PREFACE

This report (ORNL/ER-365) was developed under Work Breakdown Structure 1.4.12.6.1.01.41.12.02.11 (Activity Data Sheet 3301, "WAG 1"). This document provides the Environmental Restoration Program with analytical results and statistical analyses from sludge and supernate samples from the Gunite and Associated Tanks. Information in this report forms part of the technical basis for criticality safety, systems safety, engineering design, and waste management as they apply to the Gunite and Associated Tanks treatability study and remediation.

CONTENTS

TABLES

ABBREVIATIONS

DQO	Data Quality Objective
GAAT	Gunite and Associated Tanks
LLLW	liquid low-level (radioactive) waste
NTF	North Tank Farm
ORNL	Oak Ridge National Laboratory
PCB	polychlorinated biphenyl
RCRA	Resource Conservation and Recovery Act
RSD	relative standard deviation
STF	South Tank Farm
TCLP	Toxicity Characteristic Leaching Procedure
TDS	total dissolved solids
TOC	total organic carbon
TRU	transuranic
TS	treatability study
TSS	total suspended solids
WAG	waste area grouping

EXECUTIVE SUMMARY

The Gunite and Associated Tanks (GAAT) are located at Oak Ridge National Laboratory in Waste Area Grouping 1. GAAT is designated as a Comprehensive Environmental Response, Compensation, and Liability Act site. GAAT is considered a high priority for remediation because of the potential risk associated with the contaminants of concern and the condition of the Gunite walls.

The objective of this report is to (1) support the GAAT treatability study and (2) provide input to the Record of Decision for the remediation of selected tanks that are part of the North Tank Farm and the South Tank Farm.

This report presents a statistical and operational evaluation of GAAT sampling and analysis data from various tanks in the North Tank Farm and the South Tank Farm.

1. INTRODUCTION AND OVERVIEW

The Gunite and Associated Tanks (GAAT) are located at the Oak Ridge National Laboratory (ORNL) in Waste Area Grouping (WAG) 1. The tanks and the associated structures and appurtenances were constructed between 1943 and 1951. The tanks were designed to contain radioactive and chemical wastes generated by ORNL operations. GAAT is designated as a Comprehensive Environmental Response, Compensation, and Liability Act site.

There are 12 Gunite tanks and four stainless-steel tanks (W-1A, W-13, W-14, and W-15) located in the GAAT Operable Unit (OU). The GAAT OU is situated in a high-traffic area in the middle of the ORNL site. The North Tank Farm (NTF) is composed of tanks W-1, W-1A, W-2, W-3, W-4. W-13, W-14, and W-15. The South Tank Farm (STF) is composed of tanks W-5, W-6, W-7, W-8, W-9, and W-10. Tank W-11 is located east of the STF. Tank TH-4 is located southwest of Building 3500.

1.1 OBJECTIVES

The objective of this report is to (1) support the GAAT treatability study (TS) and (2) provide input to the Record of Decision (ROD) for the remediation of selected tanks that are part of the NTF and STF. This report presents an evaluation of GAAT sampling and analysis data from various tanks in the NTF and the STF.

1.1.1 GAAT Phase II Major Questions

The key questions associated with the Data Quality Objectives (DQOs) identified for Phase II sampling and analysis (U.S. DOE 1995) are presented. Only Question 1 is examined in this report.

- Question 1. What is the spatial homogeneity or heterogeneity of key chemical and radionuclide concentrations in tanks suspected of significant curie loading?
- Question 2. What are the locations and the composition of sludge and debris in the tanks?
- Question 3. What is the integrity of the tank walls?
- Question 4. What is the extent of contamination in the tank walls?

1.1.2 Additional Areas of Evaluation

Additional areas of evaluations and their scope are presented as follows:

- Determine current values for tank volumes. Sludge and supernate volumes for all tanks are updated based on Phase II sludge mapping information.
- Determine curie loading for each tank. Using Phase I and Phase II data, in addition to 1988 sampling data, curie loadings for sludge and supernate are determined.
- Determine tanks that are transuranic (TRU) and non-TRU under DOE Order 5820.2A. Using Phase I and Phase II data, tanks are classified as TRU or non-TRU.

- Describe risk/transport drivers for tanks. Using Phase I and Phase II data, the beta/gamma radioisotopes in the sludge and supernate that significantly affect GAAT transport modeling are determined.
- Describe physical properties of tanks. The physical properties of the sludge and supernate are updated based on additional Phase II data.
- Determine which tanks exceed Resource Conservation and Recovery Act (RCRA) metals standards. Identification of which tanks exceed RCRA metals standards in the sludge and supernate are updated based on additional Phase II data.
- Describe concentrations of process metals for tanks. The concentrations of process metals in the sludge and supernate are updated based on additional Phase II data.
- Describe concentrations of anions for tanks. The concentrations of anions in the sludge and supernate are updated based on additional Phase II data.
- Describe concentrations of other chemicals and radioisotopes [e.g., alkaloids, polychlorinated biphenyls (PCBs), etc.] for tanks. The concentrations in the sludge and supernate are updated based on additional Phase II data.

1.2 SCOPE

The scope of this evaluation is to evaluate sludge and supernate radiological, inorganic, and wet chemistry sample data for the Gunite tanks W-1, W-2, W-3, W-4, W-5, W-6, W-7, W-8, W-9, W-10, W-11, and TH-4. Tank Group 1 (W-1, W-2, W-11); Tank Group 2 (W-3, W-4, W-5, W-6, TH-4); and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational grouping definitions of the GAAT. The programmatic decision was made in the GAAT TS not to collect samples from the stainless-steel tanks (W-1A, W-13, W-14, and W-15), and these tanks are not evaluated in this report.

Organic analyses were performed in addition to radiological, inorganic, and wet chemistry sample data for Tanks W-6, W-7, W-8, W-9, and W-10 sludges or supernates. Organic results were not evaluated as part of this report.

The Toxicity Characteristic Leaching Procedure (TCLP) was performed on sludges from samples W-3S309, W-4S306, W-6S311, W-7H303, and W-10S325. TCLP results were not evaluated as part of this report. Draft TCLP results are presented for GAAT RCRA metals.

The sludge diffusion coefficient, K_d, was not evaluated as part of this report.

Sample identification is presented in Table 1.1. Phase II GAAT sampling was performed during the May through August 1995 time frame (Energy Systems 1996) and followed the GAAT Phase II sampling and analysis plan (U.S. DOE 1995). Phase I GAAT sampling was performed during the August–November 1994 time frame (Energy Systems 1995) and followed the GAAT Phase I sampling and analysis plan (U.S. DOE 1994). Sampling in 1988 (U.S. DOE 1993) followed the inactive tank sampling and analysis plan (U.S. DOE 1988). All relevant information pertaining to sample locations, sampling methods, analytical methods, and associated error sources are contained in these references. Analytical methods were selected based upon existing methods for which minimum analytical error could be expected.

Sample locations and sampling methods were selected to ensure representative samples were collected. A schematic representation of sludge sample locations is presented in Fig. 1.1. Both 1988

and Phase I sludge samples were obtained using a Lexan Push Tube. Phase II samples were obtained using Lexan Push Tube, a Stainless Push Tube, or a Clamshell Grab sampler. Supernate samples for 1988 and Phase I were obtained using a Peristatic Pump from Phase I locations. No Phase II supernate samples were collected.

Table 1.1 Identification of samples evaluated

Tank	Phase II				Phase I			1988 [1]		
	Sludge	Hard Sludge	Super-nate	Gunite Wall	Sludge	Hard Sludge	Super-nate	Sludge	Hard Sludge	Super-nate

[1] 1988 samples are combined with Phase I and Phase II samples to form the curie loading data base. This data based is used to compute curie loading only. See Chap. 4 and Appendix D.

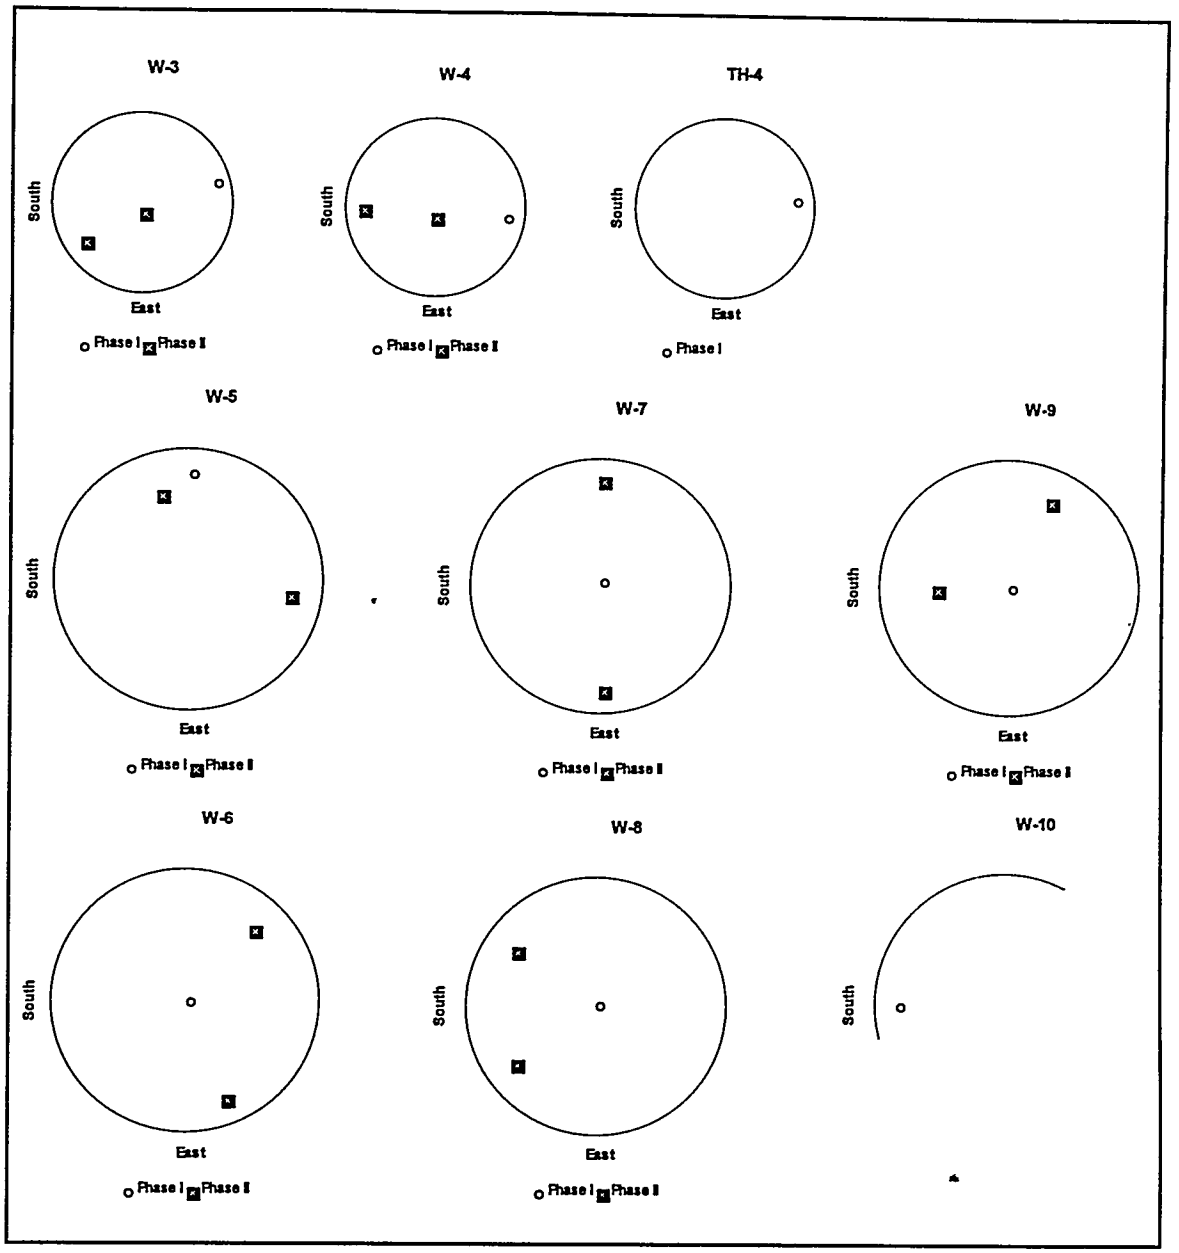

Fig. 1.1 Locations for Phase I and Phase II GAAT sludge samples.

1.3 OVERVIEW OF RESULTS

1.3.1 DQO Question 1. What is the spatial homogeneity or heterogeneity of key chemical and radionuclide concentrations in tanks suspected of significant curie loading?

The answer to this question requires three inputs: (1) an identification of the tanks suspected of significant curie loading, (2) an identification of key chemicals and radionuclides, and (3) an explanation and criteria for spatial homogeneity or heterogeneity. This information is used to identify the spatial homogeneity or heterogeneity of the key chemical and radionuclide concentrations in tanks suspected of significant curie loading.

- Input 1: Tanks contained in Tank Group 3 contains 96% of the expected (or most likely) curies in the sludge (13,420 Ci out of 14,019 Ci) and 90% of the expected curies in supernate (3,639 Ci out of 4,027 Ci) for all tank groups. Tanks suspected of significant sludge curie loading in Tank Group 3 are W-10 (6,536 Ci), W-8 (3,714 Ci), and W-7 (2,367 Ci). Tanks suspected of significant supernate curie loading in Tank Group 3 are W-8 (2,065 Ci) and W-10 (1,123 Ci). Tank W-6 in Tank Group 2 is suspected to contain 87% of the expected curies in sludge for Tank Group 2 (523 Ci out of 599 Ci) and 94% of the expected curies in supernate (364 Ci out of 388 Ci). Tank Group 1 accounts for 0% of the expected curies in the sludge and supernate. See Chap. 4 and Appendix D for details.

- Input 2: The key chemicals and radionuclides are (1) TRU radioisotopes (Np-237, Pu-238, Pu-239, Pu-240, Pu-242, Pu-244, Am-241, Am-242m, Am-243, Cm-243, Cm-246, Cm-247, Cm-248, Bk-247, Cf-249, Cf-251, and including the use of Pu-alpha measurements); (2) key risk and transport drivers (Sr-90 and Cs-137); (3) physical properties [total dissolved solids (TDS), total suspended solids (TSS), pH, moisture %, density, total carbon]; (4) RCRA metals (Ag, As, Ba, Cd, Cr, Hg, Ni, Pb, Se, Tl); (5) process metals (Al, B, Be, Ca, Co, Cu, Fe, K, Mg, Mn, Na, Sb, Si, Sr, Th, U, V, Zn); and (6) anions (Br, Cl, F, NO3, PO4, SO4). See Chaps. 5, 6, 7, 8, 9, and 10, and Appendices B and C for details.

- Input 3: Spatial homogeneity or heterogeneity is determined by the variability of average concentrations of the key chemicals and radionuclides. High variability indicates a heterogeneity in average concentrations, and low variability indicates a homogeneity in concentrations. The relative standard deviation (RSD) is a statistical measure for variability. The RSD is defined as the ratio of the standard deviation of a sample data set to the average obtained from the data set. The RSD is expressed as a percentage. Large RSD percentages (> 100%) indicate a heterogeneity in average concentrations, and low percentages (< 25%) indicate a homogeneity in average concentrations. For example, a heterogeneous average concentration of a radionuclide in sludge with an average of 1.00E+04 Bq/g and an RSD of 100% would indicate an upper 3-sigma value of 4.00E+04 Bq/g. Similarly, a heterogeneous average concentration of a radionuclide in sludge with an average of 1.00E+04 Bq/g and an RSD of 25% would indicate an upper 3-sigma value of 1.75 E+04 Bq/g. See Chaps. 5, 6, 7, 8, 9, and 10, and Appendices B and C for details.

The spatial heterogeneity of key chemical and radionuclide concentrations in tanks suspected of significant curie loading is presented in Table 1.2. If a chemical or radionuclide is presented in this table, the RSD is greater than 100%. For information purposes, the tanks with significant curie loading are presented. Note that since Tank Group 1 does not contribute to the curie loading, information for this tank group is not provided.

Note that all (1) sample locations and sampling methods were selected to ensure representative samples would be collected, and (2) analytical methods were selected to minimize analytical error. Statistics for spatial homogeneity or heterogeneity of key chemical and radionuclide concentrations are contained Appendices B and C. Details for curie loading are contained in Chap. 4 and Appendix D.

Table 1.2. Sludge spatial heterogeneity in tanks with significant curie loading

Tank ID	Chemical or Radionuclide	Heterogeneity Statistics Average Concentration and RSD	Significant Curie Loading Information
Tank Group 3			Most likely = 13,420 curies 96% of total sludge curies all Tank Groups
W-10			Most likely = 6,536 curies 59% of total sludge curies in Tank Group 3
	U-234	210.2 Bq/g, RSD = 106%	
	U-238	2.2 Bq/g, RSD = 105%	
W-8			Most likely = 3,714 curies 34% of total sludge curies in Tank Group 3
	Hg	184.23 mg/kg, RSD = 109%	
W-7			Most likely = 2,367 curies 21% of total sludge curies in Tank Group 3
	Ba in sludge	81.24 mg/kg, RSD = 108%	
	Cr in sludge layers	859 mg/kg, RSD = 114%	
	Ni in sludge layers	95.3 mg/kg, RSD = 123%	
	Pb in sludge layers	60.5 mg/kg, RSD = 106%	
	Fe in sludge layers	10,544 mg/kg, RSD = 131%	
	Mn in sludge layers	257.8 mg/kg, RSD = 121%	
	Sr-90 in sludge layers	6.9E+04 Bq/g, RSD = 102%	
	Cm-244 in sludge layers	287 Bq/g, RSD = 108%	
	Pu-240 in sludge layers	20.2 Bq/g, RSD = 117%	
	Pu-241 in sludge layers	98.6 Bq/g, RSD = 114%	
	Al in sludge Gunite chips	594 mg/kg, RSD = 137%	
	Sr-90 in sludge Gunite chips	5.9E+04 Bq/g, RSD = 98%	
Tank Group 2			Most likely = 599 curies 4% of total sludge curies all Tank Groups
W-6			Most likely = 523 curies 87% of total sludge curies in Tank Group 2
	Pb	3,480 mg/kg, RSD = 97%	
	Mg	1,459 mg/kg, RSD = 126%	
	U	39,287 mg/kg, RSD = 115%	

1.3.2 Current Values for Tank Volumes

Current values for tank sludge and supernate volumes are presented in Table 1.3. Data is from GAAT Phase I sampling and Phase II sludge mapping. Details for volumes are contained in Chap. 3.

Table 1.3 Sludge and supernate volume estimates

Tank	Capacity (gal)	Sludge Volume (gal)	Supernate Volume (gal)	Total Volume (gal)
W-1	4,800	0	2,926	2,926
W-2	4,800	0	1,995	1,995
W-3	42,500	628	15,688	16,316
W-4	42,500	1,313	29,754	31,067
W-5	170,000	3,422	27,964	31,386
W-6	170,000	7,037	41,479	48,516
W-7	170,000	8,812	3,565	12,377
W-8	170,000	10,309	64,581	74,890
W-9	170,000	2,861	45,616	48,477
W-10	170,000	9,298	105,860	115,158
W-11	1,500	0	722	722
TH-4	14,000	5,452	5,410	10,862
	Total	49,132	345,560	394,692

1.3.3 Curie Loadings for Tanks

The median and upper 95%-tile value for curie loadings in sludge and supernate are presented for all tanks in Table 1.4 and Table 1.5, respectively. For ease in discrimination of tanks and tank groups, the curie loadings are ordered by maximum to minimum median values. Data used for the curie loadings is from GAAT Phase I and Phase II, and from the 1988 data set. The minimum number of observations per tank for all radioisotopes used to compute the median and the upper 95%-tile curie values is one, and the maximum number of observations is per tank for all radioisotopes is five. Decay corrections for the 1988 data have not been included. Details for curie loading are contained in Chap. 4 and Appendix D.

