## 10    **Abstract**

11    Carbon dioxide enhanced oil recovery (CO<sub>2</sub>-EOR) projects not only extract residual oil but also  
12    sequester CO<sub>2</sub> in the depleted reservoirs. This study develops a machine-learning-based  
13    workflow to co-optimize the hydrocarbon recovery, CO<sub>2</sub> sequestration volume and project net  
14    present value (NPV) simultaneously. Considering the trade-off relationships amongst the objective  
15    functions, support vector regression with Gaussian kernel (Gaussian- SVR) proxies are coupled  
16    with multi-objective particle swarm optimization (PSO) protocol and generate Pareto optimal  
17    solutions. Taking advantage of the high computational efficacy of the proxy model, economic  
18    uncertainties introduced by tax credits, capital costs and oil price are investigated by this study. The  
19    results indicate that the tax incentive policy (Section 45Q) plays a vital role in enhancing the  
20    economic returns of CO<sub>2</sub>-EOR projects, especially under the depression of crude oil market. The  
21    proposed workflow has been successfully implemented to optimize a water alternative CO<sub>2</sub>

1 (CO<sub>2</sub>-WAG) injection project in a depleted oil sand in the US. The optimization results yield an  
2 incremental oil production of 15.8 MM STB and 1.37 MM metric tons of CO<sub>2</sub> storage in a 20-year  
3 development strategy, with the highest project NPV to be 205.6 MM US dollars.

## 4 **1. Introduction**

5 Geological long-term CO<sub>2</sub> sequestration is a critical technology to reduce CO<sub>2</sub> emission and  
6 mitigate global warming<sup>1-3</sup>. In the oil and gas industry, CO<sub>2</sub>-EOR extracts residual oil from mature  
7 oil fields by injecting CO<sub>2</sub>. Meanwhile, the injected CO<sub>2</sub> could be sequestered in the depleted  
8 porous media. Thus, CO<sub>2</sub>-EOR is seen as an cost-effective means to implement the geological  
9 storage of anthropogenic CO<sub>2</sub>.<sup>1</sup> Such a kind of project is known to be Carbon Capture, Utilization  
10 and Storage (CCUS) project.

11 The United States Department of Energy (U.S. DOE) funded the Southwest Regional Partnership  
12 on Carbon Sequestration (SWP), which has been monitoring a water-alternating-CO<sub>2</sub> injection  
13 (CO<sub>2</sub>-WAG) project at the Farnsworth Unit Field (FWU) in Ochiltree County, Texas<sup>3</sup>. The primary  
14 goals of the SWP project include monitoring the injection of over one million metric tons of  
15 anthropogenic CO<sub>2</sub>, investigating the migration of CO<sub>2</sub> plume, and studying how to store CO<sub>2</sub> in  
16 the partially depleted oil and gas reservoirs safely and permanently.<sup>2-6</sup>

17 The implementation of safe and long-term sequestration of CO<sub>2</sub> in subsurface structure is the main  
18 concern of the studies on CCUS projects. Numerous researches have been carried out on the  
19 mechanisms of the CO<sub>2</sub> trapping, including structural-stratigraphic trapping<sup>6</sup>, solubility trapping<sup>7</sup>,

1 residual trapping<sup>8</sup>, and mineral trappings<sup>9, 10</sup>. More importantly, factors related with the  
2 performance of CO<sub>2</sub> storage gains a lot of attention recently, such as three-phase hysteresis<sup>8</sup>, the  
3 impacts of heterogeneity<sup>11, 12</sup>, formation fluid dissolved components<sup>13</sup>, and CO<sub>2</sub> injectivity<sup>14</sup>, etc.  
4 For a CCUS project, the field operator seeks to optimize multiple objectives simultaneously,  
5 including oil recovery, carbon storage volume and project economic outcomes. Considering the  
6 operational parameters of numerous injection and production wells, the field development  
7 strategy design can be recognized as a high-dimensional, multi-objective optimization problem  
8 (MOP). Research efforts have been donated to solve MOPs in oil and gas industry: Guevara et al.  
9<sup>15</sup> presented a nonlinear model-based, adaptive-predictive control approach to co-optimize both  
10 steam conformance and net present value (NPV). Forooghi et al.<sup>16</sup> employed a compositional  
11 reservoir simulator to co-optimize CO<sub>2</sub> sequestration and CO<sub>2</sub>-EOR performance in a North Sea  
12 chalk field. Han et al.<sup>17</sup> used a multi-objective evolutionary algorithm (MOEA) for history  
13 matching with four objective functions. Dai et al.<sup>18</sup> proposed an integrated Monte Carlo simulation  
14 framework to optimize the net CO<sub>2</sub> injection and oil recovery after five years in a CO<sub>2</sub>-EOR  
15 project.

16 When dealing with MOPs, a commonly used approach is to develop and optimize an aggregated  
17 function by weighted summing various objectives,<sup>16, 17, 19</sup> which is known as the Weighted Sum  
18 Method (WSM). The main advantage of the WSM is that the combination of multiple objectives  
19 reduces the number of objectives functions and the computational overhead. However, defining  
20 the magnitudes of the associated weights could be challenging due<sup>20</sup>. More importantly, using

1 WSM can only find a unique optimal solution, which constrains the flexibility for  
2 decision-makers to design a project with multiple objective functions.<sup>21</sup> In petroleum industry,  
3 multiple project responses can be combined into the calculation of NPV, then the MOP is converted  
4 to a single-objective optimization problem. For example, Wang et al.<sup>22</sup> studied the economic  
5 co-optimization of oil recovery and CO<sub>2</sub> sequestration using a method introduced by Leach.<sup>23</sup> Their  
6 work focuses on optimizing the project NPV considering different economic components,  
7 including CO<sub>2</sub> sequestration subsidies. Omran et al.<sup>20</sup> introduced work to evaluate the economics  
8 in a petrochemical production project, focusing on four key factors: capital investments, operating  
9 costs, cash flow and profitability measures. However, using this method would encounter the same  
10 drawbacks as that of WSM to solve multi-objective problems.

11 The Pareto optimal theory is an alternative approach to address MOPs, which structures a solution  
12 repository (called Pareto front) containing multiple solutions for the objective functions exhibiting  
13 trade-off relationship (namely, the improvement of one of the objectives has to sacrifice at least  
14 another one). The structure of Pareto fronts would employ an optimization algorithm such as  
15 genetic algorithm (MOGA) and particle swarm optimization (MOPSO). Successfully applications  
16 of Pareto optimal theory can be found in research areas such as history matching,<sup>24</sup> field  
17 development optimization<sup>25</sup> and production performance optimization.<sup>26</sup> The design of CO<sub>2</sub>-EOR  
18 is extremely suitable to deploy the Pareto optimal theory due to the strong trade-off relationship  
19 amongst the objective functions: the maximization of oil recovery would increase the production of  
20 CO<sub>2</sub> gas, which reduces the volume of CO<sub>2</sub> residing in the porous media. Moreover, the impact of

1 the tax subsidies on the project NPV needs to be investigated. Notably, the multiple-objective  
2 optimizers are computationally intensive due to the massive volume calculation and sorting of the  
3 objective functions, which motivates the use of machine-learning proxies.

4 In this work, a field-scale numerical simulation model is employed to assess the long-term  
5 responses of the CO<sub>2</sub>-WAG project. To reduce the computational overhead of such applications,  
6 machine-learning models have been trained and acted as proxies of the high-fidelity numerical  
7 model to predict specific outcomes<sup>27</sup>. In the petroleum industry, machine-learning models such as  
8 Response Surface, Artificial Neural Network (ANN), Support Vector Regression, and Multivariate  
9 splines have been employed to solve various regression and classification problems<sup>28-35</sup>. This study  
10 develops a machine-learning-assisted workflow coupling Gaussian-SVR and MOPSO to  
11 co-optimize the oil recovery, carbon sequestration volume and project NPV. It is employed to  
12 conduct a comprehensive techno-economic assessment of the FWU CO<sub>2</sub>-WAG project considering vital  
13 economic parameters including the oil price, tax credits, carbon capture and transporting costs,  
14 field operational cost, etc. The major contributions of this work are as follows:

15 An iterative protocol is proposed to reduce the uncertainty introduced by the error margin of the  
16 proxy. New samples are added to the dataset and retrain the SVR model until the disparities  
17 between the Pareto front generated by the proxy and the numerical simulator satisfy a prescribed  
18 tolerance. Moreover, extensive uncertainty analysis is carried by taking advantage of the  
19 computational efficacy of the proposed workflow, which brings comprehensive techno-economic  
20 insights on the variation of project response with the change of economic factors.

## 2. Geological Model and History-matching

FWU is a partially depleted oil reservoir undergoing CO<sub>2</sub>-WAG injection processes. The target reservoir is the Pennsylvanian-age Morrow B sandstone formation located at a depth between 7550 ft and 7950 ft. The formation has an average dip of less than one degree<sup>6</sup> and was deposited in the late Pennsylvanian by a fluvial system in an incised valley<sup>36</sup>. The initial oil in place (OOIP) and gas initially in place (GIIP) are approximately 120MM barrels and 41.48 Bscf<sup>37</sup>. Table 1 summarizes some crucial properties of the FWU field.

