limited on a weight-percent basis as follows: $^{232}U \leq 40$ ppb U, $^{233}U \leq 0.6$ wt % U, $^{234}U \leq 2.0$ wt % U, $^{235}U \leq 100.0$ wt % U, and $^{236}U \leq 40.0$ wt % U.

6. With the exception of slug content, unirradiated TRIGA reactor fuel element content, and research reactor related content, solid HEU metal or alloy content of specified geometric shape shall be one item per loaded convenience can. HEU metal or alloy content not covered by the specified geometric shapes (cylinder, bar, button, billet, slug, or unirradiated TRIGA fuel element contents) will be in either the "HEU broken metal or solid HEU metal of unspecified geometric shape and characterized as broken metal" category or in the "HEU metal turnings, fines, or powder" category, and so limited (Table 6.2a). Broken metal is distinguished from turnings, fines, or powder as having a surface-area-to-mass ratio of not greater than 1 cm^2/g or must not pass through a 3/8-in. mesh sieve (or equivalent size-grading method).

7. The package content is defined as the HEU fissile material, bottles, the convenience cans, the can spacers, and the associated packing materials (polyethylene, nylon, or Teflon bags; pads; tape; etc.) inside the ES-3100 CV. The amount of hydrogenous packing material inside the CV shall not exceed an equivalent mass of 500 g polyethylene.

8. The mass of unidentified constituents of an HEU fissile material to be loaded into the ES-3100 will be counted against the fissile mass loading limit. The HEU fissile material will not contain unevaluated moderating materials.

9. Allowable HEU oxide bulk densities are 0.5–6.54 g/cm^3 for ground transport and 1.0–6.54 g/cm^3 for air transport.

10. For air transport, the total free water permitted in the ES-3100 packaging is limited to 12 lb (5,443.1 g).

6.3 GENERAL CONSIDERATIONS

The ES-3100 packaging configuration is shown on Drawing M2E801580A031 (Appendix 1.3.7). KENO V.a modeling of this configuration with the maximum allowable contents (Sect. 6.2) for a variety of array sizes and array conditions yields bounding calculations that determine the package's CSI (Tables 6.1a–6.1f). Can spacers are used as indicated in Table 6.2a and 6.2b for the purpose of reducing neutronic interaction between the contents of the package, aiding in maintaining the $k_{eff} + 2\sigma$ below the USL for the ES-3100 package. Key input listings are provided in Appendix 6.9.7.

The HEU content of a package is in one of the following forms: solid metal or alloy of a specified geometric shape; broken metal; turnings, fines, or powder; solid metal or alloy of unspecified geometric shape and characterized as broken metal; uranium or skull oxide; UNX crystals; or unirradiated TRIGA reactor fuel elements. The bounding types of HEU content evaluated in this criticality analysis are: 4.25-in.- and 3.24-in.-diam cylinders; 2.29-in.-square bars; 1.5-in.-diam × 2-in.-tall slugs; cubes ranging from 0.25 to 1 in. on a side; broken metal pieces of unspecified geometric shapes; product and skull oxide; Uranyl nitrate hexahydrate (UNH) crystals; and unirradiated TRIGA reactor fuel elements. UNH has a chemical formula of $UO_2(NO_3)_2 \cdot 6H_2O$. This most reactive form is used as the bounding composition for UNX crystals in the criticality evaluation. TRIGA fuel elements are 1.44-in.-diam × 15-in.-tall cylinders of $UZrH_x$ containing <310-g ^{235}U. Fuel elements are sectioned into three equal length pieces. Calculations demonstrate that these contents are bounded by 3.24-in.-diam HEU metal cylinders. Evaluation of the 3.93-in.-diam × 9.5-in.-tall U-Al cylinders is covered under the evaluation of the 4.25-in.-diam HEU metal cylinders. The evaluation of the U-Mo content is covered under the assessment of HEU contents at 95 wt % enrichment.

HEU metal shapes are distributed in an optimum arrangement in the flooded CV. For the single package and the array calculations, the HEU broken metal is modeled as a homogeneous mixture of uranium metal and water filling the interior of a flooded CV. This representation bounds the heterogeneous configuration of metal pieces interspersed with hydrogenous packing material inside of wrapped convenience cans (Appendix 6.9.3., Sect. 6.9.3.1). Water soluble UNH crystalline content is modeled as a homogeneous mixture of UN and water filling the interior of the CV.

No credit is taken for the fissile material spacing, neutron absorption, or free volume reduction provided by the presence of can pads, spacer can steel, and convenience cans inside the CV. Water is substituted for polyethylene bagging which may be in use as packing material for both the content placed inside the convenience can and the cans themselves. Pads of steel turnings rolled up into a disk-like shape may also be present in the ES-3100 package for use as cushioning and for reducing the free volume inside the convenience cans. This steel packing material acts as a neutron absorber and is excluded from the calculation model.

Criticality calculations are performed for the CV under full water reflection whereby the water content inside the CV is varied from dry to fully flooded conditions. These calculations demonstrate that the fully flooded condition is most reactive. The CV is flooded in the single-unit calculation model and the infinite and finite array calculation models for both the NCT and HAC evaluations.

The KENO V.a models discussed in the following sections are the single-unit calculation model (Sect. 6.3.1.1), the infinite and finite array calculation models (Sect. 6.3.1.2), the HAC calculation models (Sect. 6.3.1.3), and the air transport models (Sect. 6.3.1.4). The single-unit calculation model is evaluated with a vacuum boundary condition and with full water reflection. The finite array calculation model is evaluated in arrays consisting of packages stacked in 13×13×6, 9×9×4, 7×7×3, 5×5×2, ETP 27×3 and ETP 16×3 arrangements with full water reflection at the array boundary. The ETP arrangements are used specifically for defining smaller array configurations with a high CSI value.

The geometry of the ES-3100 package is depicted in Drawing M2E801580A001 (Appendix 1.3.7). Calculation models of this geometry for evaluating NCT and HAC must be constructed for the single-unit, infinite array and finite arrays within the constraints and capabilities of KENO V.a. As shown in the drawing, the ES-3100 geometry is complex. Given KENO V.a's constraints and capabilities, two methods may be used to evaluate these complex geometries: simplify the geometries with conservative approximations or construct accurate geometries from simple components. Both methods yield valid results; however, the latter method is chosen for this analysis in order to maximize accuracy and to eliminate unnecessary conservatism.

6.3.1 Model Configuration

A detailed ES-3100 geometry model is accurately constructed using many simple geometric shapes. The selection of these components is governed by two of KENO V.a's geometry constraints: geometry regions must be composed of uniform and homogeneous materials and exterior regions must completely enclose interior regions. It is apparent from Drawing M2E801580A001 (Appendix 1.3.7) that these constraints could not be simultaneously applied to the entire ES-3100 package. However, these constraints could be applied to vertical segments of the package. Segments (i.e., simple components) are defined by starting at the bottom of the package and defining geometry regions radially outward until the drum surface is reached. A vertical segment is extended upward to the point where the KENO V.a constraints are violated. This vertical position is the termination point of a segment (i.e., the interface with the adjacent segment above it). The vertical segments are constructed accordingly, ignoring the minor variations in the ES-3100 geometry (i.e., radii of curvature, beveled edges, nuts and bolts). The KENO V.a geometry model for the ES-3100 is then assembled from the vertical segments. The resulting calculation model geometry includes the HEU content, 277-4 canned spacers, the CV, the stainless-steel liner, the inner-liner cavity filled with 277-4, the outer-liner cavity filled with Kaolite, the Kaolite top plug and steel shell, the silicon rubber spacers, and the stainless-steel drum.

6.3.1.1 Single-unit packaging calculation model

The single-unit packaging calculation model is comprised of the geometry model, material compositions, and boundary conditions. Figures 6.1–6.5 depict section views of the geometry model used to evaluate a single ES-3100 package. Excluding minor variations in the ES-3100 geometry (i.e., radii of curvature, beveled edges, nuts and bolts), the single-unit packaging calculation model is an accurate representation of the ES-3100 geometry.

Figure 6.1 depicts a vertical section view of an ES-3100 package with the content of three loaded convenience cans and 277-4 can spacers inside the CV. The fissile material contents shown are HEU cylinders, but convenience cans are not modeled. As illustrated in Fig. 6.1, credit is not taken for fissile material spacing provided by convenience cans inside the CV. Appendix 6.9.1 provides wire-frame schematic and isometric diagrams depicting other fissile material contents considered in this criticality calculation.

Figures 6.2–6.5 depict vertical section views at various elevations in the package. The dimensions and the material specifications of any element of the ES-3100 single-unit packaging model may be obtained directly from the KENO V.a input listings in Appendix 6.9.7. The vertical segments (KENO V.a geometry unit numbers) are denoted in parenthesis to the right of the dimensions. The dimensions are given in units of centimeters. Material specification data for the single-unit packaging calculation model are provided in Sect. 6.3.2.

The single-unit calculation model is evaluated as both a bare system (i.e., with a vacuum boundary condition) and as a reflected system with 30.48 cm (1 ft) of water surrounding the package for effectively infinite water reflection.

10 CFR 71.55(b) requires evaluation of water leakage into the containment system disregarding any performance capability demonstrated by physical testing per 10 CFR 71.71 and 71.73. In conjunction, 10 CFR 71.55(b)(3) also requires evaluation of the efficiency of the packaging as an external reflector to the CV. The test case is defined as a flooded package. All regions within the water-reflected, single-unit packaging calculation model are flooded with water. The reference case is defined as a water-reflected flooded CV. This calculation model is a modification of the water-reflected, single-unit packaging calculation model where all regions of the packaging external to the CV are replaced with full density water.

6.3.1.2 Infinite and finite array packaging calculation models

Array packaging calculation models like the single-unit packaging calculation model are comprised of geometry, material compositions, and boundary conditions. Figures 6.6–6.10 depict section views of the geometry model used to evaluate an array of ES-3100 packages. The array geometry model incorporates a 7.0% reduction in the inside diameter of the ES-3100 drum. This reduction of the drum's inside diameter produces an array density equivalent to drums in a tightly packed, triangular pitch configuration (O'Dell). Since all array calculations in this evaluation use a square pitch package configuration, using the 7.0% reduction in diameter of uniform-shaped packages avoids the use of a nonconservative lattice arrangement in the array analysis.

As seen in Drawings M2E801580A002 and M2E801580A003 (Appendix 1.3.7), a 7.0% reduction of the inside diameter of the ES-3100 drum affects the masses of the drum, the modified 2 × 2 × ¼ in. angle (angle iron), and the Kaolite refractory material. Also, a 7.0% reduction in diameter affects the mass of interstitial water between the ES-3100 packages of a tightly packed array. To maintain the correct mass of these materials in the NCT array packaging calculation model, the drum's outside dimensions, the density of the steel in the angle iron, the density of Kaolite, and the density of interstitial water are modified. Excluding modifications required to simulate a triangular pitch and minor variations in the ES-3100 geometry (i.e., radii of curvature, beveled edges, nuts and bolts), the array geometry model is an accurate model of the ES-3100 geometry.

In the NCT array packaging calculation model, the drum outside diameter is 43.444550 cm (17.104154 in.) [21.722275-cm radius used as the input value], and the drum inside diameter is 43.11015 cm (16.972500 in.) [21.555075-cm radius]. This inside diameter corresponds to 93% of the inside diameter of the ES-3100 drum. The thicknesses of the drum wall, the drum bottom flat cover, and the drum lid are uniformly increased in order to maintain the region volume and to conserve drum mass, while the stainless steel density and volume fraction remain unchanged in the KENO V.a input specification. However, the region volume for the drum steel in the NCT array packaging calculation model is not equal to the volume in the single-unit packaging calculation model due to internal round-off in KENO V.a. Therefore, the volume fraction is changed from 1.0 to 0.99981 in the NCT array packaging calculation model for normalization of the drum mass.

The angle iron outside diameter is identical to the drum inside diameter. To maintain mass, the angle iron steel, the liner outer-cavity Kaolite, and interstitial water densities are modified by factors of 1.25705, 1.22252, and 1.16235, respectively. Excluding the modifications to drum and angle iron dimensions, the dimensions of any element of the ES-3100 array geometry model may be obtained directly from Appendix 6.9.7. Material specification data from the array calculation models are provided in Sect. 6.3.2.

O'Dell and Schlesser equate modeling triangular arrays with square pitch arrays, provided that the outer dimension of the array is reduced by a factor of 0.9306 and that the mass of materials is maintained. The actual reduction factors (ratio of the reduced radii to the single unit radii) for the Kaolite of the body weldment and for the angle iron is slightly <0.9306. Given that the array packages are closer than required by O'Dell and Schlesser, the array models are conservative with respect to their reduced radii.

The finite array calculation model is evaluated with arrays of packages stacked in 13×13×6, 9×9×4, 7×7×3, and 5×5×2 arrangements where the arrays are surrounded with 30 cm (~1 ft) of water as a boundary condition representative of full water reflection. These arrays are nearly cubic in shape for optimum reactivity of the array, thus eliminating the need for placing limitations on array configurations in terms of stack height, width, and depth.

The KENO V.a users manual (NUREG/CR-0200, Rev. 6) describes the input statements for an ETP model of cylinders in a close-pack array. This technique is adapted for modeling the ES-3100 in small compact array configurations. The ETP geometry model is much more complicated than the reduced-diameter approximation model described previously, but it yields smaller package configurations with correspondingly higher CSI values than the 7×7×3 and 5×5×2 package arrangements. Use of the ETP geometry specification allows for constructing compact package arrangements of 27×3 (27 packages in the horizontal plane stacked 3 packages high) and 16×3 packages.

6.3.1.3 Calculation models for damaged packages

Chapters 2, 3, and 4 of this report address the overall integrity of the Model ES-3100 package in tests for NCT and HAC (ORNL/NTRC-013). From a dimensional viewpoint, the only physical changes of interest for criticality safety occurred as a result of the 9-m (30-ft) drop test, the crush test, and the 1-m (40-in.) puncture test. There was significant crushing of the drum rim at the point of impact from the 9-m (30-ft) drop test and an indentation on the drum side from the 1-m (40-in.) puncture test. Even though significant crushing of the drum mid-section and bottom occurs, the effective center-to-center spacing of the contents actually increases under HAC. Selective rearrangement of alternating packages would be required to achieve a more compact array; however, this event is not credible.

The deformation of the outer diameters of the drum as predicted by finite element analysis is presented in Table 6.3. These diameters measured along the 90–270° and 0–180° axes are specified at five node points located along the vertical axis of an upright package. These node points are designated in a downward direction from the top of the drum as "UR," "MUR," "MR," "MLR," and "LR." Equivalent circular diameters for representing the deformed drum in the calculation models for the HAC study (Appendix 6.9.2) are based on the assumption that the drum cross section at each deformation point is ellipsoidal.

Table 6.3. Deformation of 18.37-in.-diam ES-3100 drum projected by finite element analysis Case "3100 RUN1HL Lower Bound Kaolite May 2004"

Deformation point	FEA node	Diameter at 90° (in.)	Diameter at 180° (in.)	Equivalent circular diameter (in.)
UR	098194	20.02	15.60	17.67
MUR	100238	20.74	15.07	17.68
MR	101589	20.74	14.18	17.15
MLR	103012	22.00	13.44	17.20
LR	105786	20.92	12.92	16.44

The package water content in the void spaces external to the CV and the interstitial spaces between drums is varied in the calculation model, while maintaining the Kaolite in the dry condition. At a low moisture content where neutronic interaction between packages of an array is greatest, there is no statistically significant difference in the calculated neutron multiplication factor for package models based on the "MR," "MLR," and "LR" node points. At high moisture content where a statistically significant difference in the calculated neutron multiplication factor occurs, the packages of an array are nearly isolated. The slight increase in k_{eff} at the smaller diameters is not numerically significant. A calculation model based on the "MLR" node point is used to represent HAC.

As concluded in Sect. 6.9.2.3, the criticality analysis of an array of HAC packages based on the "MLR" package model (diameter = 17.20 in.) in rectangular pitch bounds the analysis of damaged packages (diameter = 17.26 in.) in close-pack array configurations. Considering both the irregular shape of the deformed drums and the fact that overall (maximum) dimensions rather than a mean or minimum dimension for a damaged package would establish array spacing—this assumption is a reasonable one, and the model is conservative.

A reduced-diameter version of the "MLR" package model used for modeling a close-pack array configuration of HAC packages is not created. Instead, "MLR," the single-unit packaging model, is evaluated in a rectangular-pitch array configuration using appropriate boundary conditions. Consequently, the dimensions of the HAC array packaging calculation model do not differ from those of the HAC single-unit packaging calculation model. Therefore, the region volume of the drum and the atomic densities for the elemental constituents for the drum stainless steel are the same in both of the HAC calculation models.

The neutron poison, Kaolite refractory material, and stainless-steel components of the ES-3100 package were not significantly damaged during thermal testing. The principal material change of consequence that occurred during the thermal test was the loss of volatile material (Sect. 2.7.4). No loss of volatile material other than steam from the Kaolite was experienced during prototype testing of the Model ES-3100 package.

Physical damage is significant in terms of criticality safety when the amount of volatile hydrogenous material available for interstitial moderation is reduced. Conversely, the package could be saturated with water during water immersion conditions. Both possibilities affect only the amount of interstitial moderation. The representation of the changes to material composition from temperature extremes and water intrusion is addressed in Sect. 6.3.2.

In the case of broken metal content, the ETP geometry specification using the "MLR" package model (diameter = 17.20 in.) produces a 16×3 package configuration having a correspondingly higher CSI value than a 5×5×2 package arrangement. This allows for a greater fissile payload.

6.3.1.4 Calculation models for catastrophically-damaged packages (air-transport)

It is possible for accidents to be substantially more severe in the air transport mode than in the surface transport mode. Thus, the performance requirements for packages designed to be transported by air are more stringent. U.S. Nuclear Regulatory Commission (NRC) Regulatory Guide 7.9 states that the criticality evaluation should evaluate a single package under the expanded accident conditions specific in 10 CFR 71.55(f).

For a fissile material package designed to be transported by air, 10 CFR 71.55(f)(1) requires the criticality evaluation demonstrate that the package be subcritical, assuming reflection by 20 cm (7.9 in.) of water but no water inleakage, when subjected to the sequential application of the HAC free drop and crush tests of 10 CFR 71.73(c)(1 and 2) and the modified puncture and thermal tests of 10 CFR 71.55(f)(1)(iii and iv). 10 CFR 71.55(f)(2) requires the criticality evaluation demonstrate that the package be subcritical, assuming reflection by 20 cm (7.9 in.) of water but no water inleakage, when subjected to an impact on an unyielding surface of 90 m/s normal to the surface.

The "no water inleakage" condition of 10 CFR 71.55(f)(1) and (f)(2) signifies that the hydrogenous material present in the package during air transport is limited to the amount present in the package when it is loaded on the aircraft for transport. Potential sources of hydrogen moderator are the hydrogenous packing materials present inside the CV, moisture inside the CV well, and the moisture inside the Kaolite region of the package. The use of hydrogenous packing material is limited to 500 g. Both the use of a drum covering and administrative controls (Sects. 7 and 7.1.3.1) will ensure dryness of the CV well. Thus, the focus is on the Kaolite region of the ES-3100 package. The silicon rubber pads are not used in these calculations. The 53,420 g of dry-baked Kaolite in the drum body weldment and drum top plug consists of 51,214.9 g of vermiculite-cement constituents and 2,204.7 g of bound water. For establishing the loading limits for air transport, the total **free** water in wet Kaolite was conservatively evaluated up to 15 lb (6,803.8 g).

Physical testing of Type-B fissile material packages transported by air was not conducted for the ES-3100. In lieu of testing, criticality calculations are performed using calculation models that conform to the basic requirements of 10 CFR 71.55(f) regarding both the absence of water inleakage and reflection of the package by 20 cm of water. In addition, the air-transport calculation models incorporate features exhibiting the worst-case assumptions made regarding the geometric arrangement of the packaging and package contents. No credit is taken for the geometric form of the package content. Spherical geometry is used to represent the ultimate configuration of the ES-3100 package which undergoes catastrophic destruction.

The criticality analysis for air transport does not credit the ES-3100 for maintaining the geometry configuration of the packaged content. Fissile material is configured spherical in shape for optimization of neutron multiplication. Also, the criticality analysis does not credit the ES-3100 packaging for structural integrity of the containment and the confinement. The reactivity "enhancing" materials of the packaging may be interspersed with the fissile material content. However, selective removal of the neutron-absorbing material of the package (i.e., Kaolite and stainless steel) accompanied by retention of the moderating constituents of the neutron-absorbing material (i.e., bound water in the Kaolite) is not a credible condition. Moreover, a calculation model where the fissile material is homogenized with moderating material is only an appropriate representation when the fissile material content being shipped consists of numerous solid pieces uranium ("broken metal"), metal turnings, fines, powder, oxide, or crystals. Homogenization of fissile material with moderating material is not performed with exclusive preference given to specific constituents of the moderating material.

A set of six calculation models are constructed in order to determine the worst case or most reactive configuration with consideration given to the efficiency of moderators, loss of neutron

absorbers, rearrangement of packaging components and contents, geometry changes, and temperature effects. The fissile material component is dry in each case.

