# Effects of Vacuum Impedance Changes on MITL Flow using 3D Electromagnetic PIC Simulations

## Authors:

Troy Powell, Keith Cartwright, Tim Pointon, Andy Biller, and Chris Grabowski

Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

# Outline

## HERMES-III Background

- HERMES-III
- MITL basics (planar example)
- MITL voltage calculation
- Legacy configuration

## Redesigned Configuration

- Constant impedance design
- Floating cathode
- Simulation results
- Comparison to experiment
- Characterization of current loss along both legacy and redesigned configurations

## MITL Voltage Calculation

- Ottlinger's equations
- Fingerprint plots
- Analysis of simulated MITL sheath flow

## Conclusions and Future Work

# HERMES-III Background

# HERMES-III Background

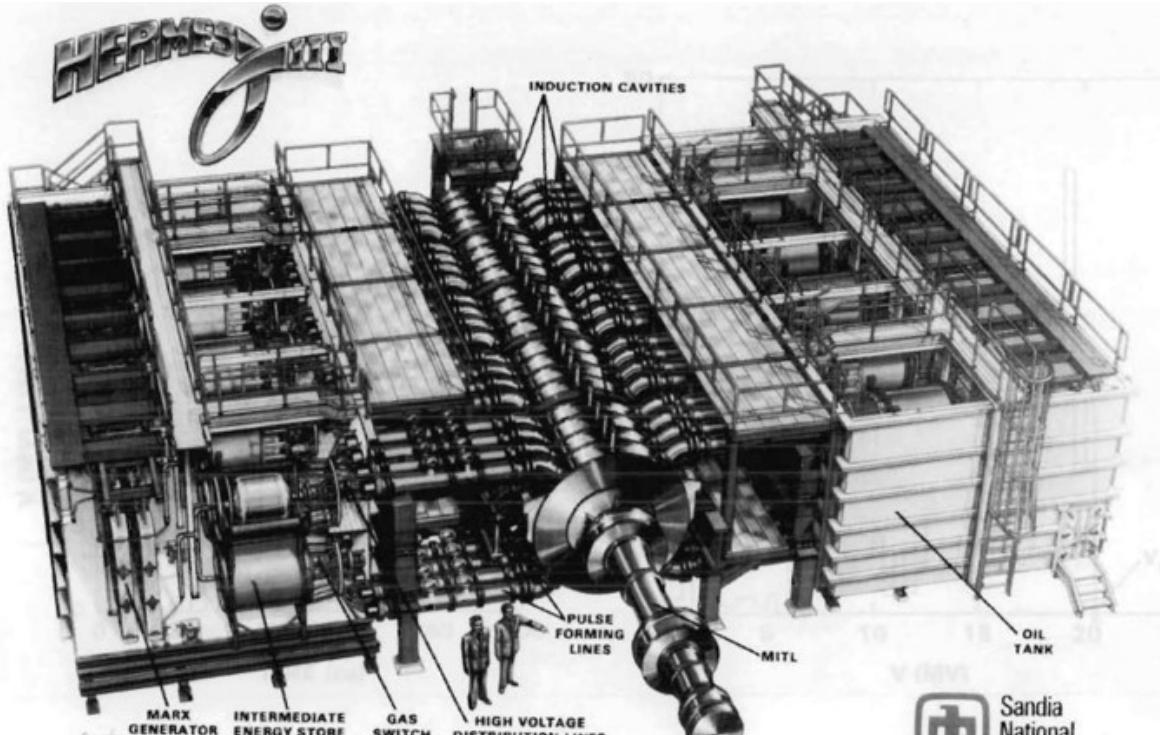

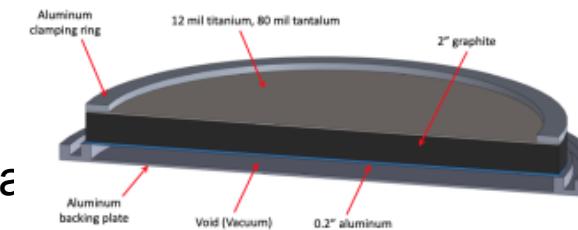

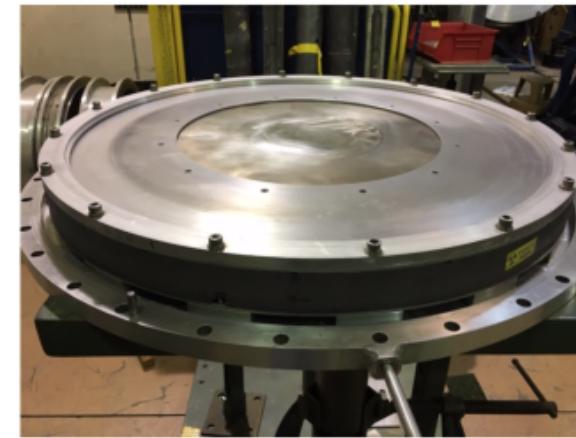

Fig 3 - Hermes III Mechanical Test

Fig 4 - Hermes III Cladding 0200

Nominally an 18MV, 550kA coaxial accelerator  
 Uses Inductive Voltage Adders (IVAs) to combine Marx pulses  
 This requires a floating cathode  
 Can operate in bremsstrahlung mode or an ion-diode mode (reverse pola

## 5 MITL Basics (Planar Example)

SCL emission once breakdown threshold is reached

Electromagnetic pressure balance yields  
approximation of MITL voltage

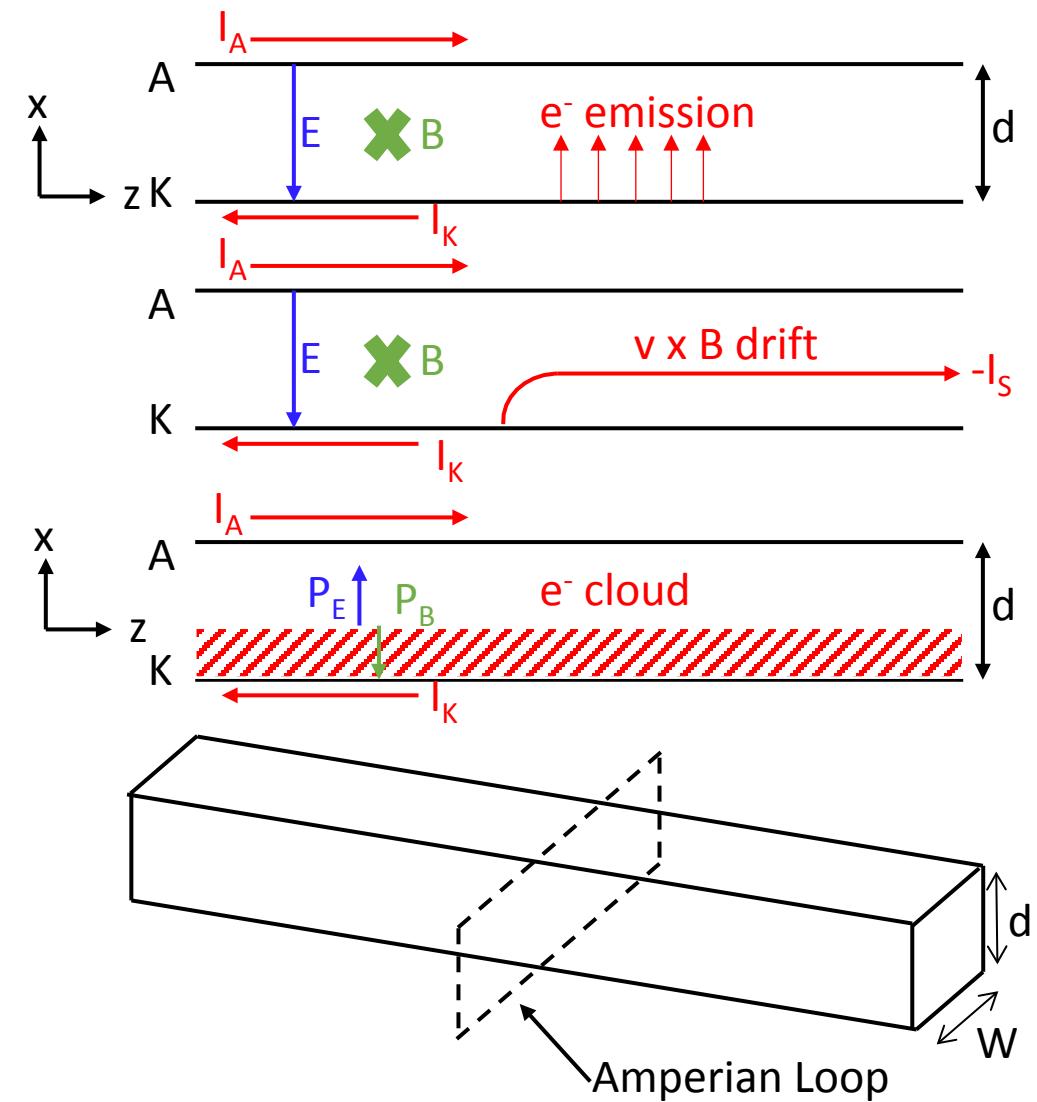

$$P_E = \epsilon_0 E^2 / 2 \quad [\text{ref 1}] \quad P_B = B^2 / 2\mu_0 \quad [\text{ref 2}]$$