**Table 1 Important properties of FUW field**

| Property                       | Value | Unit       |
|--------------------------------|-------|------------|
| OOIP                           | 120   | MM barrel  |
| GIIP                           | 41.48 | BCF        |
| Net pay thickness              | 22-54 | Ft         |
| Initial reservoir pressure     | 2203  | Psi        |
| Initial bubble point pressure  | 2059  | Psi        |
| Reservoir temperature @7900 ft | 168   | °F         |
| Mean porosity                  | 14.6% | percentage |
| Mean permeability              | 58    | mD         |

A 3-D compositional numerical reservoir simulation model is established to investigate the fluid transportation dynamic of FWU using Eclipse simulator<sup>38</sup>. The simulation is presumed to only consider the effects of structural trapping, solubility trapping and residual trapping. The mineral trapping mechanism is not considered in the simulation since it often takes years to occur and its impact on CO<sub>2</sub> storage would be observed on a very long time scale<sup>39</sup>.

A compositional geological model has been built and incorporated with the history field data collected up to 2019. The numerical model is validated via a rigorous history matching study using

1 55 years of primary and secondary (water flooding) recovery data, and nine years of CO<sub>2</sub>-WAG  
2 data (shown in Figure A- 1 in Appendices). Rose-Coss et al.<sup>40, 41</sup> established eight hydraulic flow  
3 units (HFUs) to characterize hydrogeologic heterogeneity for the Morrow B using well log and  
4 petrophysical data obtained from various scientific wells with the Farnsworth Unit field.  
5 Rasmussen et al.<sup>42</sup> found it was possible to lump some of the HFUs via an experimental study of  
6 brine-oil and CO<sub>2</sub>-oil core-flooding experiments. Each HFU is characterized using a unique  
7 permeability-porosity relationship, which is used to populate the spatial distribution of  
8 permeability of the simulation model. Moreover, the three-phase relative permeability  
9 characterization varies with the HFU distribution. Therefore, the history-matching process of the  
10 FWU field becomes even more challenging due to the high dimensionality of the uncertain  
11 petrophysical properties.

12 This history-matched work is accomplished using a machine-learning-assisted workflow<sup>43</sup>. The  
13 tuning parameters used include the permeability multipliers along with the lateral and vertical  
14 directions, and the Corey's three-phase relative permeability coefficients

### 15 **3. Forecasting Scenario and objective functions**

16 The forecasting scenario is structured based on the history-matched model to forecast the field  
17 responses of a 20-years CO<sub>2</sub>-WAG project (from 2019-12-31 to 2038-1-1). More importantly, it can  
18 be employed to optimize the development plan considering the prescribed objective functions.

19 To control the development plan more efficiently and practically, the whole development plan has

1 been split into eight time periods in total for more detailed control, as summarized in Table 2.

2

**Table 2. Time schedules of the development plan**

| Period # | Abbreviation | Start time | End time   |
|----------|--------------|------------|------------|
| 1        | PD1          | 2019/12/31 | 2020/6/30  |
| 2        | PD2          | 2020/6/30  | 2022/1/1   |
| 3        | PD3          | 2022/1/1   | 2023/1/1   |
| 4        | PD4          | 2023/1/1   | 2026/1/1   |
| 5        | PD5          | 2026/1/1   | 2028/1/1   |
| 6        | PD6          | 2028/1/1   | 2030/1/1   |
| 7        | PD7          | 2030/1/1   | 2032/1/1   |
| 8        | PD8          | 2032/1/1   | 2038/01/01 |

3 The development strategy includes the injection of purchased CO<sub>2</sub> and recycling CO<sub>2</sub> for  
4 reinjection underground. The rate of purchased CO<sub>2</sub> is 8000 Mscf/day from the beginning of the  
5 year 2020 and the end of the year 2025. After that, the CO<sub>2</sub> purchasing rate decreases to 6400  
6 Mscf/day by the end of the year 2027. From the year 2028, the CO<sub>2</sub> purchasing rate decreases to  
7 5600 Mscf/day, and this rate will be kept until the end of the year 2029. From 2030, the CO<sub>2</sub>  
8 purchasing rate will be reduced to 4800 Mscf/day and will last for another two years. Then, no  
9 more CO<sub>2</sub> will be purchased from 2032.

10 The WAG injectors are divided into four groups, and the WAG wells included in the same group  
11 will have the same operational parameters. Based on previous studies and field operator's  
12 suggestions<sup>28</sup>, some previous producers or unused wells will be converted into WAG wells during  
13 the development of the CO<sub>2</sub>-WAG project. Those new-proposed WAG injectors will be queued to  
14 come on stream based on CO<sub>2</sub> availability and/or project anticipated schedule. The WAG wells  
15 were grouped based on their year of operation, location of pattern, and injectivity. The extant

1 injectors were aligned to come on stream when more CO<sub>2</sub> is produced. It is worth noting that, the  
 2 schedules of the injectors and producers are based on the strategy as shown in Table 2. The  
 3 operational parameters are well parameters used to control the injection/production performance of  
 4 the WAG wells. The total number of operational parameters is 37, which are described in detail in  
 5 Table A - 1.

6 The forecasting scenario structures the base case simulation model to assess the objective functions  
 7 considered in the optimization workflow. The NPV is calculated using a modified equation based  
 8 on reference<sup>44</sup>, expressed as Eq. 1.

$$9 \quad NPV = -CAPEX + \sum_{i=1}^n (q_o \times r_o + q_{co2,store} \times r_{co2,credit} - q_{w,inj} \times r_w - q_{w,pro} \times r_{w,pro} -$$

$$10 \quad q_{inj,co2} \times r_{co2} - q_{co2,p} \times r_{co2,p})_i \times (1 + r_b)^{-i} \quad (\text{Eq. 1})$$

11 where  $r_o$  is the oil price after tax and royalty deduction;  $r_{co2,credit}$  is the CO<sub>2</sub> storage credit given  
 12 by the government;  $r_{w,inj}$  is the water injection cost;  $r_{w,pro}$  is the cost of produced water  
 13 treatment and recycling;  $r_{co2}$  is gas injection cost;  $r_{co2,p}$  is the CO<sub>2</sub> purchase price from the plant  
 14 (including transportation);  $q_o$  is oil production at i-th year;  $q_{co2,store}$  is CO<sub>2</sub> storage at i-th year;  
 15  $q_{w,inj}$  is water injection at i-th year;  $q_{w,pro}$  is water production at i-th year;  $q_{inj,co2}$  is CO<sub>2</sub>  
 16 injection at i-th year;  $q_{co2,p}$  is CO<sub>2</sub> purchased at i-th year;  $r_b$  is inflation rate; and  $CAPEX$  is  
 17 Capital expenditure. Subscript i is the index of year.

18 The values of those economic parameters used to calculate the NPV for the base case model are  
 19 shown in Table 3. The values are extracted from the published references.<sup>44</sup>

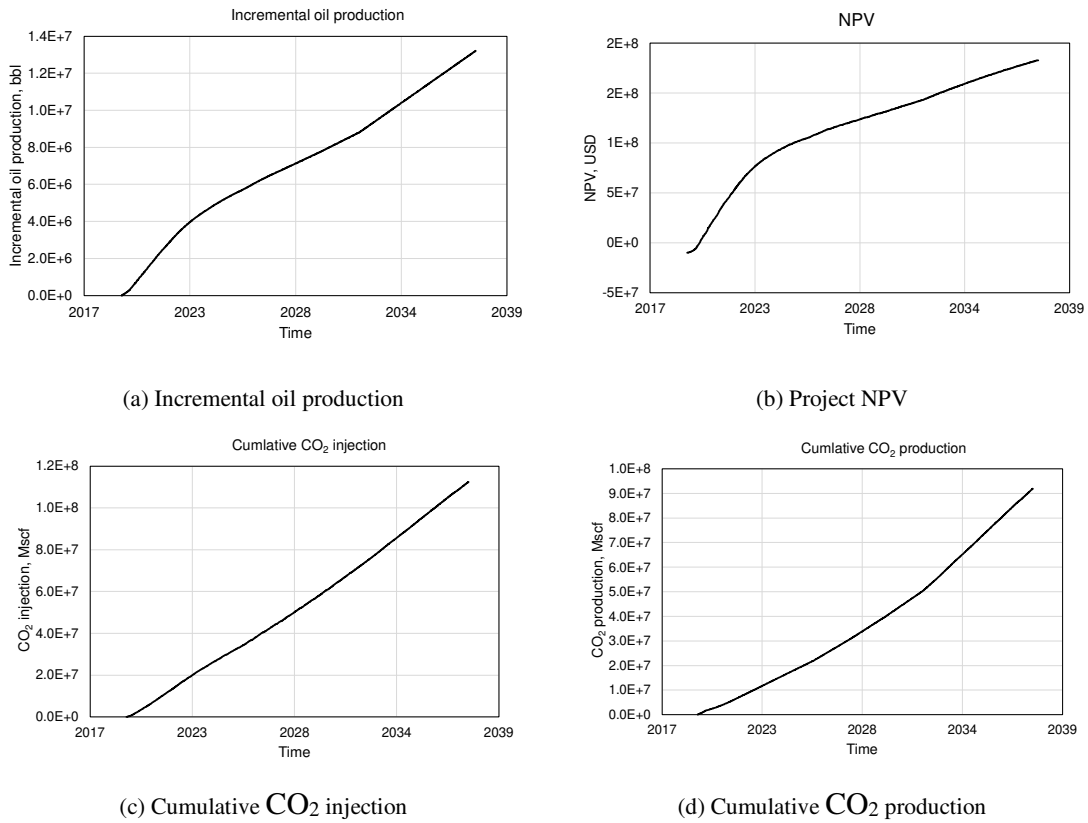

20 **Table 3. Economic parameters used to calculate NPV for the base case model (the values of those parameters are**