Model 1 (Fig. 6.11) represents the fissile material content configured into a spherical core with a 20.0-cm thick water reflector. All ES-3100 packaging material (Kaolite, stainless steel, 277-4 neutron poison, etc.) is excluded from Model 1. The fissile material content considered in the calculation model consists of a specific material form: solid HEU metal (7–10 kg ^{235}U); TRIGA fuel (10 kg $UZrH_x$ having 921-g ^{235}U); or broken HEU metal (≤ 7 kg ^{235}U). The presence of hydrogenous packing material inside the CV is also addressed in this calculation model. Five hundred grams of polyethylene is used to represent a maximum amount of hydrogenous packing material in the ES-3100. For 7 kg ^{235}U HEU homogenized with 500 g of polyethylene, the radius of the core is 6.0238 cm. The parametric variation of both the ^{235}U mass and the enrichment in Model 1 is used to establish a reference point for the evaluation neutron reflection and absorption effects on k_{eff} provided by the stainless steel and Kaolite packaging materials, addressed separately in Models 2 and 3. Case names for Model 1 are designated with the prefix "atdmr" for the HEU solid and broken metal contents. Case names for TRIGA fuel at 19.7 and 70% enrichments are designated with the prefixes "atdzr" and "atdzr70," respectively.

Model 2 (Fig. 6.12) represents a spherical core of Model 1 blanketed by a variable-thickness shell of stainless steel, and a 20.0 cm thick water reflector external to the shell. The shell at maximum thickness corresponds to the 66,133 g stainless steel of the CV and the liner and drum assembly. For 7 kg ^{235}U HEU metal homogenized with 500 g of polyethylene, the radius of the core is 6.0238 cm, while the outer radius of the stainless steel shell is 13.0198 cm. Case names for Model 2 are designated with the prefix "atdmsr" for HEU solid and broken metal content. Case names for TRIGA fuel are designated "atdzsr" and "atdzsr70."

Model 3 (Fig. 6.13) is configured the same as Model 2 with the exception that instead of stainless steel, the variable-thickness shell is composed of wet Kaolite. Maximum shell thickness corresponds to 60,223.4 g of wet Kaolite (53,419.6 g of dry-baked Kaolite plus 6,803.8 g of free water). For 7 kg ^{235}U HEU metal homogenized with 500 g of polyethylene, the radius of the core is 6.0238 cm, while the outer radius of the shell is 31.0802 cm. Case names for Model 3 are designated with the prefix "atdm15kr" for HEU solid and broken metal content. Case names for TRIGA fuel are designated "atdz15kr" and "atdz15kr70." The parametric variation of shell thickness in Models 2 and 3 is performed for the purpose of evaluating the effect on k_{eff} of neutron reflection and absorption provided by each packaging material.

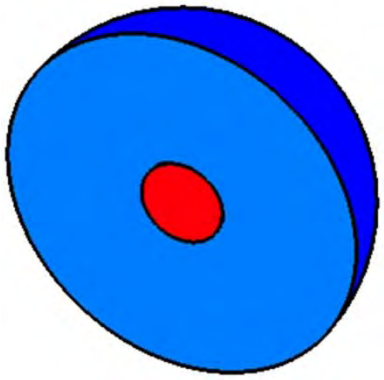

Fig. 6.11. Model 1.
7 kg ^{235}U (red) reflected by 20 cm of water (blue).

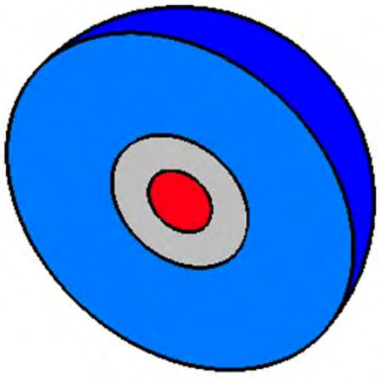

Fig. 6.12. Model 2.
7 kg ^{235}U (red) blanketed by a stainless-steel shell (gray), reflected by 20 cm of water (blue).

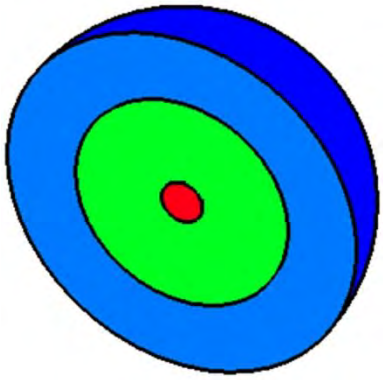

Fig. 6.13. Model 3.
7 kg ^{235}U (red) blanketed by a wet-Kaolite shell (green), reflected by 20 cm of water (blue).

Models 1–3 are applicable for establishing loading limits for air transport packages having a single piece or several pieces of solid HEU metal where the integrity of the content is demonstrated based on package tests or dynamic impact simulations per Type-C test criteria. Otherwise, the criticality evaluation of additional accident models is required for those situations where: (1) data is not available or is inadequate for discounting fragmentation of the fissile content in the air transport accident, or (2) the fissile material is in a physical form (crystals, oxide, or multiple pieces of solids) having the potential to blend with the other material of the package in the air transport accident.

Model 4 (Fig. 6.14) depicts a spherical core of broken metal homogenized with wet Kaolite and hydrogenous packing materials inside the CV represented by 500 g of polyethylene. A 20-cm thick water reflector blankets the spherical core. All other ES-3100 packaging material (stainless steel, 277-4 neutron poison, etc.) is excluded from Model 4. For 7 kg of HEU (7 kg of ^{235}U), the radius of the homogenized core is 31.0803 cm with the amount of water in Kaolite ranging from 2,204.7 g in baked-dry Kaolite to 9,008.6 g in wet Kaolite. Model 4 also applies to TRIGA fuel content. Case names for Model 4 are designated with the prefix "athmp15kr" for the HEU solid and broken metal contents. Case names for TRIGA fuel at 19.7 and 70% enrichments are designated with the prefixes "athzp15kr" and "athzp15kr70," respectively.

Model 5 (Fig. 6.15) is an extension of Model 3 applied to the case of TRIGA fuel and broken metal contents. Excess water from wet Kaolite is homogenized with the fissile material in the core. For 7 kg of HEU where 7 kg of ^{235}U is homogenized with 500 g of polyethylene and 0 g of free water from wet Kaolite, the radius of the spherical core is 6.0238 cm. The exterior Kaolite shell containing 9,008.5 g of water and the 51,214.9 g of vermiculite-cement constituents, has an outer radius of 31.0802 cm. At the extreme condition where the entire 6,803.8 g of water from wet Kaolite is homogenized with the core, the radius of the spherical core is 12.2667 cm. The exterior shell of dry Kaolite, containing 2204.72 g of bound water and 51,214.35 g of vermiculite cement constituents, has an outer radius of 31.6319 cm. Case names for Model 5 are designated with the prefix "athmpw15kr" for the HEU solid and broken metal contents. Case names for TRIGA fuel at 19.7 and 70% enrichments are designated with the prefixes "athzpw15kr" and "athzpw15kr70", respectively.

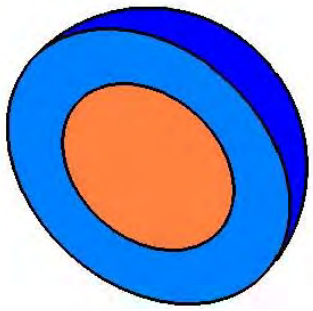

Fig. 6.14. Model 4.
Homogenized sphere of 7 kg ^{235}U, polyethylene, and wet-Kaolite (orange), reflected by 20 cm of water (blue).

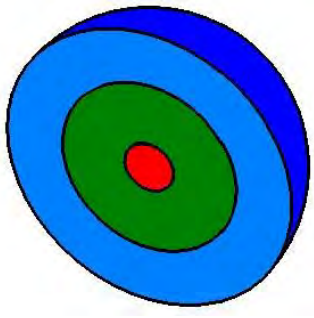

Fig. 6.15. Model 5.
Homogenized sphere of 7 kg ^{235}U, polyethylene, and excess moisture from wet-Kaolite (red), blanketed by Kaolite shell (green), reflected by 20 cm of water (blue).

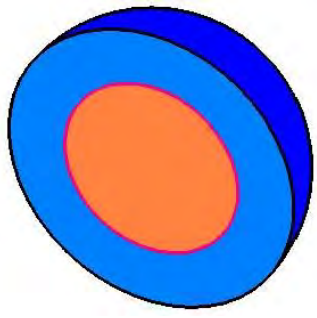

Fig. 6.16. Model 6.
Homogenized sphere of 3.5 kg ^{235}U, polyethylene, and wet-Kaolite (orange); blanketed by shell of 3.5 kg ^{235}U, reflected by 20 cm of water (blue).

Model 6 (Fig. 6.16) is configured similarly to Model 4 with the exception that only a partial amount of broken metal resides in the homogenized core. The remainder of the fissile material is modeled as a shell external to the spherical core and internal to the 20.0 cm thick water reflector. The amount of fissile material in the homogenized core is varied in 500 g increments from the full amount of Model 5 minus 500 g to a minimum amount of 500 g HEU. In the case of 7 kg of broken metal where 3.5 kg of ^{235}U is homogenized with 500 g of polyethylene and wet Kaolite, the radius of the core is 31.0649 cm, while the outer radius of the exterior 3.5 kg shell of ^{235}U is 31.0804 cm. The same dimensions apply in the case of 7.0 kg of broken metal where 3.5 kg of ^{235}U is homogenized with 500 g of polyethylene and dry Kaolite. In the case where 0.5 kg of ^{235}U is homogenized with 500 g of polyethylene and wet Kaolite, the radius of core is 31.0518 cm, while the outer radius of the exterior 6.5 kg shell of ^{235}U is 31.0804 cm. In the case where 6.5 kg of ^{235}U is homogenized with 500 g of polyethylene and wet Kaolite, the radius of core is 31.0781 cm, while the outer radius of the exterior 0.5 kg shell of ^{235}U is 31.0804 cm. Case names for Model 6 are designated with the prefix "athmpw15kmr" for the HEU solid and broken metal contents. Case names for TRIGA fuel at 19.7 and 70% enrichments are designated with the prefixes "athzpw15kmr" and "athzpw15kmr70," respectively. Model 6 addresses potential redistribution of fissile material consisting of multiple pieces, specifically the broken metal content. The parametric variation of shell thickness in Model 6 is performed for the purpose of evaluating the effect on k_{eff} of moderation efficiency of the core and enhanced neutron multiplication of the shell.

Models 1–6 are applicable to air transport of the ES-3100 package given that the physical integrity of the fissile content following the air transport accident cannot be established, or that the physical form of fissile material content may be multiple solid pieces, turnings, fines, powder, or oxide.

6.3.2 Material Properties

Criticality calculation models include the definition of material compositions in the geometry model for both NCT and HAC. The materials which affect nuclear criticality safety and may be present in the ES-3100 package during these conditions are fissile material content (HEU metal, aluminum, molybdenum, and zirconium alloys of uranium, HEU product or skull oxide, UNX crystals, or $UZrH_x$), stainless steel, 277-4 neutron poison, Kaolite, silicon rubber, Teflon or polyethylene, and various amounts of water. Other materials are present in the package (e.g., tin-coated steel convenience cans, nylon bagging, rubber O-rings, and trace impurities). However, these other materials are not present in amounts that will significantly affect the reactivity of the package. Detailed discussion of the package content and packaging materials is contained in Appendix 6.9.3. Specific topics are summarized in this section as required to support the discussion of the criticality calculations presented in Sects. 6.4–6.6.

Cat 277-4 neutron poison is designed to maximize the hydrogen content necessary for thermalizing fast neutrons for capture in the boron constituent. Cat 277-4 is a formulation of the vendor's Cat 277-0, a boron carbide additive, and water. This mixture is cast and dried. "Loss on drying" (LOD) tests are used to measure the amount of water in the as manufactured 277-4 casting. The as-manufactured neutron poison material at 100 lb/ft^3 and 31.8% LOD has a hydrogen concentration of 3.56 wt % and a natural boron concentration of 4.359 wt % (DAC-PKG-801624-A001, Table 5).

The testing of 277-4 reveals that the material will dehydrate at elevated temperatures. Test specimens were dried at 250°F for 168 hours to reach the NCT state, and weight measurements were taken. These specimens were subsequently heated to 320°F for 4 hours to reach the HAC state, and weight measurements were again taken. The compositions of 277-4 at NCT and HAC states were derived by adjustment of the formulation specification for measured losses taking into account the statistical variations in the data. Conservation of mass for non-volatiles was observed in the derivation of material specifications based upon testing. Given that hydrogen presence is key to the effectiveness of the neutron

poison, conservative material specifications were derived for minimum hydrogen content and minimum material density.

The NCT material specification for 277-4 at minimum density (95.39 lb/ft^3) and minimum hydrogen (25.15% LOD) is given in Table 11 of DAC-PKG-801624-A001. The average density of 277-4 in the ES-3100 package used for NCT calculations in KENO V.a is 1.52797 g/cm^3; the boron constituent is 7.31015E-2 g/cm^3; the residual base is 1.07070 g/cm^3; and the water component is 3.84169E-01 g/cm^3 (Appendix 6.9.3, Table 6.9.3.3-2). The HAC material specification at minimum density (95.32 lb/ft^3) and minimum hydrogen (25.09% LOD) is given in Table 12 of DAC-PKG-801624-A001. The average density of 277-4 used for HAC calculations in KENO V.a is 1.52680 g/cm^3; the boron constituent is 7.31015E-2 g/cm^3; the residual base is 1.07071 g/cm^3; and the water component is 3.82995E-1 g/cm^3 (Appendix 6.9.3, Table 6.9.3.3-3).

A set of 20 canned spacer assemblies as-manufactured has an average weight of 591.55 g. On average, the weight of an empty can with a lid is 86.05 g, and the 277-4 is 505.5 g. On the basis of volumetric measurements, the neutron poison is ~10.075 oz or 297.95 cm^3. The resultant 277-4 density is 1.6966 g/cm^3. The corresponding minimum mass is 473.84 g (given that the 277-4 material inside the spacer can is ≥4.07-in. diam and 1.31-in. thickness). Based on model dimensions of 4.13-in. diam × 1.37-in. height and use of composition data from Table 11 of DAC-PKG-801624-A001 (as-manufactured material at minimum density and hydrogen), the mass of neutron poison in the calculation model of the canned spacer is conservatively modeled as 457.15 g.

The density of 277-4 in the liner inner cavity is further reduced by a factor of 0.966893 because the actual volume of neutron poison is 12,831.4 cm^3 in the package, but 13,270.8 cm^3 is used in the calculation model. Also, guidance in Sect. 6.5.3.2 of NUREG-1609 requires that 75% of elemental boron be used in the material specification. Consequently, the minimum weight of 277-4 in the liner inner cavity of the calculation models is 19.37 kg (42.71 lb) for NCT and 19.36 kg (42.67 lb) for HAC, determined from the input density and the volume of the 277-4 region calculated by KENO V.a.

Kaolite is a lightweight, low thermal conductivity, refractory material that is used in the ES-3100 package between the drum and the inner liner. Kaolite is formed by mixing a dry constituent powder with water, pouring the mixture into a casting form, and curing and baking the cast. For NCT, the average density of Kaolite in the Model ES-3100 package is 0.34438 g/cm^3, and the residual water is 0.01493 g/cm^3 (Appendix 6.9.3, Sect. 6.9.3.4). The nominal weights of Kaolite in the liner outer cavity and in the top plug as determined from the input density and the region volumes calculated by KENO V.a are 49.04 kg (108.1 lb) and 4.37 kg (9.63 lb), respectively.

Kaolite is a nonvolatile refractory material, not significantly damaged by thermal excursions associated with HAC. It is assumed that upon immersion, a cured and dried casting will absorb a quantity of water equal to that required during preparation. This assumption is valid because the casting is fully saturated with water prior to curing and baking, and the casting does not change volume significantly during baking. The maximum water content of Kaolite refractory material is the water content of manufacture (1.5 g water per gram dry Kaolite) equivalent to a density of 0.51655 g/cm^3. For the single package, water saturation in the Kaolite region maximizes the effect of self-reflection in the surrounding package. This condition is assumed in the NCT single package calculations. For an array of packages, neutronic interaction between packages is maximized when the minimum amount of water is present in the Kaolite, which occurs in the as-manufactured condition. A volume fraction of 1.0 in the material specification corresponds to the water-saturated condition, while a volume fraction of 0.0289 corresponds to the dry condition.

ES-3100 drum body assemblies and top plugs may be fabricated with Packcrete or Kaolite. Packcrete is a fireproof, lightweight, impact limiting, thermal insulating, cast refractory material. Packcrete is similar to Kaolite in chemical composition, density, and water composition. From a criticality safety standpoint, this material is functionally equivalent to Kaolite, and ES-3100 calculations using Kaolite will bound Packcrete. Comparison calculations of Packcrete vs Kaolite may be found in Appendix 6.9.3.5.

The fissile material content packed into the CV is ordinarily dry. Given that a flooded CV is assumed for both NCT and HAC, the concurrent condition where the water-saturated Kaolite is baked dry beyond the as-manufactured condition, while the CV remains flooded is considered not credible. Therefore, the as-manufactured condition is assumed for the Kaolite water content in the HAC array analysis.

As stated in Sect. 6.3.1.2, the drum thicknesses of the NCT single-unit packaging model is increased for producing the NCT array packaging calculation model. The intent is to maintain the drum region volume thereby conserving drum mass. However, the both the region volume of the drum and the atomic densities for the elemental constituents of stainless steel in the resulting NCT array packaging calculation model are not identical to corresponding values for the single-unit packaging calculation model. This is due to internal round-off in KENO V.a. (Even though the volume fraction is changed from 1.0 to 0.99981 in the KENO V.a input specification of the NCT array packaging calculation model for normalization of the drum's region volume, the atomic densities still differ by 0.019% due to round-off.)

The material compositions for the NCT array calculation models are identical to compositions for the NCT single-unit calculation models except as noted in Table 6.4. In the NCT array calculation model, the adjusted model densities for the Kaolite in the body weldment liner inner cavity (Mix. No. 12), the stainless steel of the angle iron (Mix. No. 18), and the drum steel (Mix. No. 19) compensate for the dimensional changes of the reduced-diameter model (93% ID of drum). A difference between the NCT specifications for Kaolite (Mix. Nos. 12 and 13) in the array and the single-unit models occurs in the water component. The dry state is represented in the array model for maximizing neutronic interaction between packages of an array, while the flooded state is represented in the single-unit model for maximizing reflection.

The material compositions for the HAC single-unit calculation model are identical to those for the NCT single-unit calculation models except as noted in Table 6.4. The adjusted model densities for 277-4 neutron poison in both the canned spacers (Mix. No. 2) and the inner-liner cavity (Mix. No. 11) represent the HAC discussed earlier in this section. In the HAC single-unit calculation model, the adjusted model densities for the Kaolite in the body weldment liner inner cavity (Mix. No. 12), the stainless steel of the angle iron (Mix. No. 18), and the drum steel (Mix. No. 19) correspond to dimensional changes resulting from damage. While the atomic densities for the HAC model differ from those for the NCT model, the component masses do not change because mass is conserved.

Table 6.4. Material compositions used in the ES-3100 calculation models

[a] The theoretical density input parameter is specified for each material such that the required (or desired) mass of material is represented in the KENO V.a calculation model. The mass of material is computed by KENO V.a as the product of the theoretical density input parameter times the volume fraction times the volume of the geometry region in which the material resides in the calculation model.

[b] DAC-PKG-801624-A001.

The material compositions for the HAC array calculation model are identical to those for the NCT single-unit calculation models except as noted in Table 6.4. Also, the dimensions of the HAC array packaging calculation model do not differ from those of the HAC single-unit packaging calculation model. Therefore, both the region volumes and the atomic densities for the elemental constituents for Kaolite in the body weldment liner inner cavity are the same in both of the HAC calculation models. A difference between the HAC specifications for Kaolite (Mix. Nos. 12 and 13) in the array and the single-unit models occurs in the water component. The dry state is represented in the array model for maximizing neutronic interaction between packages of an array, while the flooded state is represented in the single-unit model for maximizing reflection.

The material composition used in the calculation model for the CV, the drum liner, and the drum is Type 304 stainless steel at a density of 7.94 g/cm^3. The density and composition of the Type 304 stainless steel for the drum is taken from the Standard Composition Library of the Standardized Computer Analysis for Licensing Evaluation (SCALE) code system. The nominal weights of these components, as determined by input density and volume calculated by KENO V.a, are 14.9 kg (32.85 lb) for the CV, 15.67 kg (34.55 lb) for the drum liner, and 25.44 kg (56.1 lb) for the drum.

