# Talk Outline

- Methane reforming
- Microwave heating
- Catalysts/susceptors
- Conductive perovskites
- Fast failure performance screening
- Test results
- Efficiency gains
- Conclusions

# Synthesis Gas

## H<sub>2</sub>:CO Ratio Determines Its Uses

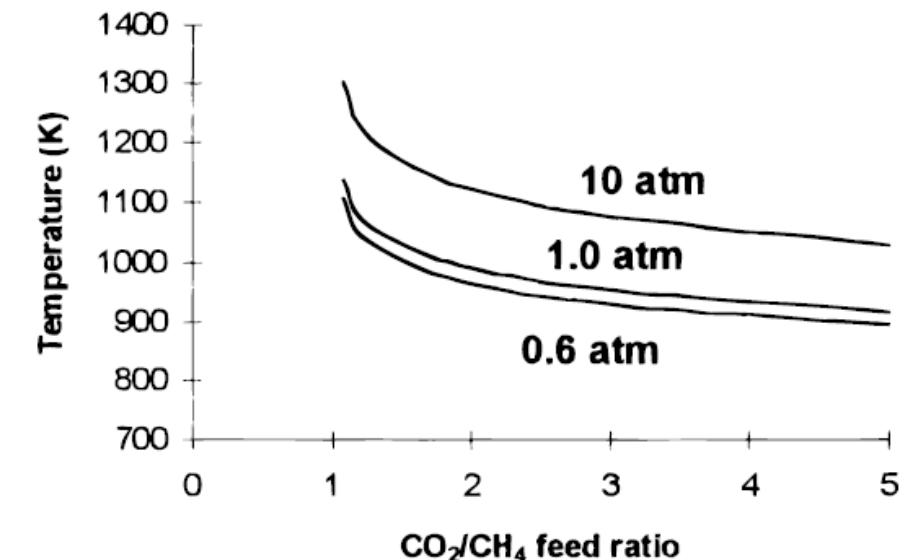

From Chae, Jung-il et al. Catalysts 10(1):99 2020 DOI: 10.3390/catal10010099

# Methane Reforming

## Methane to Syngas

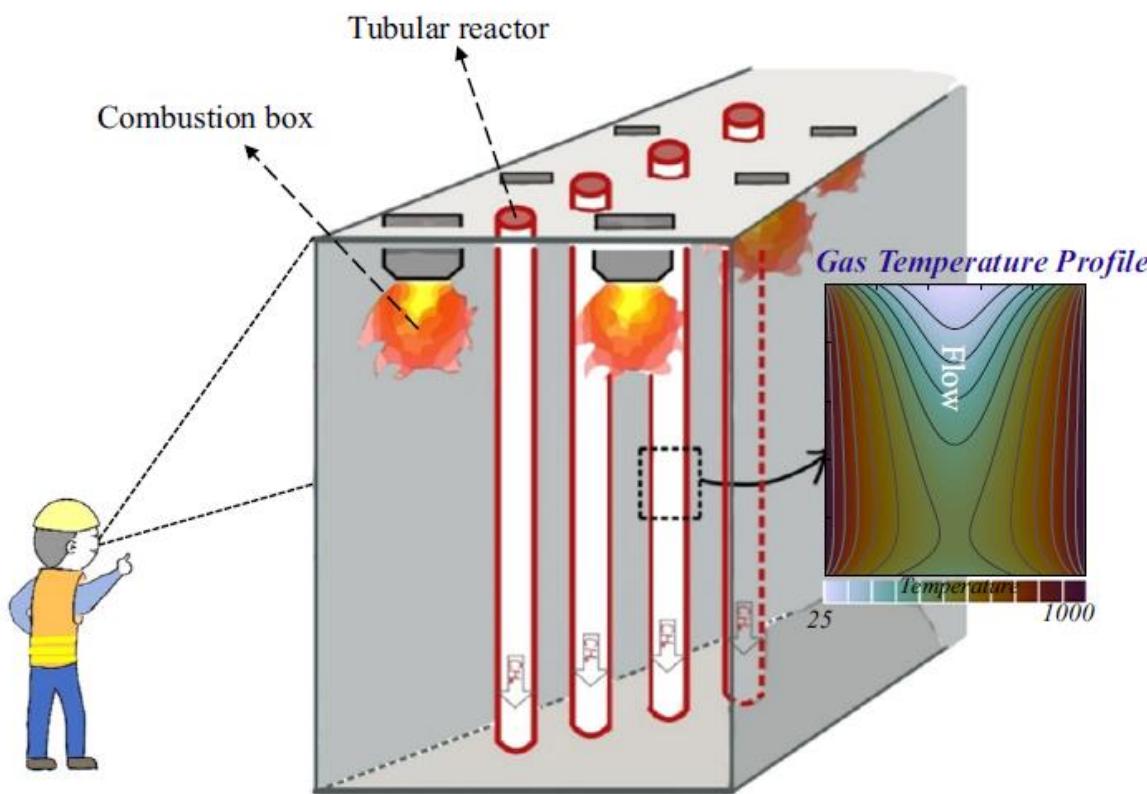

- Dry reforming of methane (DRM):  $\text{CO}_2 + \text{CH}_4 \rightarrow 2\text{CO} + 2\text{H}_2$  (**1:1 syngas**)
- Steam methane reforming (SMR):  $\text{CH}_4 + \text{H}_2\text{O} \rightarrow \text{CO} + 3\text{H}_2$  (**3:1 syngas**)
- Mixed reforming of methane (MRM):  $\text{CO}_2 + 2\text{H}_2\text{O} + 3\text{CH}_4 \rightarrow 4\text{CO} + 8\text{H}_2$  (**2:1 syngas**)
- Commercially, only steam reforming is used due to ability to run at lower temperature and higher pressure
  - $\text{CO}_2$  much softer oxidizing power than steam
  - All 3 processes are spontaneous by 687 °C
  - For DRM, coking occurs below 860 °C