$$\frac{B_A^2}{2\mu_0} - \frac{\epsilon_0 E_A^2}{2} = \frac{B_K^2}{2\mu_0} - \frac{\epsilon_0 E_K^2}{2}$$

$$E_A = c\sqrt{B_A^2 - B_K^2} \quad \mu_0 I = BW$$

$$V = E_A \cdot d = c\mu_0 \frac{d}{W} \sqrt{I_A^2 - I_K^2} \quad c\mu_0 \frac{d}{W} = Z_0 \quad [\text{ref 3}]$$

$$V = Z_0 \sqrt{I_A^2 - I_K^2}$$

## 6 MITL Voltage Calculation

Without space charge correction:  $V = Z_0 \sqrt{I_A^2 - I_K^2}$

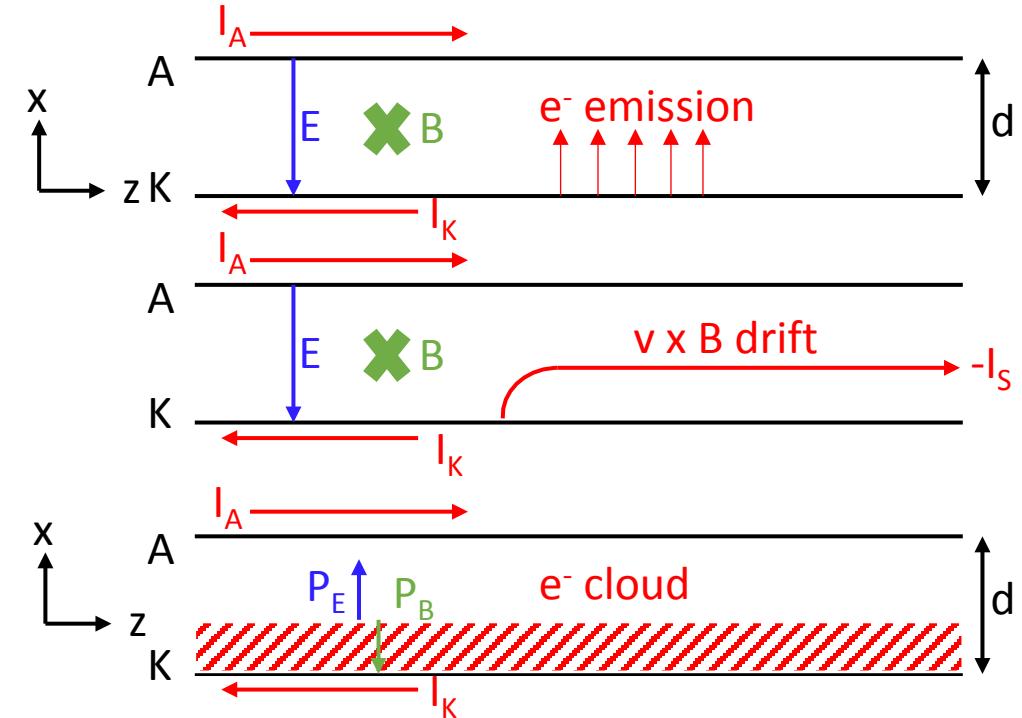

$$Z_f = \frac{V}{\sqrt{I_A^2 - I_K^2}}$$

Miller [4]:  $V = Z_0 \sqrt{I_A^2 - I_K^2} - \frac{mc^2}{2e} \frac{I_A^2 - I_K^2}{I_K^2}$

Ottinger [5]:

$$V = Z_0 \sqrt{I_A^2 - I_K^2} - \frac{mc^2}{e} \frac{Z_0 I_A - \left[ Z_0^2 I_A^2 - \left( Z_0 (I_A^2 - I_K^2) + \frac{4T_m d^2 / \epsilon_0}{Z_0 (I_A^2 - I_K^2)} \right) \right]^{1/2}}{\left[ Z_0^2 I_A^2 - \left( Z_0 (I_A^2 - I_K^2) + \frac{4T_m d^2 / \epsilon_0}{Z_0 (I_A^2 - I_K^2)} \right) \right]^{1/2}}$$

$$T_m = 0, \quad \rightarrow \quad V = Z_0 \sqrt{I_A^2 - I_K^2} - \frac{mc^2}{e} \frac{I_A - I_K}{I_K}$$

# Legacy Extended MITL Configuration

Courtyard used to test large articles

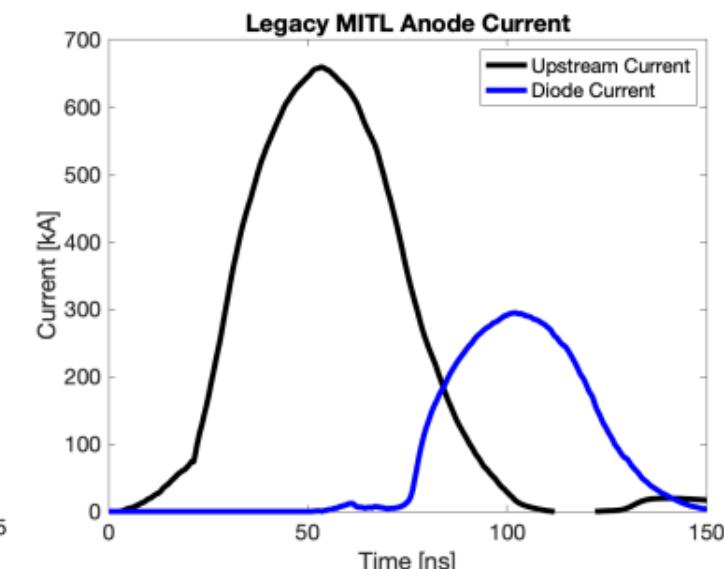

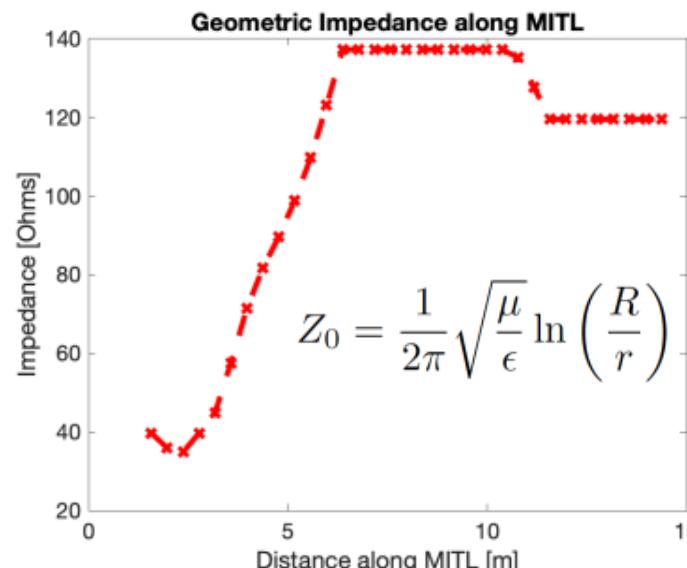

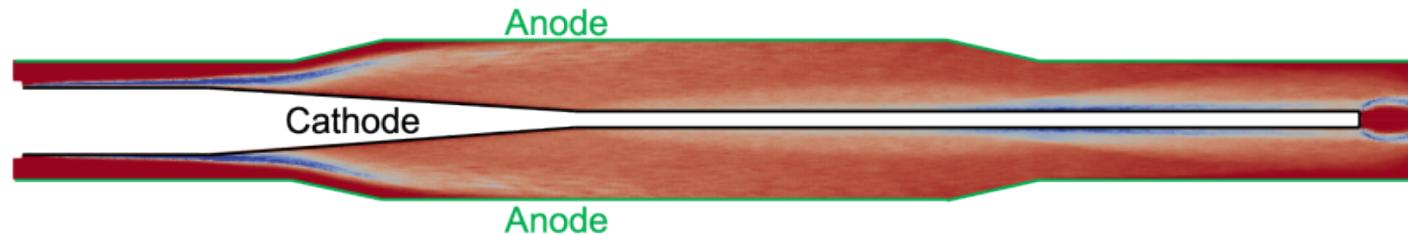

Extended MITL transports power through indoor test cell into courtyard

Anode and cathode radii varied dramatically

Impedance more than tripled in the first few meters

Sheath flow would lift off of cathode and short into anode.