1

extracted from reference <sup>44</sup>)

| Item  | Value | Unit           |
|---|-------|----------------|
| Royalty   | 17%   | -              |
| Federal income tax                              | 35%   | -              |
| Oil price, $r_o$                                | 50    | \$/bbl         |
| Water injection cost, $r_{w,inj}$               | 1.03  | \$/stb         |
| Produced water treatment cost, $r_{w,pro}$      | 0.64  | \$/stb         |
| CO <sub>2</sub> injection cost, $r_{co2}$       | 0.85  | \$/MSCF        |
| CO <sub>2</sub> purchase price, $r_{co2,p}$     | 1.72  | \$/MSCF        |
| CO <sub>2</sub> storage credit, $q_{co2,store}$ | 45    | \$/ metric ton |
| Inflation rate, $r_b$                           | 5%    | -              |
| Capital expenditure, $CAPEX$                    | 10 MM | \$             |

2 Figure 1 shows the results of the base case model.

3

**Figure 1. Simulation results of the base case model.**

4

Some crucial results of the base case model are summarized in Table 4:

1

**Table 4. Results of the base case model**

| Item   | Unit          | Value                |
|--|---------------|----------------------|
| Incremental oil production                     | MM bbl        | 13.2                 |
| Incremental CO <sub>2</sub> storage volume     | MM metric ton | 1.06                 |
| Project NPV                                    | USD           | 1.83×10 <sup>8</sup> |
| Cumulative Oil Production by Aug 2019          | MM bbl        | 3.63                 |
| Cumulative Oil Production by Jan 2038          | MM bbl        | 16.8                 |
| Cumulative CO <sub>2</sub> storage by Jan 2038 | MM metric ton | 2.36                 |
| % Storage of purchased CO <sub>2</sub>         | percentage    | 81.19%               |

2 It is observed that, in the base case model, the cumulative oil production at the end of the prediction  
3 time is 16.8 MM bbl; and the total CO<sub>2</sub> storage during the 20-years prediction is 2.36 MM metric  
4 tons, which takes up approximately 81.2% of the total purchased CO<sub>2</sub> according to the predefined  
5 CO<sub>2</sub> purchase plan. The project NPV is predicted to be 1.83×10<sup>8</sup> U.S. dollars. In the work described  
6 in the next section, by using the developed machine-learning-based optimization workflow, the  
7 three considered objectives are improved over the base case. For the convenience of discussion, the  
8 objective functions are defined as:

9  $f_1$  = cumulative oil production by Jan. 2038

10  $f_2$  = cumulative CO<sub>2</sub> storage by Jan. 2038

11  $f_3$  = project NPV

## 12 **4. SVR Assisted Multi-Objective Optimization Workflow**

### 13 **4.1 Sensitivity analysis**

14 A sensitivity analysis study was performed to investigate the impact of operational parameters on  
15 the objective functions. Those with a high impact on oil production and CO<sub>2</sub> storage were selected

1 and utilized in the following optimization work. The selection of parameters used in the sensitivity  
 2 analysis targets those that could be operated by the field engineers. A total of 37 operational  
 3 parameters were used to conduct sensitivity analysis. As shown in Table 5, 12 parameters were  
 4 selected due to their high impact on either oil production or CO<sub>2</sub> storage amount.

5 **Table 5. Summary of selected parameters used in optimization work**

| Rank | Operational parameter                     | Unit    | Base value | Min  | Max  |
|------|---|---------|------------|------|------|
| 1    | Field oil production rate from PD1 to PD4 | STB/day | 3500       | 2500 | 4500 |
| 2    | Field oil production rate for PD8         | STB/day | 2000       | 1500 | 3500 |
| 3    | Gas cycle for WAG B1 group in PD2         | month   | 3          | 2    | 12   |
| 4    | Water cycle for WAG B1 group in PD2       | month   | 1          | 0    | 3    |
| 5    | Gas cycle for WAG D1 group in PD4         | month   | 3          | 2    | 12   |
| 6    | Gas cycle for WAG D2 group in PD4         | month   | 7          | 2    | 12   |
| 7    | Gas cycle for WAG D3 group in PD4         | month   | 9          | 2    | 12   |
| 8    | Gas cycle for WAG D4 group in PD4         | month   | 1          | 2    | 12   |
| 9    | Water cycle for WAG D1 group in PD4       | month   | 1          | 0    | 3    |
| 10   | Water cycle for WAG D2 group in PD4       | month   | 1          | 0    | 3    |
| 11   | Water cycle for WAG D3 group in PD4       | month   | 1          | 0    | 3    |
| 12   | Water cycle for WAG D4 group in PD4       | month   | 1          | 0    | 3    |

6 During the development of the CO<sub>2</sub>-WAG project, some producers or nonuse wells will be  
 7 converted into WAG wells according to previous studies and field operator's suggestions<sup>28</sup>. Those  
 8 new-proposed WAG injectors will be queued to come on stream based on CO<sub>2</sub> availability and/or  
 9 project anticipated schedule. The WAG wells are divided into various groups for more flexible  
 10 controls and the wells in the same group will have the same operational parameters. The alphabets  
 11 in the name of the operational parameters represent different groups of the WAG wells and those  
 12 numbers meaning different time periods.

## 1 **4.2 Preparation of initial training dataset**

2 The proxy model is trained using synthetic data generated from high-fidelity numerical simulation  
3 models. Therefore, a certain volume of batch simulation realizations is sent to prepare the  
4 knowledgebase to develop the Gaussian-SVR proxy models. Figure 2 displays the structure of the  
5 dataset used in this part of the work. Here each set of training data contains 12 input parameters  
6 listed in Table 5. The training outputs (targets) include cumulative oil production, cumulative CO<sub>2</sub>  
7 storage amount, and project NPV.

9 **Figure 2. Structure of training dataset. The training targets include cumulative oil production (green square),**  
10 **CO<sub>2</sub> storage amount (red square) and project NPV (yellow square) at the end of the forecasting period. Training**  
11 **inputs are 12 parameters represented by blue squares.**

## 12 **4.3 Proxy modeling using Gaussian-SVR**

13 Supported vector regression with Gaussian kernel is a robust method for solving linear and  
14 nonlinear regression problems<sup>45</sup>. In Gaussian-SVR, the use of the Gaussian kernel will convert a  
15 nonlinear problem to linear regression by mapping the original input space into a higher  
16 dimensional feature space where the problem could be solved linearly. The process of using

1 Gaussian-SVR to solve nonlinear regression problems can be expressed as Eq. 2 and Eq. 3, with the  
 2 Gaussian kernel function expressed as Eq. 4.

$$3 \quad L(\alpha, \alpha^*) = \text{maximize} \begin{cases} -\frac{1}{2} \sum_{i,j=1}^l (\alpha_i - \alpha_i^*)(\alpha_j - \alpha_j^*) K(x_1, x_2) \\ -\varepsilon \sum_{i=1}^l (\alpha_i + \alpha_i^*)(\alpha_j - \alpha_j^*) + \sum_{i=1}^l y_i (\alpha_i - \alpha_i^*) \end{cases} \quad (\text{Eq. 2})$$

$$4 \quad \text{subject to } \sum_{i=1}^l (\alpha_i - \alpha_i^*) = 0 \quad \text{and } \alpha_i, \alpha_i^* \in [0, C] \quad (\text{Eq. 3})$$

$$5 \quad K(x_i, x_j) = \exp\left(-\frac{\|x_i - x_j\|^2}{2\sigma^2}\right) \quad (\text{Eq. 4})$$

6 The setting-up of the Gaussian-SVR model will determine the prediction performance of the  
 7 trained proxy model. Parameters need to be carefully designed to obtain good proxy models. The  
 8 hyperparameters to be optimized in proxy modeling work are summarized in Table 6:

9 **Table 6. Hyperparameters used in the proxy modeling**

| Hyperparameters                      | Symbol                | Function   |
|--------------------------------------|-----------------------|--|
| Constant                             | $C$                   | Control the penalty implemented on those inputted data that violate the margin.                |
| Half-width of the insensitivity zone | $\varepsilon$         | Determine the zone where observations are not considered as supported vectors in the SVR model |
| Kernel scale factor                  | $\frac{1}{2\sigma^2}$ | Determine how the kernel captures the local similarity   |

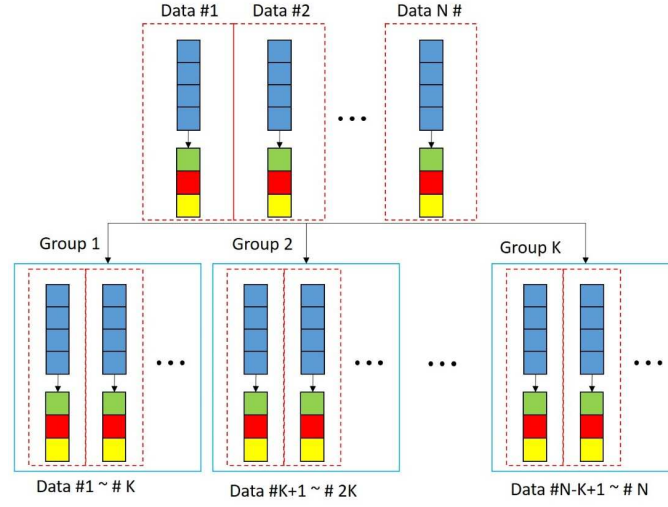

10 The Bayesian optimization algorithm (BOA) is an efficient method for the optimization of  
 11 hyperparameters when computational power is limited. One very important feature differentiating  
 12 BOA from other optimization algorithms is that BOA will use all available information based on  
 13 the previous estimation of the objective function rather than simply relying on a local gradient and  
 14 Hessian approximation,<sup>46, 47</sup> which means this method can provide a higher possibility to find the  
 15 optimal solution in limited search works.

1 The application of BOA builds on two main steps.<sup>46</sup> Firstly, one should select a prior over function  
2 that will express assumptions about the function being optimized. Secondly, an acquisition function  
3 from the model posterior is used to determine the next point.

4 For the first step, one commonly used method is Gaussian Processes (G.P.) due to its flexibility and  
5 tractability.<sup>46</sup>

6 The calculation of the acquisition function (or utility function) is based on the predictive mean  
7 function  $\mu(x; \{x_n, y_n\}, \theta)$  and the predictive variance function  $\sigma^2(x; \{x_n, y_n\}, \theta)$ .

8 The mean function and covariance are combined in the acquisition function in a certain way, and  
9 the acquisition function will be used to determine those new sampling data that are most likely to be  
10 the best ones. Commonly used acquisition functions include the Probability of Improvement,  
11 Expected Improvement, and G.P. Upper Confidence Bound.<sup>46</sup> In the training work, the knowledge  
12 base is used to train the proxy model using the K-fold cross-validation algorithm (Figure 3). In  
13 K-fold cross-validation, the original training database will be equally split into  $K$  groups. When  
14 training the proxy model, one group of data will be used as blind test data, while the other  $K-1$   
15 group will be used as the training database. Thus, a proxy model with a certain combination of  
16 hyperparameters will be trained  $K$  times using the K-fold cross-validation algorithm.

1

2 **Figure 3. Schematic plot of K-fold cross-validation. In K-fold cross-validation, the original training database**  
 3 **(containing N sets of sample data) will be equally divided into K groups. When training a proxy model, K-1**  
 4 **groups of data will be used as training data and the left group's data will be used to blind test the trained proxy.**  
 5 **The process will be looped K times until every group of data has been used in blind tests.**

6 After the trained proxy model is obtained, the absolute relative error ( $E$ ) between proxy prediction  
 7 and simulation targets is calculated based on Eq. 5:

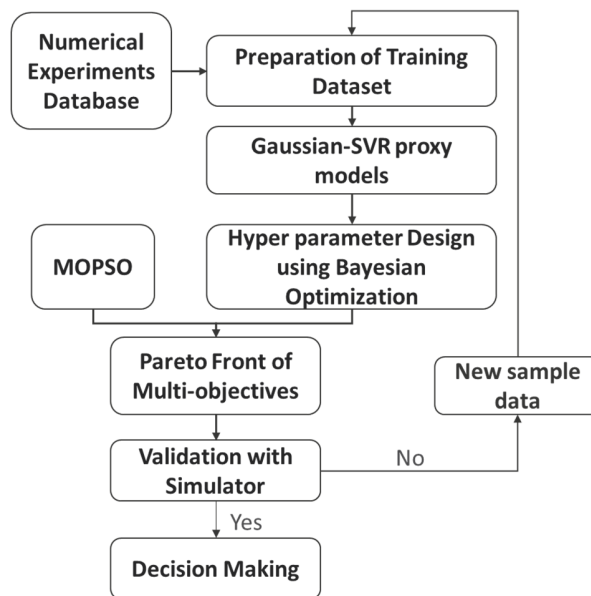

$$8 \quad E = \frac{1}{m} \sum_{n=1}^m \frac{|T_n - Y_n|}{T_n} \quad (\text{Eq. 5})$$

9 where  $T_n$  is the observed target value of  $n$ -th output,  $Y_n$  is the predicted value of  $n$ -th output, and  
 10  $m$  is the number of outputs (training targets).

11 The main advantage of the K-fold cross-validation method is that it will not waste the data obtained  
 12 already. This can be very important when obtaining more data is difficult (i.e., when conducting  
 13 more numerical simulations will take a very long time). However, this approach can lead to extra  
 14 computational time when using it in a training proxy model. That is why in this work, Bayesian  
 15 optimization is chosen as the hyperparameters optimization method.

1 **4.4 Structuring the SVR Assisted Multi-Objective Optimization Workflow**

2 As shown in Figure 4, the development of SVR proxy enables the structuring of the  
3 multi-objective optimization workflow by coupling it with the MOPSO algorithm. Pareto optimal  
4 solutions are generated to include various CO<sub>2</sub>-WAG injection designs. Although the SVR proxy  
5 is well trained with an error margin of less than 2%, inevitable uncertainties could be introduced  
6 to the Pareto fronts. An iterative loop is added to the workflow which validates the solution with  
7 the high-fidelity numerical simulator. When large disparities are observed, new data samples will  
8 be added to retrain the SVR proxy until a prescribed tolerance is reached. In the following  
9 discussions, the robustness of the proposed workflow will be validated by optimizing the  
10 CO<sub>2</sub>-WAG injection project of the FWU field.

11

12

Figure 4. Schematic chart of procedures of the workflow.

## 1 **5. Results and Discussion**

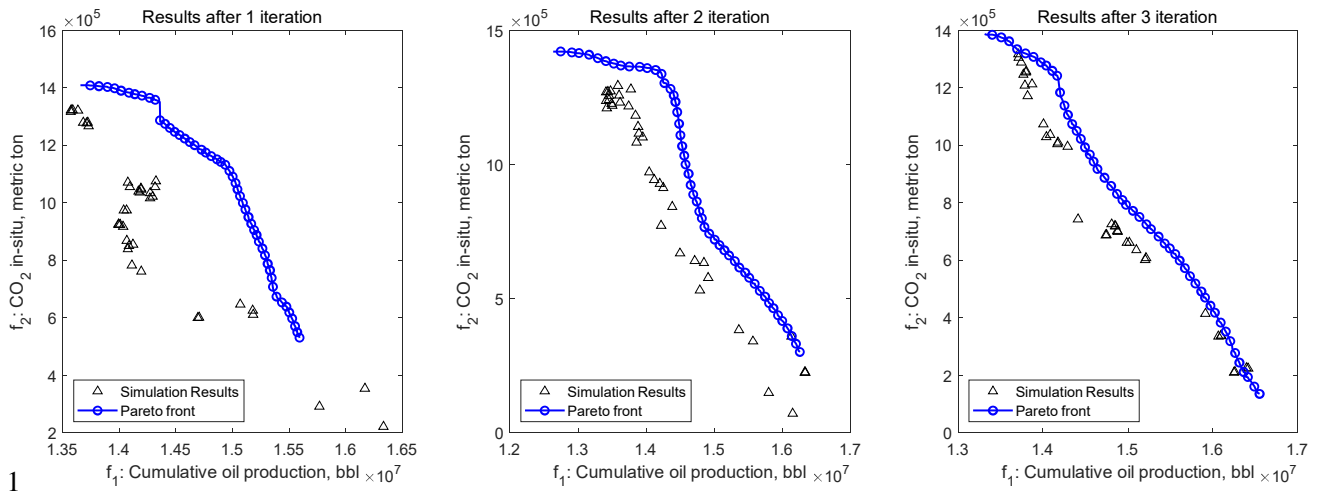

### 2 ***5.1 Optimization using Developed Multi-Objective Optimization Workflow***

3 The proposed workflow is employed to optimize the CO<sub>2</sub>-WAG operational parameter of the FWU  
4 field case. As shown in Table 7, the initial trial of the optimization indicates that the disparity  
5 between the Pareto fronts generated by the proxy and numerical simulator become less than 5%  
6 after three sets of new data samples are added.