Table 1.4. Sludge curie loading for all GAAT tanks ordered by tank groups

Sludge Tank	Tank Group	Median Ci(0.50)	95%-tile Ci(0.95)
W-10	3	6,536	18,764
W-8	3	3,714	4,386
W-7	3	2,367	3,461
W-9	3	803	950
W-6	2	523	861
W-4	2	32	89
W-5	2	24	40
W-3	2	16	37
TH-4	2	4	6
W-1	1	0	0
W-2	1	0	0
W-11	1	0	0

Table 1.5. Supernate curie loading for all GAAT tanks ordered by tank groups

Supernate Tank	Tank Group	Median Ci(0.50)	95%-tile Ci(0.95)
W-8	3	2,065	2,511
W-10	3	1,123	2,197
W-6	2	364	2,178
W-7	3	238	238
W-9	3	212	272
W-4	2	13	63
W-5	2	10	14
W-3	2	1	2
TH-4	2	0	0
W-1	1	0	0
W-2	1	0	0
W-11	1	0	0

1.3.4 Tanks that are TRU and Non-TRU Under DOE Order 5820.2A

Sludge in tanks as classified TRU and non-TRU under DOE Order 5820.2A as determined on a wet basis are presented in Table 1.6. The criteria for classification of GAAT tanks as TRU

is: if the concentration of TRU radioisotopes is greater than 100 nCi/g, the tank is classified as TRU; if not, the tank is classified as not TRU. Tanks that are considered TRU are: W-3, W-4, W-6, W-8, W-9, W-10.

Pu-alpha measurements and concentrations of TRU radioisotopes in sludge (Np-237, Pu-238, Pu-239, Pu-240, Pu-242, Pu-244, Am-241, Am-242m, Am-243, Cm-243, Cm-246, Cm-247, Cm-248, Bk-247, Cf-249, Cf-251) are used to determine if a tank in considered TRU or non-TRU. Pu-alpha measurements are used as a screening tool. These values are presented as the median (50%-tile) and the maximum observed value. If there is a conflict in the decision of the tank being TRU or non-TRU based on Pu-alpha values, the maximum cumulative value of TRU isotopics is used to determine if the tank is classified as TRU or non-TRU.

Using Pu-Alpha as a screening tool, the TRU conclusion differs for only Tanks W-3 and W-4. This is due to high variability observed between Phase I and Phase II sludge samples. Median and the Maximum nCi/g values are presented for comparative purposes to identify whether any difference in values can be attributed to Phase I or Phase II sampling and analysis. Such information is contained in the explanation portion of Table 1.6. Note that a "-" indicates no data or explanation is required. Details are contained in Chap. 5.

Table 1.6 Tanks that are TRU and non-TRU under DOE Order 5820.2A (determined by wet basis)

Tank Group	Tank	Pu-Alpha (nCi/g) Median	Pu-Alpha (nCi/g) Maximum	TRU Isotopes (nCi/g) Maximum (1)	Conclude TRU? Yes/No	Explanation	Min % Moisture
2	W-3	81	132	155	Yes	RSD > 80% for isotopics. Maximum in Phase I Samples	57.6
2	W-4	74	324	329	Yes	RSD > 100% for isotopics. Phase I samples < 100 nCi/g Phase II samples > 100 nCi/g	63.5
2	W-5	14	16	-	No	-	68.3
2	W-6	149	219	-	Yes	-	61.5
2	TH-4	2	2	-	No	-	34.5
3	W-7	59	89	-	No	-	57.7
3	W-8	219	246	-	Yes	-	78.6
3	W-9	324	676	-	Yes	-	82.8
3	W-10	297	432	-	Yes	-	61.1

(1) These include U-233 and Cm-244 values

1.3.5 Risk/Transport Drivers for Tanks

Beta/gamma emitters, particularly Sr-90 and Cs-137, are considered significant variables in the transport and human health and environmental risk modeling for GAAT. Summary statistics for Sr-90 and Cs-137 concentrations for individual tanks in Tank Group 2 and 3 are presented in Table 1.7. Details are contained in Chap. 6.

A graphical portrayal of the average Sr-90 and Cs-137 concentrations for each tank is presented in the stacked bar chart in Fig. 1.2. The way to read this figure is, for example, the average concentration of Cs-137 in W-10 sludge is 1.15E+06 Bq/g. The total average concentration of Sr-90 and Cs-137 in W-10 sludge is 4.52E+06 Bq/g. The average concentration of Sr-90 in W-10 sludge is the difference, namely 3.37E+06 Bq/g.

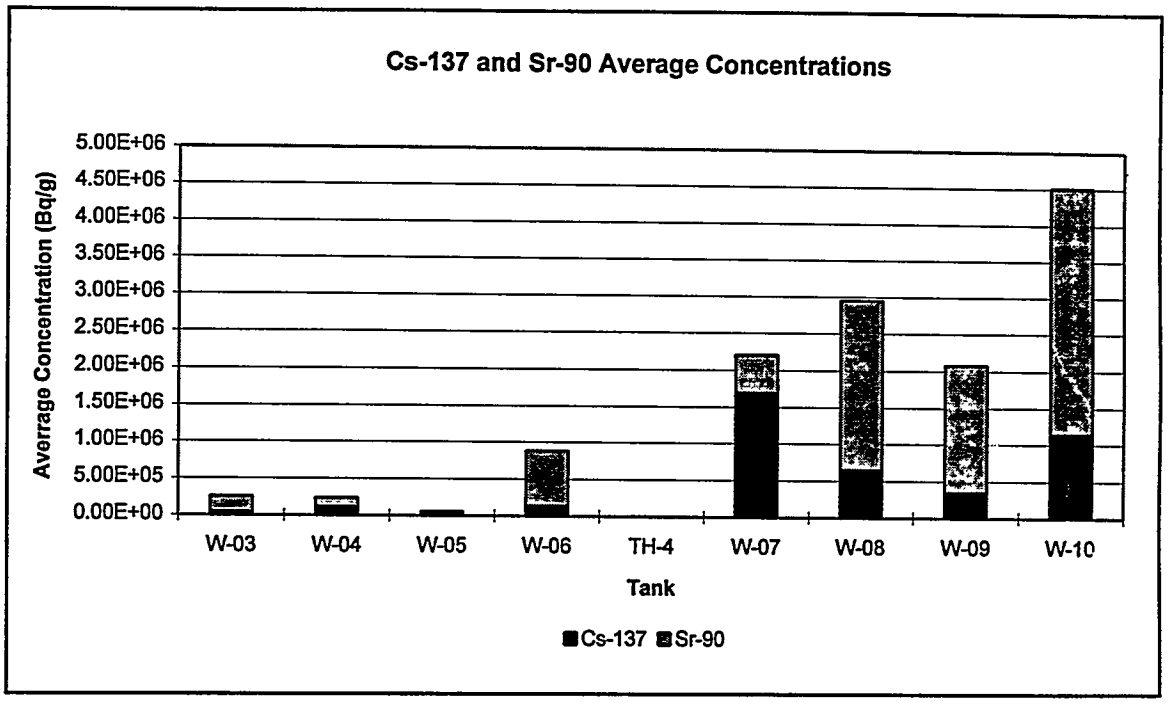

Fig. 1.2. Cs-137 and Sr-90 concentrations for sludge.

Several observations of the average concentrations and the spatial homogeneity or heterogeneity of the Sr-90 and Cs-137 concentrations are made:

- Tanks W-8, W-9, and W-10 indicate the largest average concentration of Sr-90 (> 1.73E+06 Bq/g).
- Tanks W-7 and W-10 indicate the largest average concentration of Cs-137 (> 1.15E+06 Bq/g).
- Tanks W-3 and W-4 exhibit the most heterogeneity for Sr-90 average concentration (RSD ~ 100%).
- Tank W-4 exhibits the most heterogeneity for Cs-137 average concentration (RSD > 100%).
- Tanks W-8 and W-9 exhibit the most homogeneity for Sr-90 average concentration (RSD < 25%).

- Tanks W-3, W-5, W-8, W-9, and TH-4 exhibit the most homogeneity for Cs-137 average concentration (RSD < 25%).

Table 1.7. Summary statistics for Sr-90 and Cs-137 concentrations in sludge

Tank	Tank		Sr-90 (Bq/g)		Cs-137 (Bq/g)	
ID	Group	N	Average	RSD	Average	RSD
W-3	2	3	2.13E+05	150%	4.53E+04	5%
W-4	2	4	1.22E+05	93%	1.21E+05	123%
W-5	2	3	3.97E+04	86%	1.93E+04	23%
W-6	2	3	7.47E+05	65%	1.40E+05	33%
TH-4	2	3	1.80E+03	53%	6.40E+02	3%
W-7	3	7	5.08E+05	79%	1.70E+06	47%
W-8	3	3	2.30E+06	24%	6.53E+05	20%
W-9	3	3	1.73E+06	3%	3.50E+05	10%
W-10	3	3	3.37E+06	35%	1.15E+06	42%

1.3.6 Physical Properties and Miscellaneous Data for Tanks

Supernate physical properties examined are TSS, TDS, density, pH, and total organic carbon (TOC). Sludge physical properties examined are % moisture, density, TOC, and pH. Medians of the physical properties in supernate for each tank group are presented in Table 1.8. TSS and TDS in Tank Group 2 exhibit high spatial variability, which is due to high values in TH-4 and W-6. Details are contained in Chap. 7. Medians of the physical properties in sludge for each tank group are presented in Table 1.9. The TOC RSD in Tank Group 2 is 97%, and it is due to high physical property concentrations in TH-4 and W-6. All other RSDs for Tank Group 2 and 3 are less than 75%.

Table 1.8. Summary of supernate physical properties for tank groups

Physical Property in Supernate	Tank Group 1 Median	Tank Group 2 Median	Tank Group 3 Median
TSS (mg/mL)	0.9	1.8	0.7
TDS (mg/mL)	0.2	9.6	11.0
Density (g/mL)	1.00	1.02	1.01
TOC (mg/L)	7.5	77.0	89.0
pH	8.30	9.60	9.85

NC = Not Calculated

Table 1.9. Summary of sludge physical properties for tank groups

Physical Property in Sludge	Tank Group 2 Median	Tank Group 3 Median
% Moisture (%)	69.7	72.8

1.3.7 Tanks Exceeding RCRA Metals Standards

Some GAAT supernate and sludge samples exceed RCRA criteria. The samples are derived obtained from Phase I and Phase II sampling. RCRA metals are Ag, As, Ba, Cd, Cr, Hg, Ni, Pb, Se, and Tl . RCRA metals that exceed RCRA standards for supernate are presented in Table 1.10. Table 1.11 presents information regarding sludge concentrations based upon the application of U.S. Environmental Protection Agency TOX.

In Tables 1.10 and 1.11, the criteria are contained in the table header for each RCRA metal. The tabular entries identify the number of samples upon which the statistics are based, the average, and the RSD. When there are two observations, the median and the average are equal. Blank entries indicate the RCRA metal criteria was not exceeded in the tank. Details are contained in Chap. 8.

Table 1.12 presents the results from TCLP criteria and the subsequent 20:1 dilution of metal contaminants in the leachate performed on the sludge metals (Giaquinto, Keller, and Mills 1996). Blank entries indicate the RCRA metal criteria was not exceeded in the tank.

Table 1.10. RCRA metals in GAAT supernates that exceed dilution-based RCRA standards

Tank	Statistic	Cr (5 mg/L)	Hg (0.2 mg/L)	Tl (0.9 mg/L)
W-3	N Average RSD	2 7.63 53%		
W-4	N Average RSD	1 6.95 0%		
W-8	N Average RSD	1 7.6 0%	1 0.328 0%	1 1.02 0%
W-9	N Average RSD			1 2.06 0%

Table 1.11. RCRA metals in GAAT sludges that exceed dilution-based RCRA standards

Tank	Statistic	Cr (100 mg/kg)	Hg (4 mg/kg)	Pb (100 mg/kg)
W-3	N Average RSD	3 336.0 34%	3 15.1 53%	
W-4	N Average RSD	4 228.3 29%	4 24.4 112%	
W-5	N Average RSD	3 1273.3 22%	3 103.6 29%	3 283.0 22%
W-6	N Average RSD	3 1363.3 31%	3 78.3 46%	3 3480.0 97%
W-7	N Average RSD	5 198.2 49%	5 150.8 43%	
W-8	N Average RSD	3 258.7 21%	3 184.2 109%	3 1370.0 14%
W-9	N Average RSD	3 119.7 8%	3 66.7 11%	3 496.0 3%
W-10	N Average RSD	3 169.0 27%	3 225.0 51%	3 699.7 32%
TH-4	N Average RSD	3 281.0 29%	3 7.4 15%	

Table 1.12. TCLP (1/g) results for RCRA metals in GAAT sludges

Tank	Cr (5 ppm)	Hg (0.2 ppm)	Pb (5 ppm)
W-3			None Leached
W-4		None Leached	None Leached
W-6		0.206 µg/ml Exceeds Std	None Leached
W-7		1.8 µg/ml Exceeds Std (1)	None Leached
W-10		0.402 µg/ml Exceeds Std	None Leached

(1) Exceeds standard when 20% error is incorporated into results

1.3.8 Concentrations of Process Metals for Tanks

Process metals exhibit a wide range of variability between and within tank groups. Tanks are identified in Table 1.13 for those tanks which have the maximum concentration for each process metal for sludge and supernate in each tank group. For example, W-7 exhibits the maximum concentration of boron (B) in sludge for Tank Group 3. Details are contained in Chap. 9.

Table 1.13. Identification of tanks with maximum values of process metals for tank groups

Tank Group	1	2	2	3	3
Metal	Supernate	Sludge	Supernate	Sludge	Supernate
Al	W-1	W-3	W-3	W-10	W-10
B	W-2	W-5	TH-4	W-7	W-8
Be	NC	W-4	NC	W-8	NC
Ca	W-1	W-6	TH-4	W-10	W-8
Co	NC	W-6	TH-4	W-10	W-9
Cu	W-1	W-6	W-5	W-7	W-9
Fe	W-1	W-6	TH-4	W-7	W-9
K	W-2	W-5	TH-4	W-7	W-9
Mg	W-2	W-6	TH-4	W-8	W-8
Mn	NC	W-5	TH-4	W-7	W-9

Zn	NC	W-6	W-5	W-10	W-10

NC = Not Calculated

1.3.9 Concentrations of Anions for Tanks

Medians of the concentrations for water soluble anions in supernate for each tank group is presented in Table 1.14. In most cases, Tank Group 3 contains the maximum median values, and Tank Group 1 contains the minimum median values. Although the number of samples is limited, Tank Group 2 exhibits high spatial variability in anion concentration in supernate. This is due to high anion concentrations in TH-4 and W-6. The thick supernate levels in these tanks may also have contributed to these high RSDs. Details are contained in Chap. 10.

Table 1.14. Supernate anion median concentrations (mg/L) for Tank Groups 1, 2, and 3

Anion	Median Tank Group 1	Median Tank Group 2	Median Tank Group 3
Bromide	NC	NC	NC
Chloride	4.5	51.6	306.0
Fluoride	1.7	253.5	61.0
Nitrate	11.9	1,580.0	2,500.0
Phosphate	2.4	566.0	696.0
Sulphate	12.6	676.0	408.0

NC = Not Calculated

Medians of the concentrations for anions in sludge for each tank group is presented in Table 1.15. Excluding TH-4, W-6 represents the maximum anion concentration in Tank Group 2 sludge and drives the group spatial variability. Tank W-7 represents the maximum anion concentration in the Tank Group 3 sludge and drives spatial variability.

Table 1.15. Sludge anion median concentrations (mg/kg) for Tank Groups 2 and 3

Anion	Median Tank Group 2	Median Tank Group 3
Bromide	NC	9.5
Chloride	144	2,360
Fluoride	398	518
Nitrate	1,575	6,270
Phosphate	2,874	3,660
Sulphate	1,720	4,300

NC Not Calculated

1.3.10 Miscellaneous Information

Based on Phase I information, several tanks contain PCBs. These tanks are: W-3, W-4, W-5, W-6, TH-4, W-7, W-8, W-9, and W-10. PCB analysis was not performed on samples in Phase II.

There are a significant number of non-detects for Co-60, Cs-134, Eu-152, Eu-154, Eu-155, and Am-241 in samples from Tank Groups 2 and 3. No statistical tests were performed to examined whether the proportion of non-detects was more than would be expected by chance. However, inclusion of non-detects may serve to reduce the RSD for theses isotopes, which would, in term, lower upper 95%-tile concentration and curie values.

1.4 ORGANIZATION OF REPORT

The organization of this report is presented in Table 1.16. The section, topic, and the scope of the section is provided.

Table 1.16. Organization of report

Section	Topic	Scope
2	Technical Approach	General discussion of technical approach
3	GAAT Volumes	Determine tank volumes
4	Curie Loadings	Determine curie loading for each tank
5	TRU and non-TRU GAAT	Determine tanks that are TRU and non-TRU under DOE Order 5820.2A
6	Risk/Transport Drivers	Describe Risk/Transport drivers for tanks
7	Physical Properties Characterization	Describe Physical Properties of tanks
8	RCRA Metals Characterization	Determine which tanks exceed RCRA metals standards
9	Process Metals Characterization	Describe concentrations of process metals for tanks
10	Anion Characterization	Describe concentrations of Anions for tanks
11	Summary and Conclusions	Provide a summary of evaluation and associated conclusions

Appendix	Topic	Scope
A	DQOs for GAAT Phase II Sampling and Analysis	GAAT Phase II Sampling and Analysis DQOs
B	Sludge Data Base and Summary Statistics	Sludge data base used in evaluation
C	Supernate Data Base and Summary Statistics	Supernate data base used in evaluation
D	Technical Approach and Data Base for Curie Loadings	Approach and data base used to compute curie loading for all tanks
E	Statistical Methods	Discussion of statistical methods used

2. TECHNICAL APPROACH

2.1 INTRODUCTION

The technical approach employed for the evaluation of all sludge and supernate radiological, inorganic, or wet chemistry samples is summarized. Statistical methods are contained in Appendix E.

- Identify evaluation requirements to satisfy DQO questions
- Define data requirements for evaluations to be performed
- Identify measurement and estimation error sources
- Perform exploratory data analysis
- Compute summary statistics for GAAT TS Tank Groups 1, 2, and 3
- Provide graphical portrayals of information
- Determine probability functions that describe tank constituents

Various statistics are computed as part implementing the technical approach. The minimum and the maximum provide a measure of the range of the data. The 25%-tile and the 75%-tile indicate the region in which the central 50% of the data is contained. The median (50%-tile) and the average are measures of central tendency for the data. The RSD (the ratio of the standard deviation to the average) is expressed as a percentage. The RSD provides insight to the variability of the data. Comparisons of the data using parametric and non-parametric approaches is performed as required.

Additionally, probability density functions are determined for selected physical, chemical, or radiological constituents and tank samples. The purpose is to describe, in closed form, the probabilistic behavior of the data. Confidence intervals of the constituent averages can be computed from probability density functions.