Both the type and amount of hydrogenous packaging material used for packing the content in the CV is unknown. Polyethylene with a density of 0.92 g/cm^3 and a molecular formula of CH_2 has the greatest hydrogen density of potential packing materials. Although polyethylene bags are generally used in packing for contamination control, the exact mass of the polyethylene bags used is unknown. Multiple bags may be used to package the contents and to enclose the convenience cans, or bags may be omitted altogether. Realistically, the number of polyethylene bags used to bag the contents and wrap a convenience can would be six bags at most. Given that each bag weighs ~28 g, this results in a maximum of ~510 g of polyethylene per ES-3100 package. For consistency with other sections of this document, a maximum of 500 g of polyethylene per ES-3100 is used in the criticality evaluation. Possible additional sources of hydrogenous material inside the CV include can pads, vinyl tape, and polyethylene (~85 g) or Teflon (~303 g) bottles.

For the criticality calculations, the sources of hydrogen contained in packing materials are not distinguished from other sources of hydrogen inherent in the fissile material content. Therefore, packing material mass is defined as all sources of hydrogenous packing materials inside the CV plus the actual moisture in the content as constituent (the bonded hydrogen in UNX crystals or impurities in the oxide). Given content moisture is not to exceed 6 wt %, the amount of hydrogenous material inside the CV is not expected to exceed 2,400 g.

Containment vessel flooding is assumed in calculations performed for the derivation of fissile material loading limits. Even though both the NCT tests under 10 CFR 71.71 and the HAC tests under 10 CFR 71.73 demonstrate that containment is not breached, this simulated condition produces package configurations in the criticality calculations that are more reactive than the actual package configurations. The 7.1–10.1 kg quantities of evaluation water required in both the NCT and HAC criticality calculations bound reasonable amounts of hydrogenous material and inherent moisture of fissile material (primarily HEU oxides) present inside the CV (2,400 g).

HAC alter only the amount of volatile hydrogenous material contained in the package external to the CV (Sect. 2.7.3). High temperatures may reduce the hydrogenous material content of the Kaolite. Conversely, water intrusion may increase the hydrogenous material content in the package. Thus, the package's range of possible volatile hydrogenous material content varies from none, caused by high temperatures, to the maximum possible value caused by water intrusion.

Table 6.4 lists the material, density, atomic or isotopic constituent, and atomic or isotopic weight percent as basic data for materials used in the single-unit packaging and array calculation models in this criticality safety evaluation for NCT and HAC, respectively. Appendix 6.9.3 provides the rationale, justification, or both for using the basic data for computing atomic densities listed in Table 6.4.

6.3.3 Computer Codes and Cross-Section Libraries

The Criticality Safety Analysis Sequences within the SCALE modular code system provide automated, problem-dependent, cross-section processing followed by calculation of the neutron multiplication factor (k_{eff}) for the system being modeled (NUREG/CR-0200, Rev. 6). Initiated by "=csas25" appearing on the first line in the user input, the CSAS module runs the CSAS25 control sequence. The cross-section processing functional modules BONAMI (NUREG/CR-0200, Rev. 6) and NITAWL-II (NUREG/CR-0200, Rev. 6) are activated, providing resonance-corrected cross sections to the multigroup Monte Carlo functional module, KENO V.a (NUREG/CR-0200, Rev. 6). Using the processed cross sections, KENO V.a calculates the k_{eff} of three-dimensional system models. The geometric modeling capabilities available in KENO V.a, coupled with the automated cross-section processing, allow complex, three-dimensional systems to be easily analyzed.

The CSAS25 control sequence and the 238-group ENDF/B-V cross-section library in SCALE are used for all calculations. The control sequence, functional modules, and cross-section library are summarized in the following paragraphs.

The CSAS25 control sequence reads user-specified input data, which include the required cross-section library, specifications for mixtures, information for resonance processing of nuclides (size, geometry, and temperature), and a detailed geometry model for KENO V.a. Physical and neutronic information not specified but required by the functional modules (such as theoretical density, molecular weights, and average resonance region background cross sections) is supplied by the Standard Composition Library or calculated by the Materials Information Processor. The Standard Composition Library (NUREG/CR-0200, Rev. 6) consists of a standard composition directory and table, an isotopic distribution directory and table, and a nuclide information table. The Materials Information Processor (NUREG/CR-0200, Rev. 6) checks the input data pertaining to cross-section preparation and prepares binary input files for the applicable functional modules BONAMI and NITAWL-II.

The standardized automated procedures process SCALE cross sections using the Bondarenko method (via BONAMI) and the Nordheim integral method (via NITAWL-II) to provide a resonance-corrected cross-section library based on the physical characteristics of the problem being analyzed.

BONAMI performs resonance shielding through the application of the Bondarenko shielding factor method. BONAMI reads the master format library and applies the Bondarenko correction to all nuclides that have Bondarenko data. BONAMI produces a Bondarenko-corrected master format library which is read by NITAWL-II.

NITAWL-II applies the Nordheim Integral Treatment to perform neutron cross-section processing in the resonance energy range for nuclides that have ENDF/B resonance parameter data. This technique involves the numerical integration of ENDF/B resonance parameters using a calculated flux distribution, which is based on the calculated collision density across each resonance and subsequent weighing of the reaction cross section to the desired broad group structure. In the CSAS sequence, NITAWL-II assembles the group-to-group transfer arrays from the elastic and inelastic scattering components and performs other tasks to produce a problem-dependent, working cross-section library which can be used by KENO.

KENO V.a, a multigroup Monte Carlo computer code, is used to determine k_{eff} for multidimensional systems. The basic geometrical bodies allowed in KENO V.a for defining models are cuboids, spheres, cylinders, hemispheres, and hemicylinders. KENO V.a has the following major characteristics:

- enhanced geometry package that allows arrays to be defined and positioned throughout the model;
- P_n scattering treatment;
- extended use of differential albedo reflection;
- printer plots for checking the input model;
- energy-dependent data supergrouping;
- restart capability; and
- origin specifications for cuboids, spheres, cylinders, hemicylinders, and hemispheres.

The 238-group ENDF/B-V master cross-section library in SCALE is activated in the CSAS25 control sequence by specifying 238GROUPNDF5 (238GR) as the cross-section library name. The 238-GROUP ENDF/B-V [neutron cross-section] library is a general-purpose criticality analysis library and the most complete library available in SCALE 4.4a. The library contains data for all nuclides (more than 300) available in ENDF/B-V processed by the AMPX-77 systems. It also contains data for ENDF/B-VI evaluations of ^{14}N, ^{15}N, ^{16}O, ^{154}Eu, and ^{155}Eu. The library has 148 fast groups and 90 thermal groups (below 3 eV). Most resonance nuclides in the 238 group have resonance data (to be processed by NITAWL-II in the resolved resonance range) and Bondarenko factors (to be processed by BONAMI) for the unresolved range. The 238-group library contains resolved resonance data for s-wave, p-wave, and d-wave resonances **R** = 0, **R** = 1, and **R** = 2, respectively. These data can have a significant effect on results for under-moderated, intermediate-energy problems. Resonance structures in several light-to-intermediate mass "nonresonance" ENDF nuclides (i.e., ^{7}Li, ^{19}F, ^{27}Al, ^{28}Si) are accounted for using Bondarenko shielding factors. These structures can also be important in intermediate energy problems.

All nuclides in the 238-group library use the same weighting spectrum, consisting of:

- Maxwellian spectrum (peak at 300 K) from 10^{-5} to 0.125 eV,
- a 1/E spectrum from 0.125 eV to 67.4 keV,
- a fission spectrum (effective temperature at 1.273 MeV) from 67.4 keV to 10 MeV, and
- a 1/E spectrum from 10 to 20 MeV.

The k_{eff} values for each KENO V.a case are based on 500,000 neutron histories produced by running for 215 generations with 2,500 neutrons per generation and truncating the first 15 generations of data. The convergence of the KENO V.a calculation is related to trends in the average calculated k_{eff}. In general, the KENO V.a output table of k_{eff} by Generation Skipped is reviewed for trends. If no trends are observed, the calculation is accepted, and the reported value of k_{eff} is the one with the most neutron histories. Usually there is no statistically significant difference between this result and the one with the smallest standard deviation.

No manual cross-section adjustment is performed for the criticality safety evaluation. The cross-section processing is performed automatically in the CSAS25 code sequence making use of the available cross-section treatment options, as appropriate.

The CSAS control module, the associated functional modules, cross sections, and databases used in this evaluation reside in the verified configuration control area designated **/vcc/scale4.4a** on a Hewlett Packard Series 9000 J Class workstation at the Y-12 Safety Analysis Engineering (SAE) organization in Oak Ridge, Tennessee. The detailed input and computer output for the criticality safety evaluation of the ES-3100 shipping container with HEU reside in a configuration control area **/archive/ylf717_Rv2** on the workstation. Input listings of the key cases indicated in Tables 6.1a–6.1f are provided in Appendix 6.9.7.

For low density uranium oxides, KENO V.a calculations are performed using CSAS5 in SCALE 6.1.1 on the Microway Parallel Linux Cluster ENGHPC01 at the Y-12 National Security Complex, Oak Ridge, Tennessee.

More recent calculations for broken metal, turning, fines, powders, poly wrapped reactor fuel, annular cylinders, U_3Si_2-Al and U_3Si compounds, compounds by air, thorium oxide mixed with uranium oxide in fuel pellets and bulk oxide, zircalloy oxide mixed with uranium oxide, thorium mixed with uraniuim oxide, were performed using the Monte Carlo CSAS5 and 238-group ENDF/B-VII (V7-238 gr) cross-section library of SCALE 6.1.3, executed on a Microway Parallel Linux Cluster ENGHPC.

Several CSAS control modules are contained in SCALE 6.1.1 and SCALE 6.1.3 The CSAS control modules are designed to analyze systems containing fissile material and calculate the neutron multiplication factor (k_{eff}) of the system. This validation is only applicable to the CSAS5 control module that uses the KENO V.a functional module. Prior to entering the KENO V.a functional module, the CSAS5 control module calls a series of utility modules and other functional modules to process the cross-section data. This validation used the 238-group ENDF/B-VII cross-section library. This is a multigroup library containing 238 distinct neutron energy groups based on the ENDF/B-VII library. The CSAS5 control module executes several functional modules to process the cross-section data used in KENO V.a. These programs are:

- WORKER: This functional module interfaces between the AMPX master library contained in the SCALE code package and the AMPX working library used in KENO V.a.
- BONAMI: This functional module processes the unresolved resonance data contained in the master library and places it in the working library.
- PMC: This functional module uses point-wise continuous cross-section data to solve a one dimensional equivalent problem producing a flux profile used for processing cross-section data.
- CENTRM: This functional module uses the flux profile calculated in PMC to collapse point-wise continuous cross-section data into the appropriate group structure producing a working library used in KENO V.a.
- KENO V.a: This functional module performs the three dimensional Monte Carlo calculation using the cross-section library provided by the WORKER module.

The V7-238 gr cross-section library used to perform criticality calculations is a multigroup library containing 238 discrete neutron energy groups processed from the ENDF/B-VII continuous energy cross-section data.

The CSAS5 control module, the associated functional modules, the cross-section library, and databases used in this evaluation reside in the verified configuration control area designated **/vcc/scale6** on ENGHPC. The computer input and output files for the criticality safety evaluation of the ES-3100 package also reside in a configuration control area **/wa9/archive/RP-801940-A001R3** on ENGHPC.

6.3.4 Demonstration of Maximum Reactivity

Liquid HEU is not being shipped in the ES-3100. Only the uranyl nitrate crystal content being shipped in the ES-3100 is soluble in water. The hypothetical occurrence of uranyl nitrate solution is evaluated as a consequence of evaluating the presence of water inside the CV.

As stated in Sect. 6.1.2, 10 CFR 71.55(b) requires the evaluation of water leakage into the CV or leakage of liquid contents out of the CV and other conditions that produce maximum reactivity in the single package. For solid uranium contents, water leakage conditions are simulated by flooding all regions outside and inside of the CV, including the sealed convenience cans. For liquid uranium "contents", water leakage conditions are simulated by flooding all regions outside the CV except the CV well. Uranyl nitrate solution resides inside both the CV, including the Teflon bottles, and the well external to the CV. According to the 10 CFR 71.55(b) requirement, a flooded CV under full water reflection is also evaluated.

While the loss of containment is deemed incredible by merit of the results of the physical tests performed under 10 CFR 71.71 and 10 CFR 71.73, credit for the high-integrity, watertight containment is not taken in the single package analysis [10 CFR 71.55(d) and (e)]. Only partial credit is taken in the package array analysis (10 CFR 71.59). In both the single package and package array analyses, the CV is flooded with water. This fictitious "evaluation" water provides moderation to such an extent as to cause maximum reactivity of the content consistent with the chemical and physical form of the material present. Uranyl nitrate crystals are soluble in water. In both the evaluation of undamaged packages under 10 CFR 71.59(a)(1) and damaged packages under 10 CFR 71.59(a)(2), the leakage out of the CV of content moderated to such an extent as to cause maximum reactivity consistent with the physical and chemical form of material is not considered credible during NCT or HAC, based on results for tests specified in 10 CFR 71.71 and 10 CFR 71.73.

Contents are generally dry, and only small quantities of hydrogenous packing materials are used. However, credit for the high-integrity, watertight containment is not taken in this criticality evaluation (Docket 71-9315). Fissile material loading is restricted such that if a CV were flooded, it would be adequately subcritical under full water reflection. But instead of loading limits being established in accordance with conditions of confinement and containment as demonstrated under the NCT and HAC tests, these single-unit fissile material loading limits are severely reduced on the basis of the array calculations where all of the CVs of the packages in an array are assumed to be flooded, but each packaging is dry. This has the effect of maximizing both the neutron source and neutronic interaction between packages. Because credit for the high-integrity, watertight containment is not fully taken in this criticality evaluation, the fissile material mass loading limits developed as a result are very conservative.

Section 6.3.1 provides dimensional data for content and package models, and Sect. 6.3.2 provides material composition data used in the calculation models. Appendix 6.9.3 provides justification for the composition data used in the evaluation. These sections and this appendix describe how the packaging dimensions and materials are optimized to produce a conservative model by reducing neutron-absorbing materials and maximizing the reactivity of the fissile material content through the inclusion of water in the CV.

As described in Sect. 6.3.1.1, a geometry region is defined by dimensions and the type of material contained therein. The amount of material within a region is quantified in terms of the density, material volume fraction, and the volume of the region (Sect. 6.3.2). The term "water fraction" means the fraction of the maximum specific gravity of water possible for any geometry region in the ES-3100 package. Therefore, the water content is the fraction of the maximum specific gravity of water possible in a material in the ES-3100 package when flooded.

The maximum value for the void regions (spaces external to the CV) is 1.0 for both single-unit and array geometries. For the geometry regions containing Kaolite, the maximum values are 0.51655 for the single unit and 0.63931 for the array. For the geometry regions containing 277-4, the maximum value is 0.6942 for both the single-unit and array geometries. The same single-unit values are used in the array calculation models because the 277-4–bearing regions do not require adjustment for the close-pack approximation (Sect. 6.3.1.2).

In general, boundary condition specifications are not required in KENO V.a, so calculation models analyzed using KENO V.a require no special boundary conditions. However, in this evaluation, the infinite array cases use a single package with a reduced radius modeled with specular reflection on all faces of a surrounding cuboid. The energies and angular dependence of the neutrons are treated such that an infinite system with no neutron leakage is simulated.

For simplicity, the NCT and HAC sets of calculations were performed for selected ES-3100 array sizes by varying the water content of the ES-3100 package external to the CV from zero to its maximum

value. This technique bounds all NCT and HAC; however, only the relevant calculation results are used in determination of the CSI for criticality purposes.

Although four decimal places are shown for k_{eff} values in result tables, the actual accuracy of the code, for a particular calculation, may be on the order of ± 0.02–0.03 based on the spread in results for benchmark calculations (Y/DD-896/R1 and Y/DD-972R1). Also, the standard deviation of the mean for a particular calculation is on the order of 0.001 for benchmark cases and somewhat higher for the package calculations. Therefore, numerical values are considered physically meaningful or significant to the third decimal place. The primary reason for reporting four (or five) decimal places for a calculation result is to confirm that the result reported actually originated from a given output file. A value of 0.925 is the USL used for this safety analysis report for packaging (Sect. 6.8.3).

6.4 SINGLE PACKAGE EVALUATION

The HEU content of a package is in one of the following forms: metal of a specified geometric shape; metal of an unspecified shape and characterized as broken metal; uranium oxide; or UNX crystals. The bounding types of HEU content evaluated in this criticality analysis are 3.24-in. and 4.25-in.-diam cylinders; 2.29-in.-square bars; 1.5-in.-diam × 2-in.-tall slugs; cubes ranging from 0.25 to 1 in. on a side; broken metal; metal turnings, fines, or powder; solid HEU metal of unspecified geometric shape and characterized as broken metal; product oxide; skull oxide; UNH crystals; and unirradiated TRIGA reactor fuel elements.

Dimensions for bounding calculation models of a TRIGA fuel section are 1.44 in. in diameter × 5 in. tall. The 20% enrichment fuel contains more fissile mass than the 70% enrichment fuel on account of a higher uranium weight fraction and associated material density. A 20 wt % enriched TRIGA fuel element with 45 wt % U contains ≤ 307-g ^{235}U; whereas, a 70 wt % enriched TRIGA fuel with 8.5 wt % U contains ≤ 136-g ^{235}U. The physical parameters which characterize the TRIGA fuel are enrichment, uranium weight fraction, and the fuel diameter (Appendix 6.9.3.1). These parameters are addressed in this section demonstrating that the calculation models are bounding in the criticality evaluation.

Alloys of uranium may include aluminum, molybdenum, or zirconium. Uranium-aluminum (U-Al) alloy is typically 70 to 95 wt % aluminum. Uranium-molybdenum (U-Mo) alloys are typically 1.5 to 12 wt % molybdenum. U-Mo alloys may be plated with, clad with, or contain traces of aluminum, gold, stainless steel, nickel, and/or chromium. The enrichment of U-Al, U-Mo, and U-Zr alloys range from 92.65 to 93.21 wt % ^{235}U.

6.4.1 Solid HEU Metal of Specified Geometric Shapes

For bare and reflected single packages with HEU metal content, the neutron multiplication factor increases as a function of the ^{235}U mass and the moisture fraction of the package external to the CV (MOIFR). For example, consider the ES-3100 package loaded with three convenience cans for a total of 36,000-g ^{235}U. Each press-fit lid type can contains a single 3.24-in.-diam, 12,000-g cylinder of ^{235}U. The $k_{eff} + 2\sigma$ values in the bare package increase from 0.911 to 0.955 with increasing moisture fraction of the package external to the CV (MOIFR), Cases **ncsbcyt11_36_1_1** through **ncsbcyt11_36_1_15** (Appendix 6.9.6, Table 6.9.6-2). The $k_{eff} + 2\sigma$ values increase from 0.918 to 0.955 with increasing MOIFR in the water-reflected package, Cases **ncsrcyt11_36_1_1** through **ncsrcyt11_36_1_15** (Appendix 6.9.6, Table 6.9.6-2). The addition of water to the package reduces the neutron leakage fraction (NLF), thereby increasing k_{eff}. Water reflection external to a flooded package is inconsequential to package reactivity as a comparison of results for Cases **ncsbcyt11_36_1_15** and **ncsrcyt11_36_1_15** indicates.

In this series of calculations using the ES-3100 package model with NCT geometry (Cases **ncsrcyt11_36_1_1** through **ncsrcyt11_36_1_15)**, the MOIFR is varied uniformly over the package model with the exception of the neutron poison of the body weldment liner inner cavity and the flooded CV. The single-unit case with a MOIFR = 1.0 pertains specifically to the flooded drum under conditions specified in 10 CFR 71.55(b). This pseudo-HAC condition is more reactive than either the true NCT where both the CV and Kaolite are dry [10 CFR 71.55(d)] or this evaluation for NCT where the CV is flooded and the Kaolite is dry (in the as-manufactured condition, MOIFR ~ 0.0289). At MOIFR = 1.0, external water reflection of the package is inconsequential to package reactivity. Moisture in the Kaolite and in the recesses of the package acts as a close reflector that decreases neutron leakage away from the package.

The single-unit case with a MOIFR = 1E-20 pertains specifically to a package under pseudo-HAC where both the Kaolite and the recesses of the package do not contain **any** water or bound hydrogen. This configuration is less reactive than the cases for Kaolite in the as-manufactured condition or water-saturated Kaolite because water in the Kaolite will provide some neutron moderation and reflection of neutrons back into the content.

Single package reactivity changes slightly between the bare and reflected conditions, while NLF changes considerably over the range of water fractions. This behavior illustrates the dependence of package reactivity on internal conditions of the package. Bare packages with low MOIFR values manifest low reactivity (k_{eff} = 0.911) and high neutron leakage (NLF = 0.47). These parameters indicate that fast neutrons scattered in the packaging do not slow down significantly but escape the package. Consequently, neutron interaction between these packages when they are configured into an array is high. Bare packages with MOIFR values >1E-2 manifest increasing k_{eff} values (from 0.911 to 0.955) and reduced NLF values (from 0.47 to 0.18). The increase in k_{eff} occurs due to water present in the regions of the package external to the content which reflects neutrons back into the HEU content that would otherwise escape the package.