7 **Table 7. Summary of sample datasets used in each iteration**

| Number of iterations | Sample datasets used | Error |
|----------------------|----------------------|-------|
| 1                    | 140                  | 25.8% |
| 2                    | 39                   | 20.5% |
| 3                    | 38                   | 3.8%  |
| Total                | 217                  | -     |

8 Figure 5 displays the Pareto fronts generated after each iteration when two objectives are  
9 considered (incremental oil production and incremental CO<sub>2</sub> storage). Notably, the incremental oil  
10 production and incremental CO<sub>2</sub> storage volume exclude the contribution of the history matching  
11 period (2011 to 2019).

1  
 2 **Figure 5. Pareto front (incremental oil production and incremental CO<sub>2</sub> storage) generated in each iteration, the**  
 3 **difference between prediction using proxy and simulation results is 3.8% after three iterations.**

4 The Pareto fronts indicate that the incremental oil production of the solutions on the Pareto front  
 5 ranges from 13.5 MM bbl to 16.5 MM bbl, and the incremental CO<sub>2</sub> storage ranges from 0.1 to 1.4  
 6 MM metric tons. The project NPV can also be considered in the optimization study to structure a  
 7 Pareto front in three-dimensional objective function space as shown in Figure 6.

1

2

**Figure 6. Pareto front (incremental oil production, incremental CO<sub>2</sub> storage and project NPV).**

3

To further investigate the Pareto front, its projection views into the 2-D planes are displayed in

4

Figure 7. The projection view into  $f_1$ - $f_2$  plane (Figure 7a) exhibits good agreement with the

5

two-dimensional Pareto front, which confirms the stability of the Pareto optimal solution generated

6

by the proposed workflow. The range of the incremental oil production is from 13.8 MM bbl to 16.8

7

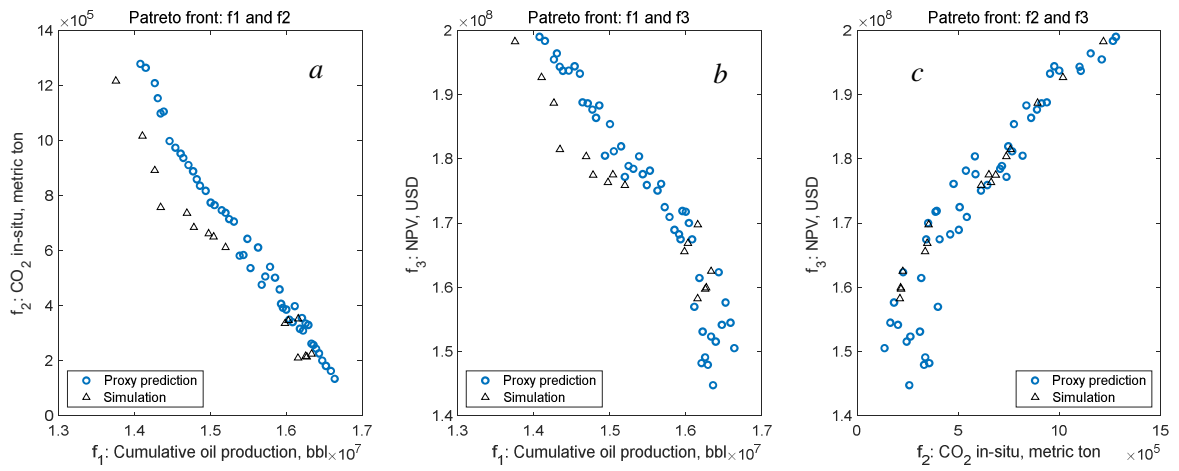

MM bbl, and the incremental CO<sub>2</sub> storage ranges from 0.17 to 1.38 MM metric tons, which are also

8

consistent with the observed in the Pareto optimal solution of two objectives. The range of the final

9

project NPV is from about  $1.45 \times 10^8$  to  $2.0 \times 10^8$  U.S. dollars.

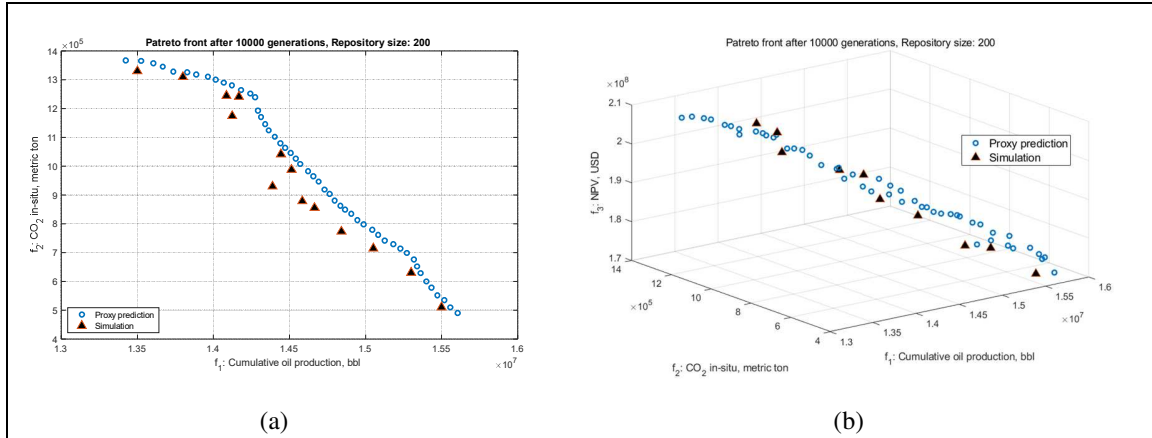

1

2 **Figure 7. View the Pareto front considering 3 objectives in a 2-D plot. (a) plot from  $f_1$  (incremental oil production)**  
 3 **and  $f_2$  (incremental  $\text{CO}_2$  storage volume) plane; (b) the plot from  $f_1$  (incremental oil production) and  $f_3$  (project**  
 4 **NPV) plane; and (c) the plot from  $f_2$  (incremental  $\text{CO}_2$  storage volume) and  $f_3$  (project NPV) plot.**

5 Practical  $\text{CO}_2$ -WAG operations would demand to sustain the reservoir pressure above the  
 6 minimum miscible pressure (MMP) and ensure a miscible displacing front.<sup>48</sup> Laboratory  
 7 experiments suggest that the minimal miscible pressure (MMP) of the hydrocarbon fluid in  
 8 Morrow B sandstone with  $\text{CO}_2$  is approximately 4000 psi.<sup>28</sup> To make sure average reservoir  
 9 pressure is maintained above the MMP, a proxy model is developed to predict the average reservoir  
 10 pressure and constrain the multi-objective optimization process.<sup>19</sup> The constrained Pareto fronts are  
 11 shown in Figure 8.

12

1 **Figure 8. Comparison between the Pareto front and numerical simulation results using some of the optimized**  
 2 **input parameters: (a) 2-objectives and (b) 3-objectives.**

3 Compared with the Pareto fronts generated without average reservoir pressure constraints, the  
 4 range of objectives covered by those with constraints is narrowed. Table 8 summarizes the  
 5 comparison between the ranges covered by Pareto fronts with and without the pressure constraint.  
 6 In the  $\text{CO}_2$ -WAG project ongoing in the Farnsworth unit,  $\text{CO}_2$  storage and oil production are  
 7 conflicting objectives, increasing in  $\text{CO}_2$  storage will typically lead to a reduction in oil production.  
 8 This is because increasing  $\text{CO}_2$  storage volume needs injecting more  $\text{CO}_2$ , which leads to the  
 9 reduction in water injections to displace additional oil to be produced. The results indicate that after  
 10 the pressure constraints are imposed, the lower limit of the  $\text{CO}_2$  storage volume range increased  
 11 while the upper limit of incremental oil production range was reduced. This indicates that those  
 12 solutions with low  $\text{CO}_2$  volume storage and high oil productions are removed from the Pareto fronts.  
 13 When oil production is high (for those Pareto optimal solutions,  $\text{CO}_2$  storage volume is low at the  
 14 same time), the reservoir depletes quickly and so does the reservoir pressure. At the same time,  
 15 more oil production at the latter stage of the project would lead to more  $\text{CO}_2$  production and lower

1 the CO<sub>2</sub> storage volume.