2.2 DISCUSSION OF TECHNICAL APPROACH

The following evaluations are needed to satisfy DQO Question 1. "What is the spatial homogeneity or heterogeneity of key chemical and radionuclide concentrations in tanks suspected of significant curie loading?" DQO questions 2, 3, and 4 are not evaluated.

All other evaluations are presented in Table 2.1. For example, one evaluation is to determine the curie loading for each tank. The data requirements include concentrations of H-3, C-14, etc. The curie loading values are determined for sludge and supernate using GAAT Phase I data, GAAT Phase II data, and 1988 data. Note that each evaluation corresponds to a specific section of this report.

Measurement error is attributed to (1) the sample (x,y,z) location in each tank, (2) the sampling method used, (3) the analytical methods used to determine concentrations, and (4) inherent random error in the behavior of the chemical or radionuclide constituents. Total measurement error represents the total precision of the data, and it is expressed either by the RSD or the range (the difference between the maximum and the minimum) of the concentrations.

Estimation error is described by various summary statistics used to describe the data. Parametric estimation methods are the calculation of the mean, the standard deviation, and the RSD. The RSD is defined as the ratio of the standard deviation of a sample data set to the average obtained from the data set. Non-parametric estimation methods are the calculation the median (the 50%-tile) and the range. When appropriate assumptions are met, statistical tests can be employed. These include analysis of variance for parametric statistics and non-parametric tests of the median and the range.

Table 2.1. Evaluations to be performed and associated data requirements

Section	Evaluation	Data Requirements	Sludge	Supernate	Phase I Data	Phase II Data	1988 Data[1]
3	Determine tank volumes	Tank Volumes	x	x	x	x	
4	Determine Curie loading for each tank	Maximum Densities, Tank Volumes, H-3, C-14, Co-60, Cs-134, Cs-137/Ba-137m, Eu-152, Eu-154, Eu-155, Sr-90, Am-241, Cm-244, Th-232, Cf-252, Np-237, U-233, U-234, U-235, U-236, U-238, Pu-238, Pu-239, Pu-240, Pu-241, Pu-242, Pu-244	x	x	x	x	x

10	Describe concentrations of Anions for tanks	Br, Cl, F, NO3, PO4, SO4	x	x	x	x	
11	Describe concentrations of miscellaneous chemicals and radioisotopes in tanks	Alkaloids, PCBs, various radioisotopes	x	x	x	x	

[1] 1988 Data is used for curie loading only

Sources for measurement and estimation error are presented in Table 2.2. Included in this table are relevant comments applicable to evaluation of the GAAT data.

Sources of measurement error are "confounded" with each other. This means that it is not statistically possible to determine if the reason for a change in a sample value between Phase I, Phase II, and 1988 sampling is due explicitly to the sample location, the sample method, or the analytical method. Confounding says we cannot "decouple" the combined measurement error effects of the sample location, the sample method, or the analytical method. Two key reasons for confounding are:

- Different sample methods were not used for samples from the same sample location (port, riser, and depth).
- Different analytical methods were not used for samples from the same location.

Cost of sampling and analysis is the key driver. There are three key sources of measurement error (sample location, sample method, and analytical method) associated with samples obtained from either GAAT sludge or supernate. If confounding were desired to be completely eliminated, a minimum of eight samples from the sludge and eight samples from the supernate per tank would have been required. Furthermore, if we wanted to compare Phase I and Phase II data with 1988 data, we would have to replicate the analytical methods used during 1995 and 1988 for each sample collected. This is prohibitive in cost, and, as such, the trade-off between cost and "confounding" occurred.

Table 2.2. Sources for measurement and estimation error

Error Type	Source	Discussion	Comment
Measurement Error Sample (x,y,z) location	Phase I	Selected depths from center riser port	Locations and depths were not the same between Phase I or Phase II or 1988 sampling
	Phase II	Selected depths from multiple riser ports	
	1988 data	Selected depths from center riser port	
Measurement Error Sampling method used	Phase I	Sludge tube	Sampling methods were not the same between Phase I or Phase II or 1988 sampling
	Phase II	Grab sample	
	1988 data	Sludge tube	
Measurement Error Analytical methods	Phase I	Same as Phase II	Analytical methods were similar between Phase I and Phase II but different than 1988 analytical methods
	Phase II	Same as Phase I	
	1988 data	Different than Phase I or II	
Estimation Error Inherent random error	Phase I	Unknown	No significant changes in tank contents expected
	Phase II	Unknown	
	1988 data	Unknown	

3. SLUDGE AND SUPERNATE VOLUMES

Sludge and supernate volumes are provided for all GAAT tanks. Sludge volumes are derived from both the Phase I sampling (Energy Systems 1995) and the Phase II sludge mapping (Bechtel 1995). Liquid volumes are current as of December 1995 (Holder and Emison 1995 Fax). Uncertainties associated with volumes are not considered. All volumes are expected values, and there is no attempt to account for measurement error. These values are presented in Table 3.1. Round off error is present for the percentages of sludge and supernate volume.

Table 3.1. Sludge and supernate volume estimates

Tank	Capacity (gal)	Sludge Volume (gal)	% Sludge Volume	Supernate Volume (gal)	% Supernate Volume	Total Volume (gal)
W-1	4,800	0	0%	2,926	1%	2,926
W-2	4,800	0	0%	1,995	1%	1,995
W-3	42,500	628	1%	15,688	5%	16,316
W-4	42,500	1,313	3%	29,754	9%	31,067
W-5	170,000	3,422	7%	27,964	8%	31,386
W-6	170,000	7,037	14%	41,479	12%	48,516
W-7	170,000	8,812	18%	3,565	1%	12,377
W-8	170,000	10,309	21%	64,581	19%	74,890
W-9	170,000	2,861	6%	45,616	13%	48,477
W-10	170,000	9,298	19%	105,860	31%	115,158
W-11	1,500	0	0%	722	0%	722
TH-4	14,000	5,452	11%	5,410	2%	10,862
	Total	49,132	100%	345,560	100%	394,692

Data sources for sludge and supernate volumes are contained in Table 3.2.

Table 3.2. Data sources for sludge and supernate volumes

Tank	Sludge Volume (gal)	Sampling Period (Data Source)	Supernate Volume (gal)	Sampling Period (Data Source)
W-1	0	Phase I (Energy Systems 1995)	2,926	Phase I (Energy Systems 1995)
W-2	0	Phase I (Energy Systems 1995)	1,995	Phase I (Energy Systems 1995)
W-3	628	Phase II sludge mapping (Bechtel 1995)	15,688	Holder and Emison 1995 Fax
W-4	1,313	Phase II sludge mapping (Bechtel 1995)	29,754	Holder and Emison 1995 Fax
W-5	3,422	Phase II sludge mapping (Bechtel 1995)	27,964	Phase I (Energy Systems 1995)
W-6	7,037	Phase II sludge mapping (Bechtel 1995)	41,479	Phase I (Energy Systems 1995)
W-7	8,812	Phase II sludge mapping (Bechtel 1995)	3,565	Phase I (Energy Systems 1995)
W-8	10,309	Phase II sludge mapping (Bechtel 1995)	64,581	Phase I (Energy Systems 1995)
W-9	2,861	Phase II sludge mapping (Bechtel 1995)	45,616	Phase I (Energy Systems 1995)
W-10	9,298	Phase II sludge mapping (Bechtel 1995)	105,860	Phase I (Energy Systems 1995)
W-11	0	Phase I (Energy Systems 1995)	722	Phase I (Energy Systems 1995)
TH-4	5,452	Phase I (Energy Systems 1995)	5,410	Phase I (Energy Systems 1995)

Tank W-6 has experienced transfer activity since October 1995, and W-8 has experienced transfer activity since September 1995 (Holder and Emison 1996). During September through October 1995, approximately 47,881 gallons of liquid low-level (radioactive) waste (LLLW) was transferred from W-8 to the active LLLW system, and approximately 50,035 gallons of LLLW was transferred from W-6 to the active LLLW system. Since Phase II GAAT sampling was performed prior to the transfers [during the May through August 1995 time frame (U.S. DOE 1995)], there is no reason to suspect that any Phase II samples were biased by transfer and mixing effects of the sludge and the supernate in W-6 or W-8. It is unknown what the transfer and mixing effects are in these two tanks for specific chemicals and radioisotopes. If tanks W-6 or W-8 are re-sampled in similar locations using identical Phase II sampling methods, this comparison can be made.

A comparison of maximum sludge depths and sludge sample depths is provided in Table 3.3. The intent of this comparison is to (1) indicate that refined maximum sludge depth estimates were obtained in Phase II and, hence, affected the volume calculations, and (2) illustrate that some Phase I and Phase II sludge sampling occurred within the 3 standard errors (0.30 ft) of measurement precision for the sludge layer estimates and some did not. Sludge sampling, therefore, was representative sampling for both Phase I and Phase II.

Table 3.3. Sludge depth and sample depths

Tank	Phase I Maximum Sludge Depth (ft)	Phase I Sludge Sample Depth (ft)	Phase II Sludge Net Maximum Depth (ft)	Phase I Sludge Sample Depth (ft)	Difference in Depth of Sludge Sample > 0.30?
W-3	0.37	< 0.37	0.20	~ 0.20	No
W-4	1.30	< 1.00	0.50	~ 0.50	Yes
W-5	0.10	< 0.10	0.40	~ 0.40	No
W-6	0.75	< 0.75	0.75	~ 0.75	No
W-7	0.67	< 0.67	0.67	~ 0.67	No
W-8	0.30	< 0.30	1.00	~ 1.00	Yes
W-9	0.10	< 0.10	0.20	~ 0.20	No
W-10	0.50	< 0.50	1.00	~ 1.00	Yes
TH-4	2.32	< 2.32	Not Sampled	Not Sampled	No Comparison

4. CURIE LOADINGS

4.1 INTRODUCTION

Curie loading for the sludge and the supernates in the tanks is determined. Individual isotope concentrations as reported from GAAT sampling and analysis are examined. Sampling and analysis data in GAAT Phase I (Energy Systems 1995), Phase II (U.S. DOE 1995), and 1988 sampling (U.S. DOE 1993) reports is used. A triangular probability density function is used to model concentrations of isotopes in each tank. The 10%-tile, the median (50%-tile), and the upper 95% confidence limit (the 95%-tile) concentration is computed for each isotope. Sludge and supernate volume and density are used to then compute the curie loading for the sludge and the supernates. Details are contained in Appendix D.

Tanks examined are: W-1, W-2, W-3, W-4, W-5, W-6, W-7, W-8, W-9, W-10, and TH-4. Tank Group 1 (W-1, W-2, W-11), Tank Group 2 (W-3, W-4, W-5, W-6, TH-4), and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational definitions of tank groups. Tanks W-1A, W-13, W-14, and W-15 are not examined due to lack of Phase I and Phase II data.

Table 4.1 summarize the curie loading for GAAT tanks and tank groups. Both the concentration values and the curie values are presented as the lower 10%-tile , the median (50%-tile), upper 95% tile values for sludge and supernate in the selected tanks. Table 4.2 summarize the relative percentages of the curie loadings by tanks within tank groups for all groups.

Table 4.3 summarizes median curie loading values for GAAT tanks and tank groups. The median curie loading is denoted as Ci(0.50).

Table 4.4 summarizes the upper 95%-tile curie loading values for GAAT tanks and tank groups. The median curie loading is denoted as Ci(0.50).

Appendix D contains (1) the technical approach used to compute curie loadings for sludge and supernate in the GAAT, (2) the curie loadings for all GAAT as based upon the technical approach, and (3) the data base used to compute the curie loadings, referred to as the Curie Loading Data Base. Note that the Curie Loading Data Base is used only for computation of curie loading and should not be compared to the GAAT Phase I and Phase II data base.

4.2 SUMMARY OF RESULTS

The following results are presented for individual tanks and between and within tank groups. Results are presented in terms of the maximum curie values, the relative percentages of the median and upper 95%-tile curie values, skewness of curie values, and actual median and upper 95%-tile curie values.

Maximum of Sludge Curie Loadings. (Table 4.1, Table 4.3, Table 4.4, and Appendix D)

- Tank W-10 exhibits the maximum median and upper 95%-tile sludge curie values in Tank Group 3 (6,356 and 18,764, respectively).

- Tank W-6 exhibits the maximum median and upper 95%-tile sludge curie values in Tank Group 2 (523 and 861, respectively). There is no sludge in tanks in Tank Group 1.

Maximum of Supernate Curie Loadings. (Table 4.1, Table 4.3, Table 4.4, and Appendix D)

- Tank W-8 exhibits the maximum median and upper 95%-tile supernate curie values in Tank Group 3 (2,065 and 2,511, respectively).
- Tank W-6 exhibits the maximum median and upper 95%-tile sludge curie values in Tank Group 2 (364 and 2,178, respectively).
- The maximum median and upper 95%-tile supernate curie values in Tank Group 1 is 0.

Relative Percentage of Median and Upper 95%-tile Total Curie Loadings. (Table 4.2)

- 95% of the total median sludge curies are contained in Tank Group 3.
- 91% of the upper 95%-tile total sludge curies are contained in Tank Group 3.
- 90% of the median supernate curies are contained in Tank Group 3. 70% of the upper 95%-tile supernate curies are contained in Group 3. The remaining 30% of the upper 95%-tile supernate curies are contained in Group 2.

Relative Percentage of Median and Upper 95%-tile Sludge Curie Loadings within Tank Groups. (Table 4.2)

- Tanks W-10, W-8, and W-7 contain 94% and 97% of the median and the upper 95%-tile sludge curies, respectively, in Tank Group 3.
- Tanks W-3 and W-4 contain 8% and 13% of the median and the upper 95%-tile sludge curies, respectively, in Tank Group 2.
- Tanks W-3, W-4, and W-6 contain 95% and 96% of the median and the upper 95%-tile sludge curies, respectively, in Tank Group 2.

Relative Percentage of Median and Upper 95%-tile Supernate Curie Loadings within Tank Groups. (Table 4.2)

- Tanks W-10 and W-8 contain 88% and 90%, respectively, of the median and the upper 95%-tile supernate curies in Tank Group 3.
- Tanks W-10, W-8, and W-7 (or Tanks W-10, W-8, and W-9) contain between 94% and 95% of the median and 95% the upper 95%-tile supernate curies, respectively, in Tank Group 3.
- Tanks W-3 and W-4 contain 3% of the median and 3% of the upper 95%-tile supernate curies, respectively, in Tank Group 2.
- Tanks W-6 contain 94% and 96% of the median and the upper 95%-tile supernate curies, respectively, in Tank Group 2.

Skewness of Sludge Curie Loadings. (Table 4.1 and Appendix D)

- Tank W-10 exhibits the greatest right skewness of sludge curie loading when comparing the median to the upper 95%-tile value. This is due to a high Cs-137 observation (1.1E+07 Bq/g) in the 1988 sludge data set. If this value is removed from the curie calculation, the lower 10%-tile value, the median value, and the upper 95%-tile value change to 3,895, 5,746, and 10,311, respectively.

Skewness of Supernate Curie Loadings. (Table 4.1 and Appendix D)

- Tank W-6 exhibits large right skewness of supernate curie loading when comparing the median to the upper 95%-tile. This is due to high Cs-137 observations (2.0E+04 Bq/g) in the 1988 sludge data set. If this value for W-6 is removed from the curie calculation, the lower 10%-tile value, the median value, and the upper 95%-tile value change to 321, 711, and 2,209 curies, respectively. This tightens the left side of the distribution, increases the median from 364 Ci to 711 Ci, and extends the upper 95%-tile by approximately 1.5%.
- Tank W-8 exhibits large right skewness of supernate curie loading when comparing the median to the upper 95%-tile. This is due to a Phase I Cs-137 sample. No sensitivity was performed by eliminating this value.

Sludge Median Curie Loading Between Tank Groups. (Table 4.1, Table 4.3, and Appendix D)

- There is a consistent ordering for the sludge median curies per tank between the tank groupings as currently defined, namely the median curies per tank in Tank Group 3 is greater than the median curies per tank in Tank Group 2.
- Sludge median curies per tank for Tank Group 3 are greater than Tank Group 2. Sludge median curies per tank for Tank Group 2 are greater than Tank Group 1.
- Tank Group 2 tank W-6 sludge median curies (523 Ci) are only 35% less than the minimum sludge median curies in Tank Group 3 tank W-9 (803 Ci).

Supernate Median Curie Loading Between Tank Groups. (Table 4.1, Table 4.3, and Appendix D)

- The supernate median curies per tank does not follow a consistent ordering between the tank groupings as currently defined, namely the median curies per tank in Tank Group 3 is sometimes greater and sometimes less than the median curies per tank in Tank Group 2.
- Tank Group 2 tank W-6 supernate median curies (364 Ci) contains at least 50% more curies as Tank Group 3 tanks W-7 supernate median curies (238 Ci) and W-9 supernate median curies (212 Ci).

Sludge Median Curie Loading Within Tank Groups. (Table 4.1, Table 4.3, and Appendix D)

- There is a consistent ordering for the sludge median curies per tank within the tank groupings as currently defined, namely the median curies per tank in Tank Group 3 is greater than the median curies per tank in Tank Group 2.
- Tank Group 2 tank W-6 sludge median curies (523 Ci) are 5x greater than the next largest sludge median curies in Tank Group 2 (W-4, 32 Ci).

Supernate Median Curie Loading Within Tank Groups. (Table 4.1, Table 4.3, and Appendix D)

- The supernate median curies per tank does not follow a consistent ordering within the tank groupings as currently defined, namely the median curies per tank in Tank Group 3 is sometimes greater and sometimes less than the median curies per tank in Tank Group 2.
- Tank Group 3 tank W-10 supernate median curies (1,123 Ci) are over 4x greater than the next largest supernate median curies in Tank Group 3 (W-7, 238 Ci).
- Tank Group 2 tank W-6 supernate median curies (364 Ci) are over 25x greater than the next largest supernate median curies in Tank Group 2 (W-4, 13 Ci).

Sludge Upper 95%-tile Curie Loading Between Tank Groups. (Table 4.1, Table 4.4, and Appendix D)

- There is a consistent ordering for the sludge Upper 95%-tile curies per tank between the tank groupings as currently defined, namely the median curies per tank in Tank Group 3 is greater than the median curies per tank in Tank Group 2.
- Sludge Upper 95%-tile curies per tank for Tank Group 3 are greater than Tank Group 2. Sludge Upper 95%-tile curies per tank for Tank Group 2 are greater than Tank Group 1.
- W-6 sludge Upper 95%-tile curies (861 Ci) are only 9% less than the minimum sludge Upper 95%-tile curies in Tank Group 3 (W-9, 950 Ci).

Supernate Upper 95%-tile Curie Loading Between Tank Groups. (Table 4.1, Table 4.4, and Appendix D)

- The supernate Upper 95%-tile curies per tank does not follow a consistent ordering between the tank groupings as currently defined, namely the median curies per tank in Tank Group 3 is sometimes greater and sometime less than the median curies per tank in Tank Group 2.
- Tank Group 2 tank W-6 supernate (2,178 Ci) contains almost 10x more curies as Tank Group 3 tank W-9 supernate (272 Ci).