Current lost was roughly half of pulse magnitude

# Redesigned Configuration

# 9 | Constant Impedance Design

Design focused on maintaining the ratio of  $R/r$

$$Z_0 = \frac{1}{2\pi} \sqrt{\frac{\mu}{\epsilon}} \ln \left( \frac{R}{r} \right)$$

Engineering problem: cantilevered floating cathode

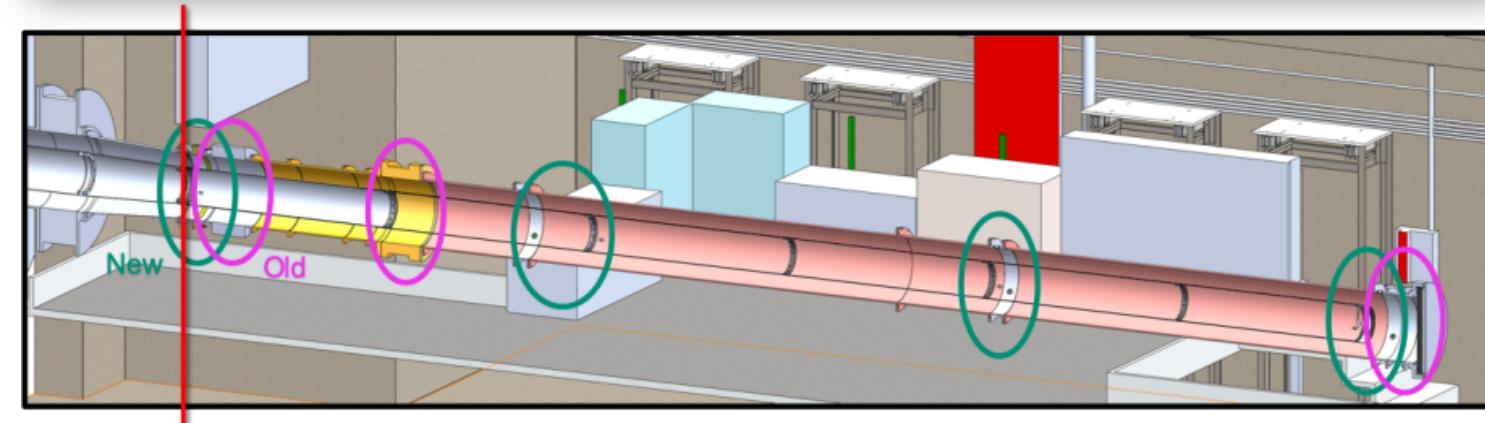

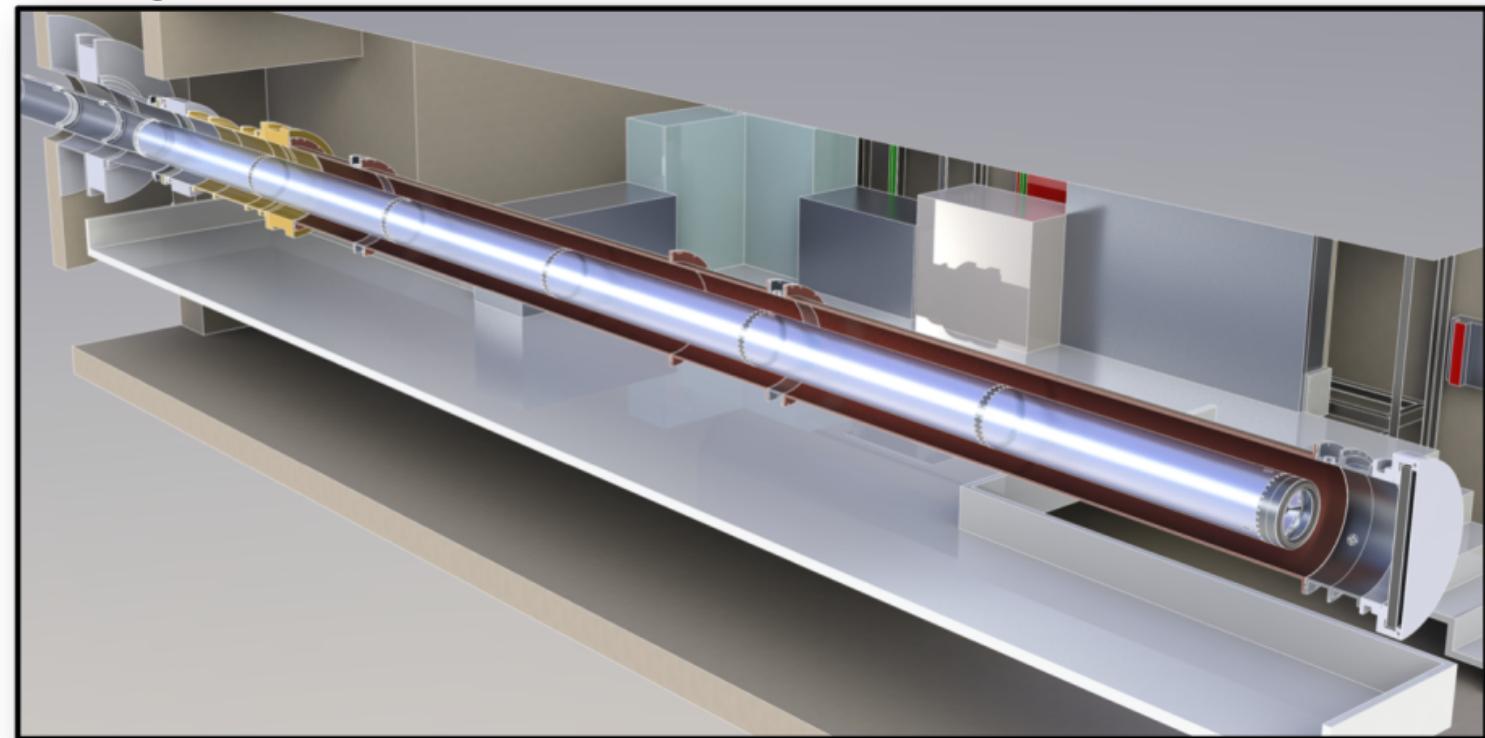

Engineering solution: Thin “nacho cheese can” cathode with clocking rings every few meters