2 Table 9 summarizes the comparison between the results of the base case and the results of solutions  
 3 on the Pareto front. It shows that the project response suggested by the Pareto optimal outperforms  
 4 the base case result. More importantly, the developed Pareto front provides not just one solution,  
 5 but a set of optimized solutions so that decision-makers can select solutions from the repository to  
 6 meet specific requirements. For example, if the project required that 90% of CO<sub>2</sub> should be stored,  
 7 then the decision-maker could filter out those solutions with a CO<sub>2</sub> storage percentage higher than  
 8 90% and find which one has the highest oil production or project NPV from the rest of the  
 9 solutions.

10 **Table 8. Comparison between the Pareto fronts with/without average reservoir pressure constraint**

|              |                 | With constraint                                | Without constraint                          |
|--------------|-----------------|--|---|
| 2-objectives | Oil             | 13.7~15.6 MM bbl                               | 13.4~ 16.5 MM bbl                           |
|              | CO <sub>2</sub> | 0.49~1.39 MM metric ton                        | 0.18~1.40 MM metric ton                     |
| 3-objectives | Oil             | 13.3~15.7 MM bbl                               | 14.0~ 16.8 MM bbl                           |
|              | CO <sub>2</sub> | 0.42~1.4 MM metric ton                         | 0.18~1.4 MM metric ton                      |
|              | NPV             | 1.70×10 <sup>8</sup> ~2.05×10 <sup>8</sup> USD | 1.42×10 <sup>8</sup> ~2×10 <sup>8</sup> USD |

11 **Table 9. Comparison between the results of the base case and optimized solutions**

| Item  | Unit          | Value     |
|---|---------------|-----------|
| Base Case Results                                   |               |           |
| Incremental oil production                          | MM bbl        | 13.2      |

| Max % Storage of purchased CO <sub>2</sub> | percentage    | 92.9%   |

1

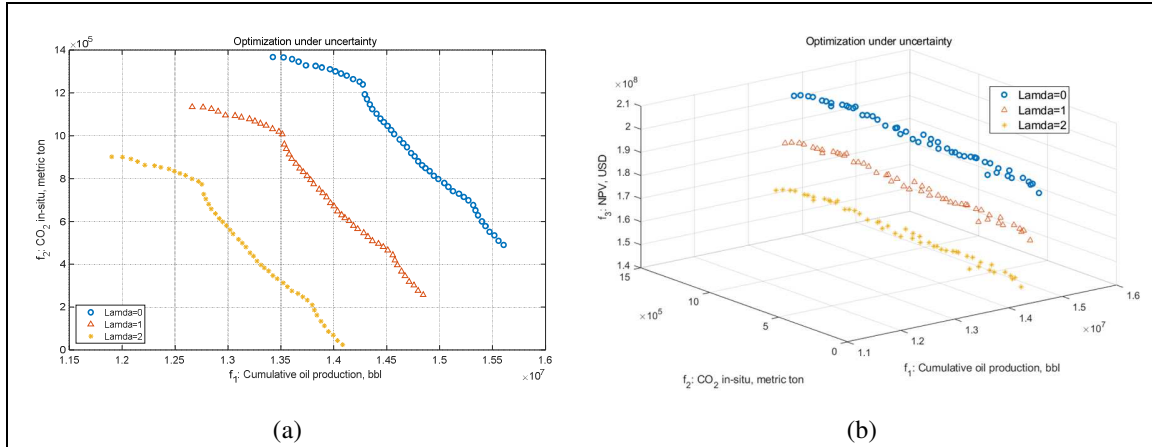

## 2 ***5.2 Optimization Results under Uncertainty***

3 In the optimization under uncertainty, the true objective function value is unknown, so some  
4 approaches should be used to estimate the confidence of the optimized results. In this work, the  
5 uncertainty of the optimization results is considered by using a combined objective function with  
6 the risk aversion factor introduced by Couet et al.<sup>49</sup> This approach is expressed as Eq. 6:

$$7 \quad \text{Combined objective function (C.F.)} = \mu - \lambda \times \sigma \quad (\text{Eq. 6})$$

8 where  $\mu$  is the mean,  $\lambda$  is the risk aversion factor, and  $\sigma$  is the standard deviation.

9 The risk aversion factor  $\lambda$  represents different levels of confidence in the results. For instance,  
10 when  $\lambda$  equals 0 it means there is a 50% probability that the true objective function value is greater  
11 than the computed objective function, while when  $\lambda$  equals 2 it means there is a 98% possibility  
12 the true objective function value is larger than the computed objective function. Figure 9 displays  
13 the results of optimization under uncertainty when two objectives and three objectives are  
14 considered, respectively.

1 **Figure 9. Comparison among the Pareto fronts with different risk factors: (a) 2-objectives and (b) 3-objectives.**

2 Table 10 summarizes the maximal incremental oil production, maximal incremental CO<sub>2</sub> storage  
 3 volume, and maximal project NPV at the end of prediction time. As the  $\lambda$  increases, the maximum  
 4 the Pareto fronts shift towards the lower ends of the objective function domains, which indicate  
 5 more conservative techno-economic project assessments.

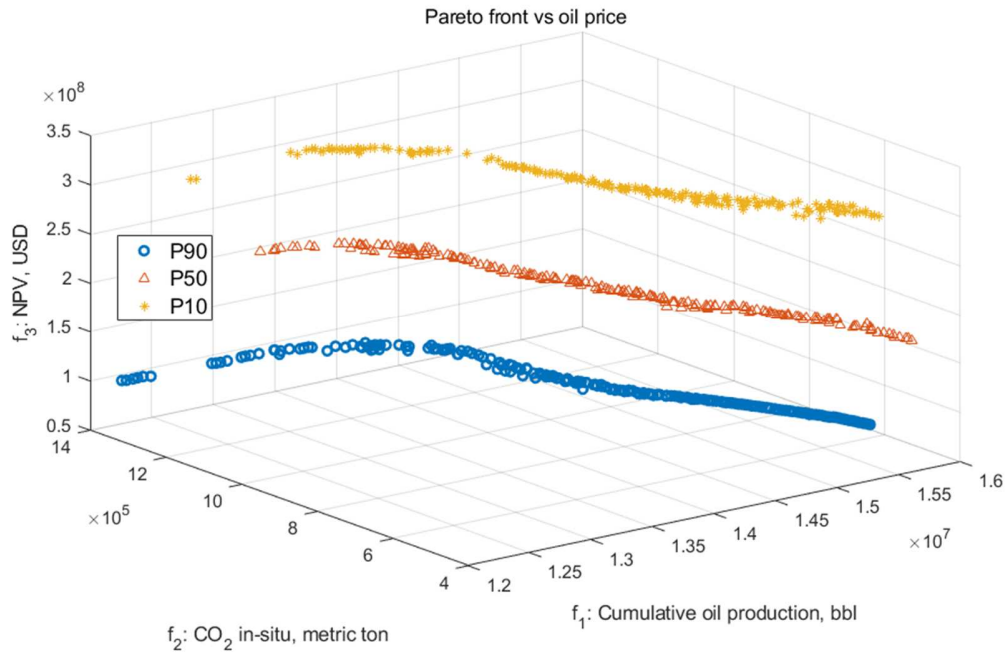

6 **Table 10 The maximal value of each objective at the end of forecasting time**

| Risk aversion factor | Oil production,<br>MM bbl | CO <sub>2</sub> storage,<br>MM metric ton | NPV,<br>MM \$ |
|----------------------|---------------------------|---|---------------|
| $\lambda = 0$        | 15.8                      | 1.37                                      | 205.60        |
| $\lambda = 1$        | 15.0                      | 1.13                                      | 193.56        |
| $\lambda = 2$        | 14.2                      | 0.90                                      | 182.27        |

7 **5.3 The Effect of Oil Price on Optimization Results**

8 Considering the drastic vibrations of the crude oil market, it is necessary to investigate the impact  
 9 of oil price on the optimization results. Assuming a base case oil price to be 50 USD/bbl, P10, P50  
 10 and P90 cases are investigated using oil prices of 70, 50 and 30 USD/bbl. P10 means that the true  
 11 oil price has a 10% possibility to be higher than the presumed oil price, with P50 and P90 having a  
 12 similar meaning. Except for oil price, other factors used in the NPV calculation are the same as the

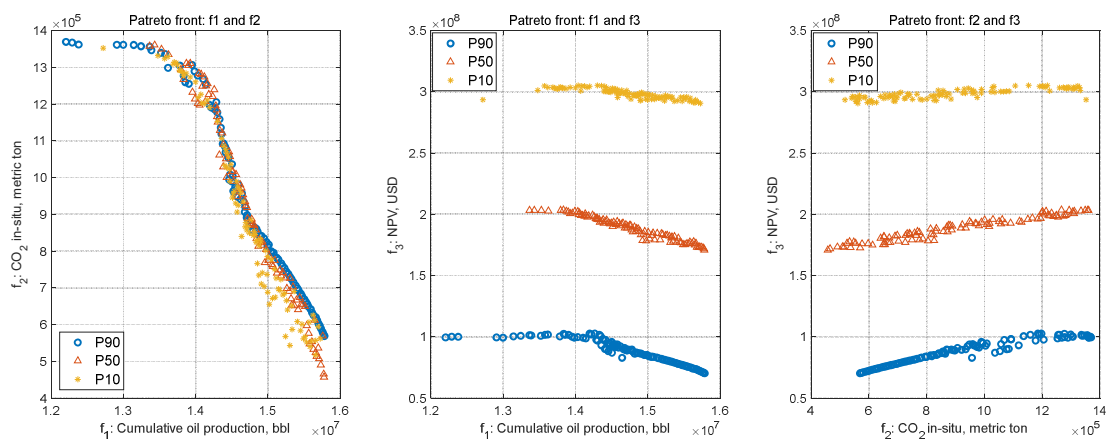

1 values listed in Table 3. The three-objective Pareto fronts and the projection views are shown in  
 2 Figure 10 and Figure 11, respectively.