Sludge Upper 95%-tile Curie Loading Within Tank Groups. (Table 4.1, Table 4.4, and Appendix D)

- There is a consistent ordering for the sludge Upper 95%-tile curies per tank within the tank groupings as currently defined, namely the median curies per tank in Tank Group 3 is greater than the median curies per tank in Tank Group 2.
- W-7 sludge Upper 95%-tile curies (3,461 Ci) are over 3.5x greater than the next largest sludge Upper 95%-tile curies in Tank Group 3 (W-9, 950 Ci).
- W-6 sludge Upper 95%-tile curies (861 Ci) are almost 10x greater than the next largest sludge Upper 95%-tile curies in Tank Group 2 (W-4, 89 Ci).

Supernate Upper 95%-tile Curie Loading Within Tank Groups. (Table 4.1, Table 4.4, and Appendix D)

- The supernate Upper 95%-tile curies per tank does not follow a consistent ordering within the tank groupings as currently defined, namely the median curies per tank in Tank Group 3 is sometimes greater and sometimes less than the median curies per tank in Tank Group 2.
- W-10 supernate Upper 95%-tile curies (2,197 Ci) are 8x greater than the next largest supernate Upper 95%-tile curies in Tank Group 3 (W-9, 272 Ci).
- W-6 supernate Upper 95%-tile curies (2,178 Ci) are over 35x greater than the next largest supernate Upper 95%-tile curies in Tank Group 2 (W-4, 63 Ci).

5. TRU IDENTIFICATION

5.1 INTRODUCTION

Tanks are identified as TRU waste and non-TRU under DOE Order 5820.2A. The definition of TRU waste as found in Attachment 2 of the Order states: "Without regard to source or form, waste that is contaminated with alpha-emitting transuranium radionuclides with half-lives greater than 20 years and concentrations greater than 100 nCi/g at the time of assay."

DOE has given the Heads of Field Elements the freedom to further define alpha-emitting wastes and thus their site-specific handling as TRU wastes (ref. DOE order 5820.2A). For ORNL, in addition to the above definition, alpha-emitting isotopes of U, Cm, and Cf (i.e. U-233, Cm-244, or Cf-252) are included in the 100 ηCi/g alpha emitter limit at the time of assay for on-site disposal acceptance and classification.

TRU determination is based upon both individual isotope concentrations and Pu-alpha values as reported from GAAT Sampling and analysis data in GAAT Phase I (Energy Systems 1995) and Phase II (U.S. DOE 1995). Pu-alpha is a rapid estimation technique to determine if a tank is TRU or not. If Pu-alpha indicates a tank is TRU, this will always be confirmed by the isotopics. TRU isotopics (Np-237, Pu-238, Pu-239, Pu-240, Pu-242, Pu-244, Am-241, Am-242m, Am-243, Cm-243, Cm-246, Cm-247, Cm-248, Bk-247, Cf-249, Cf-251, U-233, and Cm-244) are used to affirm TRU identification when TRU values are close to 100 nCi/g.

Sludges in Tank Groups 2 and 3 are examined. Tank Group 2 (W-3, W-4, W-5, W-6, TH-4) and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational definitions of tank groups.

5.2 SUMMARY OF RESULTS

Table 5.1 summarize the TRU values (based on Pu-alpha values measured on a wet basis) for all tanks by tank groups. The median and the maximum Pu-alpha values are provided for all tanks. When these values result in differing conclusions that a tank is TRU or non-TRU, the maximum TRU value as computed by the TRU isotopics is presented. Note that the TRU conclusion differs for only Tanks W-3 and W-4. (The TRU values are not portrayed in a statistical or probabilistic manner; however, the median and the maximum nCi/g values are presented for comparative purposes to identify whether any difference in values can be attributed to Phase I or Phase II sampling and analysis.) This type of information is contained in the explanation portion of Table 5.1. Note that a "-" indicates no data or explanation is required.

Table 5.1. Identification of TRU or non-TRU sludges in tanks (wet basis)

Tank Group	Tank	TRU	Pu-Alpha (nCi/g) Median	Pu-Alpha (nCi/g) Maximum	TRU Isotopes (nCi/g) Maximum (1)	Explanation	Min % Moisture
2	W-3	Yes	81	132	155	RSD > 80% for isotopics. Maximum in Phase I Samples	57.6
	W-4	Yes	74	324	329	RSD > 100% for isotopics. Phase I samples < 100 nCi/g Phase II samples > 100 nCi/g	63.5
	W-5	No	14	16	-	-	68.3
	W-6	Yes	149	219	-	-	61.5
	TH-4	No	2	2	-	-	34.5
3	W-7	No	59	89	-	-	57.7
	W-8	Yes	219	246	-	-	78.6
	W-9	Yes	324	676	-	-	82.8
	W-10	Yes	297	432	-	-	61.1

(1) These include U-233 and Cm-244 values

5.3 GROUT REQUIREMENTS FOR TRU REDUCTION

Grout requirements for TRU reduction are identified. A deterministic linear model is used to estimate the volume of grout to add to the tanks to reduce the TRU concentration to 100 nCi/g or less.

5.3.1 Approach

A deterministic model is used to compute the volume of grout to add to a tank to reduce the TRU concentration to 100 nCi/g or less:

$$V_g = \left(\frac{C_s}{C_{TRU}} \right) V_s - V_s = \left(\frac{C_s}{C_{TRU}} - 1 \right) V_s$$

where

V_g = Volume of grout to add [gal]
V_s = Volume of waste in a tank [gal]
C_s = Concentration of waste in a tank [nCi/g)]
C_{TRU} = TRU threshold (equal to 100nCi/g)

The value $[(C_s / C_{TRU}) - 1]$ represents the marginal contribution of the concentration of waste in a tank normalized by the TRU criteria. If the value is less than or equal to 0, namely a tank in which $C_s \leq 100$nCi/g, then the volume of grout to add is zero since the concentration of waste in a tank meets the minimum TRU criteria. If the value is greater than 0, the tank volume is weighted by this amount to prescribe the amount of grout to add to the tank to reduce the concentration of waste so that it meets the minimum TRU criteria.

This approach does not consider (1) differences in density between the sludge and the grout, and (2) any process specific requirements that would affect the grout volumes required. As such, the model provides an envelope for consideration of the volume of grout required to reduce TRU to less than 100 nCi/, and refinements should be pursued.

5.3.2 Results

Tables 5.2 and 5.3 present the expected volume of grout to add to tanks in Tank Group 2 and 3, respectively, to reduce TRU to less than 100 nCi/g. For information purposes, the total volume and the volume of sludge in each tank is provided.

Two measurement bases are provided: wet and dry. Each basis assumes the minimum moisture content for each tank. The transformation is:

$$C_{Dry} = \left(\frac{1}{1 - W_{Wet}} \right) C_{Wet}$$

where W_{Wet} represents the wet moisture content (%) and C represents the concentration (nCi/g).

The volume of grout to add (measured in gallons) is then computed for each basis for the median and the maximum Pu-alpha concentration (measured in nCi/g). This information provides an envelope for consideration of the volume of grout required to reduce TRU to less than 100 nCi/g.

For example, under a wet basis, W-7 is not considered a TRU tank, but using a dry basis, it is. If the dry basis reflects TRU reality, then the volume of grout to add to W-7 to reduce the concentration to less than 100 nCi/g is between 3,575 gal and 9,768 gal. Note that these values are expected values and do not incorporate the underlying variability (RSD) of the Pu-alpha concentrations. This means that two standard deviations could be as large as, say, 2 x 9,768 x RSD(%).

Table 5.2. Expected volume of grout to add to tanks in Tank Group 2 to reduce TRU < 100 nCi/g

Tank	W-3	W-4	W-5	W-6	TH-4
Tank Volume (gal)	42,500	42,500	170,000	170,000	14,000

6. BETA-GAMMA RISK/TRANSPORT DRIVERS

6.1 INTRODUCTION

Beta/gamma emitters, particularly Sr-90 and Cs-137, are considered significant variables in the transport and human health and environmental risk modeling for the GAAT. The statistical behavior of average concentration values for Sr-90 and Cs-137 in sludge are discussed in this section. Closed form statistical representations of Sr-90 and Cs-137 concentrations can also support effectiveness evaluation of GAAT sludge removal systems.

Concentration values for beta/gamma emitters are based upon values as reported from GAAT Phase I (Energy Systems 1995) and Phase II (U.S. DOE 1995) sampling and analysis data. Only sludges in Tank Groups 2 and 3 are examined. Tank Group 2 (W-3, W-4, W-5, W-6, TH-4) and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational definitions of tank groups.

6.2 SUMMARY OF RESULTS

6.2.1 Sr-90 and Cs-137 Average Concentrations Fit to an Exponential Probability Distribution

Sr-90 and Cs-137 concentrations account for 19% to 65% of all gross beta values for Tank Group 2, and the same isotopes account for 50% to 85% of all gross beta values for Tank Group 3. When TH-4 is omitted from Tank Group 2, Sr-90 and Cs-137 concentrations account for 25% to 65% of all gross beta values.

However, Sr-90 and Cs-137 account for over 80% of all curie values for each tank in either Tank Group 2 or Tank Group 3. This clearly implies that Sr-90 and Cs-137 are key risk drivers in beta-gamma emitters.

Summary statistics for Sr-90 and Cs-137 concentrations for individual tanks in Tank Groups 2 and 3 are presented in Table 6.1. The same data is sorted by either Sr-90 or Cs-137 concentrations as indicated in Tables 6.2 and 6.3, respectively. A graphical portrayal of the average Sr-90 and Cs-137 concentrations for each tank is presented in the stacked bar chart in Fig. 6.1. The way to read this figure is, for example, the average concentration of Cs-137 in W-10 sludge is 1.15E+06 Bq/g, and the total average concentration of Sr-90 and Cs-137 in W-10 sludge is 4.52E+06 Bq/g. The average concentration of Sr-90 in W-10 sludge is the difference, namely, 3.37E+06 Bq/g.

Using this information, several observations of the average concentrations and the spatial homogeneity or heterogeneity of the concentrations are made:

- Tanks W-8, W-9, and W-10 indicate the largest average concentration of Sr-90 in sludge (> 1.73E+06 Bq/g)
- Tanks W-7 and W-10 indicate the largest average concentration of Cs-137 in sludge (> 1.15E+06 Bq/g)
- Tanks W-3 and W-4 exhibit the most heterogeneity for Sr-90 average concentration in sludge (RSD ~ 100%).

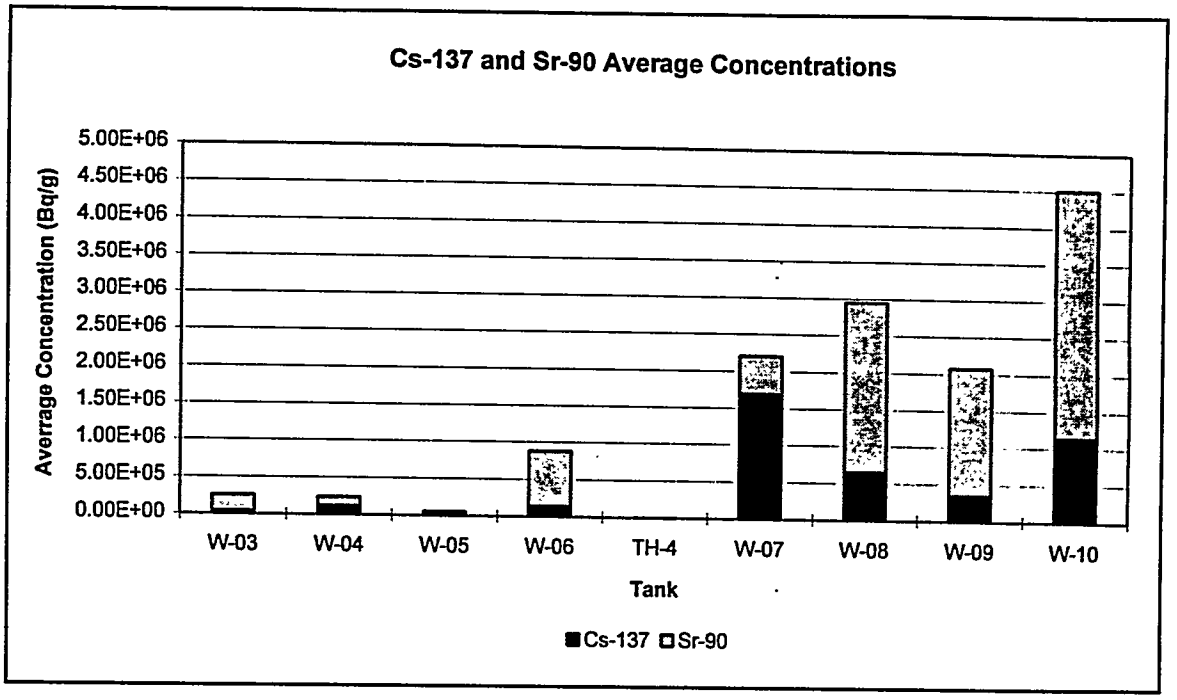

Fig. 6.1. Cs-137 and Sr-90 concentrations for sludge.

- Tank W-4 exhibits the most heterogeneity for Cs-137 average concentration in sludge (RSD > 100%).
- Tanks W-8 and W-9 exhibit the most homogeneity for Sr-90 average concentration in sludge (RSD < 25%).
- Tanks W-3, W-5, W-8, W-9, and TH-4 exhibit the most homogeneity for Cs-137 average concentration in sludge (RSD < 25%).

Table 6.1. Summary statistics for Sr-90 and Cs-137 concentrations in sludge

Tank	Tank		Sr-90 (Bq/g)		Cs-137 (Bq/g)

W-3	2	3	2.13E+05	150%	4.53E+04	5%
W-7	3	7	5.08E+05	79%	1.70E+06	47%
W-6	2	3	7.47E+05	65%	1.40E+05	33%
W-9	2	3	1.73E+06	3%	3.50E+05	10%
W-8	2	3	2.30E+06	24%	6.53E+05	20%
W-10	2	3	3.37E+06	35%	1.15E+06	42%

Statistical Goodness of Fit Tests were performed on the combined concentrations for each tank group. The concentration values for tanks W-3, W-4, W-5, W-6, and TH-4 were combined for Tank Group 2. The concentration values for tanks W-7, W-8, W-9, W-10 were combined for Tank Group 3. The rationale for this is to quantify the similarity or differences in the current tank group categories, since there is insufficient data for individual tanks to make a meaningful assessment of the underlying probability functions that describe the individual tanks.

The result of the statistical Goodness of Fit Test is that each of the Sr-90 and Cs-137 average concentrations in each tank group follow an exponential probability density function with at least a 99% probability of having chosen the correct probability distribution. Both the χ^2 and the

Kolmorgrov-Smirnov Goodness of Fit tests were used to determine this finding. The results are illustrated in Table 6.4. A significance test of the difference of the averages of the two groups was not performed.

Figs. 6.2 and 6.3 portray the Exponential Cumulative Distribution Function (CDF) for Sr-90 and Cs-137 based upon the computed parameters of Table 6.4. For example, read Fig. 6.2 as "there is a 25% chance that the average concentration in of Sr-90 in sludges in Tank Group 3 is 1.4E+05 Bg/g or less," or "If all sludges from all tanks in Tank Group 2 (excluding TH-4) were combined, we can be 100% confident that the average concentration of the Sr-90 concentrations in the sludge would be less than 1.2E+05 Bq/g."

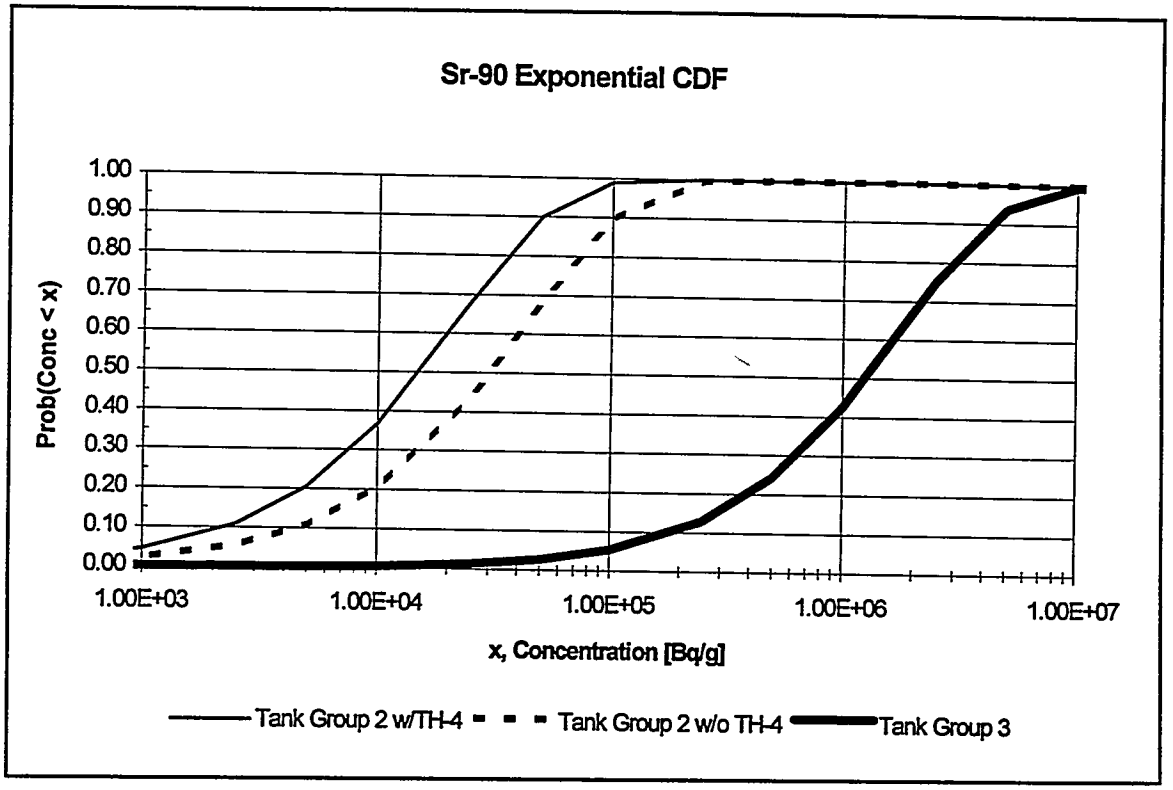

Fig. 6.2. Sr-90 sludge concentration exponential cumulative distribution function.

Since the Sr-90 and Cs-137 average concentrations in Tank Groups 2 and 3 sludge follow an exponential probability density function, descriptions and inferences regarding the Sr-90 and Cs-137 average concentration in these tanks is now both greatly simplified and statistically rigorous.