Deflection at diode was typically fractions of an inch

Addition of several cathode B-dot sensors

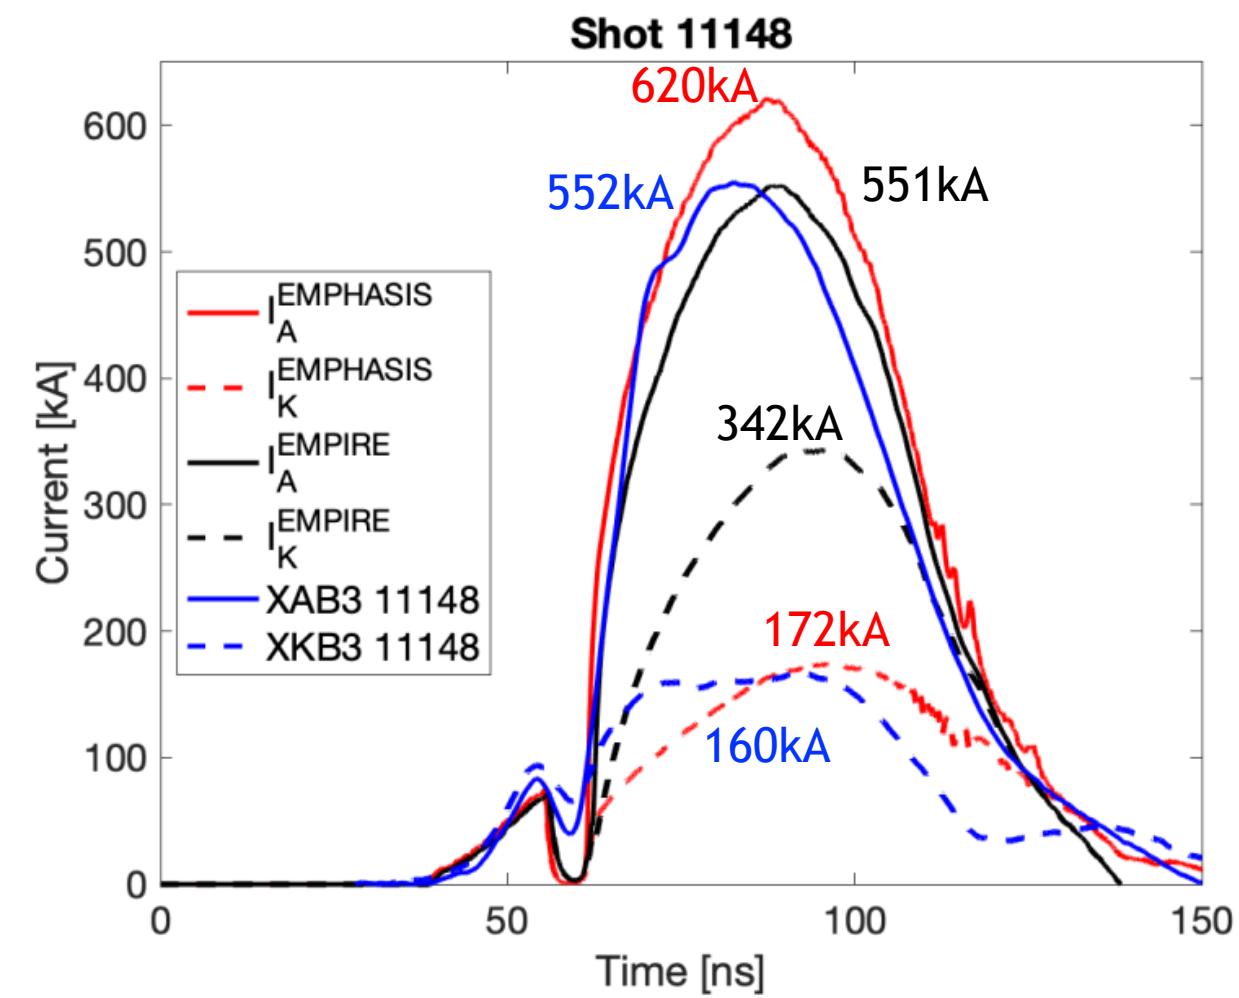

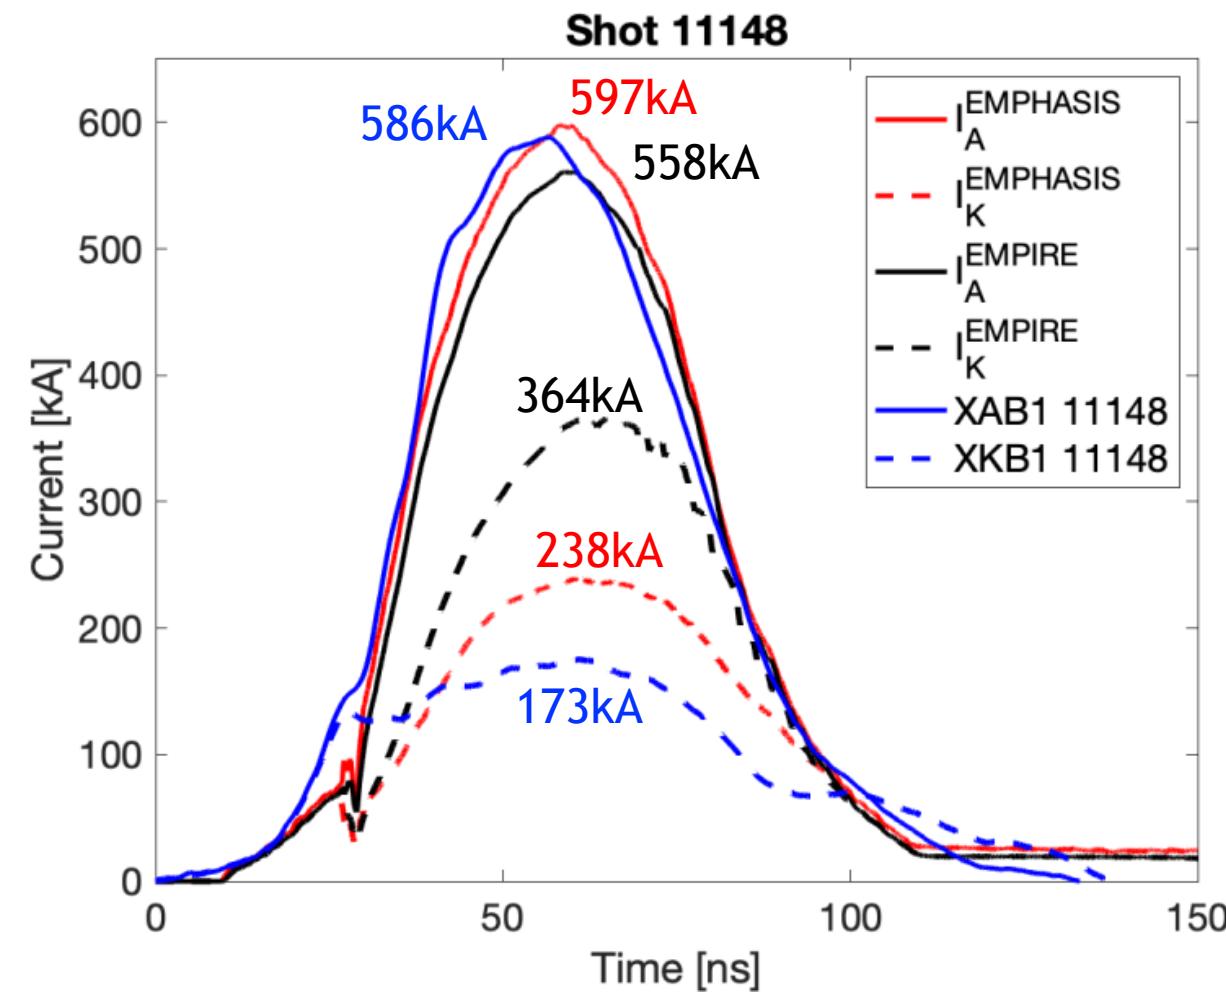

Simulations performed in both EMPHASIS and EMPIRE

- EMPHASIS: Legacy PIC code developed at Sandia National Laboratories
- EMPIRE: PIC-Fluid-Hybrid code in development at Sandia National Laboratories