A series of calculations are performed using the calculation model of a water-reflected CV loaded with 3.24-in.–diam cylinders. The three cylinders are aligned as depicted in Fig. 6.9.1-1 (Appendix 6.9.1) but in very close proximity due to the omission of can spacers. A parametric variation of water density from zero to 1.0 sp gr inside the CV is performed for establishing moderation by water to the most credible extent. The calculated $k_{eff} + 2\sigma$ values for Cases **cvcrcyt11_36_1_1** through **cvcrcyt11_36_1_15** (Appendix 6.9.6, Table 6.9.6-1) increase monotonically from 0.907 to 0.974 with increasing moisture fraction inside the CV (MOCFR). Maximum reactivity of the fissile material occurs in the flooded CV.

10 CFR 71.55(b)(3) requires evaluation of the efficiency of the packaging as an external reflector to the CV. Comparison of the calculated $k_{eff} + 2\sigma$ value for Case **cvcrcyt11_36_1_15** to the value for Case **ncsrcyt11_36_1_15** reveals that the flooded CV under full water reflection is a more reactive configuration than the CV inside a flooded ES-3100 packaging. The ES-3100 package is not as efficient a reflector as full water reflection provided to the flooded CV. For this reason, calculation results for the flooded CV rather than a flooded package are reported in Tables 6.1a (and Tables 6.1b–6.1f) for the evaluation of 10 CFR 71.55(b) requirements.

Examination of the results for Cases **cvcrcyt11_36_1** through **cvcrcyt11_18_1** indicates that an adequately subcritical loading is achieved when the mass loading is limited to 21,000-g ^{235}U (Case **cvcrcyt11_21_1**). Case **cvcrcyt11_36_2** reveals that the 277-4 canned spacers are adequate for mass loading >18,000-g ^{235}U but ≤ 36,000-g ^{235}U. These potential fissile (^{235}U) mass loading limits derived through the evaluation of 10 CFR 71.55(b) are listed in Table 6.1a in the information block where a description of the content appears for fissile material, “the most reactive credible configuration consistent with the chemical and physical form of the content.” The finalized mass loading limit is derived at the conclusion of the array analysis for these content configurations.

The NCT tests under 10 CFR 71.71 and the HAC tests under 10 CFR 71.73 demonstrate that containment is not breached. Nevertheless, CV flooding is assumed in the criticality calculations performed for the derivation of fissile material loading limits. The 7.1–10.1 kg quantities of evaluation water in both the NCT and HAC criticality calculations are not actually present in the CV. Simulation of this condition in the criticality calculations produces fissile material content that is more reactive than actual. The evaluation water required in both the NCT and HAC criticality calculations bounds reasonable amounts of hydrogenous material present inside the CV for solid HEU shapes.

Consider Case **cvcrcyt11_21_1** as the reference case where the calculated $k_{eff} + 2\sigma = 0.923$ (Table 6.9.6-1). The fissile material content is 21,000 g HEU metal at 100% enrichment and a density of 18.81109 g/cm^3. Three HEU cylinders (3.24-in. diam and 2.75425-in. tall) are stacked end-to-end starting at 0.0005 cm above the bottom of the CV. The stack height is 20.98987 cm where each cylinder is separated by a 0.0001-cm–thick 277-4 canned spacer and 0.0012 cm of moderating material. Effectively, this configuration does not have 277-4 canned spacers, and no polyethylene is used in this calculation model. The water-filled cavity above the content is 57.74963 cm in height. As the input listing for Case **cvcrcyt11_21_1** (Appendix 6.9.7) indicates, ~9083 g of **evaluation** water fills the flooded CV and the calculated H/X ratio is ~11.29. The calculated H/X ratio for the HEU content wrapped in 500 g polyethylene (hydrogenous packing material) inside a dry CV is ~0.80.

Case **cvcrpcyt11_21_1** is the same as reference Case **cvcrcyt11_21_1,** except that 500-g polyethylene wraps three HEU cylinders with a uniform thickness of 0.54956 cm. The three wrapped HEU cylinders are stacked end-to-end starting at 0.0005 cm above the bottom of the CV. Each wrapped cylinder is separated by a 0.0001-cm–thick 277-4 canned spacer and 0.0012 cm of moderating material resulting in a stack height of 24.28733 cm. The water-filled cavity above the content is 57.74963 cm in height. At a density of 0.9200 g/cm^3, 500 g polyethylene adds 543.47826 cm^3 to the volume of the content and reduces the free volume of the CV by an equal amount. As indicated in the case title card, 8540.1 g of **evaluation** water fills the flooded CV. The 500 g polyethylene increases the overall H/X ratio inside the flooded CV to 11.41. The calculated $k_{eff} + 2\sigma$ is 0.908 for this configuration (Table 6.9.6-1). While polyethylene having a greater hydrogen density than water is a slightly better moderating material than water, the presence of polyethylene in the calculation model provides separation between the fissile material resulting in a slight reduction in the calculated $k_{eff} + 2\sigma$ value. Case **cvdcrpcyt11_21_1** is the same as Case **cvcrpcyt11_21_1**, except that the CV is dry. The calculated $k_{eff} + 2\sigma$ is 0.847 for Case **cvdcrpcyt11_21_1** (Table 6.9.6-1). The calculated $k_{eff} + 2\sigma$ value of 0.923 for reference Case **cvcrcyt11_21_1** without polyethylene is greater than the values for Cases **cvcrpcyt11_21_1** and **cvdcrpcyt11_21_1** with polyethylene. In the case of solid HEU shapes, the 7.1–10.1 kg quantities of evaluation water required in both the NCT and HAC criticality calculations bound reasonable amounts of hydrogenous material present inside the CV.

Because convenience cans are not credited for providing configuration control in the CV, it is possible for the fissile material to be spaced farther apart than shown in Fig. 6.9.1-1. A series of cases was run to evaluate the axial spacing of content inside the CV. As shown in Table 6.9.6-3b, the separation distances between adjacent cylinders range from 0.0 to 8.75 in. (12.225 cm). Zero separation occurs when the base surfaces of adjacent cylinders are flush with the 277-4 canned spacer between them. Figure 6.9.1-1b depicts a section view of the CV with 3.24-in.-diam cylinders at 4.826 and 0.254 cm separation. The calculated $k_{eff}+2\sigma$ values for Cases **ncsrcyat11_1_2_15** through **ncsrcyat11_12_2_15** (Table 6.9.6-3c) decrease with increasing separation distance. Loading configurations where solid HEU of specified geometric shape is axially positioned in contact with the can spacers are the most reactive ones.

Additional CV cases were performed to exam the effect that 500 g of polyethylene will have on HEU metal cylinders and bars. The original cases previously found in Table 6.1a were rerun using SCALE 6.1.3, with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Table 6.5.

Table 6.5. Reflected CV model, HEU metal cylinders and bars, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
cvcrcyt11_21_1	21 kg ^{235}U, 3.24 in.-diam cylinder, no spacers or polyethylene	0.92680	0.00056	0.92792
cvcrcyt11p_21_1	21 kg ^{235}U, 3.24in.-diam cylinder, no spacers, 500 g polyethylene	0.91355	0.00071	0.91497
cvcrcyt11_36_2	36 kg ^{235}U, 3.24 in.-diam cylinder, with spacers and no polyethylene	0.88803	0.00064	0.88931
cvcrcyt11p_36_2	36 kg ^{235}U, 3.24 in.-diam cylinder, with spacers and 500 g polyethylene	0.88486	0.00062	0.88610
cvcrsqt11_36_1	36 kg ^{235}U, 2.29 in. l,w bars, no spacers or polyethylene	0.88228	0.00060	0.88348
cvcrsqt11p_36_1	36 kg ^{235}U, 2.29 in. l,w bars, no spacers, 500 g polyethylene	0.87699	0.00064	0.87827
cvcrcyct11_17_1	17 kg ^{235}U, 4.25 in.-diam cylinder, no spacers or polyethylene	0.92476	0.00067	0.92610
cvcrcyct11p_17_1	17 kg ^{235}U, 4.25 in.-diam cylinder, no spacers, 500 g polyethylene	0.92373	0.00064	0.92501
cvcrcyct11_32_2	32 kg ^{235}U, 4.25 in.-diam cylinder, with spacers and no polyethylene	0.92141	0.00062	0.92265
cvcrcyct11p_32_2	32 kg ^{235}U, 4.25 in.-diam cylinder, with spacers and 500 g polyethylene	0.90981	0.00062	0.91105

From the results of the CV cases for HEU metal cylinders and bars, modeling 500 g of polyethylene surrounding the HEU metal is slightly less reactive than no polyethylene.

Case **hcsrcyt12_36_1_15** (Appendix 6.9.6, Table 6.9.6-3) represents the HAC model of the damaged ES-3100 package, where the outer dimensions of the package are reduced accordingly and the entire package is flooded with the exception of the neutron poison of the body weldment liner inner cavity. The CV well is flooded with water, and the Kaolite contains maximum water content. This single-unit case with a MOIFR = 1.0 pertains specifically to the flooded drum under conditions specified in 10 CFR 71.55(e). The $k_{eff} + 2\sigma = 0.955$ for this HAC. The changes in both the outer dimensions of the package and the compositions of the Kaolite and 277-4 due to HAC result in an ~0.002 change in the neutron multiplication factor.

Repeated for 4.25-in.-diam cylinders (Appendix 6.9.6, Tables 6.9.6-6 and 6.9.6-7); 2.29-in.-square bars (Tables 6.9.6-4 and 6.9.6-5); and 1.5-in.-diam × 2-in.-tall slugs (Tables 6.9.6-8 and 6.9.6-9), this type of analysis for the 3.24-in.-diam cylinders demonstrates that single packages with restricted fissile material (^{235}U) loading remain subcritical over the entire range of water content or MOIFR. HEU metal or alloy content not covered by the specified geometric shapes (cylinder, square bar, or slug contents) will be in the HEU broken metal category, and so limited.

Additional cases were performed to exam the effect that 500 g of polyethylene will have on HEU metal cylinders and bars for single packages. The original cases previously found in Table 6.1a were rerun using SCALE 6.1.3, with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Tables 6.6 and 6.7.

hcsrcyct12_17_1_15	17 kg ^{235}U, 4.25 in.-diam cylinder, no spacers or polyethylene	0.89820	0.00069	0.89958
hcsrcyct12p_17_1_15	17 kg ^{235}U, 4.25 in.-diam cylinder, no spacers, 500 g polyethylene	0.89598	0.00061	0.89720
hcsrcyct12_32_2_15	32 kg ^{235}U, 4.25 in.-diam cylinder, with spacers and no polyethylene	0.89778	0.00061	0.89900
hcsrcyct12p_32_2_15	32 kg ^{235}U, 4.25 in.-diam cylinder, with spacers and 500 g polyethylene	0.88811	0.00063	0.88937

From the results of the single package cases for HEU metal cylinders and bars, modeling 500 g of polyethylene surrounding the HEU metal cylinders and bars is slightly less reactive than no polyethylene.

The examination of two types of annular cylinders, one per ES-3100 CV, is also evaluated. Cylinder C is a uranium-molybdenum alloy (U-Mo) with ≤ 95 wt % uranium and ≤ 93.5% ^{235}U enrichment. The Cylinder C length is ≤ 3.30 in. with an inner diameter of ≥ 1.5 in., an outer diameter of ≤ 4.35 in., and a mass of ≤ 13.5 kg. Cylinder D is also a U-Mo alloy with ≤ 95 wt % uranium and ≤ 93.5% ^{235}U enrichment. The length of Cylinder D is ≤ 5.80 in. with an inner diameter of ≥ 1.35 in., an outer diameter of ≤ 3.86 in., and a mass of ≤ 16.5 kg. Each cylinder may be wrapped in a polyethylene bag limited to ≤ 500 g. The USL for these calculations is 0.93520.

For the CV cases (Appendix 6.9.6, Table 6.9.6-1a), the CV is modeled fully flooded and reflected on all sides by 30.48 cm of water, and each cylinder is modeled at the bottom of the CV. Case **cycrcylc** for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.83037 (k_{eff} = 0.82909, σ = 0.00064), while Case **cycrcyld** for Cylinder D has a calculated $k_{eff} \pm 2\sigma$ value of 0.84469 (k_{eff} = 0.84347, σ = 0.00061). Additional cases were run with the cylinder modeled vertically centered in the CV. Case **cycrcylcc** for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.83645 (k_{eff} = 0.83511, σ = 0.00067), while Case **cycrcyldc** for Cylinder D has a calculated $k_{eff} \pm 2\sigma$ value of 0.84558 (k_{eff} = 0.84400, σ = 0.00059).

For the NCT cases with a single package (Appendix 6.9.6, Table 6.9.6-2a), the CV is modeled fully flooded and the single package is modeled reflected on all sides by 30.48 cm of water. Each cylinder is modeled at the bottom of the CV. Case **ncsrcylc11** for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.80262 (k_{eff} = 0.80138, σ = 0.00062), while Case **ncsrcyld11** for Cylinder D has a calculated

k_{eff} ± 2σ value of 0.81544 (k_{eff} = 0.81420, σ = 0.00062). Additional cases were run with the cylinder modeled vertically centered in the CV. Case **ncsrcylcc11** for Cylinder C has a calculated k_{eff} ± 2σ value of 0.80887 (k_{eff} = 0.80765, σ = 0.00061), while Case **ncsrcyldc11** for Cylinder D has a calculated k_{eff} ± 2σ value is 0.81940 (k_{eff} = 0.81812, σ = 0.00064).

For the HAC cases with a single ES-3100 package (Appendix 6.9.6, Table 6.9.6-2a), the CV is modeled fully flooded and the single damaged package is modeled reflected on all sides by 30.48 cm of water. Each cylinder is modeled at the bottom of the CV. Case **hcsrcylc12** for Cylinder C has a calculated k_{eff} ± 2σ value of 0.80262 (k_{eff} = 0.80138, σ = 0.00062), while Case **hcsrcyld12** for Cylinder D has a calculated k_{eff} ± 2σ value of 0.81544 (k_{eff} = 0.81420, σ = 0.00062). Additional cases were run with the cylinder modeled vertically centered in the CV. Case **hcsrcylcc12** for Cylinder C has a calculated k_{eff} ± 2σ value of 0.81042 (k_{eff} = 0.80930, σ = 0.00056), while Case **hcsrcyldc12** for Cylinder D has a calculated k_{eff} ± 2σ value of 0.81938 (k_{eff} = 0.81814, σ = 0.00062).

Calculations were also performed to exam the effect of aluminum shielding to Cylinder D (Appendix 6.9.6, Table 6.9.6-2a). Reactivity decreases as the amount of aluminum shielding is added. This is due to the fact that the CV is flooded, and in order to add aluminum cladding, water must be removed to conserve volume. Thus, aluminum cladding is not controlled for Cylinder D.

All Cylinder C and D cases were shown to be below the USL of 0.9352, with the models in which the cylinders are centered vertically inside the CV being the most reactive.

Each TRIGA fuel element for shipment in the ES-3100 is to be disassembled. The active fuel consisting of three 5-in.-tall cylinders of $UZrH_{1.6}$ is to be packed into a metal-type convenience can (Sect. 6.2.1). The use of three loaded convenience cans in the ES-3100 is assumed in the criticality calculation models for ground transport. However, credit is only taken for vertical spacing provided by canned spacers when present. For configurations where canned spacers are not used, the TRIGA content is assumed stacked end-to-end. The three cylinders of the active fuel are modeled in triangular-pitch configuration within the radial boundary of the convenience can(s). The pitch used in the criticality calculation models for the NCT and HAC ground transport is 4.9809 cm (1.96 in.).

As shown in Table 6.9.6-19b, a set of parametric cases were run where the triangular pitch for the fuel content is varied from 1.44 in. (fuel sections touching) to 2.413 in. (fuel sections at maximum separation and touching the inner boundary of the convenience can). As shown in Fig. 6.17, the calculated k_{eff} + 2σ values increase slightly from 0.48 to an asymptotic value of ~ 0.53 at a pitch of 2.121 in. or a foci of 3.1106 cm (Table 6.9.6-19b). The foci of 2.8757 cm. for the TRIGA fuel sections used in the criticality calculation models, corresponds to a 1.96-in. pitch. The calculated k_{eff} + 2σ value is 0.527 for Case **cvcrtriga_1_15** (Table 6.9.6-19a) indicating that the configuration is in the range of optimum moderation. Moreover, the calculated k_{eff} + 2σ value is substantially below the USL. The foci is the distance perpendicular from the CV's vertical axis to the center of each fuel section. The value is obtained from the computer input listing on the comment line for geometry unit 1006 which reads: " -2.875700 minus-y location lower cylinder."

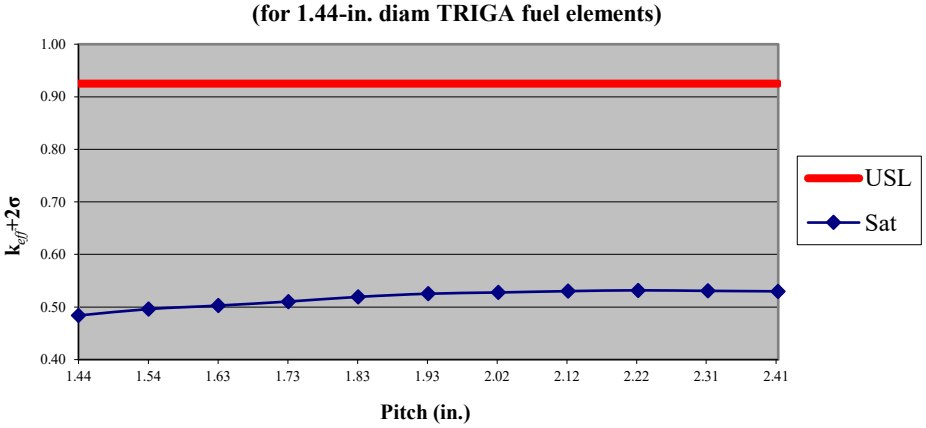

Fig. 6.17. k_{eff} + 2σ versus pitch for triangular arrangement of content in the containment vessel.

Parametric cases were also run as a function of the moisture fraction ("mocfr") in the CV. As shown in Fig. 6.18, the k_{eff} + 2σ values decrease with decreasing water content in the CV; and content spacing has less of an effect on k_{eff} at lower at the lower fractions.

The first of the three physical parameters which characterize the TRIGA fuel is enrichment. Table 6.9.6-19a presents results for 20 % enriched and 70 % enriched TRIGA fuel where the diameter of the active fuel is 1.44 in. The calculated k_{eff} + 2σ values for TRIGA fuel content at the lower enrichment is greater than for the fuel with the higher enrichment due to the greater quantity of fissile isotope present. The 20% enriched TRIGA fuel is considered the bounding content.

The second physical parameter which characterizes the TRIGA fuel is the uranium weight fraction. For a TRIGA fuel enriched to 20 wt % ^{235}U in U, the uranium weight fractions for the $UZrH_{1.6}$ fuel are: 45 wt %; 30 wt %; 20 wt %; 12 wt %; and 8.5 wt % U. A set of parametric cases were run where the uranium weight fraction is varied from the minimum value of 8.5 wt % to the maximum value of 45 wt %. Additionally, moderation in the CV is varied from the dry to the flooded condition. As shown in Fig. 6.19, the k_{eff} + 2σ values decrease with both decreasing uranium weight fraction and decreasing water content in the CV. Details are provided in Table 6.9.6-19c.

Third physical parameter which characterizes the TRIGA fuel is active fuel diameter. The active fuel diameters are: 1.44 in.; 1.41 in.; 1.40 in.; 1.37 in.; 1.34in.; and 1.31 in. The smaller the diameter, the less the amount of ^{235}U is present resulting in lower k_{eff} + 2σ values, as demonstrated later in this section.

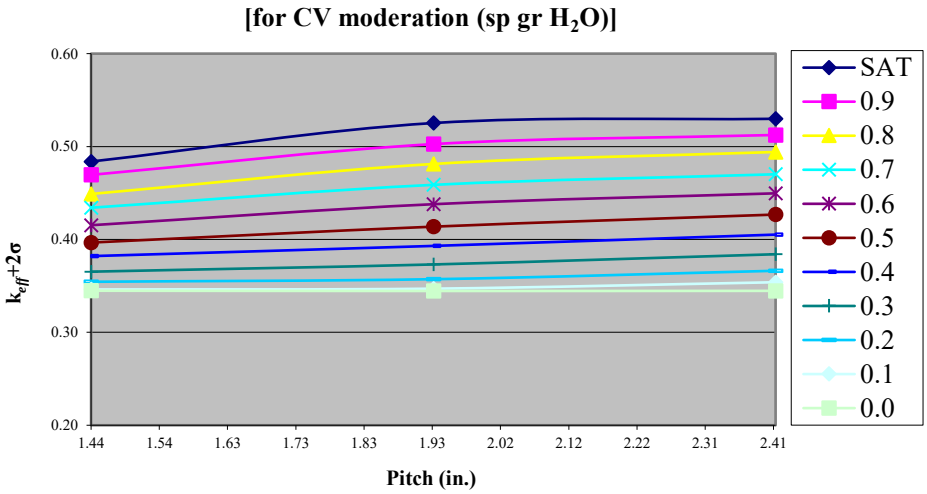

Fig. 6.18. k_{eff} + 2σ versus triangular pitch over range of containment vessel moderation.