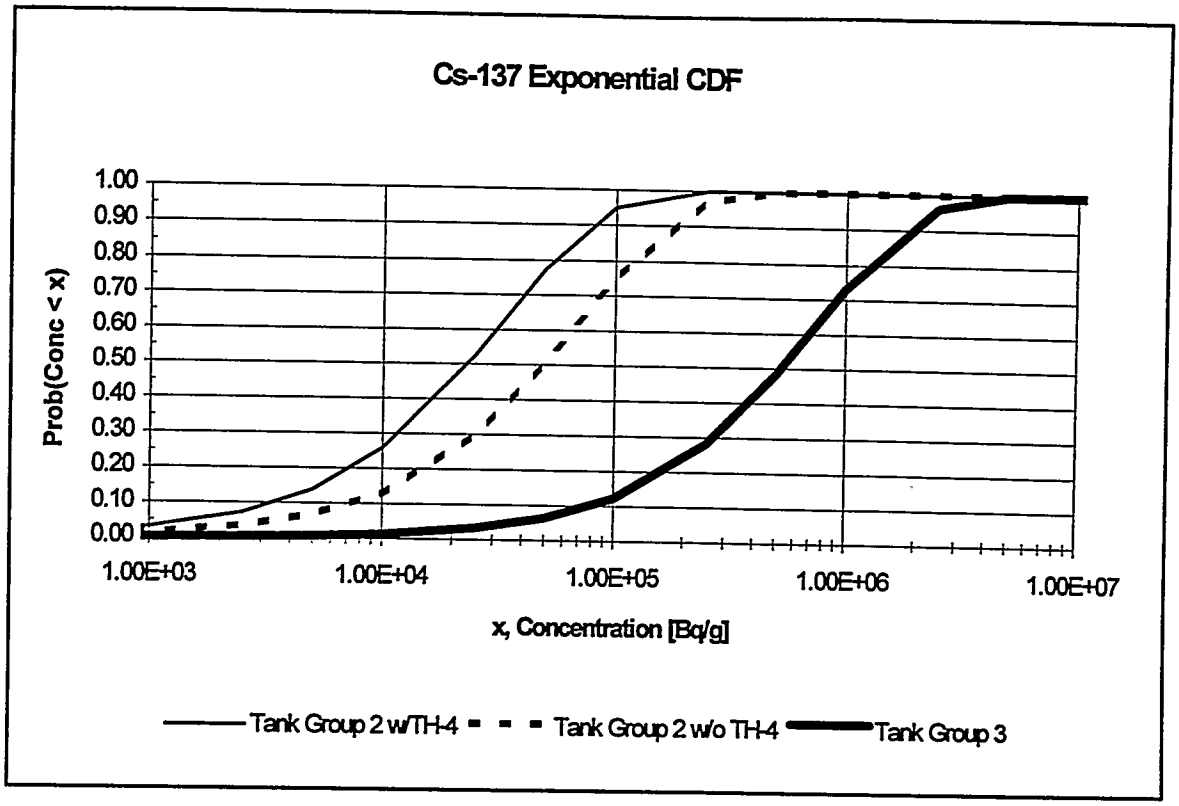

Fig. 6.3. Cs-137 sludge concentration exponential cumulative distribution function.

- The average Sr-90 concentration in sludge for Tank Group 2 (2.18E+04 Bq/g) is approximately 2 orders of magnitude less than the average Sr-90 concentration in sludge for Tank Group 3 (1.80E+06 Bq/g) when an exponential probability distribution is used to describe average Sr-90 concentration.
- The average Sr-90 concentration in sludge for Tank Group 2 when TH-4 Sr-90 concentrations are not included (4.38E+04 Bq/g) is approximately 2 orders of magnitude less than the average Sr-90 concentration in sludge for Tank Group 3 (1.80E+06 Bq/g) when an exponential probability distribution is used to describe average Sr-90 concentration.
- The average Cs-137 concentration in sludge for Tank Group 2 (3.35+04 Bq/g) is approximately 1 order of magnitude less than the average Cs-137 concentration in sludge for Tank Group 3 (7.60E+05 Bq/g) when an exponential probability distribution is used to describe average Cs-137 concentration.
- The average Cs-137 concentration in sludge for Tank Group 2 when TH-4 Cs-137 concentrations are not included (7.14E+04 Bq/g) is approximately 1 order of magnitude less than the average Cs-137 concentration in sludge for Tank Group 3 (7.60E+05 Bq/g) when an exponential probability distribution is used to describe average Cs-137 concentration.

Table 6.4. Exponential distribution summary statistics

Tank Group	Parameter μ Sr-90 (Bq/g)	Confidence that Sr-90 Sample Data Fits an Exponential Probability Distribution	Parameter μ Cs-137 (Bq/g)	Confidence that Cs-137 Sample Data Fits an Exponential Probability Distribution
Tank Group 2	2.18E+04	> 99%	3.35E+04	> 99%
Tank Group excluding TH-4	4.38E+04	> 99%	7.14E+04	> 99%
Tank Group 3	1.80E+06	> 99%	7.60E+05	> 99%

For reference purposes, the general form of this exponential probability density function, f(x), and the Exponential Cumulative Distribution Function, F(x), is presented. Using this notation, x represents the concentration value for either Sr-90 or Cs-137, X represents the random variable Sr-90 or Cs-137, Pr(X=x) means the probability that the average concentration of Sr-90 or Cs-137 will be equal to a specific value x, and $Pr(X \leq x)$ means the probability that the average concentration of Sr-90 or Cs-137 will be less than or equal to a specific value x:

$$Pr(X=x)=f(x)=\frac{1}{\mu}e^{\frac{-x}{\mu}} \; for \; x>0$$

$$Pr(X\leq x)=F(x)=1-e^{\frac{-x}{\mu}} \; for \; x>0$$

Note that μ is the parameter as described in Table 6.4 for the distribution function. This parameter is estimated as the arithmetic average of the concentrations. Upper confidence limits are easily computed for the isotopes is a closed form, namely:

$$x_p = -\mu \ln(1-p)$$

where $0 < 1\text{-}p < 1$ is the desired confidence value (e.g. 95%).

Upper confidence bounds for average Sr-90 and Cs-137 concentrations within tank groups as fit to an exponential probability function can be easily expressed. If the value of the parameter is 1.80E+06 Bq/g for Sr-90 in Tank Group 3, then the upper 95% confidence value for the average concentration of Sr-90 is 5.39E+06 Bq/g. This is computed as 5.39E+06 = -1.80E+06 * ln(1-0.95).

Table 6.4. Upper 95%-tile values using exponential distribution

Tank Group	Parameter μ Sr-90 (Bq/g)	Upper 95%-tile Value (Bq/g)	Parameter μ Cs-137 (Bq/g)	Upper 95%-tile Value (Bq/g)
Tank Group 2	2.18E+04	6.53E+04	3.35E+04	1.00E+05
Tank Group excluding TH-4	4.38E+04	1.31E+05	7.14E+04	2.14E+05
Tank Group 3	1.80E+06	5.39E+06	7.60E+05	2.28E+06

6.2.2 Sr-90 and Cs-137 Average Concentrations Fit to an Alternative Probability Distribution

Sr-90 and Cs-137 average concentrations in sludge can also be fit to a triangular probability distribution with 99% statistical confidence for Tank Group 3 and for Tank Group 2 excluding TH-4. The hypothesis is rejected that the Sr-90 and Cs-137 average concentrations follow a triangular distribution when TH-4 is included in Tank Group 2. (This means that the Sr-90 and Cs-137 average concentrations in Tank Group 2 including TH-4 do not follow a triangular distribution.) A summary of the triangular distribution statistics and upper 95%-tile values are presented in Tables 6.5 and 6.6 for Sr-90 and Cs-137 average concentrations in sludge, respectively.

The operational significance of these results is:

- Tank Group 2 including TH-4:
  - Only the exponential distribution should be used for Sr-90 average concentrations and upper 95%-tile values.
  - Only the exponential distribution should be used for Cs-137 average concentrations and upper 95%-tile values.
- Tank Group 2 excluding TH-4:
  - Either the exponential distribution or the triangular distribution can be used for Sr-90 average concentrations and upper 95%-tile values.
  - Either the exponential distribution or the triangular distribution can be used for Cs-137 average concentrations and upper 95%-tile values.
- Tank Group 3:
  - Either the exponential distribution or the triangular distribution can be used for Sr-90 average concentrations and upper 95%-tile values.
  - Either the exponential distribution or the triangular distribution can be used for Cs-137 average concentrations and upper 95%-tile values.

Table 6.5. Triangular distribution summary statistics for Sr-90 and comparison of upper 95%-tile values

Tank Group	Parameters Min, Most Likely, Max for Sr-90 (Bq/g)	Confidence that Sr-90 Sample Data Fits an Triangular Probability Distribution	Upper 95%-tile Sr-90 Concentration (Bq/g)	Ratio of Exponential Upper 95%-tile Sr-90 Concentration to Triangular Upper 95%-tile Sr-90 Concentration (Bq/g)
Tank Group 2	0.00E+00 8.02E+03 9.50E+05	None	N/A	N/A
Tank Group excluding TH-4	0.00E+00 1.18E+04 9.50E+05	> 99%	7.39E+05	0.2
Tank Group 3	0.00E+00 1.66E+06 4.70E+06	> 99%	3.85E+06	1.4

Table 6.6. Triangular distribution summary statistics for Cs-137 and comparison to upper 95%-tile values

Tank Group	Parameters Min, Most Likely, Max for Cs-137 (Bq/g)	Confidence that Cs-137 Sample Data Fits an Triangular Probability Distribution	Upper 95%-tile Cs-137 Concentration (Bq/g)	Ratio of Exponential Upper 95%-tile Cs-137 Concentration to Triangular Upper 95%-tile Cs-137 Concentration (Bq/g)
Tank Group 2	0.00E+00 3.76E+02 3.40E+05	None	N/A	N/A
Tank Group excluding TH-4	0.00E+00 1.49E+04 3.40E+05	> 99%	2.66E+05	0.8
Tank Group 3	0.00E+00 2.03E+05 3.10E+06	> 99%	2.43E+06	0.9

The statistical significance of these results are as follows:

- Tank Group 2 excluding TH-4:
  - The most likely value for the Sr-90 exponential distribution (4.38E+04 Bq/g) is relatively close to the most likely value for the Sr-90 triangular distribution (1.18E+04 Bq/g). Both values fall within the minimum RSD that would be expected for either probability distribution, namely an RSD equal to 100% for the exponential distribution.
  - The upper 95%-tile for Sr-90 average concentration computed by the exponential distribution (1.31E+05 Bq/g) is approximately 20% the upper 95%-tile for Sr-90 average concentration computed by the triangular distribution (7.39E+05) Bq/g.

- The most likely value for the Cs-137 exponential distribution (7.14E+04 Bq/g) is relatively close to the most likely value for the Cs-137 triangular distribution (1.49E+04 Bq/g). Both values fall within the minimum RSD that would be expected for either probability distribution, namely an RSD equal to 100% for the exponential distribution.
- The upper 95%-tile for Cs-137 average concentration computed by the exponential distribution (2.14E+04 Bq/g) is approximately 80% the upper 95%-tile for Cs-137 average concentration computed by the triangular distribution (2.66E+05) Bq/g.

• Tank Group 3:

- The most likely value for the Sr-90 exponential distribution (1.80E+06 Bq/g) is 1.1x the most likely value for the Sr-90 triangular distribution (1.66E+06 Bq/g). Both values fall within the minimum RSD that would be expected for either probability distribution, namely an RSD equal to 100% for the exponential distribution.
- The upper 95%-tile for Sr-90 average concentration computed by the exponential distribution (5.39E+06 Bq/g) is approximately 140% the upper 95%-tile for Sr-90 average concentration computed by the triangular distribution (3.85E+06) Bq/g.
- The most likely value for the Cs-137 exponential distribution (7.60E+05 Bq/g) is 3.7x the most likely value for the Cs-137 triangular distribution (2.03+05 Bq/g). Both values fall within the minimum RSD that would be expected for either probability distribution, namely an RSD equal to 100% for the exponential distribution.
- The upper 95%-tile for Cs-137 average concentration computed by the exponential distribution (2.28E+06 Bq/g) is approximately 95% the upper 95%-tile for Cs-137 average concentration computed by the triangular distribution (2.43E+06) Bq/g.

7. PHYSICAL PROPERTIES

7.1 INTRODUCTION

Physical properties are described based on GAAT sampling and analysis data for Phase I (Energy Systems 1995) and Phase II (U.S. DOE 1995). Supernate physical properties examined are TSS, TDS, density, pH, and TOC. Sludge physical properties examined are % moisture, density, TOC, and pH. Knowledge of physical properties can support GAAT system design and operational remedial actions that comply with waste acceptance criteria at proposed storage and disposal facilities

Physical properties statistics for supernate and sludge for Tank Groups. Tank Group 1 (W-1, W-2, W-11), Tank Group 2 (W-3, W-4, W-5, W-6, TH-4), and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational definitions of Tank Groups. Supernate and sludge samples are pooled for the Tank Groups. These values are used to compute the minimum, median, maximum, average, and RSD for each physical property for the Tank Group.

Physical properties statistics for supernate and sludge for individual tanks. Supernate and sludge samples from each tank are used to compute the minimum, the 25%-tile, the median, the 75%-tile, the maximum, the average, and the RSD for each physical property for individual tanks. The minimum and the maximum provide a measure of the range of the physical property data. The 25%-tile and the 75%-tile indicate the region in which the central 50% of the reported physical property data is contained. The median and the average are measures of central tendency for the physical property data. The RSD (the ratio of the standard deviation to the average) is expressed as a percentage. The RSD provides insight to the variability of the physical property data.

7.2 PHYSICAL PROPERTIES IN SUPERNATES

Summary statistics of the physical properties in supernate for each tank group is presented in Tables 7.1 through 7.3.

In most cases, Tank Groups 2 and 3 contain the maximum median values, and Tank Group 1 contains the minimum median values. TSS and TDS in Tank Group 2 exhibit high spatial variability, which is due to high values in TH-4 and W-6.

A summary of the concentrations for individual physical properties in supernate for Tank Groups is presented. Samples which contain the largest and smallest median concentrations are indicated. The RSD is also provided.

TSS — The largest median concentration is in Tank Group 2 (1.8 mg/mL), and the smallest median concentration is in Tank Group 3 (0.7 mg/mL). TH-4 and W-4 contain the maximum values, and W-6 contains the minimum value. Spatial variability in Tank Group 2 is greater than 100%.

TDS — The largest median concentration is in Tank Group 3 (11.0 mg/mL), and the smallest median concentration is in Tank Group 1 (0.2 mg/mL). TH-4 and W-8 contain the

maximum values, and W-11 contains the minimum value. Spatial variability in Tank Group 2 is greater than 100%.

Density — The largest median concentration is in Tank Group 2 (1.02 g/mL), and the smallest median concentration is in Tank Group 1 (1.00 g/mL). TH-4 and W-6 contain the maximum values, and W-11 contains the minimum value. Spatial variability is 2% or less for all groups.

TOC — The largest median concentration is in Tank Group 3 (89.0 mg/L), and the smallest median concentration is in Tank Group 1 (7.5 mg/L). W-3 contains the maximum values, and W-1 contains the minimum value. Spatial variability ranges from 66% to 85%.

pH — The largest median concentration is in Tank Group 3 (9.85), and the smallest median concentration is in Tank Group 1 (8.30). W-3 contains the maximum value, and W-1 contains the minimum value. Spatial variability ranges from 2% to 14%.

Table 7.1. Summary of physical properties for Tank Group 1 for GAAT supernate

Median values for physical properties for sludge for individual tanks in tank groups are presented in Tables 7.14 and 7.15. The TOC RSD in Tank Group 2 is the largest RSD at 97%. This is due to high physical property concentrations in TH-4 and W-6. All other RSDs for Tank Group 2 and 3 are less than 75%.

Table 7.14. Sludge median values for physical properties for Tank Group 2

Summary statistics of the physical properties in sludge tank groups are presented in Tables 7.16 and 7.17. A discussion of the concentrations for individual physical properties in supernate for Tank Groups is presented. Samples which contain the largest and smallest median concentrations are indicated. The RSD is also provided.

% Moisture — The larger median concentration is in Tank Group 3 (72%), and the smaller median concentration is in Tank Group 2 (69.7%). W-3 contains the maximum value, and W-7 sludge layers contains the minimum value. Spatial variability between Tank Groups ranges from 14% to 19%.

Density — The larger median concentration is in Tank Group 3 (1.24 g/mL), and the smaller median concentration is in Tank Group 2 (1.23 g/mL). W-7 contain the maximum values, and W-3 contains the minimum value. Spatial variability is less than 12% for all groups.

TOC — The larger median concentration is in Tank Group 2 (2,855 mg/kg), and the smaller median concentration is in Tank Group 3 (2,380 mg/kg). TH-4 contains the maximum values, and W-4 contains the minimum value. Spatial variability ranges from 75% to 95%.

pH — The larger median concentration is in Tank Group 2 (10.50), and the smaller median concentration is in Tank Group 3 (9.90). W-6 contains the maximum value, and TH-4 contains the minimum value. Spatial variability ranges from 6% to 10%.

Table 7.16. Summary statistics for physical properties for Tank Group 2

8. RCRA METALS

Concentrations of RCRA metals are described in several ways using GAAT Sampling and analysis data in GAAT Phase I (Energy Systems 1995) and Phase II (U.S. DOE 1995).

- Concentration statistics for supernate and sludge for individual tanks. Supernate and sludge samples from each tank are used to compute the minimum, the 25%-tile, the median, the 75%-tile, the maximum, the average, and the RSD for each RCRA metal concentration for individual tanks. The minimum and the maximum provide a measure of the range of the concentration data. The 25%-tile and the 75%-tile indicate the region in which the central 50% of the reported concentration data is contained. The median and the average are measures of central tendency for the concentration data. The RSD (the ratio of the standard deviation to the average) provides insight to the variability of the concentration data.
- Concentration statistics for supernate and sludge for tank groups. Tank Group 1 (W-1, W-2, W-11), Tank Group 2 (W-3, W-4, W-5, W-6, TH-4), and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational definitions of tank groups. Supernate and sludge samples are pooled for the tank groups. These concentrations are used to compute the minimum, median, maximum, average, and RSD for each RCRA metal for tank group.
- Maximum supernate and sludge concentrations for tanks within each tank group. The maximum sludge and supernate concentrations of each RCRA metal for each tank group are used to identify which tanks within a tank group exhibit the largest concentration.
- Maximum concentrations sorted by individual tanks within tank groups for supernate or sludge. Sorts of the maximum concentrations for the tank groups are performed to easily display which individual tanks within the tank group exhibit the largest concentrations in the supernate and the sludge.

8.1 RCRA METALS IN SUPERNATES

8.1.1 RCRA Concentrations in Supernate that Exceed RCRA Standards

Samples in which RCRA metals for GAAT supernates exceed dilution-based and TCLP RCRA criteria occur in some GAAT tanks. These values are derived obtained from Phase I sampling. These are presented in Table 8.1. The entries identify the number of samples upon which the statistics are based, the average, and the RSD (i.e., the ratio of the standard deviation to the average expressed as a percentage). When there are two observations, the median and the average are equal.

Table 8.1. RCRA metals in GAAT supernates that exceed dilution-based RCRA standards

Tank	Statistic	Cr (5 mg/L)	Hg (0.2 mg/L)	Tl (0.9 mg/L)
W-3	N Average RSD	2 7.63 53%		
W-4	N Average RSD	1 6.95 0%		
W-8	N Average RSD	1 7.6 0%	1 0.328 0%	1 1.02 0%
W-9	N Average RSD			1 2.06 0%

A summary of the concentrations for individual metals is presented. Samples which contain the largest and smallest median concentrations are indicated. The RSD is also provided.

Ag The largest median concentration in supernate occurs in samples from W-4 (1.07 mg/L). The tank has only one observation, so an RSD is not computed. The smallest median concentration in supernate occurs in samples from W-3 (0.1445 mg/L). The RSD is 51%.

As The largest median concentration in supernate occurs in samples from W-6 (0.032 mg/L). The tank has only one observation, so an RSD is not computed. The smallest median concentration in supernate occurs in samples from W-10 (0.008 mg/L). The tank has only one observation, so an RSD is not computed.

Ba The largest median concentration in supernate occurs in samples from W-4 (0.165 mg/L). The tank has only one observation, so an RSD is not computed. The smallest median concentration in supernate occurs in samples from W-6 (0.005 mg/L). The tank has only one observation, so an RSD is not computed.