$$V = Z_0 \sqrt{I_A^2 - I_K^2} - \frac{mc^2}{e} \frac{I_A - I_K}{I_K}$$

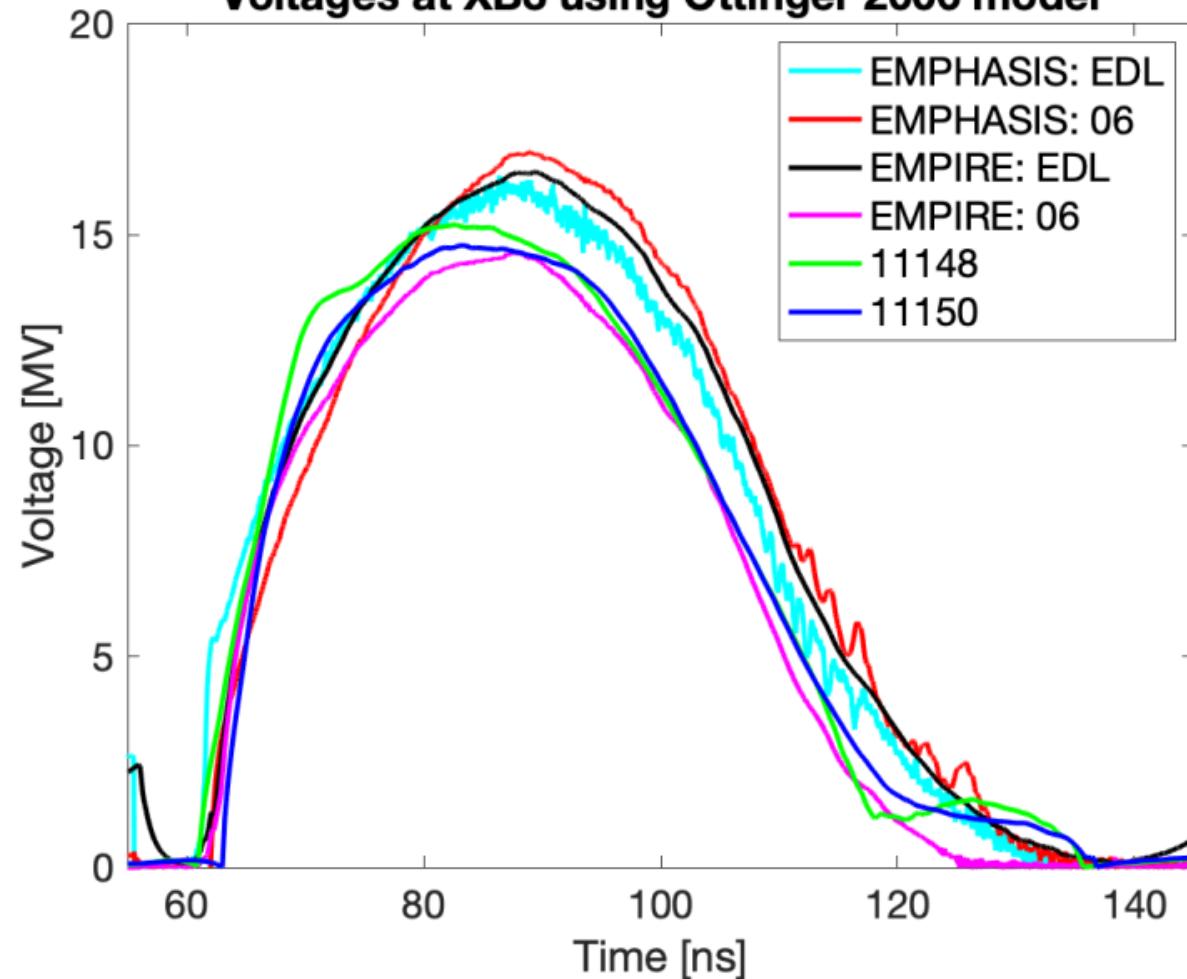

# Voltage Calculation (Sensor Station 3)

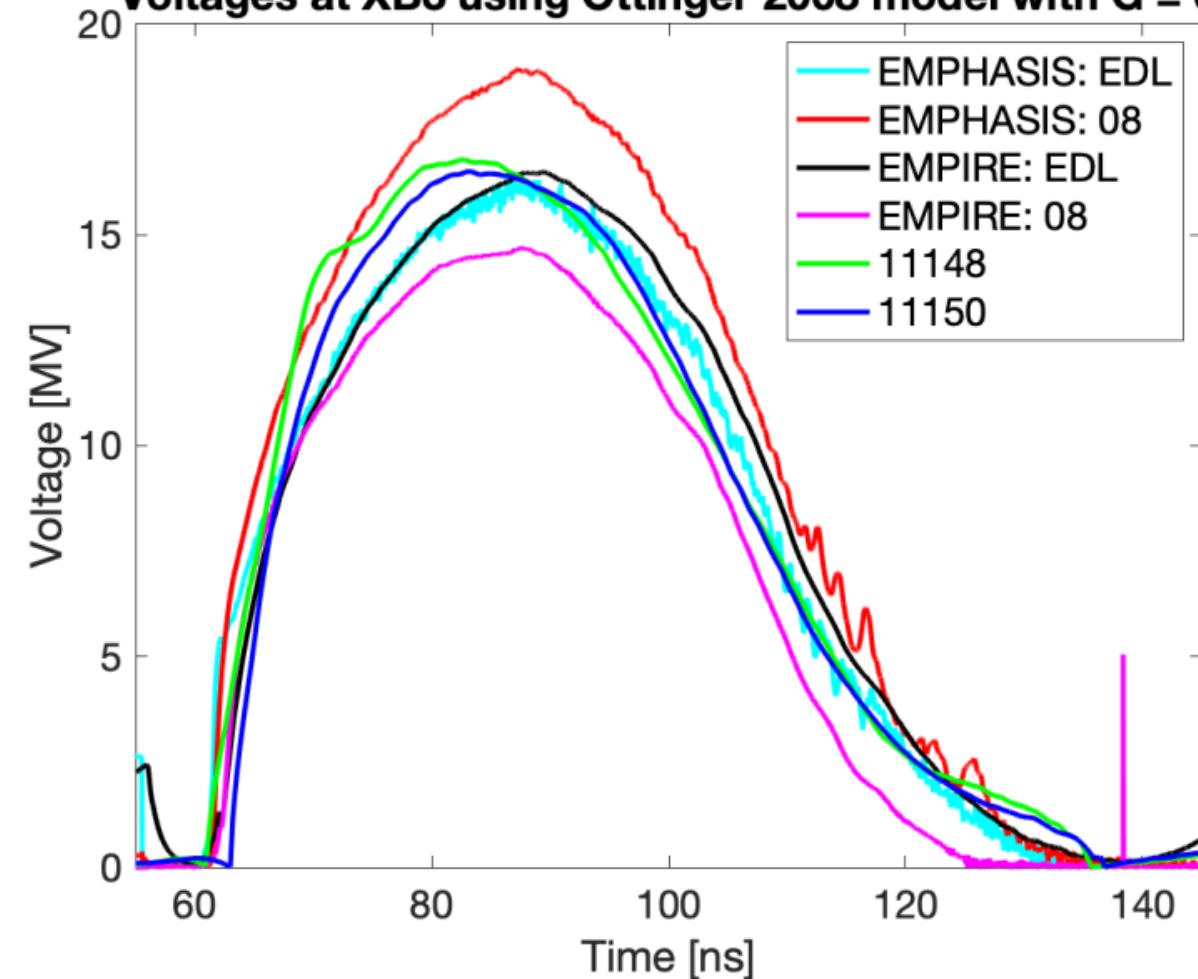

$$V = Z_0 \sqrt{I_A^2 - I_K^2} - \frac{gmc^2}{2e} \frac{I_A^2 - I_K^2}{I_K^2}$$

$$V = Z_0 \sqrt{I_A^2 - I_K^2} - \frac{mc^2}{e} \frac{I_A - I_K}{I_K}$$

**Voltages at XB3 using Ottlinger 2006 model**

**Voltages at XB3 using Ottlinger 2008 model with G = 0**

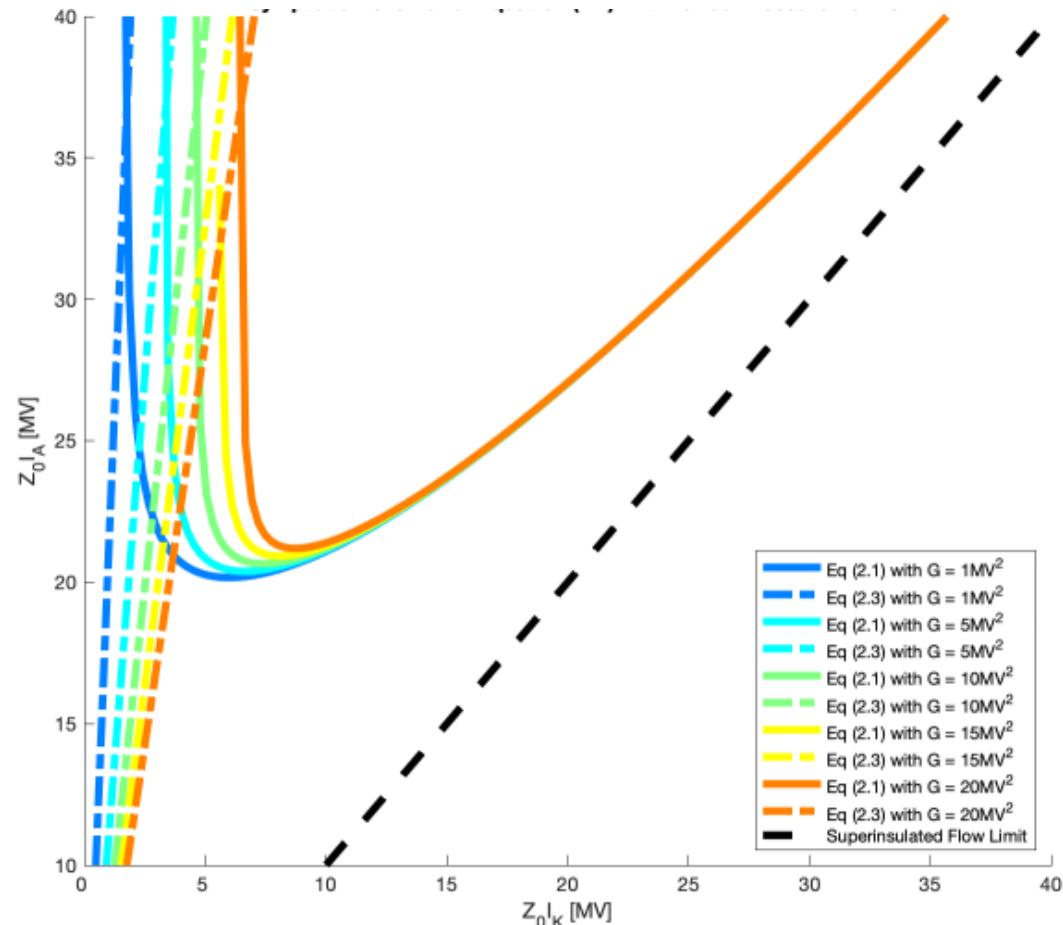