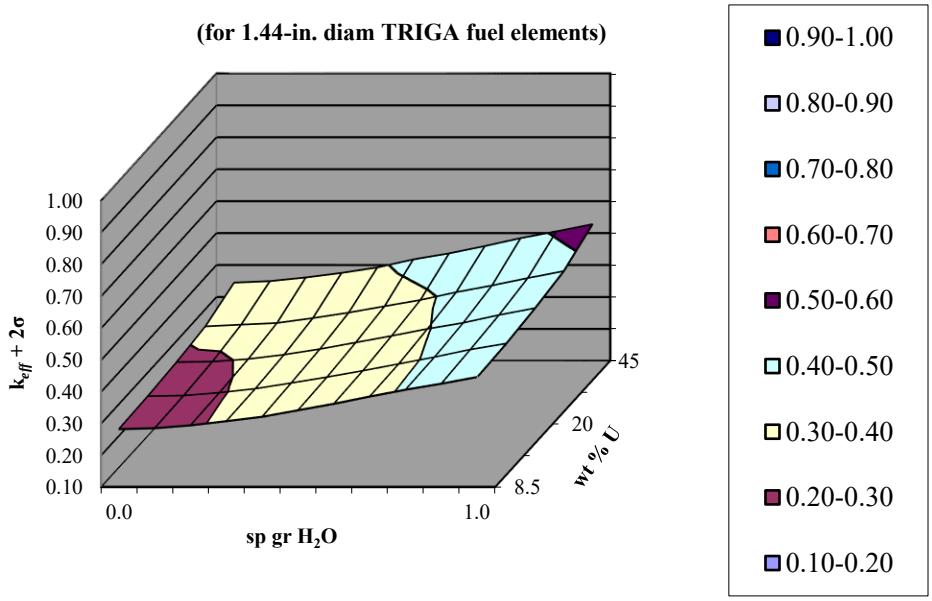

Fig. 6.19. k_{eff} + 2σ as a function of uranium weight fraction and moderation.

Cases **cvcrtriga_1_1** through **cvcrtriga_1_15** (Appendix 6.9.6, Table 6.9.6-19a) represent the TRIGA fuel content in a flooded CV, reflected by 30.48 cm of water. The flooded CV under full water reflection is a more reactive configuration than the CV inside of flooded ES-3100 packaging, Case **ncsrtriga_1_15_15** (Appendix 6.9.6, Table 6.9.6-20a). Further examination of the results in Table 6.9.6-20a indicates the content loading is adequately subcritical loading and that 277-4 canned spacers are not required for criticality control. Comparison of results for the NCT Case **ncsrtriga_1_15_15** and the HAC **hcsrtriga_1_15_15**, both with $k_{eff} + 2\sigma = 0.495$, reveal that changes to the packaging external to the CV due to the HAC do not result in an appreciable change in the neutron multiplication factor for the single package.

Additional CV cases were performed to exam the effect that 500 g of polyethylene will have on TRIGA fuel evaluations. The original cases previously found in Table 6.1f were rerun using SCALE 6.1.3, with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Table 6.8.

Table 6.8. Reflected CV model, TRIGA fuel, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
cvcrtriga_1_15	Three 5 in.-tall TRIGA fuel elements per can, no spacers or polyethylene	0.52737	0.00065	0.52867
cvcrtrigap_1_15	Three 5 in.-tall TRIGA fuel elements per can, no spacers, 500 g polyethylene	0.53581	0.00064	0.53709
cvcrtriga_70_1_15	Three 5 in.-tall TRIGA fuel elements per can, no spacers or polyethylene, 70% enriched	0.49000	0.00065	0.49130
cvcrtrigap_70_1_15	Three 5 in.-tall TRIGA fuel elements per can, no spacers, 500 g polyethylene, 70% enriched	0.49726	0.00065	0.49856

From the results of the CV cases for TRIGA fuel, modeling 500 g of polyethylene surrounding the HEU metal are more reactive than no polyethylene.

Cases **ncsrtriga70_1_1_1** through **ncsrtriga70_1_15_15** (Appendix 6.9.6, Table 6.9.6-20b) represent the 70 % enriched TRIGA fuel content in a flooded ES-3100 package, reflected by 30.48 cm of water. Comparison of results for these cases with results for the 20 % enriched TRIGA fuel (Cases **ncsrtriga_1_1_1** through **ncsrtriga_1_15_15**) confirm that the 20 % enriched TRIGA fuel is the bounding content.

Cases **ncsrT70_131_1_1_15** through **ncsrT70_131_1_15_15** (Appendix 6.9.6, Table 6.9.6-20c) represent the 1.31-in.-diam TRIGA fuel content in a flooded ES-3100 package, reflected by 30.48 cm of water. Comparison of results for these cases with results for the larger 1.44-in.-diam TRIGA fuel content (Cases **ncsrtriga70_1_1_1** through ncsrtriga70_1_15_15) confirm that the 1.44-in.-diam TRIGA fuel is the bounding content.

Additional cases were performed to exam the effect that 500 g of polyethylene will have on TRIGA fuel for single packages. The original cases previously found in Table 6.1f were rerun using SCALE 6.1.3, with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Tables 6.9 and 6.10.

ncsrtrigap_70_1_15_15	Three 5 in.-tall TRIGA fuel elements per can, no spacers, 500 g polyethylene, 70% enriched	0.46768	0.00061	0.46890

Table 6.10. Reflected HAC single package model, TRIGA fuel, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
hcsrtriga_1_15_15	Three 5 in.-tall TRIGA fuel element per can, no spacers or polyethylene	0.49431	0.00063	0.49557
hcsrtrigap_1_15_15	Three 5 in.-tall TRIGA fuel element per can, no spacers, 500 g polyethylene	0.50541	0.00074	0.50689
hcsrtriga_70_1_15_15	Three 5 in.-tall TRIGA fuel element per can, no spacers or polyethylene, 70% enriched	0.45831	0.00059	0.45949
hcsrtrigap_70_1_15_15	Three 5 in.-tall TRIGA fuel element per can, no spacers, 500 g polyethylene, 70% enriched	0.46890	0.00060	0.47010

From the results of the single package cases for TRIGA fuel, modeling 500 g of polyethylene surrounding the HEU metal are more reactive than no polyethylene.

10 CFR 71.55(d)(2) requires the geometric form of a package's content not be substantially altered under the NCT. Also, 10 CFR 7155(e)(1) requires that the package be adequately subcritical under HAC with the package contents in the most reactive credible configuration. However, conclusions about damage to the fuel content cannot be extrapolated from test data because a mock (test weight) content rather than actual TRIGA content is evaluated in the NCT and HAC tests of 10 CFR 71.71 and 10 CFR 71.73. Consequently, one way for addressing these requirements is to model the content in an extremely damaged condition and make a determination of subcriticality through a series of criticality calculations. Cases **ncsrt55d2_ 1_1_1**5 through **ncsrt55d2_1_15_15** (Appendix 6.9.6, Table 6.9.6-20d) represent TRIGA fuel content homogenized with variable density water over the free volume of the CV, where the ES-3100 packaging is flooded and reflected by 30.48 cm of water. The variable density water ranges from the dry containment condition to the fully flooded condition. Credit for physical integrity of the content is not taken in this set of cases which model the substantially altered content. The calculation results in Table 6.9.6-20d indicate extremely damaged content (Case **ncsrt55d2_1_15_15** with $k_{eff} + 2\sigma = 0.611$) is more reactive than the unaltered configuration (Case **ncsrtriga_1_15_15** with $k_{eff} + 2\sigma = 0.403$). Nevertheless, both cases are adequately below the USL of 0.925 and the requirement of 10 CFR 71.55(d)(2) is satisfied. Given that changes external to the CV due to the HAC do not result in an appreciable change in the neutron multiplication for the single package, similar results are expected for the cases demonstrating compliance with 10 CFR 7155(e)(1).

The shipping configuration for disassembled TRIGA fuel addressed in this subsection is not the only permissible shipping configuration for TRIGA fuel in the ES-3100. TRIGA fuel may also be configured as clad fuel rods (Appendix 6.9.3.1). Each 15-in.-long rod is derived from a single TRIGA fuel element. The clad fuel rod consists of the 3 fuel pellets and the exterior sheath of stainless steel or aluminum clad. Clad fuel rods are packed into stainless steel or tin-plated carbon steel convenience cans with a maximum of three fuel rods per loaded convenience can. This shipping configuration requires that only one convenience can is loaded with clad fuel rods.

Except for a 0.02-in.-thick sheath of stainless steel clad added to the exterior surface of the $UZrH_{1.6}$, a calculation model for the clad fuel rod configuration is essentially the same as the NCT shipping configuration model for disassembled TRIGA fuel. A 0.02-in. thickness of stainless steel is insignificant for an external reflection. As illustrated in Fig. 6.24 (Sect. 6.7.2), stainless steel up to several cm in thickness acts as a neutron absorber. Several inches in thickness are required for neutron multiplication to increase from neutron reflection by the stainless steel. The NCT shipping configuration model for disassembled TRIGA fuel is bounding. The same applies for TRIGA fuel with aluminum clad.

A clad fuel rod with 1.44-in.-diam fuel pellets contains 2,282.4-g $UZrH_x$ (Appendix 6.9.3.1) and ~179 to 191 g of stainless steel. Stainless steel tends to act as a neutron absorber; moreover, its presence as clad in the TRIGA fuel content replaces water moderator otherwise present in the geometry configuration of TRIGA fuel meats. When stainless steel is homogenized with the $UZrH_{1.6}$ as in the calculation model for package content in the extremely damaged condition [10 CFR 71.55(d)(2) and 10 CFR 7155(e)(1)], the stainless steel acts more effectively as a neutron absorber. However, the amount of stainless steel added and water displaced is not expected to have a statistically significant affect on neutron multiplication. Thus, the HAC shipping configuration model for disassembled TRIGA fuel (bare fuel meats) is bounding.

A clad fuel rod with 1.41-in.-diam fuel pellets contains ~2,188-g $UZrH_x$ and ~90 to 96 g of aluminum. While aluminum tends to act as a neutron scatter, its presence in the TRIGA fuel content replaces water moderator otherwise present in the geometry configuration of TRIGA fuel meats. The amount of aluminum added and water displaced is not sufficient to have a statistically significant affect on neutron multiplication. Thus, the HAC shipping configuration model for disassembled TRIGA fuel is also bounding for aluminum clad TRIGA fuel content.

The TRIGA content is to be transported by air; consequently, additional discussion is included in Sect. 6.7.

The 1.5-in.–diam × 2-in.–tall slugs may be packed up to ten items per press-fit lid type convenience can and up to twelve items per crimp-lid type convenience can. With nominal dimensions, each slug weighs ~1,090 g. With +1/16-in. tolerance on both the diameter and height, each slug in the calculation model weighs ~1218 g. As described in Appendix 6.9.1, different arrangements of slugs in the convenience cans are possible. A configuration of slugs in a flooded reflected CV must be shown to be adequately subcritical and so limited either by the use of 277-4 canned spacers, by limitation of fissile mass, or by both.

Several slug arrangements depicted in Fig. 6.9.1-4b are evaluated for demonstrating that the most conservative arrangement of slugs is being analyzed. The blue marker shown in Fig. 6.9.1-4c depicts the 4.13-in. diam of the canned spacer. Content within a configuration radius of 2.125 in. (5.4 cm) are within the boundary of the convenience can wall. The convenience cans are not modeled and contents are allowed to project beyond the convenience can wall boundary. The slugs are modeled only as 100 wt % ^{235}U for this portion of the criticality evaluation. Cases **cvcr5st11_1_1**, **cvcr5est11_1_1**, **cvcr50st11_1**, **cvcr5e0st11_1**, **cvcr5u0st11_1**, and **cvcr5l0st11_1** depict very different spacing arrangements with five slugs per convenience can, three cans per package. The statistical difference in the calculated "$k_{eff} + 2\sigma$" values is

insignificant. Cases **cvcr6e0st11_1** and **cvcr6st11_1_1** depict arrangements with six slugs per convenience can, and Case **cvcr70st11_1** depicts seven slugs per convenience can. (Considerable deformation of the 4.25-in.–diam convenience can wall is required to achieve all but the simple pentagonal-ring arrangement of slugs.) Calculation results reveal the primary dependence of the "$k_{eff} + 2\sigma$" value is on the fissile mass loading and the secondary dependence is on the arrangement and spacing of slugs. The calculation results presented in Table 6.9.6-8 (Appendix 6.9.6) for a flooded CV indicate that only five slugs per convenience can (18,277-g ^{235}U per package) may be loaded without the use of 277-4 canned spacers (Cases **cvcr5st11_1_1** and **cvcr5est11_1_1**). Further evaluation of the single package and array configurations are required. Also, results highlighted in red indicate that 277-4 canned spacers are required for the slug content.

The sensitivity of k_{eff} to the space between slugs arranged in a pentagonal ring is evident in the calculation results for Cases **cvcr5st11_1_2** and **cvcr5est11_1_2,** which model content for three convenience cans, each location with two pentagonal rings (10 slugs) per can. These two configurations represent degrees of separation between adjacent neighbors in the pentagonal rings of 0.0 cm and 1.0 cm, respectively. The most reactive configuration occurs when the slugs are spaced 1.0 cm apart from direct contact with adjacent neighbors in the pentagonal rings. Because positioning devices are not used in the convenience cans to control spacing and prevent an optimal arrangement of contents from occurring, both calculation models for slug arrangement are the basis for additional calculations where 277-4 canned spacers may not be required.

Cases **cvcr5st11_2_1**, **cvcr5est11_2_1**, **cvcr50st11_2**, **cvcr5e0st11_2**, **cvcr5u0st11_2**, and **cvcr5l0st11_2** represent the different spacing arrangements with five slugs per convenience can, three cans per package, and cans separated by canned spacers. Likewise, Cases **cvcr6e0st11_2** and **cvcr6st11_2_1** represent arrangements with six slugs per convenience can, three can per package, and cans separated by can spacers. Case **cvcr70st11_2** represents seven slugs per convenience can. While the differences in the calculated "$k_{eff} + 2\sigma$" values for equal numbers of slugs per can are ≤ 0.006, the "$k_{eff} + 2\sigma$" values are significantly below the USL. Again, the calculation results presented in Table 6.9.6-8 (Appendix 6.9.6) for these cases reveal the primary dependence of the "$k_{eff} + 2\sigma$" value is on fissile mass loading, and the secondary dependence is on the arrangement and spacing of slugs.

Additional CV cases were performed to exam the effect that 500 g of polyethylene will have on HEU metal slugs. The original cases previously found in Table 6.1b were rerun using SCALE 6.1.3, with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Table 6.11.

Table 6.11. Reflected CV model, HEU metal slugs, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
cvcr5st11_1_1	18.277 kg ^{235}U, 5 slugs per can, d=1.5625 in., h=2.0624 in., no spacers or polyethylene	0.91514	0.0006	0.91634
cvcr5st11p_1_1	18.277 kg ^{235}U, 5 slugs per can, d=1.5625 in., h=2.0624 in., no spacers, 500 g polyethylene	0.92015	0.00073	0.92161
cvcr5st11_2_2	36.555 kg ^{235}U, 10 slugs per can, d=1.5625 in., h=2.0624 in., no spacers or polyethylene	0.90561	0.00061	0.90683
cvcr5st11p_2_2	36.555 kg ^{235}U, 10 slugs per can, d=1.5625 in., h=2.0624 in., no spacers, 500 g polyethylene	0.90566	0.0007	0.90706

From the result of the CV cases for HEU metal slugs, modeling 500 g of polyethylene surrounding the HEU metal are as or slightly more reactive than no polyethylene.

Case **cvcr6e0st11_2** models three sets of slugs, six slugs in a pentagonal ring with one slug in the center, and each set of slugs separated by a 277-4 canned spacer. Cases **cv0r6e0st11_2** and **cvwr6e0st11_2** are variations of the reference case where the 1.4-in. spacer is replaced with void in the first case and is replaced with water in the second case. Comparison of the "$k_{eff} + 2\sigma$" values between Cases **cvcr6e0st11_2** and **cv0r6e0st11_2** reveals that the spacers reduce k_{eff} by ~ 0.03. Comparison of the "$k_{eff} + 2\sigma$" values for Cases **cvcr6e0st11_2** and **cvwr6e0st11_2** reveals that axial spacing of the content provided by the content cans inside the CV serves to reduce k_{eff}.

The calculation results presented in Table 6.9.1-8 for a flooded CV indicate that up to ten slugs per convenience can (36,555-g ^{235}U per package) *might* be loaded when 277-4 canned spacers are used. Conceivable arrangements are considered in Cases **cvcr5st11_2_2**, **cvcr5est11_2_2**, **cvcr6e4st11_2**, and **cvcr73st11_2** (Table 6.9.6-8). Suitability is contingent on the results of single package and array calculations.

Cases **ncsr5est11_2_1_1** through **ncsr5est11_2_1_15** (Appendix 6.9.6, Table 6.9.6-9) model a reflected package with one pentagonal ring of slugs per content location with 277-4 canned spacers between content locations and HEU content at 100 wt % ^{235}U. The $k_{eff} + 2\sigma$ values range from a low value of 0.688 to 0.736. These results show that the most reactive configuration is the flooded condition with MOIFR=1.0.

As shown by the cylindrical content calculation models, the ES-3100 package is not as an efficient reflector as full water reflection provided to the flooded CV. This is also true for content loadings of one pentagonal ring of slugs per content location without 277-4 canned spacers between locations and HEU content at 100 wt % ^{235}U. For Cases **cvcr5est11_1_1** and **ncsr5est11_1_1_15**, the $k_{eff} + 2\sigma$ values are 0.910 and 0.871, respectively. Likewise, the $k_{eff} + 2\sigma$ values are 0.901 and 0.867 for content loadings of two pentagonal rings of slugs per content location with 277-4 canned spacers between locations, Cases **cvcr5est11_2_2** and **ncsr5est11_2_2_15**, respectively.

For the flooded CV under full water reflection and loaded with the slugs in a pentagonal arrangement and 277-4 canned spacers between content locations, the $k_{eff} + 2\sigma$ value is 0.903, Case **cvcr5st11_2_2** [10 CFR 71.55(b)]. This value is below the USL value of 0.925. For packages with the required 1.4-in. spacers, the calculated $k_{eff} + 2\sigma$ value is 0.878 for the water-reflected package, Case **ncsr5st11_2_2_15** [10 CFR 71.55(d)]. Case **hcsr5st11_02_2_15** represents the HAC model of the damaged ES-3100 package, where the outer dimensions of the package are reduced accordingly and the entire package is flooded except the neutron poison of the body weldment liner inner cavity. This single-unit case with a MOIFR = 1.0 pertains specifically to the flooded drum under conditions specified in 10 CFR 71.55(e). The $k_{eff} + 2\sigma$ value is 0.872 for this HAC. The changes in both the outer dimensions of the package and the compositions of the Kaolite and 277-4 due to HAC result in an ~0.001 change in the neutron multiplication factor.

Additional cases were performed to exam the effect that 500 g of polyethylene will have on HEU metal slugs for a single package. The original cases previously found in Table 6.1b were rerun using SCALE 6.1.3, with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Tables 6.12 and 6.13.

Table 6.12. Reflected NCT single package, HEU metal slugs, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
ncsr5st11_1_1_15	18.277 kg ^{235}U, 5 slugs per can, d=1.5625 in., h=2.0624 in., no spacers or polyethylene	0.87487	0.00068	0.87623
ncsr5st11p_1_1_15	18.277 kg ^{235}U, 5 slugs per can, d=1.5625 in., h=2.0624 in., no spacers, 500 g polyethylene	0.88341	0.00067	0.88475
ncsr5st11_2_2_15	36.555 kg ^{235}U, 10 slugs per can, d=1.5625 in., h=2.0624 in., with spacers or polyethylene	0.87962	0.00065	0.88092
ncsr5st11p_2_2_15	36.555 kg ^{235}U, 10 slugs per can, d=1.5625 in., h=2.0624 in., with spacers, 500 g polyethylene	0.87589	0.00064	0.87717

Table 6.13. Reflected HAC single package, HEU metal slugs, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
hcsr5st12_1_1_15	18.277 kg ^{235}U, 5 slugs per can, d=1.5625 in., h=2.0624 in., no spacers or polyethylene	0.88673	0.00061	0.88795
hcsr5st12p_1_1_15	18.277 kg ^{235}U, 5 slugs per can, d=1.5625 in., h=2.0624 in., no spacers, 500 g polyethylene	0.87734	0.00064	0.87862
hcsr5st12_2_2_15	36.555 kg ^{235}U, 10 slugs per can, d=1.5625 in., h=2.0624 in., with spacers or polyethylene	0.88067	0.00064	0.88195
hcsr5st12p_2_2_15	36.555 kg ^{235}U, 10 slugs per can, d=1.5625 in., h=2.0624 in., with spacers, 500 g polyethylene	0.87734	0.00064	0.87862

From the results of the single package cases for HEU metal slugs, modeling 500 g of polyethylene surrounding the HEU metal are as or slightly more reactive than no polyethylene.