Cd All concentrations are reported as less than detection limits.

Cr The largest median concentration in supernate occurs in samples from W-3 and W-8 (7.625 mg/L and 7.6 mg/L, respectively). The RSD for W-3 is 53%, and W-8 has only one observation, so an RSD is not computed. The smallest median concentration in supernate occurs in samples from W-11 (0.013 mg/L). The RSD is 10%.

Hg The largest median concentration in supernate occurs in samples from W-8 (0.328 mg/L). There is only one observation, so an RSD is not computed. The smallest median concentration in supernate occurs in samples from W-2 (0.003 mg/L). There is only one observation, so an RSD is not computed.

Ni The largest median concentration in supernate occurs in samples from TH-4 (0.58 mg/L). The RSD is 58%. The smallest median concentration in supernate occurs in samples from W-2 (0.012 mg/L). There is only one observation, so an RSD is not computed.

Pb The largest median concentration in supernate occurs in samples from W-9 (1.03 mg/L). There is only one observation, so an RSD is not computed. The smallest median concentration in supernate occurs in samples from W-2 (0.0066 mg/L). There is only one observation, so an RSD is not computed.

Se The largest median concentration in supernate occurs in samples from W-4 (0.0128 mg/L). There is only one observation, so an RSD is not computed. The smallest median concentration in supernate occurs in samples from W-3 (0.0098 mg/L). The RSD is 3%.

Tl The largest median concentration in supernate occurs in samples from W-9 (2.06 mg/L). There is only one observation, so an RSD is not computed. The smallest median concentration in supernate occurs in samples from W-6 (0.554 mg/L). There is only one observation, so an RSD is not computed.

8.1.2 RCRA Concentration Statistics for Supernate for Tank Groups

Concentration statistics for supernate for individual tanks in tank groups are presented in Tables 8.2–8.4. Statistics presented are the minimum, the 25%-tile, the median, the 75%-tile, the maximum, the average, and the RSD for each RCRA metal concentration for individual tanks. Concentration statistics for supernate for Tank Groups are presented in Tables 9.5 through 9.7.

8.13 Maximum Supernate Concentrations by Tanks Within Each Tank Group

The tanks that exhibit the maximum supernate RCRA metal concentrations for each tank group are identified in Table 8.8. Tanks that exhibit the maximum sludge concentrations are also identified for comparison purposes. As an example, Tanks W-11, W-3, and W-8 exhibit the maximum concentration for Cr in supernate for tank groups 1, 2, and 3, respectively.

Table 8.8. Identification of tank ID maximum values of RCRA metals for tank groups

Tank Group	1	2	2	3	3
Metal	Supernate	Sludge	Supernate	Sludge	Supernate

8.14 Maximum Supernate RCRA Concentrations by Tanks Sorted by Tank Groups

Tanks that exhibit the maximum supernate RCRA metal concentrations are ordered for each tank group and presented in Tables 8.9, 8.10, and 8.11 for Tank Groups 1, 2, and 3, respectively. Tanks that exhibit the maximum sludge concentrations are also identified for comparison purposes. For example, Tank W-1 exhibits the maximum supernate RCRA metal concentrations for Ba and Hg. As a second example, Tank W-3 exhibits the maximum supernate RCRA metal concentrations for Cr and Hg. Similarly, Tank W-8 exhibits the maximum supernate RCRA metal concentrations for Cr and Hg.

8.2 RCRA METALS IN SLUDGES

8.2.1 RCRA Concentrations in Sludge That Exceed RCRA Standards

Some GAAT supernate and sludge samples exceed RCRA criteria. The samples are derived obtained from Phase I and Phase II sampling. RCRA metals are Ag, As, Ba, Cd, Cr, Hg, Ni, Pb, Se, and Tl . RCRA metals that exceed RCRA standards for supernate are presented in Table 8.12. Table 8.13 presents information regarding sludge concentrations based upon the application of U.S. Environmental Protection Agency TOX.

In Tables 8.12 and 8.13, the criteria are contained in the table header for each RCRA metal. The tabular entries identify the number of samples upon which the statistics are based, the average, and the RSD. When there are two observations, the median and the average are equal. Blank entries indicate the RCRA metal criteria was not exceeded in the tank. Details are contained in Chap. 8.

Tables 8.14–8.22 present the results from TCLP criteria and the subsequent 20:1 dilution of metal contaminants in the leachate performed on the sludge metals (Giaquinto, Keller, and Mills 1996). Blank entries indicate the RCRA metal criteria was not exceeded in the tank.

Table 8.12. RCRA metals (mg/kg) in GAAT sludges that exceed RCRA standards

Tank	Statistic	Cr (100 mg/kg)	Hg (4 mg/kg)	Pb (100 mg/kg)
W-3	N	3	3	
	Average	336.0	15.1	
	RSD	34%	53%	
W-4	N	4	4	
	Average	228.3	24.4	
	RSD	29%	112%	
W-5	N	3	3	3
	Average	1273.3	103.6	283.0
	RSD	22%	29%	22%
W-6	N	3	3	3
	Average	1363.3	78.3	3480.0
	RSD	31%	46%	97%
W-7	N	5	5	
	Average	198.2	150.8	
	RSD	49%	43%	
W-8	N	3	3	3
	Average	258.7	184.2	1370.0

W-9	N	3	3	3
	Average	119.7	66.7	496.0
	RSD	8%	11%	3%
W-10	N	3	3	3
	Average	169.0	225.0	699.7
	RSD	27%	51%	32%
TH-4	N	3	3	
	Average	281.0	7.4	
	RSD	29%	15%	

Table 8.13. TCLP (1/g) results for RCRA metals in GAAT sludges

Tank	Cr (5 ppm)	Hg (0.2 ppm)	Pb (5 ppm)
W-3			None Leached
W-4		None Leached	None Leached
W-6		0.206 µg/ml Exceeds Std	None Leached
W-7		1.8 µg/ml Exceeds Std (1)	None Leached
W-10		0.402 µg/ml Exceeds Std	None Leached

A summary of the concentrations for individual metals is presented. Samples which contain the largest and smallest median concentrations are indicated. The RSD is also provided.

Ag The largest median concentration in sludge occurs in samples from W-4 (24.7 mg/kg). The RSD is 9%. The smallest median concentration in sludge occurs in samples from W-10 (5.8 mg/kg). The RSD is 58%.

As The largest median concentration in sludge occurs in samples from TH-4 (4.2 mg/kg). The RSD is 7%. The smallest median concentration in sludge occurs in samples from W-5 (0.7 mg/kg). The RSD is 1%.

Ba The largest median concentration in sludge occurs in samples from W-6 (210.0 mg/kg). The RSD is 34%. The smallest median concentration in sludge occurs in samples from W-3 (5.4 mg/kg). The RSD is 53%.

Cd The largest median concentration in sludge occurs in samples from W-6 (6.8 mg/kg). The RSD is 24%. The smallest median concentration in sludge occurs in samples from W-9 (3.1 mg/kg). The RSD is 13%.

Cr The largest median concentration in sludge occurs in samples from W-6 and W-5 (1390 mg/kg and 1220 mg/kg, respectively). The RSDs are 31% and 22%, respectfully. The smallest median concentration in sludge occurs in samples from W-9 (115 mg/kg). The RSD is 8%.

Hg The largest median concentration in sludge occurs in samples from W-10 (288 mg/kg). The RSD is 51%. The smallest median concentration in sludge occurs in samples from TH-4 (7.4 mg/kg). The RSD is 15%. Tanks W-4 and W-8 exhibit the largest heterogeneity (RSD > 100%).

Ni The largest median concentration in sludge occurs in samples from W-6 and w-8 (138 mg/kg and 130 mg/kg respectively). The RSDs are 37% and 17%, respectively. The smallest median concentration in sludge occurs in samples from W-3 (5.7 mg/kg). The RSD is 3%.

Pb The largest median concentration in sludge occurs in samples from W-6 and W-8 (2110 mg/kg and 1440 mg/kg, respectively). The RSDs are 97% and 14% respectively. The smallest median concentration in sludge occurs in samples from W-4 (16.4 mg/kg). The RSD is 6%.

Se All concentrations are reported as less than detection limits.

Tl All concentrations except W-6 (36.1 mg/kg) are reported as less than detection limits.

8.2.2 RCRA Concentration Statistics for Sludge for Tank Groups

RCRA concentration statistics for sludge for Tank Groups 2 and 3 are presented in Tables 8.23 and 8.24.

An Analysis of Variance was performed to compare average sludge concentrations given the associated RSDs between Tank Groups 2 and 3 for selected RCRA metals (Cd, Cr, and Hg). The results indicate that there is no statistically significant difference (probability greater than 95%) between the average concentrations for Cd between Tank Groups 2 and 3.

There is a statistically significant difference (probability greater than 95%) between the average concentrations for Cr and Hg in sludges between Tank Groups 2 and 3. The average concentration for Cr in sludges in Tank Group 2 (667.13 mg/kg) is statistically greater (probability greater than 95%) than the average concentration for Cr in sludges in Tank Group 3 (271.94 mg/kg). The average concentration for Hg in sludges in Tank Group 3 (152.68 mg/kg) is statistically greater (probability greater than 95%) than the average concentration for Hg in sludges in Tank Group 2 (44.45 mg/kg).

8.2.3 Maximum Sludge Concentrations by Tanks Within Each Tank Group

The tanks that exhibit the maximum sludge metal concentrations for each tank group are identified in Table 8.25. Tanks that exhibit the maximum supernate concentrations are also

identified for comparison purposes. As an example, Tanks W-1, W-3, and W-10 exhibit the maximum concentration for Al in supernate for tank groups 1, 2, and 3.

Table 8.25. Identification of tank ID maximum values of RCRA metals for tank groups

Tank Group	1	2	2	3	3

8.2.4 Maximum RCRA Concentrations by Tanks Sorted by Tank Groups

Tanks that exhibit the maximum sludge RCRA metal concentrations are ordered for each tank group and presented in Tables 8.26 and 8.27 for Tank Groups 2 and 3, respectively. Tanks that exhibit the maximum supernate concentrations are also identified for comparison purposes. As a first example, Tank W-6 exhibits the maximum sludge RCRA metal concentrations for Ba, Cd, Hg, Ni, and Tl. As a second example, Tank W-10 exhibits the maximum sludge metal concentrations for Ag, Cd, and Ni.

9. PROCESS METALS

Process metals include: Al, B, Be, Ca, Co, Cu, Fe, K, Mg, Mn, Na, Sb, Si, Sr, Th, U, V, Zn. Concentrations of process metals are described to support potential GAAT system design and operational remedial actions that comply with waste acceptance criteria at proposed storage and disposal facilities. A substantial amount of information is presented in this section, and the reader may rapidly refer to individual subsections to obtain information of interest.

- Concentration statistics for supernate and sludge for individual tanks. Supernate (Sect. 10.1.1) and sludge (Sect. 10.2.1) samples from each tank are used to compute the minimum, the 25%-tile, the median, the 75%-tile, the maximum, the average, and the RSD for each process metal concentration for individual tanks. The minimum and the maximum provide a measure of the range of the concentration data. The 25%-tile and the 75%-tile indicate the region in which the central 50% of the reported concentration data is contained. The median and the average are measures of central tendency for the concentration data. The RSD (the ratio of the standard deviation to the average) is expressed as a percentage. The RSD provides insight to the variability of the concentration data.
- Concentration statistics for supernate and sludge for tank groups. Tank Group 1 (W-1, W-2, W-11), Tank Group 2 (W-3, W-4, W-5, W-6, TH-4), and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational definitions of tank groups. Supernate samples (Sects. 10.1.1 and 10.1.2) are pooled for the tank groups, and the same is accomplished for sludge samples (Sects. 10.2.1 and 10.2.2) for the tank groups. These concentrations are used to compute the minimum, median, maximum, average, and RSD for each process metal for tank group.
- Maximum supernate and sludge concentrations for tanks within each tank group. The maximum supernate (Sect. 10.1.3) and sludge (Sect. 10.2.3) concentrations of each process metal for each tank group are used to identify which tanks within a tank group exhibit the largest concentration.
- Maximum concentrations sorted by individual tanks within tank groups for supernate or sludge. Sorts of the maximum concentrations for the tank groups are performed to easily display which individual tanks within the tank group exhibit the largest concentrations in the supernate (Sect. 10.1.4) and the sludge (Sect. 10.2.4).

9.1 PROCESS METALS IN SUPERNATES

9.1.1 Concentration Statistics for Supernate for Individual Tanks

Concentration statistics for process metals in supernate for individual tanks are presented in Tables 9.1 through 9.3. Given the paucity of observations (N=2 or less for any tank), statistics presented include only the median and the RSD for each process metal concentration for individual tanks. The following observations are provided for median concentrations and, where applicable, for the spatial variability of the concentrations.

Median Concentrations. Medians for supernate concentrations indicate that value such that 50% of the concentrations occur either above or below the median value. For two observations, the median and the average are equivalent. RSDs that exceed 100% indicate large spatial

variability. RSDs that are less than 25% to 50% indicate small spatial variability. The maximum number of samples used to compute the RSD is 2.

Al The largest median concentration of metals in supernate occur in samples from W-3 and W-6 (5.14 mg/L and 2.55 mg/L, respectively). Both RSDs are greater than 100%. The smallest median concentration of metals in supernate occurs in samples from W-2 and W-11 (0.0242 mg/L and 0.026 mg/L, respectively). Both tanks have only one observation, so an RSD is not computed.

B The largest median concentration of metals in supernate occur in samples from TH-4 and W-8 (1.018 mg/L and 0.713 mg/L, respectively). The RSD for TH-4 is 20%. The RSD is not computed for the single observation in W-8. The smallest median concentration of metals in supernate occurs in samples from W-1 and W-11 (0.033 mg/L and 0203 mg/L, respectively). There is one observation from W-1 and W-11, and the RSD is not computed.

Be All concentrations are reported as less than detection limits.

Ca The largest median concentration of metals in supernate occur in the samples from TH-4, W-4, and W-1 (263 mg/L, 47.1 mg/L, and 42.5 mg/L, respectively). The RSD for TH-4 is 8%. There is one observation for W-4 and W-1. The smallest median concentration of metals in supernate occurs in samples from W-6 and W-5 (11.835 mg/L and 6.84 mg/L, respectively). The RSD for W-6 is 95%. There is one observation from W-5, and the RSD is not computed.

Co The largest median concentration of metals in supernate occur in the samples from W-9 and W-4 (0.215 mg/L and 0.19 mg/L, respectively). There is one observation for W-9 and W-4. The smallest median concentration of metals in supernate occurs in samples from W-3 and W-10 (0.0285 mg/L and 0.0116 mg/L, respectively). There is one observation from W-3 and W-10, and the RSD is not computed.

Cu The largest median concentration of metals in supernate occur in the samples from W-9 and W-8 (0.694 mg/L and 0.586 mg/L, respectively). There is one observation for W-9 and W-8. The smallest median concentration of metals in supernate occurs in samples from W-2 and W-11 (0.005 mg/L and 0.003 mg/L, respectively). There is one observation from W-2 and W-11, and the RSD is not computed.

Fe The largest median concentration of metals in supernate occur in the samples from TH-4 and W-4 (0.5165 mg/L and 0.448 mg/L, respectively). The RSD for TH-4 is 5%. There is one observation for W-4. The smallest median concentration of metals in supernate occurs in samples from W-10 and W-11 (0.0296 mg/L and 0.0135 mg/L, respectively). There is one observation from W-10, and the RSD is not computed. The RSD for W-11 is 47%.

K The largest median concentration of metals in supernate occur in samples from TH-4 and W-2 (8.255 mg/L and 7.85 mg/L, respectively). There is one observation per tank, and RSDs are not computed. The smallest median concentration of metals in supernate occurs in samples from W-1 and W-11 (15.4 mg/L and 7.665 mg/L, respectively). There is one observation from W-1, and the RSD for W-11 is 1%.

Mg The largest median concentration of metals in supernate occur in samples from W-9 and W-10 (896 mg/L and 819 mg/L, respectively). The RSDs are less than 5%. The smallest median concentration of metals in supernate occurs in samples from W-5 and W-6

(1.98 mg/L and 1.336 mg/L, respectively). There is one observation from W-5, and the RSD for W-6 is 77%.

Mn The largest median concentration of metals in supernate occur in the samples from TH-4 and W-4 (0.398 mg/L and 0.173 mg/L, respectively). The RSD for TH-4 is 1%. There is one observation for W-4. The smallest median concentration of metals in supernate occurs in samples from W-5 and W-10 (0.008 mg/L and 0.007 mg/L, respectively). There is one observation from W-5 and W-10, and the RSD is not computed.

Na The largest median concentration of metals in supernate occur in the samples from TH-4, W-8, and W-5 (14,500 mg/L, 4,370 mg/L, and 4,250 mg/L, respectively). The RSD for TH-4 is 42%. There is one observation for W-8 and W-5. The smallest median concentration of metals in supernate occurs in samples from W-1 and W-11 (6.56 mg/L and 5.345 mg/L, respectively). The RSD for W-11 is 4%. There is one observation from W-1, and the RSD is not computed.

Sb All concentrations are reported as less than detection limits.

Sl The largest median concentration of metals in supernate occur in the samples from TH-4 and W-1 (6.785 mg/L and 5.54 mg/L, respectively). The RSD for TH-4 is 9%. There is one observation for W-1. The smallest median concentration of metals in supernate occurs in samples from W-4 and W-11 (2.36 mg/L and 2.245 mg/L, respectively). The RSD for W-11 is 0%. There is one observation from W-4, and the RSD is not computed.

Sr The largest median concentration of metals in supernate occur in the samples from TH-4 and W-4 (0.3745 mg/L and 0.262 mg/L, respectively). The RSD for TH-4 is 3%. There is one observation for W-4. The smallest median concentration of metals in supernate occurs in samples from W-3 and W-5 (0.0315 mg/L and 0.0084 mg/L, respectively). There is one observation from W-3 and W-5, and the RSD is not computed.

Th The largest median concentration of metals in supernate occur in the samples from TH-4 and W-4 (130.9 mg/L and 39.6 mg/L, respectively). The RSD for TH-4 is 81%. There is one observation for W-4. The smallest median concentration of metals in supernate occurs in samples from W-11 and W-5 (0.101 mg/L and 0.097 mg/L, respectively). There is one observation from W-11 and W-5, and the RSD is not computed.

U The largest median concentration of metals in supernate occur in the samples from TH-4, W-4, and W-9 (7,865 mg/L, 1,540 mg/L, and 1,520 mg/L, respectively). The RSD for TH-4 is 76%. There is one observation for W-4 and W-9. The smallest median concentration of metals in supernate occurs in samples from W-11 and W-2 (1.65 mg/L and 0.1 mg/L, respectively). The RSD for W-11 is 23%. There is one observation from W-2, and the RSD is not computed.

V All concentrations are reported as less than detection limits.

Zn The largest median concentration of metals in supernate occur in the samples from W-10 (0.368 mg/L). There is one observation for W-10. The smallest median concentration of metals in supernate occurs in samples from W-8 (0.0349 mg/L). There is one observation from W-8, and the RSD is not computed.

9.1.2 Concentration Statistics for Supernate for Tank Groups

Concentration statistics for supernate for Tank Groups 1, 2, and 3 are presented in Tables 9.4–9.7. The following observations are made for each tank group.

Tank Group 1 Supernate RSDs.