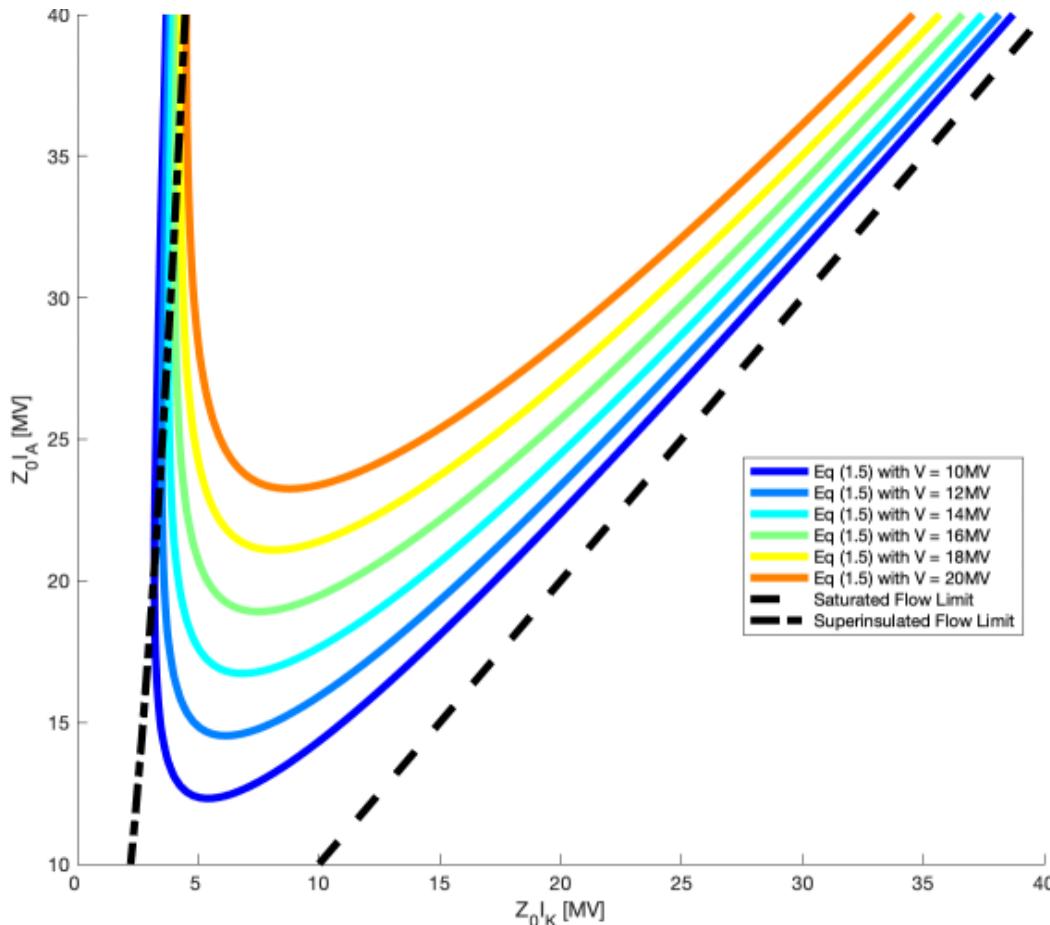

# Voltage Calculation (Fingerprint Plots)

$$V = Z_0 \sqrt{I_A^2 - I_K^2} - \frac{mc^2}{2e} \frac{I_A^2 - I_K^2}{I_K^2}$$

$$V_{Ott(08)} = Z_0 \sqrt{I_A^2 - I_K^2} - \frac{mc^2}{e} \frac{Z_0 I_A - \left[ Z_0^2 I_A^2 - \left( Z_0 \sqrt{I_A^2 - I_K^2} + \frac{4T_m d^2 / \epsilon_0}{Z_0 \sqrt{I_A^2 - I_K^2}} \right)^2 \right]^{1/2}}{\left[ Z_0^2 I_A^2 - \left( Z_0 \sqrt{I_A^2 - I_K^2} + \frac{4T_m d^2 / \epsilon_0}{Z_0 \sqrt{I_A^2 - I_K^2}} \right)^2 \right]^{1/2}}$$