6.4.2 HEU Broken Metal; Solid HEU Metal with Unspecified Geometric Shape and Characterized as Broken Metal; or Turnings, Fines, or Powder

Broken metal pieces are distinguished from turnings, fines, or powder as having a surface-area-to-mass ratio of not greater than 1 cm^2/g or must not pass through a 3/8-in. mesh sieve (or equivalent size-grading method). In the CV calculations, broken metal is evaluated using the "lha" content model (Fig. 6.9.1-5c). The "lha" approximation model is derived from the "sqa" model (Figs. 6.9.1-5b) where HEU metal is homogenized with the water inside the rectangular lattice formed by an array of discretely modeled items of uniform size and shape (Appendix 6.9.1). The overall volume (and shape) of the content "envelope" containing the HEU and the amount of interstitial moderator between the actual pieces of HEU is preserved in the "lha" content model. This representation of discrete solid HEU broken metal in the CV calculation model as fissile material homogenized with moderator is bounding (Table 6.9.3.1-2). In the CV calculations, turnings, fines, and powder are evaluated using the "cha" content model (Fig. 6.9.1-5d) where HEU metal and the water inside a flooded CV are homogenized as a uranium "solution" and dispersed over the internal volume of the CV.

Credit for the presence of convenience cans is not taken in either the "lha" or the "cha" model. Content spacing provided by the convenience cans is absent in the models such that the canned spacer, if present, is located above the rectangular lattice (content envelop) between the convenience can locations

(Fig. 6.9.1-5c). Credit for the presence of canned spacers is taken for broken metal but not for fines, turnings, and powder where the fissile material form is not conducive to maintaining spacer separation nor prevent gravitation of the canned spacers to the bottom of the CV. For conservatism, the "cha" model was used to represent HEU metal content in the single package calculations.

Like packages with solid HEU metal shapes, the neutron multiplication factor for reflected single packages with HEU broken metal, turnings, fines, or powder increases as a function of the ^{235}U mass and the MOIFR. For example, consider the ES-3100 package loaded with three convenience cans for a total of 35,142-g ^{235}U. The $k_{eff} + 2\sigma$ values range from 0.814 to 0.891 with increasing MOIFR in the water-reflected package [Cases **ncsrbmt11_36_1_1** through **ncsrbmt11_36_1_15** (Appendix 6.9.6, Table 6.9.6-11)]. The addition of water to the package reduces the NLF, thereby increasing k_{eff}.

For the CV loaded with the broken metal content (excluding turnings, fines, or powder) and without 277-4 canned spacers between content locations, the $k_{eff} + 2\sigma$ values increase from 0.751 to 0.949 as the water content in the CV increases [Cases **cvr3lha_36_1_8_1** through **cvr3lha_36_1_8_15** (Appendix 6.9.6, Table 6.9.6-10)]. Cases **cvr3lha_36_1_8_15** through **cvr3lha_36_1_1_15** model the flooded CV with 35 kg of broken HEU metal where the enrichment ranges from 100 to 19 wt % ^{235}U. The $k_{eff} + 2\sigma$ values decrease from 0.949 to 0.657. The $k_{eff} + 2\sigma = 0.949$ for Case **cvr3lha_36_1_8_15** indicates that the 35,142-g ^{235}U mass loading at 100% enrichment with canned spacers absent must be reduced below 35,142-g ^{235}U for establishing a loading limit over the range of 95 to 100 wt % ^{235}U. The result for Case **cvr3lha_26_1_8_15** indicates that for an enrichment of 100 wt % ^{235}U, the mass loading over the range $95 < \text{enr.} \leq 100$ wt % ^{235}U cannot exceed 25,894-g ^{235}U in the absence of canned spacers. (The orange highlighted cases in Table 6.9.6-10 indicate potential fissile loading limits, or evaluation limits.)

The result for Case **cvr3lha_29_1_7_15** indicates that for an enrichment of 95 wt % ^{235}U, the mass loading limit conservatively applied over the range $90 < \text{enr.} \leq 95$ wt % ^{235}U cannot exceed 27,252-g ^{235}U in the absence of canned spacers. Application of this 27,252-g ^{235}U limit to higher enrichment material is non-conservative, as illustrated by the result for Case **cvr3lha_28_1_8_15** where $k_{eff} + 2\sigma = 0.933$ for 100 wt % ^{235}U. As the enrichment increases, the mass loading limit must decrease from 27,252-g to 25,894-g^{235}U in this example due to less ^{238}U present for neutron absorption. Potential fissile loading limits for the reduced enrichment ranges are derived in a similar manner. For enrichments ≤ 60 wt % ^{235}U, the CV is load-limited to 35,320-g U. As enrichment drops from 60 to 19 wt % ^{235}U, the $k_{eff} + 2\sigma$ values decrease from 0.829 to 0.657. The ^{235}U (or U) evaluation limits conservatively applied over the indicated ranges of enrichment are listed in the column headings of Table 6.1c. These evaluation limits represent the maximum amount of ^{235}U (or U) permissible in a flooded, reflected CV for maintaining an adequate margin of subcriticality.

For the CV loaded with the HEU metal content in the form of turnings, fines, or powder and without 277-4 canned spacers between content locations, the $k_{eff} + 2\sigma$ values increase from 0.613 to 0.983 as the water content in the CV increases [Cases **cvr3cha_36_1_8_1** through **cvr3cha_36_1_8_15** (Appendix 6.9.6, Table 6.9.6-10)]. Cases **cvr3cha_36_1_8_15** through **cvr3cha_36_1_1_15** model the flooded CV with 35.32 kg of HEU metal turnings, fines, or powder having an enrichment ranging from 100 to 19 wt % ^{235}U. The $k_{eff} + 2\sigma$ values decrease from 0.983 to 0.791. The $k_{eff} + 2\sigma = 0.983$ for Case **cvr3cha_36_1_8_15** indicates that the 35,142-g ^{235}U mass loading at 100% enrichment without canned spacers must be reduced in order to be considered as a loading limit over the range of 95 to 100 wt % ^{235}U. The result for Case **cvr3cha_8_1_8_15** indicates that for an enrichment of 100 wt % ^{235}U, the mass loading conservatively applied over the range $95 < \text{enr.} \leq 100$ wt % ^{235}U cannot exceed 7,398-g ^{235}U in the absence of canned spacers.

The result for Case **cvr3cha_12_1_7_15** indicates that for an enrichment of 95 wt % ^{235}U, the mass loading conservatively applied over the range $90 < \text{enr.} \leq 95$ wt % ^{235}U cannot exceed 10,549-g ^{235}U

in the absence of canned spacers. Similarly, the application of this 10,549-g ^{235}U limit for HEU metal turnings, fines, or powder in the range 90 < enr. ≤ 95 wt % ^{235}U to higher enrichment material in the range 95 < enr. ≤ 100 wt % ^{235}U is non-conservative. As the enrichment increases, the mass loading limit must decrease from 10,549-g to 7,398-g ^{235}U in this example due to less ^{238}U present for neutron absorption. The result for Case **cvr3cha_16_1_6_15** indicates that for an enrichment of 90 wt % ^{235}U, the mass loading conservatively applied over the range 80 < enr. ≤ 90 wt % ^{235}U cannot exceed 14,167-g ^{235}U in the absence of canned spacers. The result for Case **cvr3cha_25_1_5_15** indicates that for an enrichment of 80 wt % ^{235}U, the mass loading conservatively applied over the range 70 < enr. ≤ 80 wt % ^{235}U cannot exceed 19,284-g ^{235}U in the absence of canned spacers. The result for Case **cvr3cha_36_1_4_15** indicates that for an enrichment of 70 wt % ^{235}U, the mass loading conservatively applied over the range 60 < enr. ≤ 70 wt % ^{235}U cannot exceed 24,693-g ^{235}U in the absence of canned spacers. The result for Case **cvr3cha_36_1_3_15** indicates that for an enrichment of 60 wt % ^{235}U, the mass loading conservatively applied over the range 40 < enr. ≤ 60 wt % ^{235}U cannot exceed 21,192-g ^{235}U in the absence of canned spacers. As enrichment drops from 60 to 19 wt % ^{235}U, the $k_{eff} + 2\sigma$ values decrease from 0.900 to 0.791. However, the CV is load-limited to 35,320-g U; therefore, the maximum permissible loadings shown for Cases **cvr3cha_36_1_2_15** and **cvr3cha_36_1_1_15** are not achievable. For this reason, the uranium mass rather the fissile isotope mass (g ^{235}U) is indicated as the potential mass loading limit for ≤ 60 wt % ^{235}U. The ^{235}U (or U) evaluation limits conservatively applied over the indicated ranges of enrichment are listed in the column headings of Tables 6.1d. These evaluation limits represent the maximum amount of ^{235}U (or U) in the form of HEU metal turnings, fines, or powder permissible in a flooded, reflected CV for maintaining an adequate margin of subcriticality.

Additional calculations were performed modeling 500 g of polyethylene for both HEU broken metal (**cvr3lha_*** cases) and HEU metal turning, fines, or powder (**cvr3cha_*** cases). These calculations were performed using an updated version of the SCALE code as discussed in Sect. 6.3.3 and using a validation with a higher USL. The models used in these calculations also evaluated the amount of uranium in smaller increments (100 g) instead of the higher increments used in the previous calculations. This resulted in higher uranium mass limits calculated in some of the array calculations, with lower uranium mass limits in some of the more recent calculations. Enrichments from 60% up to 100% were evaluated for both HEU broken metal and HEU metal turning, fines, or powder. The range of water inside the CV was not evaluated since it is already shown in the non-polyethylene cases that a flooded CV is most reactive. The results of these calculations can be found in Table 6.9.6-10a. The most reactive results that are below the USL were rerun to examine the effect of adding thorium metal. The results of these calculations are found in Table 6.9.6-10b.

For the CV loaded with broken metal content (excluding turnings, fines, or powder) with 500 g of polyethylene, the result for Case **cvr3lhap_9_1_6_15** indicates that for an enrichment of 100%, the mass loading limit cannot exceed 22.4 kg uranium (22.4 kg ^{235}U) in the absence of canned spacers. The result for Case **cvr3lhpa_18_1_5_15** indicates that for an enrichment of 95%, the mass loading limit cannot exceed 24.6 kg uranium (23.37 kg ^{235}U) in the absence of canned spacers. The result for Case **cvr3lhap_28_1_4_15** indicates that for an enrichment of 90%, the mass loading limit cannot exceed 31.1 kg uranium (27.99 kg ^{235}U) in the absence of canned spacers. The result for Case **cvr3lhap_34_1_3_15** indicates that for an enrichment of 80% and lower, the mass loading limit cannot exceed 36 kg uranium in the absence of canned spacers. As the enrichment increases, the mass loading limit must decrease. The ^{235}U (or U) evaluation limits conservatively applied over the indicated ranges of enrichment are listed in the column headings of Table 6.1c. These evaluation limits represent the maximum amount of ^{235}U (or U) permissible in a flooded, reflected CV for maintaining an adequate margin of subcriticality.

For the CV loaded with the turnings, fines, or powder content with 500 g of polyethylene, the result for Case **cvr3chap_5_1_6_15** indicates that for an enrichment of 100%, the mass loading limit cannot exceed 10.5 kg uranium (10.5 kg ^{235}U) in the absence of canned spacers. The result for Case

cvr3chap_14_1_5_15 indicates that for an enrichment of 95%, the mass loading limit cannot exceed 16.1 kg uranium (15.295 kg ^{235}U) in the absence of canned spacers. The result for Case **cvr3chap_23_1_4_15** indicates that for an enrichment of 90%, the mass loading limit cannot exceed 22.0 kg uranium (19.80 kg ^{235}U) in the absence of canned spacers. The result for Case **cvr3chap_34_1_3_15** indicates that for an enrichment of 80%, the mass loading limit cannot exceed 33.0 kg uranium (26.40 kg ^{235}U) in the absence of canned spacers. The result for Case **cvr3chap_38_1_2_15** indicates that for an enrichment of 70% and lower, the mass loading limit cannot exceed 36 kg uranium in the absence of canned spacers. As the enrichment increases, the mass loading limit must decrease. The ^{235}U (or U) evaluation limits conservatively applied over the indicated ranges of enrichment are listed in the column headings of Table 6.1c. These evaluation limits represent the maximum amount of ^{235}U (or U) permissible in a flooded, reflected CV for maintaining an adequate margin of subcriticality. Comparative calculations were performed to exam the effect of thorium metal mixed with HEU broken metal, turnings, fines, and powders. Up to 5 kg of thorium metal was evaluated with the mass loading limit model. The results of these calculations (Table 6.9.6-10b) show that reactivity decreases as thorium metal is added to HEU.

The most reactive credible configuration consistent with the chemical and physical form of the material consists of the CV under full water reflection but with 277-4 canned spacers absent between content locations. For the flooded CV loaded with the HEU broken metal content at 100% enrichment (excluding turnings, fines, or powder), the $k_{eff} + 2\sigma = 0.918$ in Case **cvr3lha_26_1_8_15,** and for HEU broken metal content with 500 g of polyethylene at 100% enrichment, the $k_{eff} + 2\sigma = 0.934$ in Case **cvr3lhap_9_1_6_15** [Table 6.1c, 10 CFR 71.55(b)]. For the flooded CV loaded with HEU metal turnings, fines, or powder (excluding unspecified geometric shape and characterized as broken metal, or broken metal), the $k_{eff} + 2\sigma = 0.923$ in Case **cvr3cha_8_1_8_15**, and for HEU broken turnings, fines, or powders with 500 g polyethylene the $k_{eff} + 2\sigma = 0.934$ in Case **cvr3chap_5_1_6_15** [Table 6.1d, 10 CFR 71.55(b)].

For single packages loaded with HEU content (solid metal of unspecified geometric shape and characterized as broken metal, broken metal, turnings, fines, or powder), the calculated $k_{eff} + 2\sigma$ value for Case **ncsrbmt11_36_1_15** is 0.891 and for HEU broken metal content with 500 g of polyethylene, the $k_{eff} + 2\sigma = 0.892$ in Case **ncsrbmt11p_8_6_15** [Tables 6.1c and 6.1d, 10 CFR 71.55(d)]. Case **hcsrbmt12_36_1_15** (Appendix 6.9.6, Table 6.9.6-11) represents the HAC model of the damaged ES-3100 package, where the outer dimensions of the package are reduced accordingly and the entire package is flooded except the neutron poison of the body weldment liner inner cavity. This single-unit case with a MOIFR = 1.0 pertains specifically to the flooded drum under conditions specified in 10 CFR 71.55(e) (Tables 6.1c and 6.1d). The $k_{eff} + 2\sigma = 0.891$ for this HAC condition. For HEU broken turnings, fines, or powders with 500 g of polyethylene the $k_{eff} + 2\sigma = 0.984$ in Case **hcsrbmt12p_8_6_15**. The changes in both the outer dimensions of the package and the compositions of the Kaolite and 277-4 due to HAC does not result in detectible change in the neutron multiplication factor.

The finalized mass loading limits documented in Table 6.2a are derived from Tables 6.1c and 6.1d at the conclusion of the array analyses after consideration of other packing arrangements (i.e., single package under NCT and HAC and the various package array configurations under NCT and HAC).

6.4.3 HEU Oxide

HEU product oxide content is non-hygroscopic or mildly hygroscopic. The bulk density of HEU oxides considered for shipment in the ES-3100 ranges from 0.5 to 6.54 g/cm^3. HEU skull oxide is a less dense form of U_3O_8 intermixed with graphite. Of interest are those compositions with carbon/fissile uranium (C/^{235}U) ratios up to 2.3×10^5 μg C/g^{235}U. The quantity of fissile uranium is extremely low where even higher C/^{235}U ratios are present. Removal of the carbon limit (i.e., 921-g C) is addressed in Appendix 6.9.11.

HEU product oxide content may be packed in polyethylene bottles or metal convenience cans; HEU skull oxide content is packed in metal convenience cans. Polyethylene bottles and hydrogenous packing material are represented by 500 g polyethylene. While both the size and shape of the polyethylene bottles prevents the use of 277-4 canned spacers with product oxide loadings, the 10-in. height of the metal convenience cans eliminates the use of 277-4 canned spacers for product or skull oxide content packaged in these size cans. However, the convenience cans are not modeled in this criticality evaluation and this analysis is performed from the standpoint that metal-type convenience cans may be used for both oxide types.

HEU oxide content is not considered a "rigid" content like solid or broken HEU metal. For the calculation models of HEU oxides, the polyethylene is homogenized with the saturated bulk oxide. At a density of 0.9200 g/cm^3, polyethylene adds 543.47826 cm^3 to the volume of the saturated bulk oxide and reduces the free volume of the CV by an equal amount. The evaluation water in the void region of the CV fills the volume of the CV that not occupied by oxide content. (The void region of the CV is defined as the CV volume minus the oxide content volume.) Because of the differences in densities and compositions, product oxides are addressed separately from skull oxides.

Like packages with HEU metal or broken metal, the neutron multiplication factor for reflected single packages with HEU oxide increases as a function of increasing MOIFR and decreases with decreasing ^{235}U mass. For example, consider the ES-3100 package loaded with oxide at 6.54 g/cm^3 in three convenience cans for a total of 24,000-g UO_2 (21,125-g ^{235}U). The $k_{eff} + 2\sigma$ values range from 0.724 to 0.804 with increasing MOIFR in the reflected package [Cases **ncsrpoxt11_1_24_1** through **ncsrpoxt11_1_24_15** (Table 6.9.6-13)]. The addition of water to the package reduces the NLF, thereby increasing k_{eff}. The flooded, reflected package is the most reactive single package configuration; consequently, MOIFR is treated as a constant rather than a variable in subsequent "**pdox**" cases.

Parametric calculations are performed for oxide content loadings in a flooded, reflected package by varying the oxide bulk density from 6.54 g/cm^3 to a lower value limited by the capacity of the convenience cans. The maximum content capacity of the ES-3100 is ~6,975 cm^3, where each of three 4.25-in.-diam × 10.0-in.-tall convenience cans has a capacity of ~2,325 cm^3. As shown in Table 6.9.6-13a, calculations for a loading of 24,000-g UO_2 are performed at bulk densities of 6.54 g/cm^3, 5.0 g/cm^3, and 4.0 g/cm^3, but not 3.0 g/cm^3 because the capacity of the convenience cans is exceeded for this mass loading. Note that Case **ncsrpoxt11_1_24_15** (Table 6.9.6-13) is identical to Case **ncsrpdoxt11_1_5_24** (Table 6.9.6-13a). Results for the parametric Cases **ncsrpdoxt11_1_*n*_24**, **ncsrpdoxt11_1_*n*_20**, and **ncsrpdoxt11_1_*n*_15** reveal the consistent increase in the $k_{eff} + 2\sigma$ values as the bulk density decreases. This increase in neutron multiplication is due to the increased moderation of the HEU oxide.

Cases **ncsrpdoxt11_1_*n*_14** for UO_2 (12,323-g ^{235}U), **ncsrpdoxt11_2_*n*_14** for U_3O_8 (11,850-g ^{235}U), and **ncsrpdoxt11_3_*n*_14** for UO_3 (11,627-g ^{235}U) evaluate the ES-3100 package loaded with 14 kg oxide over the range of bulk density "*n*." The $k_{eff} + 2\sigma$ values reveal a consistent increase over the range of density. Results for Cases **ncsrpdoxt11_2_1_14** and **ncsrpdoxt11_3_1_14** indicate that both the U_3O_8 content ($k_{eff} + 2\sigma = 0.778$) and the UO_3 content ($k_{eff} + 2\sigma = 0.760$) are bounded by the UO_2 content ($k_{eff} + 2\sigma = 0.814$). Even though the capacity of the convenience cans is exceeded by 25 g, these cases are retained for the purpose of illustrating this point.

Results for a reflected CV loaded with HEU oxide reveal the same trends in the $k_{eff} + 2\sigma$ values as do results for the reflected package; however, the $k_{eff} + 2\sigma$ values are ~0.1 greater in the CV cases. For the flooded CV loaded with UO_2, the $k_{eff} + 2\sigma$ values increase from 0.838 to 0.911 with decreasing bulk density [Cases **cvcrpdoxt11_1_5_14_15** through **cvcrpdoxt11_1_1_14_15** (Table 6.9.6-12 and Fig. 6.9.1-6)]. For the dry CV, the $k_{eff} + 2\sigma$ values increase from 0.824 to 0.912 [Cases **cvcrpdoxt11_1_5_14_1** through **cvcrpdoxt11_1_1_14_1** (Table 6.9.6-12 and Fig. 6.9.1-6)]. Comparison of results for high density UO_2 oxide saturated with 862 g water reveals a small increase in $k_{eff} + 2\sigma$ from 0.824 to 0.838 due to flooding of the CV. Comparison of results for low density UO_2 oxide saturated with 5,712 g water reveals an insignificant increase in $k_{eff} + 2\sigma$ due to flooding of the CV, [Cases **cvcrpdoxt11_1_5_14_15** and **cvcrpdoxt11_1_5_14_1** (Table 6.9.6-12 and Fig. 6.9.1-6)].