RSD > 100%	Al, Fe, Na
50% < RSD < 100%	K, U
50% < RSD	B, Ca, Cu, Mg, Si, Sr
RSD Not Computed	Be, Co, Mn, Sb, Th, V, Zn

Tank Group 2 Supernate RSDs. High RSD (> 100%) is due to samples from TH-4 supernate.

RSD > 100%	Al, B, Ca, K, Mn, Na, Sr, Th, U
50% < RSD < 100%	Co, Cu, Fe, Mg,

50% < RSD	Si
RSD Not Computed	Be, Sb, V, Zn

Tank Group 3 Supernate RSDs.

RSD > 100%	Al
50% < RSD < 100%	Co, Cu, Fe, Mn, U
50% < RSD	B, Ca, K, Mg, Na, Sr, Th
RSD Not Computed	Al, Be, Sb, Si, V

Table 9.4. Process metal concentration statistics for all tank groups, supernate (mg/L)

9.1.3 Maximum Supernate Concentrations by Tanks Within Each Tank Group

The tanks that exhibit the maximum supernate metal concentrations for each tank group are identified in Table 9.8. Tanks that exhibit the maximum sludge concentrations are also identified for comparison purposes. As an example, Tanks W-1, W-3, and W-10 exhibit the maximum concentration for Al in supernate for tank groups 1, 2, and 3.

Table 9.8. Identification of tanks with maximum values of process metals for tank groups

Tank Group	1	2	2	3	3

9.1.4 Maximum Supernate Concentrations by Tanks Sorted by Tank Groups

Tanks that exhibit the maximum supernate metal concentrations are ordered for each tank group and presented in Tables 9.9, 9.10, and 9.11 for Tank Groups 1, 2, and 3, respectively. Tanks that exhibit the maximum sludge concentrations are also identified for comparison purposes. As a first example, Tank W-1 exhibits the maximum supernate metal concentrations for Al, Ca, Cu, Fe, Si, and Sr. As a second example, Tank W-3 exhibits the maximum supernate metal concentrations for Al. As a third example, Tank W-8 exhibits the maximum supernate metal concentrations for B, Ca, Mg, Na, and Sr.

9.2 PROCESS METALS IN SLUDGES

9.2.1 Concentration Statistics for Sludge for Individual Tanks

Concentration statistics for sludge for individual tanks are presented in Tables 9.12–9.22. Statistics presented are the minimum, the 25%-tile, the median, the 75%-tile, the maximum, the average, and the RSD for each process metal concentration for individual tanks. The following observations are provided for median concentrations and for the spatial variability of the concentrations.

Median Concentrations. The median concentration is that value such that 50% of the concentrations occur either above or below the median value. The median is always less than the average for concentrations that are highly skewed to the right. Concentrations that are highly skewed to the right occur when the difference between the median (or the average) concentration and the maximum concentration is large. Concentrations that are highly skewed will exhibit a

large (> 100%) RSD. Concentrations that are not highly skewed to the right occur when the difference between the median (or the average) concentration and the maximum concentration is small. Concentrations that are not highly skewed will exhibit a small (< 25% to 50%) RSD.

Al The largest median concentration of metals in sludges occur in samples from W-10, W-5, and W-6 (30,200 mg/kg, 15,700 mg/kg, and 10,900 mg/kg, respectively). All RSDs are less than 35%. The smallest median concentration of metals in sludges occur in samples from W-3 and W-7 Chips (913 mg/kg and 594 mg/kg, respectively). All RSDs are greater than 100%.

B The largest median concentration of metals in sludges occur in samples from W-7 Layer, W-7, W-5 (38.60 mg/kg, 24.20 mg/kg, and 16.30 mg/kg, respectively). RSDs are 85%, 16%, and 118%, respectively. The smallest median concentration of metals in sludges occur in samples from W-10 and W-3 (3.50 mg/kg and 3.12 mg/kg, respectively). RSDs are 63% and 8%, respectively.

Be The largest median concentration of metals in sludges occur in samples from W-4 and W-8 (11.08 mg/kg and 9.71 mg/kg, respectively). RSDs are less than 60%. The smallest median concentration of metals in sludges occur in samples from W-7, TH-4, and W-5 (2.19 mg/kg, 3.12 mg/kg, and 0.67 mg/kg, respectively). RSDs are 40% and 43%, respectively, for W-7 and TH-4. The RSD was not computed for the one observation for W-5.

Ca The largest median concentration of metals in sludges occur in samples from W-6, W-5, and W-10 (29,800 mg/kg, 11,300 mg/kg, and 8,810 mg/kg, respectively). All RSDs are less than 45%. The smallest median concentration of metals in sludges occur in samples from W-7 Layer and W-7 Chips (702 mg/kg and 314 mg/kg, respectively). All RSDs are greater than 65%.

Co The largest median concentration of metals in sludges occur in samples from W-6, W-4, and W-10 (7.35 mg/kg, 5.20 mg/kg, and 4.50 mg/kg, respectively). RSDs are 87%. and 12% for W-6 and W-4. The RSD was not computed for the one observation for W-10. The smallest median concentration of metals in sludges occur in samples from W-9 and W-8, and W-7 Chips (2.90 mg/kg, 2.70 mg/kg, and 2.67 mg/kg, respectively). All RSDs are less than 30%. The RSD was not computed for the one observation for the W-7 Chips.

Cu The largest median concentration of metals in sludges occur in samples from W-7, W-10, and W-8 (98.0 mg/kg, 75.0 mg/kg, and 62.2 mg/kg, respectively). All RSDs are less than 20%. The smallest median concentration of metals in sludges occur in samples from W-4 and TH-4 (22.7 mg/kg and 16.4 mg/kg, respectively). RSDs are 82% and 21%, respectively.

Fe The largest median concentration of metals in sludges occur in samples from W-5, W-6, and W-7 Layer (19,200 mg/kg, 14,200 mg/kg, and 10,544 mg/kg, respectively). RSDs for W-5 and W-6 are less than 20%. W-7 Layer RSD is 131%. The smallest median concentration of metals in sludges occur in samples from W-7 Chips and W-3 (332 mg/kg and 245 mg/kg, respectively). W-7 Chips RSD is 39% and W-3 RSD is 139%.

K The largest median concentration of metals in sludges occur in samples from W-7 Chips, W-7, and W-7 Layer (10,015 mg/kg, 9,170 mg/kg, and 8,175 mg/kg, respectively). All RSDs are less than 35%. The smallest median concentration of metals in sludges occur

in samples from W-3 and W-4 (334 mg/kg and 275 mg/kg, respectively). All RSDs are less than 35%.

Mg The largest median concentration of metals in sludges occurs in samples from W-8 (5,520 mg/kg). The RSD is less than 45%. The smallest median concentration of metals in sludges occur in samples from W-4 and W-7 Layer (179 mg/kg and 149 mg/kg, respectively). The RSDs are 97% and 51%, respectively.

Mn The largest median concentration of metals in sludges occur in samples from W-6 and W-5 (801 mg/kg and 433 mg/kg, respectively). All RSDs are less than 70%. The smallest median concentration of metals in sludges occur in samples from W-4 and W-7 Chips (26.8 mg/kg and 23.7 mg/kg, respectively). All RSDs are less than 45%.

Na The largest median concentration of metals in sludges occur in samples from W-7 Layer, W-7 Chips, and W-7 Chips (67,400 mg/kg, 57,800 mg/kg, and 43,200 mg/kg, respectively). All RSDs are less than 20%. The smallest median concentration of metals in sludges occur in samples from W-3 and W-9 (9,540 mg/kg and 6,310 mg/kg, respectively). All RSDs are less than 40%.

Sb All samples were reported as less than detection limits.

Si The largest median concentration of metals in sludges occur in samples from W-6 and W-3 (3,360 mg/kg and 509 mg/kg, respectively). Only one observation was reported for both tanks. The smallest median concentration of metals in sludges occur in samples from W-4 and TH-4 (234 mg/kg and 198 mg/kg, respectively). All RSDs are less than 26%.

Sr The largest median concentration of metals in sludges occur in samples from W-6, W-10, and W-8 (64.6 mg/kg, 63.9 mg/kg, and 50.2 mg/kg, respectively). All RSDs are less than 35%. The smallest median concentration of metals in sludges occur in samples from W-7 Layer and W-7 Chips (8.6 mg/kg and 3.1 mg/kg, respectively). All RSDs are less than 75%.

Th The largest median concentration of metals in sludges occur in samples from TH-4 and W-8 (115,000 mg/kg and 14,300 mg/kg, respectively). All RSDs are less than 50%. The smallest median concentration of metals in sludges occur in samples from W-6 and W-5 (679 mg/kg and 319 mg/kg, respectively). The RSD for W-6 is 89% and for W-5 is 161%.

U The largest median concentration of metals in sludges occur in samples from W-7 Chips, W-7 Layer, and W-7 (217,000 mg/kg, 121,050 mg/kg, and 117,950 mg/kg, respectively). All RSDs are less than 75%. The smallest median concentration of metals in sludges occur in samples from W-5 (927 mg/kg). The RSD is 163%.

V The median concentration of metals in sludges occur in samples from W-7 Chips , W-7, and W-7 Layer (2.6 mg/kg, 2.1 mg/kg, and 1.5 mg/kg, respectively). All RSDs are less than 25%.

Zn The largest median concentration of metals in sludges occur in samples from W-6, W-10, and W-8 (157 mg/kg, 110 mg/kg, and 95.6 mg/kg, respectively). W-6 RSDs is 70% and the other RSDs are less than 15%. The smallest median concentration of metals in sludges occur in samples from W-3, W-4, and W-7 Chips (10.7 mg/kg, 10.1 mg/kg, and 8.2 mg/kg, respectively). The RSD for W-3 is 100%, and the other RSDs are less than 20%.

Spatial Variability. RSDs for concentrations for metals for each tank that exceed 100% indicate large spatial variability. RSDs for concentrations for metals for each tank that are less

than 25% to 50% indicate small spatial variability. The maximum number of samples used to compute the RSD is 5, and the minimum number of samples used to compute the RSD is 2.

Al The greatest spatial variability of metals in sludges occur in samples from W-3 and W-7 Chips (165% and 137%, respectively). The least spatial variability of metals in sludges occur in samples from Tanks W-6, W-10, W-9, W-8 (11% to 3%).

B The greatest spatial variability of metals in sludges occur in samples from W-5 (118%). The least spatial variability of metals in sludges occur in samples from Tanks W-7, W-3, W-4, W-9, and W-7 Chips (16% to 1%).

Be No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-9 (22%).

Ca No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-8, W-6, TH-4, W-7 Chips, and W-9 (12% to 3%).

Co No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-8, W-3, and W-4 (13% to 12%).

Cu No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-5, W-7 Layer, TH-4, W-8, W-7, W-10, and W-9 (22% to 4%).

Fe The greatest spatial variability of metals in sludges occur in samples from W-3 and W-7 Layer (139% to 131%). The least spatial variability of metals in sludges occur in samples from Tanks W-6, W-5, TH-4, and W-9 (20% to 6%).

K No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-5, W-7, W-10, W-7 Chips, W-3, and W-8 (24% to 5%).

Mg The greatest spatial variability of metals in sludges occur in samples from W-5, W-6, and W-4 (155% to 97%). The least spatial variability of metals in sludges occur in samples from Tanks W-7 Chips and W-9 (24% to 17%).

Mn The greatest spatial variability of metals in sludges occur in samples from W-7 Layer (121%). The least spatial variability of metals in sludges occur in samples from Tanks W-7 Chips, W-8, TH-4, and W-9 (25% to 3%).

Na No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-7, W-10, W-9, W-6, TH-4, W-7 Chips, and W-7 Layer (20% to 3%).

Si No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-4 and TH-4 (26% to 23%). Si was analyzed only in Phase I, and it was reviewed as an estimated detect and as a matrix spike.

Sr No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-8, W-5, W-6, and W-9 (22% to 5%).

Th The greatest spatial variability of metals in sludges occur in samples from W-5 (161%). The least spatial variability of metals in sludges occur in samples from Tanks W-4, W-8, W-7, W-9, and W-7 Chips (26% to 1%).

U The greatest spatial variability of metals in sludges occur in samples from W-5 and W-6 (163 to 115%%). There is a tight cluster of variability for samples from W-4, W-10, W-7 Layer, W-3, TH-4, W-9, and W-7 (72% to 53%). The least spatial variability of metals in sludges occur in samples from Tanks W-8 and W-7 Chips (8% to 3%).

V No samples exhibit spatial variability of metals in sludges greater than 100%. The least spatial variability of metals in sludges occur in samples from Tanks W-7, W-7 Chips, and W-7 Layer (25% to 0%).

Zn The greatest spatial variability of metals in sludges occur in samples from W-3 (100%). The least spatial variability of metals in sludges occur in samples from Tanks W-4, W-5, W-9, W-8, W-10, and W-7 Chips (19% to 1%).

Table 9.12. Process metal concentration statistics for sludge for Tank W-3 (mg/kg)

9.2.2 Concentration Statistics for Sludge for Tank Groups

Concentration statistics for sludge for Tank Groups 2 and 3 are presented in Tables 9.23–19.25.

An Analysis of Variance was performed to compare average sludge concentrations given the associated RSDs between Tank Groups 2 and 3 for selected metals (Al, Ca, Cu, Fe, K, Mg, Mn, Na, Sr, and U). The results indicate that there is no statistically significant difference between the average concentrations for Al, Fe, Mg, Mn, Na, Sr, and U between Tank Groups 2 and 3.

There is a statistically significant difference between the average concentrations for Ca, Cu, and K between Tank Groups 2 and 3. The average concentration for Ca in Tank Group 2 is statistically smaller than the average concentration for Ca in Tank Group 3. The average concentration for Cu in Tank Group 2 is statistically greater than the average concentration for Cu in Tank Group 3. The average concentration for K in Tank Group 2 is statistically smaller than the average concentration for K in Tank Group 3.

9.2.3 Maximum Sludge Concentrations by Tanks Within Each Tank Group

The tanks that exhibit the maximum sludge metal concentrations for each tank group are identified in Table 9.26. Tanks that exhibit the maximum supernate concentrations are also identified for comparison purposes. As an example, Tanks W-6 and W-10 exhibit the maximum sludge metal concentrations for Ca, Co, Sr, and Zn in tank groups 2 and 3.

Table 9.26. Identification of tanks with maximum values of process metals for tank groups

9.2.4 Maximum Sludge Concentrations by Tanks Sorted by Tank Groups

Tanks that exhibit the maximum sludge metal concentrations are ordered for each tank group and presented in Tables 9.27 and 9.28 for Tank Groups 2 and 3, respectively. Tanks that exhibit the maximum sludge concentrations are also identified for comparison purposes. As a first example, Tank W-6 in Tank Group 2 exhibits the maximum sludge metal concentrations for Ca, Co, Cu, Fe. Mg, Na, Si, Sr, and Zn. As a second example, Tank W-7 in Tank Group 3 exhibits the maximum sludge metal concentrations for B, Cu, Fe, K, Mn, Na, and U. There are no reported concentrations for sludge in Tank Group 1.

10. ANIONS

10.1 INTRODUCTION

Concentrations of water soluble anions (Chloride, Bromide, Fluoride, Nitrate, Phosphate, Sulphate) are described in several ways using GAAT Sampling and analysis data from GAAT Phase I (Energy Systems 1995) and Phase II (U.S. DOE 1995). Knowledge of anions can support GAAT system design and operational remedial actions that comply with waste acceptance criteria at proposed storage and disposal facilities.

Anion statistics for supernate and sludge for Tank Groups. Tank Group 1 (W-1, W-2, W-11), Tank Group 2 (W-3, W-4, W-5, W-6, TH-4), and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational definitions of Tank Groups. Supernate and sludge samples are pooled for the Tank Groups. These values are used to compute the minimum, median, maximum, average, and RSD for each anion for the Tank Group.

Anion statistics for supernate and sludge for individual tanks. Supernate and sludge samples from each tank are used to compute the minimum, the 25%-tile, the median, the 75%-tile, the maximum, the average, and the RSD for each anion for individual tanks. The minimum and the maximum provide a measure of the range of the anion data. The 25%-tile and the 75%-tile indicate the region in which the central 50% of the reported anion data is contained. The median and the average are measures of central tendency for the anion data. The RSD (the ratio of the standard deviation to the average) is expressed as a percentage. The RSD provides insight to the variability of the anion data.

10.2 ANIONS IN SUPERNATES

Summary statistics of the concentrations for anions in supernate for each tank group are presented in Tables 10.1 through 10.3. In most cases, Tank Group 3 contains the maximum median values, and Tank Group 1 contains the minimum median values. Although the number of samples is limited, Tank Group 2 clearly exhibits high spatial variability in anion concentration in supernate. This is due to high anion concentrations in TH-4 and W-6. The thick supernate levels in these tanks may also have contributed to these high RSDs.

Table 10.1. Summary of anion concentrations (mg/L) for Tank Group 1 for GAAT supernate

NC = Not Calculated

A summary of the concentrations for individual anions in supernate for Tank Groups is presented. Samples which contain the largest and smallest median concentrations are indicated. The RSD is also provided.

Bromide All samples were non-detects.

Chloride The largest median concentration is in Tank Group 3 (306.0 mg/L), and the smallest median concentration is in Tank Group 1 (4.5 mg/L). W-10 contains the maximum value, and W-11 contains the minimum value. Spatial variability between Tank Groups ranges from 41% to 87%

Fluoride The largest median concentration is in Tank Group 2 (253.5 mg/L), and the smallest median concentration is in Tank Group 1 (1.7 mg/L). W-6 contains the maximum value, and W-11 contains the minimum value. Tank Groups 1 and 2 exhibit spatial variability greater than 100%.

Nitrate The largest median concentration is in Tank Group 3 (2,500.0 mg/L), and the smallest median concentration is in Tank Group 1 (11.9 mg/L). W-6 and TH-4 contain the maximum values, and W-3 contains the minimum value. Tank Group 2 exhibits spatial variability greater than 100%.

Phosphate The largest median concentration is in Tank Group 3 (696.0 mg/L), and the smallest median concentration is in Tank Group 1 (2.4 mg/L). W-10 contains the maximum value, and W-2 contains the minimum value. Tank Groups 2 and 3 exhibit spatial variability greater than 100%.

Sulphate The largest median concentration is in Tank Group 3 (676.0 mg/L), and the smallest median concentration is in Tank Group 1 (12.6 mg/L). TH-4, W-6, and W-8 contain the maximum values, and W-11 contains the minimum value. Tank Group 2 exhibits spatial variability greater than 100%.

10.3 ANIONS IN SLUDGES

Sludge samples from each tank are used to compute the minimum, the 25%-tile, the median, the 75%-tile, the maximum, the average, and the RSD for each anion for individual tanks in Tank Groups 2 and 3. These are presented in Tables 10.4 through 10.13.

Table 10.4. Anion concentrations (mg/kg) in sludge for Tank W-3

Median concentrations for anions in sludge for each tank is presented in Tables 10.14 and 10.15. Excluding TH-4, W-6 in Tank Group 2 represents the maximum anion concentration in the sludge and drives the group spatial variability. Tank W-7 represents the maximum anion concentration in the sludge and drives Tank Group 3 spatial variability.

Table 10.14. Sludge anion median concentrations (mg/kg) for individual tanks in Tank Group 2

Anions	W-3	W-4	W-5	W-6	TH-4	Min	Max

NC = Not Calculated

Summary statistics of concentrations for individual anions in sludge for Tank Groups 2 and 3 are presented in Tables 10.16 and 10.17. Although the number of samples is limited, Tank Group 2 clearly exhibits high spatial variability in anion concentration in sludge. Samples which contain the largest and smallest median concentrations are indicated. The RSD is also provided.