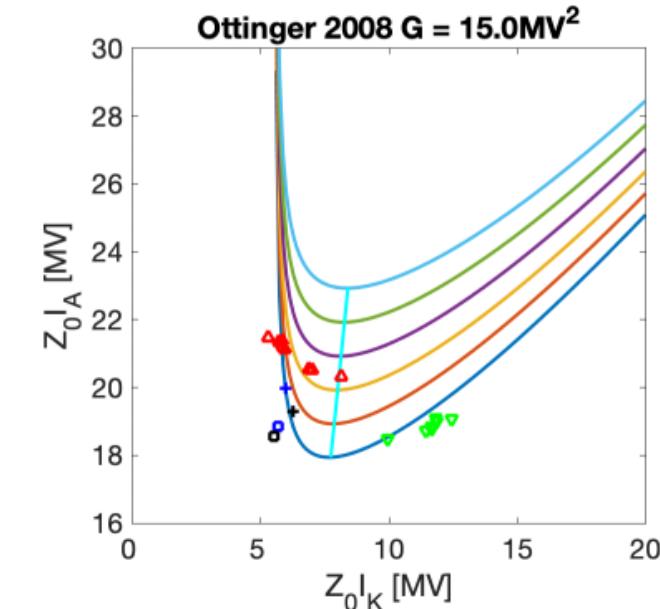

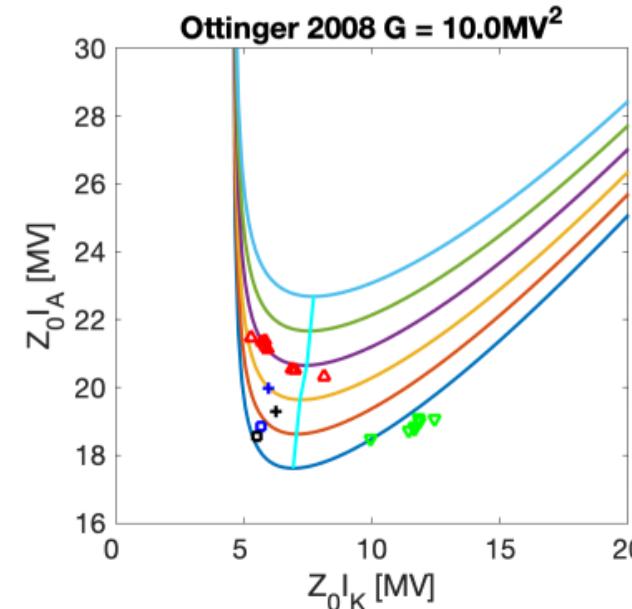

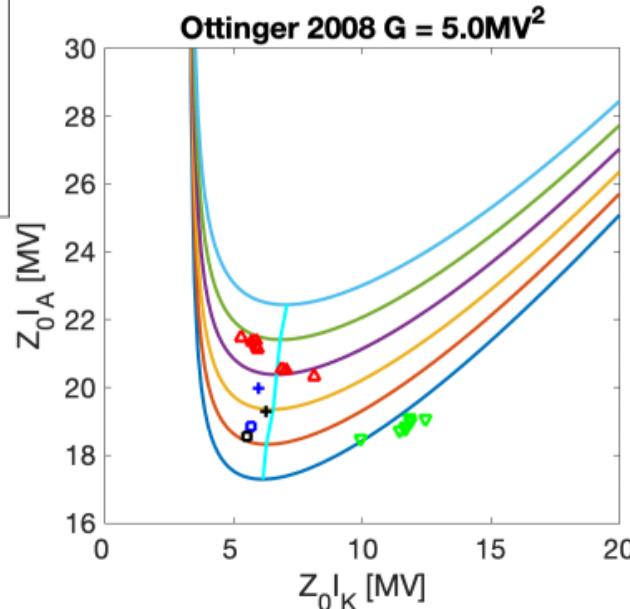

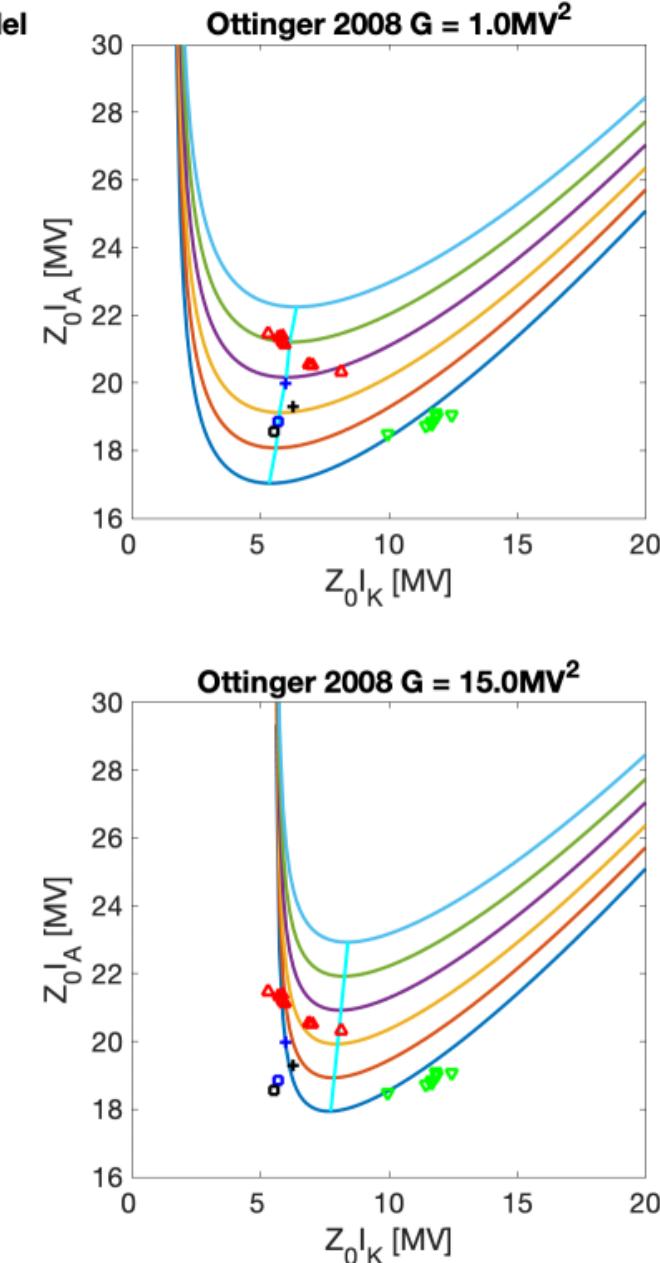

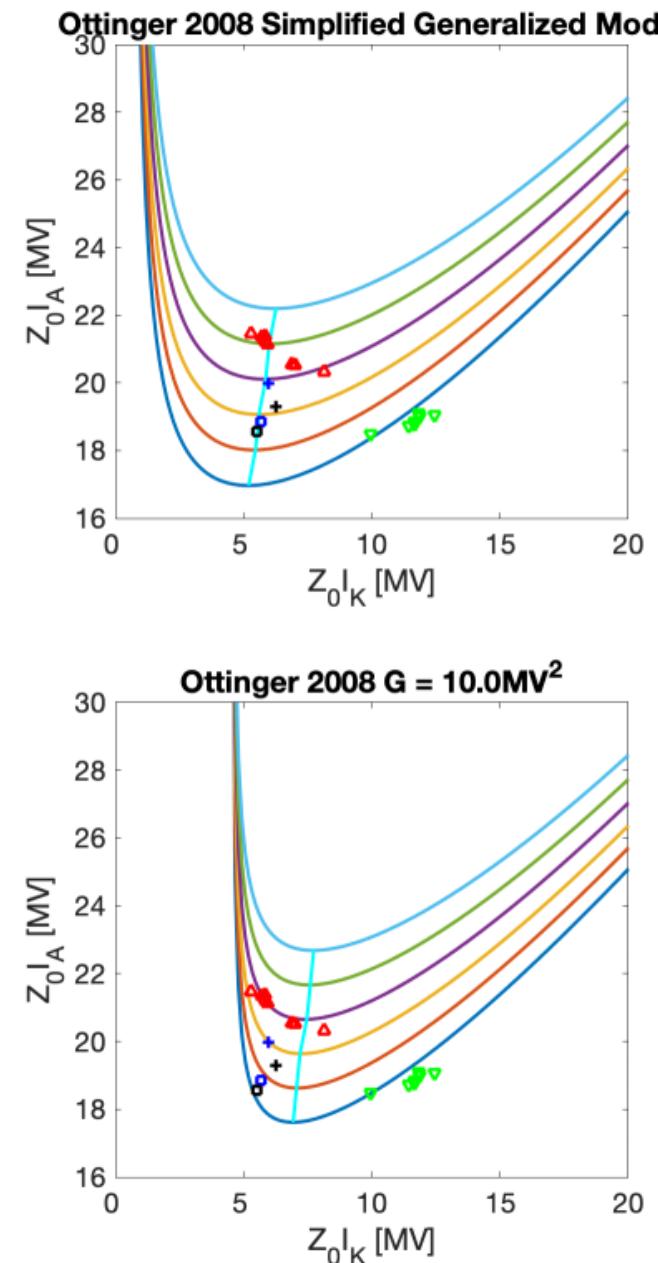

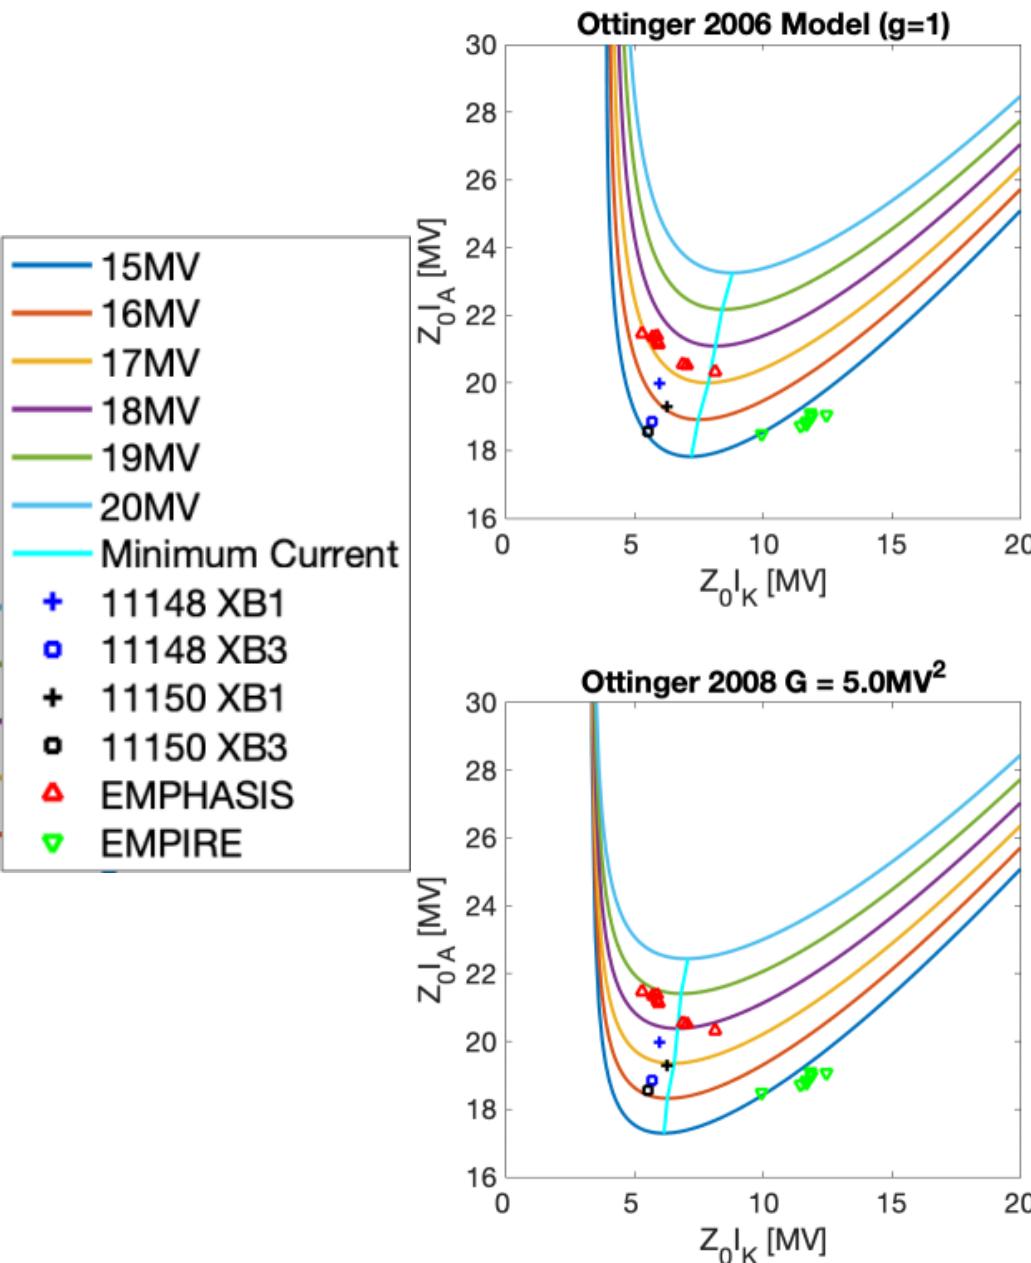

$$G \equiv 4T_m d^2 / \epsilon_0$$

# Voltage Calculation (Fingerprint Plots)

$$G \equiv 4T_m d^2 / \epsilon_0$$

# A look at electron pressure

$$G \equiv 4T_m d^2 / \epsilon_0$$

$$T_m = K T * n_{\max}$$

$$K T = 100 \text{ eV}$$

$$\frac{\partial T}{\partial x} = \rho(E - v_z B)$$

$$G = 5.3 \times 10^{17} \text{ MV}^2$$

$$G = 1.8 \times 10^{17} \text{ MV}^2$$

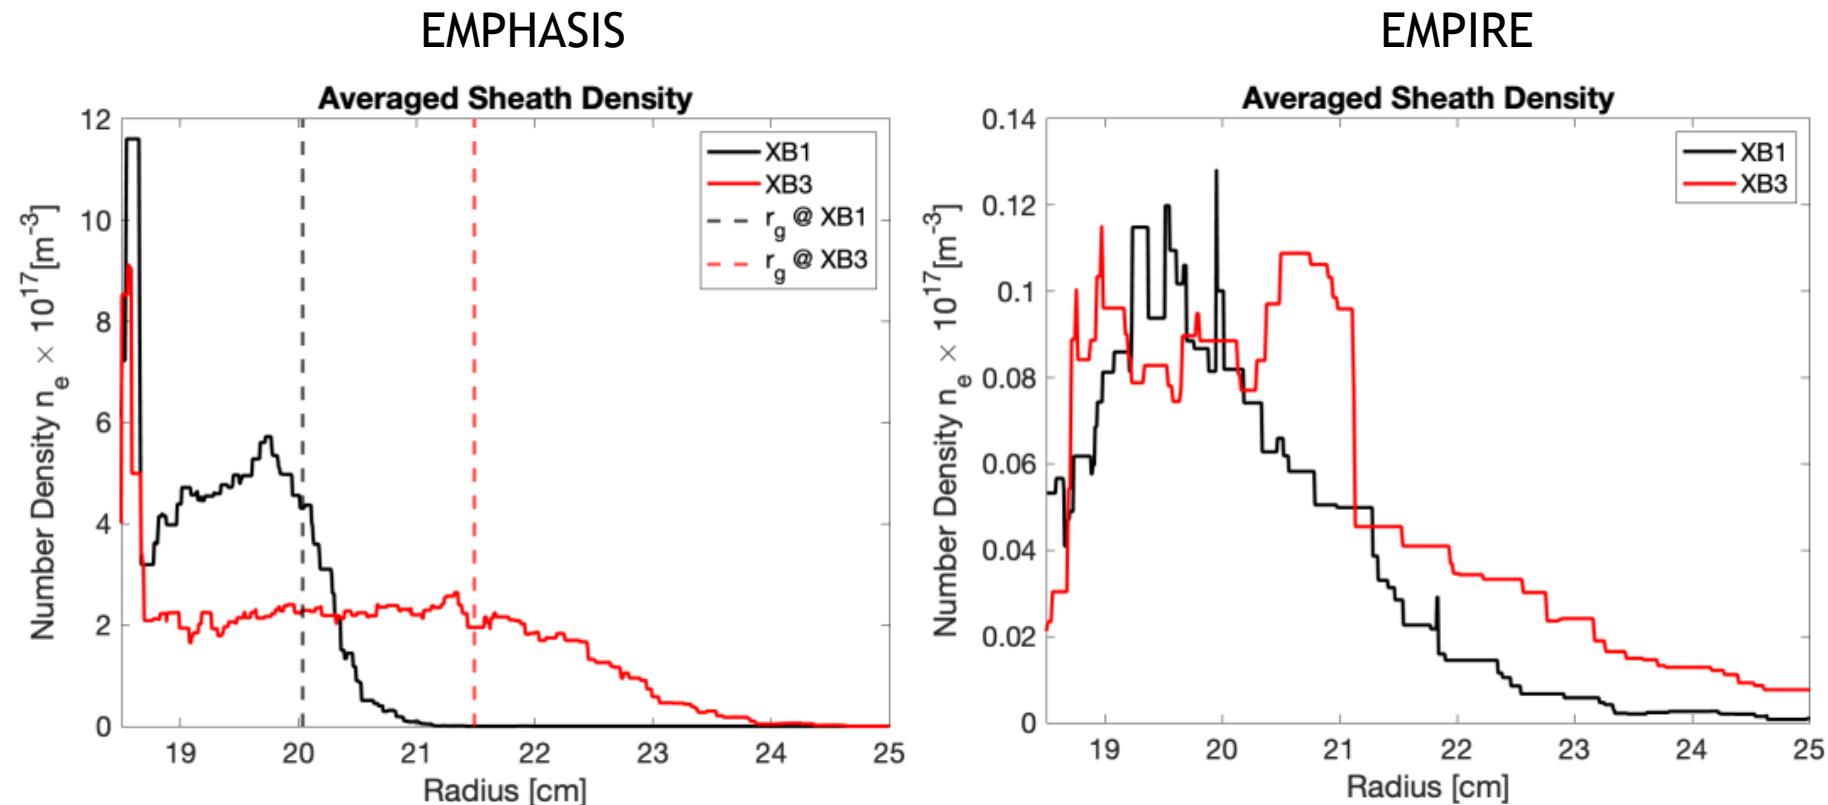

??

$$\text{Suppose } T_m = K T * \rho_{\max}$$

$$G = 0.022 \text{ MV}^2$$

$$G = 0.0072 \text{ MV}^2$$

More believable...

# Conclusions and Future Work

Maintaining constant geometric impedance in the MITL transports power much more effectively.

EMPHASIS: Overpredicts both sheath and anode currents

- Due to Dirichlet voltage boundary condition

EMPIRE: Underestimates sheath current overall

- Using TLBC gives better agreement

Ottinger's simplified model yields decent approximations for voltages

More work needs to be done to understand the sheath parameters in simulation

A better TLBC will be implemented in EMPIRE in the future (but not for EMPHASIS)