3

4

**Figure 10. Comparison among the Pareto fronts with different oil prices.**

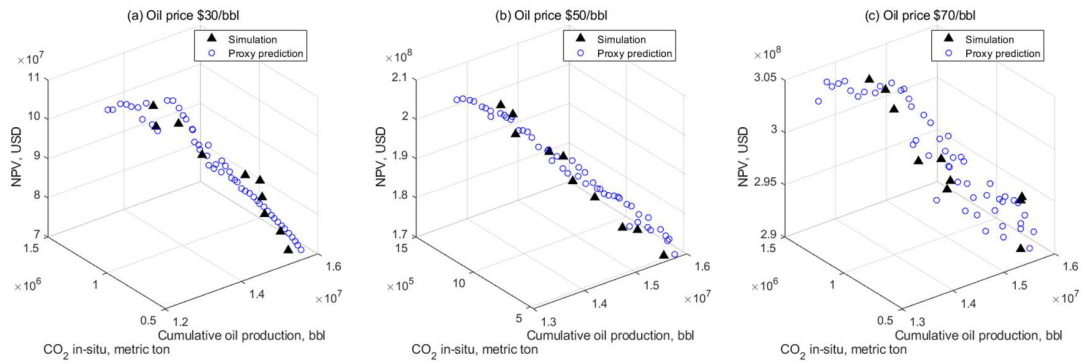

5

6

**Figure 11. A 2-D view of the comparison among the Pareto fronts with different oil prices.**

7 To validate the optimization results obtained, for each of the generated Pareto fronts, some

- 1 solutions located on the Pareto front are selected and their optimized input parameters are revisited
- 2 by the original numerical simulation model. The simulation results are compared with their
- 3 corresponding Pareto fronts that are generated using proxy models.

- 4
- 5
- 6
- 7

**Figure 12. Comparison between proxy predictions and simulation results: Proxy predictions (circle) and simulation results (black triangle). CO<sub>2</sub> storage credit: \$45/ metric ton.**

(a) CO<sub>2</sub> credit: \$45/ metric ton of CO<sub>2</sub> storage, oil price: \$30/bbl.

(b) CO<sub>2</sub> credit: \$45/ metric ton of CO<sub>2</sub> storage, oil price: \$50/bbl.

(c) CO<sub>2</sub> credit: \$45/ metric ton of CO<sub>2</sub> storage, oil price: \$70/bbl.

- 1 Figure 13. A 2-D view of the comparison between Pareto fronts generated using different oil prices (P90, P50 and P10) and corresponding simulation results (CO<sub>2</sub> credit: \$45/ metric ton).
- 2
- 3 Figure 12 and Figure 13 confirm the validity of these generated Pareto fronts by comparing the

1 results with the high-fidelity numerical simulator. It is observed that the shape of the generated  
2 Pareto front in the  $f_1$ - $f_2$  plane is very similar for all three levels of oil price, meaning that the change  
3 of the oil price has a negligible impact on the shape of the Pareto front in oil production and CO<sub>2</sub>  
4 storage volume domain. This indicates that when only oil production and CO<sub>2</sub> storage volume are  
5 considered as objectives, the Pareto-optimal solutions are mainly determined by operational  
6 development strategies, but not those economic factors to calculate project NPV. Nevertheless, the  
7 oil price has a great influence on project NPV. When oil prices change from \$30/bbl to \$70/bbl, it is  
8 obvious that both the higher and lower limit of the project NPV of the Pareto-optimal solutions are  
9 increased.

10 More importantly, when investigating Pareto front from  $f_1 - f_3$  plane and  $f_2 - f_3$  plane, it was found  
11 that the highest NPV is not always achieved at either the highest oil production or the highest CO<sub>2</sub>  
12 storage. This is because the NPV calculation considers many economic terms such as water  
13 injection cost, produced water treatment cost, CO<sub>2</sub> injection cost, and CO<sub>2</sub> purchase cost. The  
14 increase in oil production can lead to more benefits directly from selling oil, but it also increases the  
15 water injection and production as the byproduct, as well as increasing produced CO<sub>2</sub> so that the cost  
16 for those parts will increase and hence reducing the final project NPV. For the CO<sub>2</sub> storage, the  
17 reason is similar. Increasing CO<sub>2</sub> storage volume will reduce the production of oil and increase the  
18 costs of CO<sub>2</sub> injection and will lead to more cost on CO<sub>2</sub> purchases at the same time. The  
19 consideration of different economic factors in project NPV calculation makes the optimization  
20 results considering oil production, CO<sub>2</sub> storage, and project NPV very complex and even

1 counterintuitive. The trade-offs among those three objectives are much more difficult to evaluate  
2 using traditional methods.

3 Thus, when considering the project NPV as a third optimization objective, the Pareto-front-based  
4 multi-objective optimization methodology helps evaluate this kind of trade-off and hence  
5 providing more information and flexibility to the decision-maker.

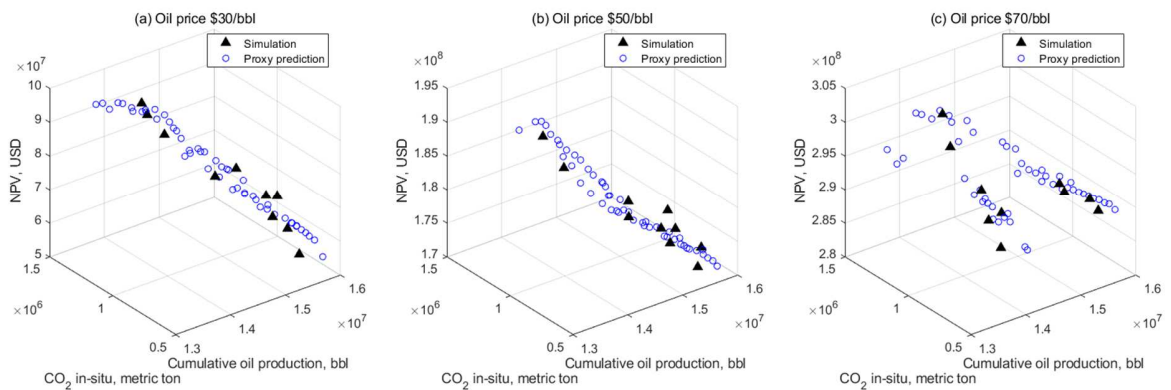

#### 6 ***5.4 The effect of a CO<sub>2</sub> storage credit on optimization results***

7 This work will also evaluate the impact of CO<sub>2</sub> storage credit on the optimization results. Aside  
8 from the oil price, another significant economic factor to determine the economic outcomes of a  
9 CCUS project is the consideration of any tax credit for CO<sub>2</sub> storage. In the U.S., according to  
10 related policies (such as Section 45Q of the US tax code<sup>50</sup>), the government will provide incentives  
11 to qualified carbon storage projects to encourage more anthropogenic CO<sub>2</sub> to be sequestered  
12 underground. The Section 45Q tax credit for carbon capture projects provides a foundational policy  
13 for increasing the deployment of carbon capture projects in the U.S. It states that the tax credit  
14 amount can be from \$35/ metric ton to \$50/ metric ton of CO<sub>2</sub> storage depending on different  
15 project types. In the previous section, the CO<sub>2</sub> credit is presumed to be \$45/ metric ton of CO<sub>2</sub>  
16 storage. In the following work, the CO<sub>2</sub> credit is set to be \$35/ metric ton of CO<sub>2</sub> storage and the  
17 multi-objective optimization is redone once to compare how the CO<sub>2</sub> storage credit influences the  
18 optimization results. The optimization process is performed under the condition that CO<sub>2</sub> tax  
19 credits are set to be \$35/ metric ton of CO<sub>2</sub> storage and the oil price is presumed to be at three  
20 different possibility levels (e.g. \$30, \$50, \$70), while the other economic parameters remain the

1 same as what is listed in Table 3.

2 Figure 14 and Figure 15 show the generated Pareto fronts for different oil prices. Some solutions  
3 located on the Pareto front are selected and their optimized input parameters are revisited by the  
4 original numerical simulation model to validate the optimization results obtained. Results of the  
5 comparison are also displayed in Figure 14 and Figure 15.