Wang et al. Energy & Fuels 1996

# Conventional (Indirect) Heating

## Heat Transfer Between a Fire and a Hot Place

**A. Conventional Heating**

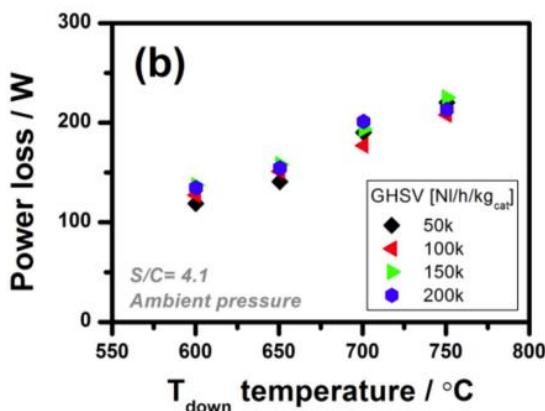

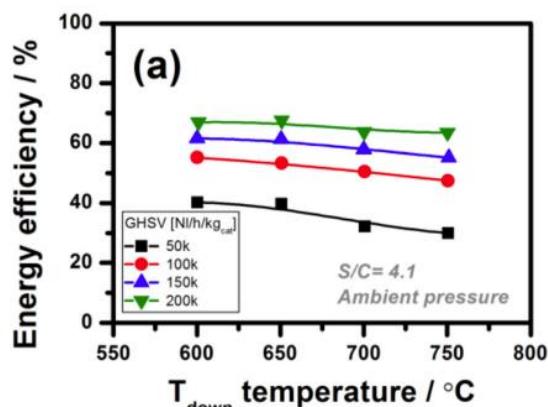

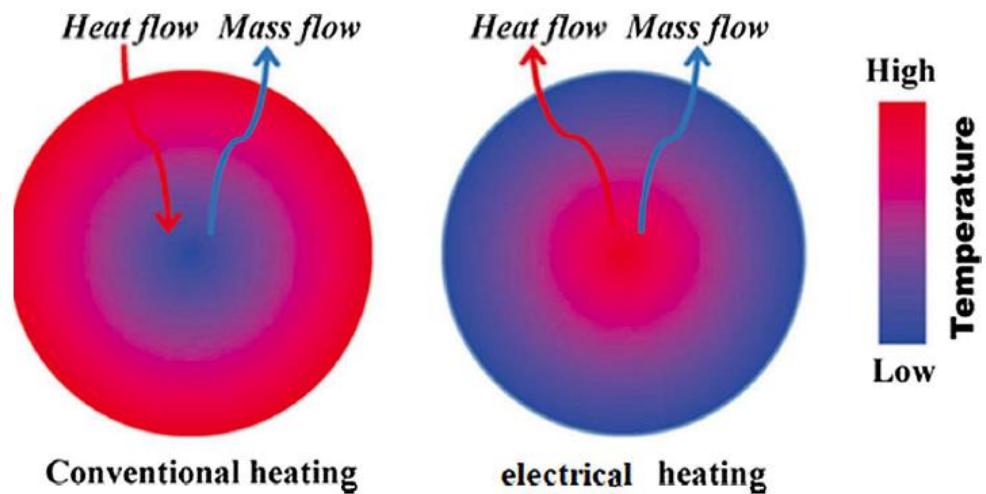

- Conventional SMR reactors use methane as both fuel and reactant
  - 8-10 kg CO<sub>2</sub> per kg H<sub>2</sub> with ~20% from heating<sup>2</sup>
- Long startup and cool down times due to reactor insulation
- Difficult to scale down efficiently due to heat transfer
  - Long tubes needed to ensure middle of channel gets warm
  - Many tubes due to low flow rates to ensure enough residence time

<sup>1</sup> Yang et al. Nature Comm (2024)15:3868

<sup>2</sup> Rapier, Robert. Forbes "Estimating the Carbon Footprint of H<sub>2</sub> Production June 6, 2020

# Distributed Electrified (Direct) Heating

## Warmth from Within

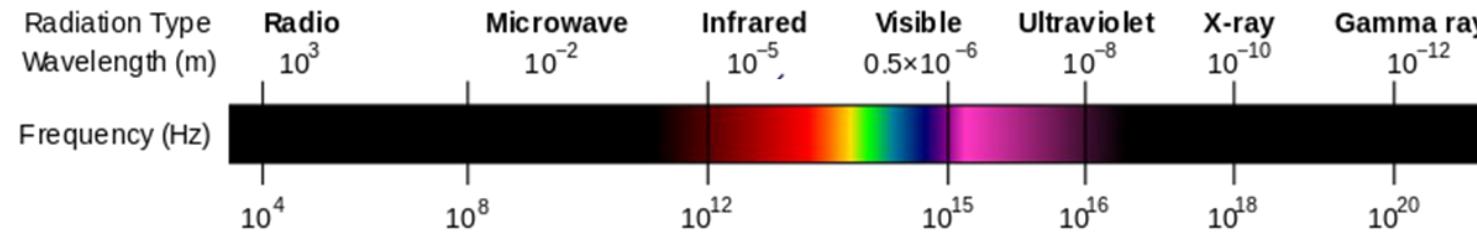