Cases **cvcrpdoxt11_1_11_14_15** through **cvcrpdoxt11_1_1_14_15** demonstrate that the $k_{eff} + 2\sigma$ values decrease for decreased mass loadings of HEU oxide at constant bulk density.

For the flooded CV under full water reflection containment, the $k_{eff} + 2\sigma$ value is 0.914, Case **cvcrpdoxt11_1_3_24_15** [10 CFR 71.55(b)]. The $k_{eff} + 2\sigma$ value is 0.817 for water-reflected package, Case **ncsrpdoxt11_1_3_24** [10 CFR 71.55(d)]. Case **hcsrpdoxt12_1_3_24** (Table 6.9.6-13a) represents the HAC model of the damaged ES-3100 package, where the outer dimensions of the package are reduced accordingly and the entire package is flooded except the neutron poison of the body weldment liner inner cavity. This single-unit case pertains specifically to the flooded drum under conditions specified in 10 CFR 71.55(e). The $k_{eff} + 2\sigma$ value is 0.819 for this HAC condition. The changes in both the outer dimensions of the package and the compositions of the Kaolite and 277-4 due to HAC result in an ~0.002 change in the neutron multiplication factor.

Calculations were performed for bulk densities from 1.75 g/cm^3 to 0.5 g/cm^3. In this analysis, the CV is examined as dry (MOCFR of 1.0E-20) and fully flooded (MOCFR of 1.0). For the reflected CV cases, calculations are performed to exam uranium oxide at bulk densities of 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The results of these calculations can be found in Tables 6.9.6-12a and 6.9.6-13c. At a density of 1.75 g/cm^3 the highest uranium oxide mass that was evaluated is 16 kg (maximum uranium oxide allowed is 15.13 kg due to structural limitations). For densities of 1.5 g/cm^3 and less, uranium oxide masses above a certain point were not evaluated, since larger amounts would exceed the CV internal volume.

In these calculations, the CV is modeled as dry and fully flooded. The bulk densities were evaluated from 1.75 g/cm^3 down to 0.5 g/cm^3, and the maximum amount of oxide evaluated was limited to either the maximum allowed or the maximum volume of oxide that would fill the CV. These calculations were evaluated in increments of 1 kg except for the 0.5 g/cm^3 cases, where the oxide was evaluated in increments of 500 g. The results for the highest oxide mass are found in Tables 6.14 and 6.15, and the results of all of these calculations are found in Table 6.9.6-12a.

Table 6.14. Reflected CV model, oxide mixed with 500 g polyethylene, MOCFR of 1.0E-20, (USL=0.935)

Case	Density (g/cm^3)	UO_2 mass (kg)	k_{eff}	σ	$k_{eff} + 2\sigma$

cvcrldoxt11_6_8_15	0.50	4.5	0.8915	0.0014	0.8943

In the single package calculations, the CV is modeled as fully flooded, and the NCT and HAC package is fully reflected on all sides at the same densities as the CV cases. As the CV cases, the maximum amount of oxide evaluated was limited to either the maximum allowed or the maximum volume of oxide that would fill the CV. These calculations were evaluated in increments of 1 kg except for the 0.5 g/cm^3 cases, where the oxide was evaluated in increments of 500 g. The results for the highest oxide mass are found in Tables 6.16 and 6.17, and the results of all of these calculations are found in Table 6.9.6-13c.

Table 6.16. Reflected NCT single package model, oxide mixed with 500 g polyethylene, MOCFR of 1.0, (USL=0.935)

Case	Density (g/cm^3)	UO_2 mass (kg)	k_{eff}	σ	$k_{eff} + 2\sigma$
ncsrldoxt11_1_20	1.75	16.0	0.8095	0.0014	0.8123

From the results in the Tables 6.14–6.17, all cases are well below the USL. The comparison of the single package case results with corresponding case results for the reflected CV reveals that 30.48-cm water surrounding the CV is a better reflector than the flooded ES-3100 packaging. Additional calculations were performed for uranium oxide mixed with thorium oxide and uranium oxide mixed with thorium metal at the same densities as uranium oxide. Thorium is not fissile and would not increase the reactivity of this system; however, the saturated water that is in the thorium oxide and thorium metal model may provide a more optimum moderation configuration, especially at lower bulk densities. Parametric studies were performed for various uranium oxide loadings varying the amount of thorium oxide and thorium metal.

In the CV cases, the CV loaded with UO_2 mixed with either ThO_2 or thorium metal is modeled fully flooded and reflected. For the reflected CV cases, calculations are performed to exam UO_2 mixed with ThO_2 or thorium metal at bulk densities of 2.0, 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The amount of ThO_2 or thorium metal that is added is dependent upon the amount of available space within the CV and the total amount of oxide allowed (13.15 kg). At lower densities, the amount of ThO_2 or thorium metal that can be added to the CV decreases with decreasing density. As shown in Tables 6.9.6-12b and 6.9.6-12d for all bulk oxide densities, reactivity decreases as ThO_2 or thorium metal is added.

In the single package calculations, the CV is modeled as fully flooded and the NCT and HAC package is fully reflected on all sides at the same densities as the CV cases. As in the CV cases, calculations are performed to exam UO_2 mixed with ThO_2 or thorium metal at bulk densities of 2.0, 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The amount of ThO_2 or thorium metal that is added is dependent upon the amount of available space within the CV. At lower densities, the amount of ThO_2 and thorium metal that can be added to the CV decreases with decreasing density. As shown in Table 6.9.6-13e and 6.9.6-13g, for all bulk oxide densities, as ThO_2 or thorium metal is added, reactivity decreases.

Calculations were also performed for zirconium oxide mixed with uranium oxide at the same densities as uranium oxide. The saturated water that is in the zirconium oxide model may provide a more optimum moderation configuration, especially at lower bulk densities. Parametric studies were performed for various uranium oxide loadings varying the amount of oxide.

In the CV cases, the CV loaded with UO_2 and $ZrO_2$is modeled fully flooded and reflected. For the reflected CV cases, calculations are performed to exam UO_2 mixed with ZrO_2 at bulk densities of 2.0, 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The amount of ZrO_2 that is added is dependent upon the amount of available space within the CV and the total

amount of oxide allowed (13.15 kg). At lower densities, as for the ThO_2, the amount of ZrO_2 that can be added to the CV decreases with decreasing density. As shown in Table 6.9.6-12c for all bulk oxide densities, reactivity decreases as ZrO_2 is added.

In the single package calculations, the CV is modeled as fully flooded, and the NCT and HAC package is fully reflected on all sides at the same densities as the CV cases. As in the CV cases, calculations are performed to exam UO_2 mixed with ZrO_2 at bulk densities of 2.0, 1.75, 1.5, 1.25, 1.0, 0.75, and 0.5 g/cm^3 at 100% enrichment mixed with 500 g of polyethylene. The amount of ZrO_2 that is added is dependent upon the amount of available space within the CV. At lower densities, the amount of ZrO_2 that can be added to the CV decreases with decreasing density. As shown in Table 6.9.6-13f for all bulk oxide densities, reactivity decreases as ZrO_2 is added.

Cases **cvcrsk3cc_1_15_17** through **cvcrsk3cc_10_15_17** (Appendix 6.9.6, Table 6.9.6-17) evaluate the 10 skull oxide compositions identified Table 6.9.3.1-3b, where the CV is loaded with 3 convenience cans. The fissile enrichment is ~70 wt % ^{235}U for contents "**sk3cc_1**" through "**sk3cc_5**" and ~38 wt % ^{235}U for contents "**sk3cc_6**" through "**sk3cc_8**." The observed maximums of 7.1 kg skull oxide and ~93.2 wt % ^{235}U enrichment present in 292 convenience cans are the basis for the hypothetical contents "**sk3cc_9**" and "**sk3cc_10**," where unidentified material is treated as ^{235}U and the carbon content is either maximized or minimized. Content "**sk3cc_10**" differs from "**sk3cc_9**" in that 921 g of graphite in the skull oxide is replaced with 921-g ^{235}U in the form of U_3O_8. Content "**sk3cc_10**" is more representative of high enrichment skull oxides where < 85 g of graphite is present. For each of the 10 content models, 513 g of the skull oxide content is modeled as polyethylene, representing the potential use of hydrogenous packing material. The U_3O_8 content ranges from 8 to 21 kg, while the ^{235}U content ranges from 3.7 to 16.4 kg. The graphite content ranges from 0 to 921-g C, and the C/^{235}U ratio ranges from 0 to 223,432 µg C/g ^{235}U. For Cases **cvcrsk3cc_1_15_17** through **cvcrsk3cc_10_15_17** at both saturation moisture and full graphite content, the $k_{eff} + 2\sigma$ values range from 0.759 to 0.855 in the flooded, water-reflected CV. Cases **cvcrsk3cc_9_15_17** and **cvcrsk3cc_10_15_17** reveal that $k_{eff} + 2\sigma$ increases slightly when the 921 g of carbon in the skull oxide is replaced with 726-g ^{235}U in the form of U_3O_8.

Cases **cvcrsk3cc_4_1_1** through **cvcrsk3cc_4_*m*_*g*** evaluate the effects of moisture and skull oxide graphite content on reactivity. The case designator "***m***" ranges from 1 to 15, signifying the variation in moisture; "***g***" ranges from 1 to 17, signifying the variation in graphite. Examination of results indicates that moisture content has a predominate effect on the neutron multiplication factor, while variation in graphite content has a minor effect. The peak $k_{eff} + 2\sigma$ value occurs at saturated moisture and full graphite content.

Mixtures of UO_2 and ThO_2 are also examined. Thorium is not fissile and as such would not increase reactivity; however, since the CV is modeled fully flooded, the additional water that would be provided by the ThO_2 may increase reactivity, especially at densities lower than 2.0 g/cm^3. Parametric studies are performed to exam the mixing of UO_2 with varying amounts of ThO_2.

Cases **ncsrsk_1_15** through **ncsrsk_10_15** (Appendix 6.9.6, Table 6.9.6-18a) model the 10 skull oxide compositions in a flooded CV in a water reflected package. The $k_{eff} + 2\sigma$ values range from 0.641 to 0.745. Likewise, Cases **hcsrsk_1_15** through **hcsrsk_10_15** (Appendix 6.9.6, Table 6.9.6-18b) evaluate infinite arrays damage packages. The $k_{eff} + 2\sigma$ values ranging from 0.658 to 0.767 are not statistically significantly different from the NCT case results.

Cases **ncsrsk_9_1** through **ncsrsk_9_15** evaluate the bounding skull oxide content containing ~19.9 kg U_3O_8 and 921 g graphite, where the saturation moisture is varied from 0 to 3801 g water. Likewise, Cases **ncsrsk_10_1** through **ncsrsk_10_15** evaluate the skull oxide content containing ~20.8 kg U_3O_8 where the 921 g of graphite in the skull oxide is replaced with 726-g ^{235}U in the form of U_3O_8. The $k_{eff} + 2\sigma$ values range from 0.403 to 0.741 in the former set of cases and range from

0.404 to 0.746 in the latter set of cases. The $k_{eff} + 2\sigma$ values are well below the USL value of 0.925, indicating that canned spacers are not required for criticality control. Moreover, these results indicate that moisture content has a predominate effect on the neutron multiplication factor, while the graphite content has an insignificant effect.

6.4.4 UNH Crystals

UNH crystal content is to be packed in Teflon bottles, which may be placed in polyethylene bags. The Teflon bottles are not credited for containing the UNH crystal content. The 277-4 canned spacers are not used in this packing configuration. Teflon is polytetrafluoroethylene (or polyethylene tetrafluoride) having a monomer formula of C_2F_4 with a melting point of ~280°C (536°F). Teflon will not melt at the much lower CV inner wall temperatures associated with NCT and HAC. The use of Teflon and polyethylene packing material is conservatively represented by 500 g of polyethylene in the calculation model. UNH crystal content is not considered a "rigid" content like solid or broken HEU metal. Like HEU oxide content, the UNH crystal content is homogenized with the polyethylene.

Unlike the other HEU contents, UNH crystals are soluble in water. The most reactive content condition occurs at an optimum solution concentration derived from the UNH crystal loading and the volume of water flooding the CV. Both flooding of the CV and a reduced loading of UNH crystals going into solution is required to achieve the most reactive configuration.

Consider a flooded CV with the UNH crystals in solution and no polyethylene. For Cases **cvcrunhct11_24_1** through **cvcrunhct11_1_1** (Table 6.9.6-14), the $k_{eff} + 2\sigma$ values range from 0.823 to 0.609 and optimum concentration occurs at ~9,000-g UNH (Case **cvcrunhct11_9_1**, $k_{eff} + 2\sigma = 0.857$). Consider a flooded CV with a solution of UNH crystals homogenized with 500 g polyethylene. For Cases **cvcrpunhct11_24_15** through **cvcrpunhct11_1_15** (Table 6.9.6-14), the $k_{eff} + 2\sigma$ values range from 0.827 to 0.613 and optimum concentration occurs at ~10,000-g UNH (Case **cvcrpunhct11_10_15**, $k_{eff} + 2\sigma = 0.863$). The replacement of water with 500 g of polyethylene in the latter set of cases results in changes to the neutron multiplication factor on the order of ~0.004 to 0.006. The concentration for a 24,000 g loading in both set of cases is 1,106-g ^{235}U per liter of flooded CV. In the calculation of the uranium concentration, the solution volume is not reduced by the volume of polyethylene because polyethylene is homogenized with UNH in the solution.

For Cases **cvcrpunhct11_24_1** through **cvcrpunhct11_1_1** (Table 6.9.6-14), the homogenized UNH crystals and polyethylene are dispersed over a dry CV. The $k_{eff} + 2\sigma$ values range from 0.769 to 0.251 as the mass loading decreases. Comparison with results for corresponding Cases **cvcrpunhct11_24_15** through **cvcrpunhct11_1_15** for a flooded CV reveals that the most reactive content condition occurs for UNH in the solution state.

For Cases **cvcrbpunhct11_24_15** through **cvcrbpunhct11_1_15** (Table 6.9.6-14), homogenized UNH crystals and polyethylene are settled on the bottom of the CV and the residual volume above it is flooded. The $k_{eff} + 2\sigma$ values range from 0.817 to 0.553 as the mass loading decreases. For Cases **cvcrbpunhct11_24_1** through **cvcrbpunhct11_1_1**, the residual volume above the content is dry. Likewise, the $k_{eff} + 2\sigma$ values range from 0.815 to 0.478 as the mass loading decreases.

Comparison of results for corresponding Cases **cvdrpunhct11_*n*_1** and **cvcrbpunhct11_*n*_15** reveal greater changes in the k_{eff} values occurring at the lower mass loadings when dispersed content is settled to the bottom of the CV. Nevertheless, interspersed moderation has a dominant effect on k_{eff} occurring when settled content goes into solution (Case **cvcrbpunhct11_10_15** vs Case **cvcrpunhct11_10_15**).

Similar to packages loaded with HEU metal, broken metal, or oxide, the neutron multiplication factor for a reflected single package with UNH crystals increases as a function of MOIFR. Consider the ES-3100 package loaded with bottles for a total of 24,000-g UNH crystals (11,303-g ^{235}U). For Cases **ncsrunhct11_24_1_1** through **ncsrunhct11_24_1_15** (Table 6.9.6-15), the $k_{eff} + 2\sigma$ values range from 0.605 to 0.702 with increasing MOIFR in the water-reflected package. For Cases **ncsrpunhct11_24_1** and **ncsrpunhct11_24_15** (Table 6.9.6-15), the $k_{eff} + 2\sigma$ values range from 0.609 to 0.708 with increasing MOIFR in the water-reflected package. These cases confirm that the replacement of water with 500 g of polyethylene results in changes to the neutron multiplication factor on the order of ~0.004 to 0.006.

For a flooded CV with UNH crystals in solution, the $k_{eff} + 2\sigma$ values range from 0.702 to 0.646 [Cases **ncsrunhct11_24_1_15** through **ncsrunhct11_2_1_15** (Table 6.9.6-15)]. Similarly, for a flooded CV with a solution of UNH crystals homogenized with 500 g of polyethylene, the $k_{eff} + 2\sigma$ values range from 0.708 to 0.545 [Cases **ncsrpunhct11_24_15** through **ncsrpunhct11_1_15** (Table 6.9.6-15)]. At optimal concentration (~8,000-g UNH), the calculated $k_{eff} + 2\sigma$ value is 0.863 for Case **cvcrpunhct11_10_15** and $k_{eff} + 2\sigma = 0.753$ for Case **ncsrpunhct11_8_15**. The water-reflected CV is more reactive than the water-reflected package; therefore, the result for Case **cvcrpunhct11_10_15** is reported [10 CFR 71.55(b)]. The result for Case **ncsrpunhct11_8_15** having the maximum $k_{eff} + 2\sigma$ value is reported for the NCT water-reflected package [10 CFR 71.55(d)].

Unlike solid HEU metal and oxide content, which are confined to the CV and only water leakage into the CV need be considered, the evaluation of UNH crystal content for compliance with 10 CFR 71.55(b) also requires that the leakage of liquid HEU contents out of the containment be addressed. This is because UNH crystals are soluble in water and would dissolve in the water flooding the CV and the CV well. For a content loading of 24,000-g UNH, the uranium concentration inside the CV drops from 1,106-g ^{235}U/L to 710-g ^{235}U/L. Optimum solution concentrations occurs for fissile mass loadings of ~15,000-g UNH. In the calculation of the uranium concentration, the solution volume is not reduced by the volume of polyethylene because polyethylene is homogenized with UNH in the solution.

Cases **hcsrpunhct12_8_15** (Table 6.9.6-15) and **icsrpunhct12_15_15** (Table 6.9.6-16) represent the HAC model of the damaged ES-3100 package where the outer dimensions of the package are reduced accordingly. For Case **hcsrpunhct12_8_15**, the dilution of the UNH crystals is confined to the CV, and maximum reactivity occurs at ~8000-g UNH homogenized with 500 g polyethylene. For Case **icsrpunhct12_15_15**, UNH crystals are dissolved in the water flooding the CV and the CV well. The fissile material is uniformly distributed over the volume of the CV and the well, but the polyethylene is confined to the CV. Maximum reactivity occurs at ~15,000-g UNH. These single-unit cases with a MOIFR = 1.0 pertain specifically to the flooded drum under conditions specified in 10 CFR 71.55(e), where the $k_{eff} + 2\sigma$ values are 0.752 and 0.814 for this HAC condition. The result for Case **icsrpunhct12_15_15** having the maximum $k_{eff} + 2\sigma$ value is reported for the HAC water-reflected package [10 CFR 71.55(e)].

6.5 EVALUATION OF PACKAGE ARRAYS UNDER NORMAL CONDITIONS OF TRANSPORT

For the NCT array evaluation of ES-3100 packages, the package content is confined within the CV, consistent with the result of the tests specified in §71.71 (Normal Conditions of Transport). The array sizes examined in this evaluation are infinite, 13×13×6, 9×9×4, 7×7×3, 5×5×2, ETP 27×3, and the degenerate single unit. The "N" and corresponding CSI values for arrays determined to be adequately subcritical are as follows: N = ∞, CSI = 0; N = 202, CSI = 0.3; N = 64, CSI = 0.8; N = 29, CSI = 1.7; and N = 16, CSI = 3.2. All arrays, except the infinite array, are reflected with 30 cm (1 ft) of water. These arrays are nearly cubic in shape for optimum array reactivity, thus eliminating the need for placing criticality controls on package arrangements in terms of stack height, width, and depth of an array. The array configurations and the range of water contents (Table 6.4) evaluated bound all possible packaging arrangements and moderation conditions for NCT.

6.5.1 Solid HEU Metal of Specified Geometric Shapes

For infinite and finite arrays of packages with HEU metal, the neutron multiplication factor increases as a function of the ^{235}U mass and decreases as a function of MOIFR. For example, consider the ES-3100 package loaded with three convenience cans for a total of 36,000-g ^{235}U where each can contains a 3.24-in.-diam cylinder. For package content without 277-4 canned spacers, the $k_{eff} + 2\sigma$ values range from 1.027 to 0.963 with increasing MOIFR in the package [Cases **nciacyt11_36_1_1** through **nciacyt11_36_1_15** (Appendix 6.9.6, Table 6.9.6-3)]. For package content with 277-4 canned spacers, the $k_{eff} + 2\sigma$ values range from 0.957 to 0.880 with increasing MOIFR in the package [Cases **nciacyt11_36_2_1** through **nciacyt11_36_2_15** (Appendix 6.9.6, Table 6.9.6-3)].