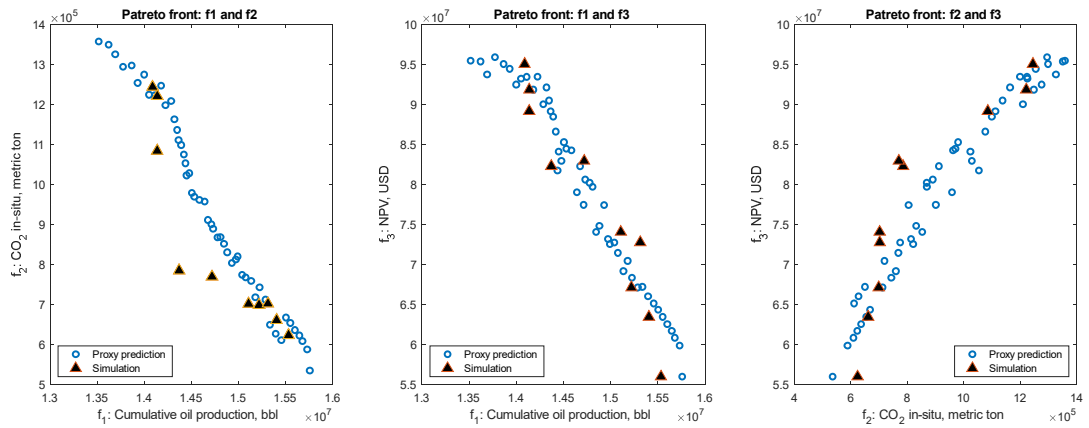

6 Figure 16 compares the Pareto fronts generated using two different CO<sub>2</sub> credits in 2-D planes. It  
7 was found that, for different values of CO<sub>2</sub> credit used, the shape of the generated Pareto front in the  
8 f<sub>1</sub>- f<sub>2</sub> plane stays almost the same. This tells us that once again, the upper and lower limits of the  
9 incremental oil production and incremental CO<sub>2</sub> storage volume of the Pareto front are mostly  
10 determined by the petrophysical properties of the numerical model. Changing economic factors  
11 will not lead to a significant impact on the range of incremental oil production and incremental CO<sub>2</sub>  
12 storage volume covered by the developed Pareto front.

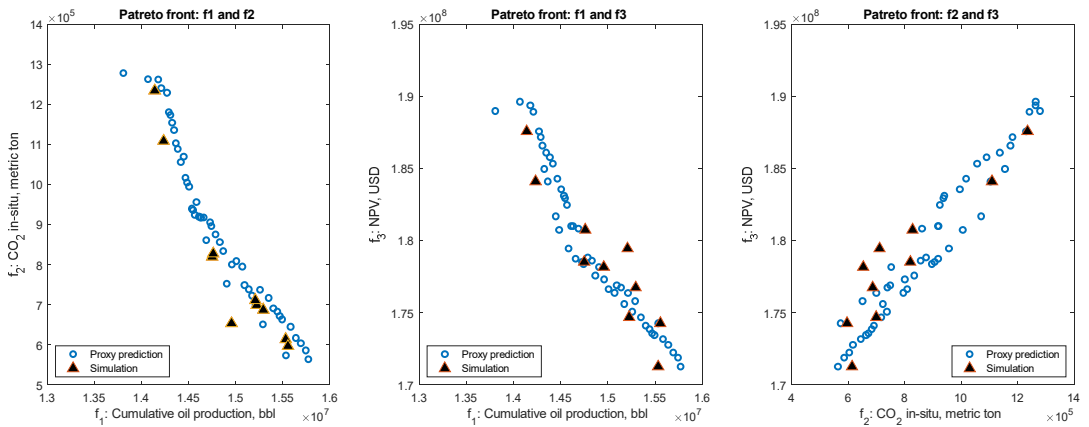

13

(b) Oil price: \$50/bbl.

(c) Oil price: \$70/bbl.

1 Figure 16. A 2-D view of the comparison between Pareto fronts under different CO2 storage credits: \$35/ metric  
 2 ton (circle) and \$45/ metric ton (square).

3

1 However, when CO<sub>2</sub> credit is increased, the upper and lower limits of the project NPV are increased  
2 since more profit can be obtained when the same volume of CO<sub>2</sub> is sequestered underground. The  
3 shapes of developed Pareto fronts in the  $f_1$ -  $f_3$  plane and  $f_2$ -  $f_3$  plane become very different when  
4 compared against those using \$45/ metric ton of CO<sub>2</sub> credit. The trend of project NPV is not  
5 monotonous, but demonstrates irregularity.

## 6 **6. Conclusion and Summary**

7 In this work, a developed Pareto-front-theory-based multi-objective optimization workflow is  
8 applied to optimize the development strategies in cooperation with FWU's geological model. The  
9 development plan for a CO<sub>2</sub>-WAG project is optimized according to a presumed CO<sub>2</sub> purchase plan  
10 of the following 20 years. Besides optimizing oil production and CO<sub>2</sub> storage, efforts are also given  
11 to assessing the project NPV that considers different economic parameters in its calculation. The  
12 impacts of oil price and CO<sub>2</sub> storage credit on project NPV are comprehensively studied. This  
13 research will serve as a benchmark and brings insights into the simultaneous optimization and  
14 techno-economic analysis of CCUS projects considering similar multiple objectives as the  
15 CO<sub>2</sub>-WAG project ongoing at FWU. The following conclusions are drawn from this work:

- 16 1. The developed Pareto-front-based multi-objective optimization workflow successfully  
17 structures the Pareto fronts considering two objectives and three objectives. The developed  
18 Pareto fronts are validated by comparing them with numerical simulation results using the  
19 same optimized input parameters.
- 20 2. When the average reservoir pressure is considered as an optimization constraint, the

1 corresponding Pareto fronts will be narrowed compared to those without such a constraint. The  
2 reason is that the optimization workflow will remove those solutions that will lead to great  
3 reservoir pressure depletion from the final generated Pareto front.

4 3. The formula used to calculate the project NPV makes the developed Pareto front considering  
5 NPV as the third objective very complex. It was found that the change in oil price and the CO<sub>2</sub>  
6 tax credit will significantly affect the generated Pareto front. However, the trade-offs among  
7 those three objectives are difficult to evaluate using traditional methods.

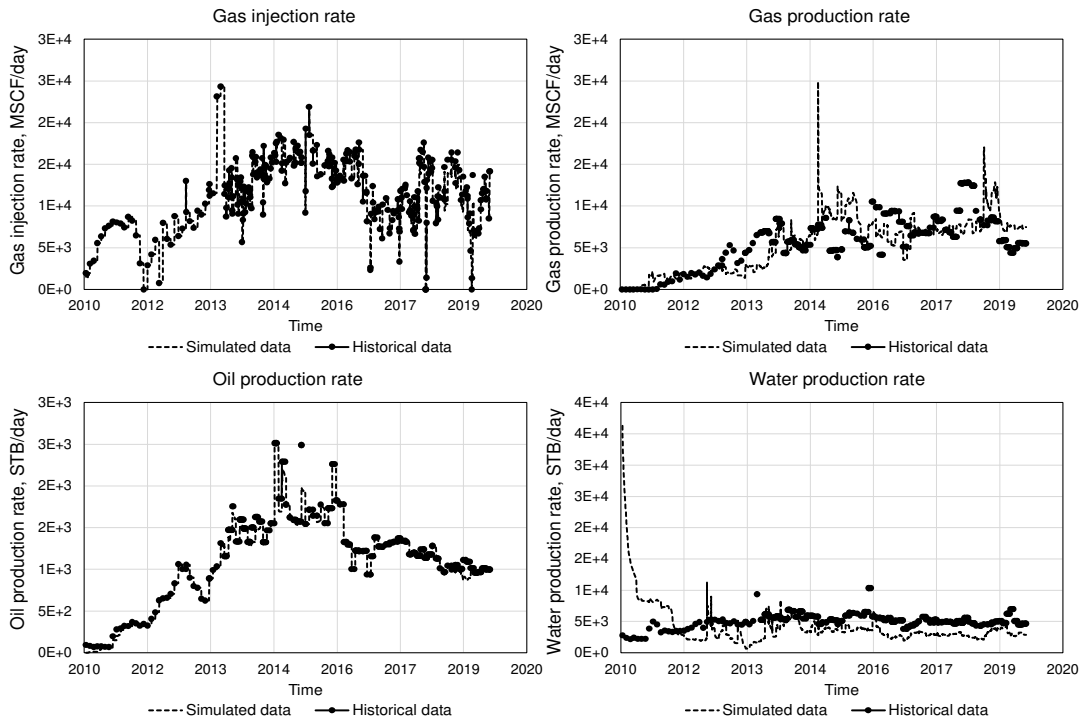

8 4. The Pareto-front-based multi-objective optimization methodology is very helpful in evaluating  
9 the trade-offs among those three objectives, and hence provides more information and  
10 flexibility to decision-makers.