Bromide Samples were reported for only Tank Group 3. The median concentration is 9.5 mg/kg. The maximum concentration is in W-7. Spatial variability is 76%.

Chloride The largest median concentration is in Tank Group 3 (2,360 mg/kg), and the smallest median concentration is in Tank Group 2 (144 mg/kg). W-7 contains the maximum value, and W-5 contains the minimum value. Spatial variability between Tank Groups ranges from 38% to 76%

Fluoride The largest median concentration is in Tank Group 3 (518 mg/kg), and the smallest median concentration is in Tank Group 2 (398 mg/kg). TH-4 and W-6 contain the maximum values, and W-3 contains the minimum value. Tank Group 2 exhibits spatial variability greater than 100%.

Nitrate The largest median concentration is in Tank Group 3 (6,270 mg/kg), and the smallest median concentration is in Tank Group 2 (1,575 mg/kg). W-7 contains the maximum value, and W-3 contains the minimum value. While Tank Group 2 exhibits spatial variability greater than 100%, Tank Group 2 spatial variability is 97%.

Phosphate The largest median concentration is in Tank Group 3 (3,660 mg/kg), and the smallest median concentration is in Tank Group 2 (2,874 mg/kg). W-6 contains the maximum value, and TH-4 contains the minimum value. RSDs are less than 100%.

Sulphate The largest median concentration is in Tank Group 3 (4,300 mg/kg), and the smallest median concentration is in Tank Group 2 (1,720 mg/kg). TH-4 and W-6 contain the maximum values, and W-5 contains the minimum value. Spatial variability in Tank Group 2 is greater than 100%.

Table 10.16. Summary statistics for anion concentrations (mg/kg) for Tank Group 2

11. SUMMARY AND CONCLUSIONS

11.1 SUMMARY

The report has provided evaluations to (1) support the GAAT TS and (2) provide input to the Record of Decision for the remediation of selected tanks that are part of the NTF and STF. This report presents an evaluation of GAAT sampling and analysis data from various tanks in the NTF and the STF.

Several major areas of evaluation have been performed:

- Answer DQO Question 1. What is the spatial homogeneity or heterogeneity of key chemical and radionuclide concentrations in tanks suspected of significant curie loading?
- Determine current values for tank volumes. Sludge and supernate volumes for all tanks are updated based on Phase II sludge mapping information.
- Determine curie loading for each tank. Using Phase I and Phase II data, in addition to 1988 sampling data, curie loadings for sludge and supernate are determined.
- Determine tanks that are TRU and non-TRU under DOE Order 5820.2A. Using Phase I and Phase II data, tanks are classified as TRU or non-TRU.
- Describe risk/transport drivers for tanks. Using Phase I and Phase II data, the beta/gamma radioisotopes in the sludge and supernate that significantly affect GAAT transport modeling are determined.
- Describe Physical Properties of tanks. The physical properties of the sludge and supernate are updated based on additional Phase II data.
- Determine which tanks exceed RCRA metals standards. Identification of which tanks exceed RCRA metals standards in the sludge and supernate are updated based on additional Phase II data.
- Describe concentrations of process metals for tanks. The concentrations of process metals in the sludge and supernate are updated based on additional Phase II data.
- Describe concentrations of Anions for tanks. The concentrations of anions in the sludge and supernate are updated based on additional Phase II data.
- Describe concentrations of other chemicals and radioisotopes (e.g., alkaloids, PCBs, etc.) for tanks. The concentrations in the sludge and supernate are updated based on additional Phase II data.

The scope was to evaluate sludge and supernate radiological, inorganic, and wet chemistry sample data for the Gunite tanks W-1, W-2, W-3, W-4, W-5, W-6, W-7, W-8, W-9, W-10, W-11, and TH-4. Tank Group 1 (W-1, W-2, W-11), Tank Group 2 (W-3, W-4, W-5, W-6, TH-4), and Tank Group 3 (W-7, W-8, W-9, W-10) represent current operational grouping definitions of the GAAT. The GAAT TS has made the programmatic decision not to collect samples from the stainless-steel tanks (W-1A, W-13, W-14, and W-15), and these tanks are not evaluated in this report.

11.2 CONCLUSIONS

Tanks contained in Tank Group 3 contain 96% of the expected (or most likely) curies in the sludge and 90% of the expected curies in supernate for all tank groups. Tanks suspected of significant sludge curie loading in Tank Group 3 are W-10, W-8, and W-7. Tanks suspected of significant supernate curie loading in Tank Group 3 are W-8 and W-10. Tank W-6 in Tank Group 2 is suspected to contain 87% of the expected curies in sludge for Tank Group 2 and 94% of the expected curies in supernate in Tank Group 2. Tank Group 1 accounts for 0% of the expected curies in the sludge and supernate

Tanks W-3, W-4, W-6, W-8, W-9, and W-10 are considered TRU under DOE Order 5820.2A.

Beta/gamma emitters, particularly Sr-90 and Cs-137, are considered significant variables in the transport and human health and environmental risk modeling for the GAAT. Several observations of the average concentrations and the spatial homogeneity or heterogeneity of the Sr-90 and Cs-137 concentrations are made:

- Tanks W-8, W-9, and W-10 indicate the largest average concentration of Sr-90
- Tanks W-7 and W-10 indicate the largest average concentration of Cs-137
- Tanks W-3 and W-4 exhibit the most heterogeneity for Sr-90 average concentration
- Tank W-4 exhibits the most heterogeneity for Cs-137 average concentration
- Tanks W-8 and W-9 exhibit the most homogeneity for Sr-90 average concentration
- Tanks W-3, W-5, W-8, W-9, and TH-4 exhibit the most homogeneity for Cs-137 average concentration

There are 3 key sources of measurement error (sample location, sample method, and analytical method) associated with samples obtained from either GAAT sludge or supernate. Sources of measurement error are "confounded" with each other. This means that it is not statistically possible to determine if the reason for a change in a sample value between Phase I, Phase II, and 1988 sampling is due explicitly to the sample location, the sample method, or the analytical method. Confounding says we cannot "decouple" the combined measurement error effects of the sample location, the sample method, or the analytical method. Two key reasons for confounding are:

- Different sample methods were not used for samples from the same sample location (port, riser, and depth)
- Different analytical methods were not used for samples from the same location

Cost of sampling and analysis is the key driver. If confounding were desired to be completely eliminated, a minimum of eight samples from the sludge and eight samples from the supernate per tank would have been required. Furthermore, if we wanted to compare Phase I and Phase II data with 1988 data, we would have to replicate the analytical methods used during 1995 and 1988 for each sample collected. This is prohibitive in cost, and, as such, the trade-off between cost and "confounding" occurred.

Based upon the statistical evaluations performed, the benefit of additional sampling after 1988 considerably supports the remediation decisions planned for the GAAT TS.

Appendix A

DATA QUALITY OBJECTIVES FOR GAAT PHASE II SAMPLING AND ANALYSIS

This appendix contains the major questions and the DQOs for the Phase II GAAT sampling and analysis effort performed in FY 1995. The major questions are contained in *Oak Ridge National Laboratory Inactive Tanks Sampling and Analysis Plan, Addendum 1, Revision 2, Oak Ridge, Tennessee*, DOE/OR/02-1354&D2, February 1995. The DQOs are presentation material associated with DQO workshop for the Phase II sampling held in January 1995.

- Question 1. What is the spatial homogeneity or heterogeneity of key chemical and radionuclide concentrations in tanks suspected of significant curie loading?
- Question 2. What are the locations and the composition of sludge and debris in the tanks?
- Question 3. What is the integrity of the tank walls?
- Question 4. What is the extent of contamination in the tank walls?

Question 1	**What is the spatial homogeneity or heterogeneity of key chemical and radionuclide concentrations in tanks suspected of significant Curie loading?** ***Determine average concentration and variance of average concentration of analytes or radionuclides; compare to Phase I results.***

Appendix B

SLUDGE DATA BASE AND SUMMARY STATISTICS

INTRODUCTION

The GAAT sludge TS Phase I and Phase II data base presented. The following sample information is provided for W-03, W-04, W-05, W-06, W-07, W-08, W-09, W-10, and TH-4:

- Physical properties
- RCRA metals
- Process metals
- Anions by ion chromatography (water wash)
- Beta/gamma emitters
- Alpha emitters by alpha spectrometry
- Uranium isotopics by mass spectrometry
- Plutonium isotopics by mass spectrometry

Analytical data for each sample from each tank is presented. If the maximum value exceeds RCRA standards, this information is indicated. Summary statistics include: the number of observations (samples), the minimum, the 25%-tile, the median value, the 75%-tile, and the maximum value. Additional summary statistics are: the arithmetic average, RSD expressed as a percentage, and the range of the sample values (the difference between the maximum and the minimum).

Appendix C

SUPERNATE DATA BASE AND SUMMARY STATISTICS

INTRODUCTION

The supernate GAAT TS Phase I data base is presented. The following sample information is provided for W-01, W-02, W-03, W-04, W-05, W-06, W-08, W-09, W-10, W-11, and TH-4:

- Physical properties
- RCRA metals
- Process metals
- Alkalinity
- Anions by ion chromatography (water wash)
- Beta/gamma emitters
- Alpha emitters by alpha spectrometry
- Uranium isotopics by mass spectrometry
- Plutonium isotopics by mass spectrometry

Analytical data for each sample from each tank is presented.

Appendix D

TECHNICAL APPROACH FOR CURIE LOADINGS

PROCESS FOR ESTIMATION OF UPPER 95% CONFIDENCE LIMITS FOR RADIONUCLIDE CONCENTRATION AND CURIE LOADING

SUMMARY

This appendix contains (1) the technical approach used to compute curie loadings for sludge and supernate in the GAAT, (2) the curie loadings for all GAAT as based upon the technical approach, and (3) the data base used to compute the curie loadings. For reference purposes, this data base is called the "Curie Loading Data Base."

The technical approach provides a probabilistic representation of curie loadings in sludge and supernate for the GAAT. Individual isotope concentrations are used to determine the probability density function (PDF) for the concentrations. An upper 95% confidence limit is computed for the concentration for each isotope. Sludge and supernate volume and density are used to compute the curie loading for the sludge and the supernates in the tanks.

Curie loadings for sludge and supernate in the GAAT are contained in Tables D.1 through D.13. Tanks examined are: W-1, W-2, W-3, W-4, W-5, W-6, W-7, W-8, W-9, W-10, and TH-4. Table D.1 provides a summary of curie loadings for sludge and supernate in the GAAT. Table D.2 provides this information in a percentage form for all tanks within each tank group for all tank groups. Tables D.3 through D.13 identify (1) the GAAT tank examined, (2) the waste form (sludge or supernate), (3) the capacity and the volume of the tank, (4) the maximum reported density, (5) the total and the individual isotope concentration expressed as either the 10%-tile, the median, or the 95%-tile (denoted as 0.10, 0.50, and 0.95, respectively), and (6) the total and the individual isotope curie loading expressed as either the 10%-tile, the median, or the 95%-tile [denoted as Ci(0.10), Ci(0.50), and Ci (0.95), respectively].

The Curie Loading Data Base uses sampling and analysis data from GAAT Phase I sampling (Energy Systems 1995), Phase II sampling (Energy Systems, 1996), and the 1988 sampling (U.S. DOE 1993). This data is presented immediately following the curie loading tables in this appendix.

There are several important points regarding the use of the Curie Loading Data Base:

1. The Curie Loading Data Base is a combination of reported values and computed concentration values. Reported values are those concentrations as reported from either Phase I, Phase II, or 1988 sampling. Computed values represent the more precise concentrations when concentrations are determined by two or more methods. This use of analytical precision as a Curie Loading Data Base screening tool eliminates the potential for double counting of concentrations. Specifically, this requirement is applicable to alpha emitters measured by both alpha spectrometry and mass spectrometry. If an isotope is measured using both techniques, the mass spectrometry reported value used as a raw value, the isotopic concentration is computed (Platfoot 1995), the computed concentration is reported in the data base, and the alpha spectrometry value is reported as "NC." If a value is not reported or is reported less than the detection limits, it is indicated as "NR." If an isotope is measured by only alpha spectrometry, this is the reported value in the data base. Since an isotope is measured initially by alpha spectrometry and then by mass spectrometry, there is no inconsistency in this screening approach.

2. Since the Curie Loading Data Base uses both reported values and computed concentration values, it is unwise to directly compare the GAAT Phase I and Phase II data base with the Curie Loading Data Base. The reason for this is that the GAAT Phase I and Phase II data base addresses GAAT TS issues that extend beyond only curie loading computation, while the Curie Loading Data Base is used only to compute curie loadings for the GAAT.

ASSUMPTIONS OF TECHNICAL APPROACH

The primary assumption is that isotope concentration in sludge or supernate is a random variable described by a triangular probability density function. A conservative estimate for the upper 95% confidence value of concentration for each isotope will always be produced when a Triangular probability density function is used.

Sludge and liquid volumes and densities are represented as deterministic variables, i.e., they are not random variables. There is a small relative standard deviation exhibited in the sample data for individual tank volumes and densities (< 15%). No assumptions are made regarding concentration measurement or estimation error due to sample location (center riser, other location), sample period (Phase I, Phase II, and the 1988 sampling efforts), sample method (sludge tube, clamshell), or analytical method.

INPUTS REQUIRED FOR THE TECHNICAL APPROACH

Individual isotope concentrations are needed to determine the underlying PDF and to compute the upper 95% confidence limit on concentration values. Volumes and densities are needed to compute curie loading.

Concentrations are based upon GAAT Phase I (Energy Systems 1995), Phase II (Energy Systems 1996), and the 1988 sampling (U. S. DOE 1993). This allows taking full advantage of GAAT Phase I, GAAT Phase II data, and 1988 data for concentrations to provide 4 or more observations per tank for sludge or supernate.

Volumes and densities are contained in 1994 Phase I GAAT TS sampling data (Energy Systems 1995 and Bechtel, 1995). Sludge volume is the "Integrated Volume" based upon sludge mapping during Phase II and contained in Bechtel, 1995; or, the volume is as reported in Energy Systems 1995 if sludge mapping was not performed. Liquid volume is contained in Energy Systems 1995. Integrated sludge volumes are computed using at least 20 sludge depth observations (except for W-7, N = 3) in Phase II with a measurement precision of $\pm$ 0.1 foot.

Sludge density is the maximum density as computed using Phase I and Phase II data sets. Sludge density has relatively small variability (4% to 15% of the average density over all tanks). Supernate density is the maximum density as computed using Phase I, Phase II data sets, and the 1988 data sets.

DETAILS OF THE TECHNICAL APPROACH

Verification of Distribution Assumptions

A χ^2 and a Kolmorgrov-Smirnoff Goodness of Fit Test are performed on the concentration data to determine the PDF of the concentration values. In a majority of the isotopes, the hypothesis that the isotope concentration follows a triangular PDF cannot be rejected. However, the hypothesis that the data follows some other distribution (e.g., beta and log-normal) also cannot be rejected. If, during the Goodness of Fit Test, the triangular PDF is one of the top five distributions that describe the data, the triangular PDF is used. If not, the best fitting distribution is used. Since the triangular PDF is a conservative PDF, there is no reason not to use the triangular PDF for the concentration of the isotopes examined.

Verification of Non-Reported Value or Non-Detect Assumptions

The nonreported assumption cannot be verified except by performing a new analysis on a new or the same sample. The non-detect assumption can be verified by determining the proportion of non-detects out of all detects and modeling non-detects as a binomial distribution. This was not performed for this analysis. Instead, non-detects were not included in the calculations. If a nondetect value is substituted for a reported non-detect, this can lead to misleading conclusions.

Verification of Concentration Values to Eliminate Double Counting

The Curie Loading Data Base is a combination of reported values and computed concentration values. Reported values are those concentrations as reported from either Phase I, Phase II, or 1988 sampling. Computed values represent the most precise concentrations when concentrations are determined by two or more methods. This use of analytical precision as a Curie Loading Data Base screening tool eliminates the potential for double counting of concentrations. Specifically, this requirement is applicable to alpha emitters measured by both alpha spectrometry and mass spectrometry. If an isotope is measured using both techniques, the mass spectrometry reported value used as a raw value, the isotopic concentration is computed (Platfoot, 1995), the computed concentration is reported in the data base, and the alpha spectrometry value is reported as "NC." If an isotope is measured by only alpha spectrometry, this is the reported value in the data base. Since an isotope is measured initially by alpha spectrometry and then by mass spectrometry, there is no inconsistency in this screening approach.

Upper 95% Confidence Limit for the Triangular PDF

The triangular PDF is used to represent the underlying distribution of the concentration and, subsequently, the curie loading. The triangular probability function describes a random variable, X, in terms of a PDF and a Cumulative Distribution Function (CDF). Let X represent the random concentration of an isotope in a tank.

The parameters of the distribution are a, b, and c, such that $a < b < c$ and $a < x < c$, where a is the minimum concentration of X, b is the most likely concentration of X, and c is the maximum concentration of X. Let x denote concentration values of X, where, $a < x < c$. A summary of the triangular PDF is:

Mean	$(a+b+c)/3$
Mode	b
Variance	$(a^2+b^2+c^2-ab-ac-bc)/18$

Probability density function (PDF)

$$f(x) = \Pr(X = x) = \begin{cases} \dfrac{2(x-a)}{(b-a)(c-a)} & \text{if } a < x < b \\ \dfrac{2(c-x)}{(c-a)(c-b)} & \text{if } b < x < c \end{cases}$$

Cumulative distribution function (CDF)

$$F(x) = \Pr(X \le x) = \begin{cases} 0 & x < a \\ \dfrac{(x-a)^2}{(b-a)(c-a)} & a < x < b \\ 1 - \dfrac{(c-x)^2}{(c-a)(c-b)} & b < x < c \\ 1 & c > x \end{cases}$$

The upper 95% Confidence Limit for the concentration is determined as follows. Let $F(x) = P(X < x) = 0.95$ in the CDF. Find the value x, denoted as $x_{0.95}$, such that $P(X \le x_{0.95}) = 0.95$. Since $b < x_{0.95} < c$, an analytical representation is obtained:

$$x_{0.95} = c - \sqrt{(1-0.95)(c-a)(c-b)}$$

Estimation of Curie Loading

Given the upper 95% Confidence Limit for the concentration, $x_{0.95}$, the upper 95% Confidence Limit for the curie loading is determined by computing $C_{0.95}$:

$$C_{0.95} = (3.785)(1{,}000)\, x_{0.95} V \rho_{max} / (3.7E{+}10)$$

where volume, V, is measured in gal; density, ρ_{max}, is measured in g/cc or g/ml; and, the constants are such that 3.785L = 1 gal, 1000 cc = 1 L, and 3.7E+10Bq = 1 Ci.

SUMMARY OF STATISTICAL METHODS

Statistical methods are used for GAAT data analysis to describe sample data and account for variability from numerous physical, chemical, or operational sources. Common statistical methods include:

Summary (descriptive) statistics	Calculate mean (average), standard deviation, relative standard deviation, minimum, maximum, median, 25%-tile, 75%-tile, and range for the data
Exploratory methods	Examine the summary statistics and determine any outliers
Empirical distribution function	Plot the ordered raw data versus cumulative percentage of occurrence
Goodness of fit tests	Determine what probability function best describes the sample data. Use this information to compute confidence intervals for selected summary statistics.
Analysis of variance	Examine the differences in variability between two samples
Correlation	Examine degree of association between constituents within a tank or the association between tanks for selected constituents.