The effect of increasing the water content of the array is straightforward. As interspersed water is added to the packages of an array, two reactivity effects occur in series. The first effect is the tendency for reactivity to remain constant due to controlled neutron interaction between the packages of the array. For an infinite array where neutrons cannot escape from the system, neutrons are scattered about the array. In the MOIFR range of 1E-20 to 1E-02, both the interspersed moderator inside the packages of the dry array and the interstitial moderator between the package drums of the array are not sufficient for neutron thermalization and absorption to occur in the adjacent packaging materials. However, hydrogen in the 277-4 provides moderation, and neutrons are absorbed in the interspersed boron of this neutron poison. This results in a subcritical system with near constant neutron multiplication factors over the range of MOIFR. The second effect is the tendency for reactivity to decrease due to internal moderation in packages of the array. The introduction of water above ~0.01 MOIFR shows the effect of isolating the individual array units from each other. The neutron multiplication factor approaches k_{eff} for the single, water-reflected unit at a full-content water fraction (MOIFR = 1.0).

The array case with a water fraction of MOIFR = 1E-04 pertains specifically to packages under NCT where the Kaolite and recesses of the package external to the CV do not contain any residual moisture. This NCT case is more reactive than all other NCT cases where more moisture is present in the Kaolite and recesses of the package. Interspersed water between the CVs in the array will reduce neutronic interaction between the flooded contents because neutrons are absorbed in the hydrogen of the water. As more water is added, the packages of the array become isolated, and array reactivity ($k_{eff} + 2\sigma$ = 0.880, Case **nciacyt11_36_2_1**5) approaches the reactivity of the single unit ($k_{eff} + 2\sigma$ = 0.873, Case **ncsrcyt11_36_2_1**5).

Repeated for 4.25-in.-diam cylinders (Appendix 6.9.6, Table 6.9.6-7); 2.29-in. -square bars (Table 6.9.6-5); and 1.5-in.-diam × 2-in.-tall slugs (Table 6.9.6-9), this type of analysis for the 3.24-in.-diam cylinders demonstrates that arrays of packages with restricted fissile material (^{235}U) loading remain subcritical over the entire range of water content or MOIFR. HEU metal or alloy content not covered by the specified geometric shapes (cylinder, square bar, or slug contents) will be in the HEU broken metal category, and so limited.

Additional cases were performed to exam the effect that 500 g of polyethylene will have on HEU metal cylinders and bars in arrays of packages for both NCT and HAC. The original cases previously found in Table 6.1a were rerun using SCALE 6.1.3 with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Tables 6.18 and 6.19.

Table 6.18. NCT infinite array model, HEU metal cylinders and bars, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$

From the result of the infinite array package cases for HEU metal cylinders and bars, modeling 500 g of polyethylene surrounding the HEU metal is as reactive or slightly less reactive than no polyethylene. For the two types of annular cylinders the NCT cases for an infinite array of packages (Appendix 6.9.6, Table 6.9.6-3d), the CV is modeled fully flooded and the interstitial water moderation is modeled at MOIFR = 1E-04. Each cylinder is modeled at the bottom of the CV. Case **nciacylc11** for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.83219 (k_{eff} = 0.83107, σ = 0.00056), while Case **nciacyld11** for Cylinder D has a calculated $k_{eff} \pm 2\sigma$ value of 0.85387 (k_{eff} = 0.85241, σ = 0.00073). Additional cases were run with the cylinder modeled vertically centered in the CV. Case **nciacylcc11** for Cylinder C has a calculated $k_{eff} \pm 2\sigma$ value of 0.80889 (k_{eff} = 0.80727, σ = 0.00081), while Case **nciacyldc11** for Cylinder D has a calculated $k_{eff} \pm 2\sigma$ value is 0.82521 (k_{eff} = 0.82393, σ = 0.00064).

Calculations were also performed to exam the effect of aluminum shielding to Cylinder D (Appendix 6.9.6, Table 6.9.6-3d). As the amount of aluminum shielding is added, reactivity decreases. This is due to the fact that the CV is flooded, and in order to add aluminum cladding, water must be removed to conserve volume. Thus, aluminum cladding is not controlled for Cylinder D.

All Cylinder C and D infinite array cases were shown to be below the USL of 0.9352, and the models with the cylinders located at the bottom of the CV were the most reactive.

Cases **nciatriga_1_1_3** through **nciatriga_1_15_3** (Appendix 6.9.6, Table 6.9.6-20a) represent infinite arrays of packages containing the bounding TRIGA fuel content (20 % enrichment with 45 wt % U containing 307-g ^{235}U), without 277-4 canned spacers. The MOIFR is set at 1.0E-04 such that neutronic interaction between packages is maximized. For these cases, the $k_{eff} + 2\sigma$ values increase from 0.218 to 0.525 as MOIFR increases. The $k_{eff} + 2\sigma = 0.525$ for Case **nciatriga_1_15_3** is substantially below the USL value of 0.925, indicating that canned spacers are not required for criticality control.

As stated in Sect. 6.4.1, 10 CFR 71.55(d)(2) requires the geometric form of a package's content not be substantially altered under the NCT. Similarly, 10 CFR 71.55(e)(1) requires that the package be adequately subcritical under HAC with the package contents in the most reactive credible configuration. Even though visible signs of damage to the metal convenience can have not been observed resulting from the regulatory tests, conclusions about damage to the TRIGA fuel content are not extrapolated from test data. The regulatory requirements are addressed by modeling the TRIGA fuel content in an extremely damaged condition. A series of criticality calculations is performed for making a determination of subcriticality. Cases **nciat55d2_1_1_3** through **ncia55d2_1_15_3** (Appendix 6.9.6, Table 6.9.6-20d) represent TRIGA fuel content homogenized with variable density water over the free volume of the CV. The packaging is flooded in each ES-3100 package of the infinite array. The variable density water ranges from the dry containment condition to the fully flooded condition. Credit for physical integrity of the content is not taken in this set of cases which model the substantially altered content. The calculation results in Table 6.9.6-20d indicate extremely damaged content (Case **nciat55d2_1_15_3** with $k_{eff} + 2\sigma = 0.716$) is more reactive than the unaltered configuration (Case **nciatriga_1_15_3** with $k_{eff} + 2\sigma = 0.442$). Nevertheless, both cases are adequately below the USL of 0.925 and the requirement of 10 CFR 71.55(d)(2) is satisfied. Given that changes external to the CV due to the HAC do not result in an appreciable change in neutron multiplication for an array of packages, similar results are expected for the cases demonstrating compliance with 10 CFR 71.55(e)(1).

For TRIGA fuel content as clad fuel rods, the amount of cladding added (stainless steel as a neutron absorber or aluminum as a neutron scatter) and corresponding amount of water moderator displaced by the cladding is not expected to have a statistically significant affect on the calculated k_{eff}. Thus, the NCT shipping configuration model for disassembled TRIGA fuel (bare fuel meats) bounds shipping configuration model for TRIGA fuel configured as clad fuel rods (Appendix 6.9.3.1).

Additional cases were performed to exam the effect that 500 g of polyethylene will have on TRIGA fuel for arrays. The original cases previously found in Table 6.1f were rerun using SCALE 6.1.3, with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Tables 6.20 and 6.21.

Table 6.20 NCT array model, TRIGA fuel, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
nciatriga_1_15_3	Three 5 in.-tall TRIGA fuel elements per can, no spacers or polyethylene	0.54514	0.00064	0.54642
nciatrigap_1_15_3	Three 5 in.-tall TRIGA fuel elements per can, no spacers, 500 g polyethylene	0.53671	0.00059	0.53789
nciatriga_2_15_3	Three 5 in.-tall TRIGA fuel elements per can, with spacers or polyethylene	0.44062	0.00056	0.44174
nciatrigap_2_15_3	Three 5 in-all TRIGA fuel elements per can, with spacers, 500 g polyethylene	0.45166	0.00057	0.45280
nciatriga_70_1_15_3	Three 5 in.-tall TRIGA fuel elements per can, no spacers or polyethylene, 70% enriched	0.48635	0.00061	0.48757
nciatrigap_70_1_15_3	Three 5 in.-tall TRIGA fuel elements per can, no spacers, 500 g polyethylene, 70% enriched	0.49667	0.00062	0.49791

Table 6.21. Reflected HAC array model, TRIGA fuel, with and without 500 g polyethylene, (USL=0.9352)

Case	Description	k_{eff}	σ	$k_{eff} + 2\sigma$
hciatriga_1_15_3	Three 5 in.-tall TRIGA fuel element per can, no spacers or polyethylene	0.52553	0.00061	0.52675
hciatrigap_1_15_3	Three 5 in.-tall TRIGA fuel element per can, no spacers, 500 g polyethylene	0.53602	0.00069	0.53740
hciatriga_2_15_3	Three 5 in.-tall TRIGA fuel element per can, with spacers or polyethylene	0.44070	0.00067	0.44204
hciatrigap_2_15_3	Three 5 in.-tall TRIGA fuel element per can, with spacers, 500 g polyethylene	0.45229	0.00054	0.45337
hciatriga_70_1_15_3	Three 5 in.-tall TRIGA fuel element per can, no spacers or polyethylene, 70% enriched	0.48713	0.00058	0.48829
hciatrigap_70_1_15_3	Three 5 in.-tall TRIGA fuel element per can, no spacers, 500 g polyethylene, 70% enriched	0.49812	0.00070	0.49952

From the results of the CV cases for TRIGA fuel, modeling 500 g of polyethylene surrounding the HEU metal is more reactive than no polyethylene.

The array results for three slug configurations presented in Table 6.9.6-9 (Appendix 6.9.6) are for five or ten slugs touching or spaced apart in a pentagonal ring (Cases **ncia5st11** and **ncia5est11**) and for seven slugs formed by a hexagonal ring of slugs with one slug in the center of the ring **(ncia70st11**). These cases are used to establish the mass loading limitations, which in turn limit the number of slugs in the package to less than the number required to assemble a critical configuration.

Cases **ncia5est11_1_1_8_3** through **ncia5est11_1_1_1_3** (Appendix 6.9.6, Table 6.9.6-9) represent infinite arrays of packages containing 18,277-g U without 277-4 canned spacers. For these cases, the $k_{eff} + 2\sigma$ values increase from 0.550 to 0.924 as the enrichment is increased from 19.0 wt % to 100.0 wt % ^{235}U. The $k_{eff} + 2\sigma$ value is 0.924 for Case **ncia5est11_1_1_8_3**, which is below the USL of 0.925. Likewise, the $k_{eff} + 2\sigma$ values for Cases **ncia5st11_1_1_8_3** through **ncia5st11_1_1_1_3** increase from 0.521 to 0.929 as the enrichment is increased. However, the $k_{eff} + 2\sigma$ value is 0.929 for Case **ncia5st11_1_1_8_3**, which is slightly above the USL of 0.925. For simplification of the criticality evaluation, the maximum enrichment is limited to 95% and the corresponding fissile mass limit is 17,374-g ^{235}U. For Cases **ncia5st11_1_1_7_3** and **ncia5est11_1_1_7_3**, the $k_{eff} + 2\sigma$ values are below the USL. Moreover, the values are not statistically different.

Cases **ncia70st11_2_8_3** through **ncia70st11_2_1_3** (Appendix 6.9.6, Table 6.9.6-9) represent infinite arrays of packages containing 25,588-g U with 277-4 canned spacers. For these cases, the $k_{eff} + 2\sigma$ values increase from 0.473 to 0.915 as the enrichment is increased from 19.0 wt % to 100.0 wt % ^{235}U. The $k_{eff} + 2\sigma$ value of 0.894 for Case **ncia70st11_2_7_3** at the 95% enrichment limit is adequately below the USL of 0.925.

Cases **ncia5est11_2_2_8_3** through **ncia5est11_2_2_1_3** (Appendix 6.9.6, Table 6.9.6-9) represent infinite arrays of packages containing 36,555-g ^{235}U with 277-4 canned spacers. For these cases, the $k_{eff} + 2\sigma$ values increase from 0.583 to 0.983 as the enrichment is increased from 19.0 wt % to 100.0 wt % ^{235}U. At 80 wt % ^{235}U, the $k_{eff} + 2\sigma$ value (0.908) for Case **ncia5est11_2_2_5_3** with spaced-apart slugs is just below the USL. Similarly, Case **ncia5st11_2_2_5_3** with touching slugs has a calculated $k_{eff} + 2\sigma$ value of 0.902. Therefore, a restriction on mass and enrichment for slug content is that for ≤ 80 wt % ^{235}U, the mass of ^{235}U in the package must not exceed 29,318 g as a prerequisite for the shipment of the package slug content and with 277-4 canned spacers under a CSI = 0.0.

Cases **ncf15est11_2_2_8_3** through **ncf15est11_2_2_1_3** (Appendix 6.9.6, Table 6.9.6-9) represent a 13 × 13 × 6 array of packages containing 36,555-g ^{235}U with 277-4 canned spacers for which the corresponding rounded CSI = 0.4. For these cases, the $k_{eff} + 2\sigma$ values increase from 0.550 to 0.942 as the enrichment is increased from 19.0 wt % to 100.0 wt % ^{235}U. Case **ncf15est11_2_2_7_3** at 95 wt % ^{235}U with $k_{eff} + 2\sigma = 0.922$ is below the USL of 0.93520 to permit increasing the limit on enrichment for mass loadings of ≤ 34.7 kg uranium metal.

Additional calculations were also performed to exam the effect that 500 g of polyethylene will have on HEU metal slugs in arrays of packages for both NCT and HAC. The original cases previously found in Table 6.1b were rerun using SCALE 6.1.3 with updated cross-sections and more particles. These cases were also modified by adding 500 g of polyethylene. The results of these cases are found in Tables 6.22 and 6.23.

From the results of the array package cases for HEU metal slugs, modeling 500 g of polyethylene surrounding the HEU metal is as or slightly less reactive than no polyethylene.

The CSI determinations provided in this section are contingent upon satisfactory results under the HAC evaluation (Sect. 6.6.1).

6.5.2 HEU Broken Metal; Solid HEU Metal of Unspecified Geometric Shape and Characterized as Broken Metal; or Turnings, Fines, or Powder

The ^{235}U (or U) evaluation limits listed in the column headings of Tables 6.1c and 6.1d represent the maximum amount of ^{235}U (or U) permissible in a flooded, reflected CV for maintaining an adequate margin of subcriticality. These potential loading limits are taken into consideration for the determination of the fissile mass loading limit specified for a given CSI over a specified enrichment range. Under the subheading "Standards for arrays of fissile material packages (§ 71.59)," the fissile mass loading limits are identified for HEU broken metal in Table 6.1c and for HEU metal turnings, fines, or powder in Table 6.1d.

Consider the enrichment range >95 to 100 wt % ^{235}U. Comparison of results in Table 6.9.6-10 for Case **cvr3lha_26_1_8_15** (broken metal without canned spacers) and for Case **cvr3lha_36_2_8_15** (broken metal with canned spacers) reveals a considerable increase in the fissile mass loading from 25,894-g to 35,142-g ^{235}U is possible when 277-4 canned spacers are used. This result suggests the possibility of canned spacers not being required for certain packaging array configurations with broken metal. However, the comparison of results for Case **cvr3cha_8_1_8_15** without canned spacers and Case **cvr3cha_10_2_8_15** with canned spacers indicates only a minor increase from 7,398-g to 9,248-g ^{235}U in the fissile mass loading of metal turnings, fines, or powder might be possible if 277-4 canned spacers are used. The evaluation of the NCT and HAC array configuration for establishing the CSI = 0 for the ES-3100 package with broken metal (Table 6.9.6-11) reveals that 277-4 canned spacers are required in packages with enrichments >80% (Cases **nciabmt11_4_1_5_3** and **hciabmt12_4_1_5_3**).

Like arrays of packages with solid HEU metal shapes, the neutron multiplication factor for arrays of packages with HEU broken metal, turnings, fines, or powder decreases as a function of MOIFR and increases as a function of the ^{235}U mass. Consider the ES-3100 package loaded with three convenience cans for a total of 35,142-g ^{235}U and no canned spacers between content locations. The $k_{eff} + 2\sigma$ values range from 1.138 to 0.913 with increasing MOIFR [Cases **nciabmt11_36_1_8_1** through **nciabmt11_36_1_8_15** (Appendix 6.9.6, Table 6.9.6-11)]. The introduction of water above MOIFR = 0.01 shows the effect of isolating the individual array units from each other. Array reactivity ($k_{eff} + 2\sigma = 0.913$) approaches the reactivity of the water-saturated, water-reflected single package Case **ncsrbmt11_36_1_15** ($k_{eff} + 2\sigma = 0.891$).

In the series of calculations using the ES-3100 package model with NCT geometry (Cases **nciabmt11_1_*n*_*m*_3** through **nciabmt11_*36*_*n*_*m*_3**), the enrichment of the content is varied from 19 wt % to 100 wt % ^{235}U. These array cases with a water fraction of MOIFR = 1E-04 pertain specifically to NCT packages where both the neutron poison of the body weldment liner inner cavity and the Kaolite are dry (in the as-manufactured condition) and both the recesses of the package external to the CV and the interstitial space between the drums of the array do not contain any residual moisture. As stated before, this NCT case is more reactive than all other NCT cases where more moisture is present in the Kaolite and recesses of the package. Increased interspersed water between the CVs in the array will reduce neutronic interaction between the flooded contents to a point where the packages of the array become isolated.

Evaluation of arrays of packages with HEU broken metal and canned spacers present. For enrichments <95 wt % ^{235}U, the maximum amount of ^{235}U permissible in a flooded ES-3100 package is 25,894-g ^{235}U of the broken metal. With 277-4 canned spacers present in the NCT package, the potential fissile mass loading limit for broken metal with enrichments >95% to 100 wt % ^{235}U and for a CSI = 0 must be limited to 2,774-g ^{235}U (Case **nciabmt11_3_2_8_3**) in order for the $k_{eff} + 2\sigma$ value (= 0.904) to be below the USL of 0.925. Suitability of this 2,774-g ^{235}U fissile mass loading limit for a CSI = 0, which is based

on an infinite array of NCT packages, is contingent upon the infinite array of damaged packages also being adequately subcritical for HAC (Sect. 6.6.2).

For NCT arrays loaded with broken metal content, (excluding turnings, fines, or powder) with 500 g of polyethylene and with canned spacers, calculations were performed for various enrichments with a CSI of 0.0, 0.4, 0.8, 2.0, and 3.2. The original broken metal models were used for these calculations. These models were modified by adding 500 g of polyethylene, modifying the format of the input decks to run on SCALE 6.1.3, and adding more particles. The results for the highest broken metal mass are found in Table 6.24, with all cases shown to be below the USL. The results of all of these calculations are found in Table 6.9.6-11a. Cases **nciambt11_14_2_6_3**, **nciambt11_18_2_5_3**, and **nciambt11_22_2_4_3** were rerun modeling no polyethylene for comparison purposes. The $k_{eff} + 2\sigma$ results of these cases are lower than the cases modeled with polyethylene shown in Table 6.24. The results of the no polyethylene cases, with $k_{eff} + 2\sigma$ of 0.92757, 0.92695, and 0.92708 respectively, are less than the polyethylene cases in Table 6.24.

The loading limits for solid HEU metal of unspecified geometric shape or for HEU broken metal are summarized in Table 6.2a based on array calculations performed using the uniform dispersal approximation "**cha**" model (Fig. 6.9.1-5d). The calculation results on which the determination of the loading limits is based are summarized in Table 6.1c.

As discussed in Appendix 6.9.1, the "**cha**" model is a first-order approximation model. The 500 g polyethylene representing the use of hydrogenous packing material is replaced with water in the flooded CV. Broken metal and water is homogenized as a uranium "solution" and uniformly dispersed over the entire volume of the CV. The vertical location of the 277-4 canned spacers inside the CV is based on a fixed HEU packing fraction of ~0.59. The use of this large packing fraction results in minimum separation between canned spacers, which minimizes the size of the lower and middle content locations and maximizes the size of the upper content location. Reactivity of the CV is driven by the oversized upper content location having a proportionately greater amount of fissile material. Conversely, the use of a small packing fraction (~0.2) in the "**cha**" model would result in greater separation between the canned spacers, which increases the size of the lower and middle content locations, while reducing the size of the upper content location. Reactivity of the CV would decrease as the proportions of fissile material in the content regions equalize. Calculations based on a packing fraction of ~0.59 bound similar cases based on lower packing fractions.

The "**cha**" model is characteristic of the situation where the dimensions of the broken metal pieces are sufficiently small to allow pieces of HEU to pass between the void spaces formed between the inner wall of the CV and the exterior wall of the canned spacers.

As shown in Fig. 6.9.3.1-3, HEU broken metal content typically consists of irregular pieces, sufficiently large (0.5 in. to several inches on a side), that will not pass between the 277-4 canned spacer locations. The packing fraction calculation model "**fl**" and the dispersed content calculation model "**fd**" better represent broken metal content which does not pass between the canned spacer locations. Inside the CV, the content locations between canned spacers are established based on a variable packing fraction for HEU broken metal ranging from 0.2 to 0.6. The 500 g polyethylene is included in the flooded CV. HEU broken metal, polyethylene and water are homogenized as a uranium "solution" residing within the content locations (Figs. 6.9.1-5e and 6.9.1-5f) rather than distributed uniformly over the CV (Fig. 6.9.1-5d). The "**fl**" model defines the upper content location based on packing fraction, while the "**fd**" model defines the upper content location as the entire region above the upper canned spacer.

Table 6.24. Array, NCT package model, broken metal mixed with 500 g polyethylene, with canned spacers