<sup>1</sup> Yang et al. Nature Comm (2024) 15:3868

<sup>2</sup> Zheng et al. International Journal of Hydrogen Energy (2023) 48:14681-14696

- Recent papers have highlighted the efficiency gains in endothermic reactions by internally (directly) heating the catalyst<sup>1</sup>
- Heat losses found to grow ~linearly with reactor temperature but ~independent from the space velocity so overall efficiency increases with flow rate<sup>2</sup>
- Approaches range between direct resistive (joule) heating the catalyst bed, inductive heating, and microwave heating

# Microwave Heating

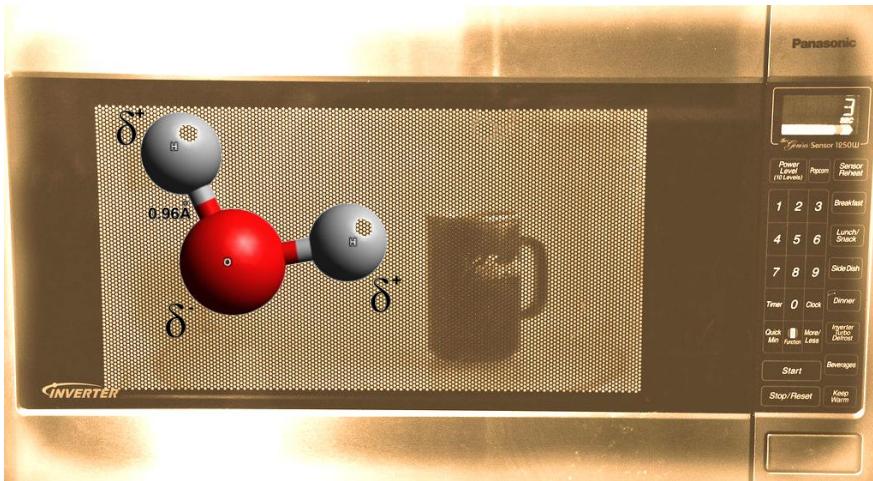

- Microwaves are electromagnetic waves from ~10 cm to ~1 mm
- Lower frequency than infrared
- Interact weakly with most matter allowing for wireless selective heating
- Microwave heating efficiency (susceptibility) determined by the loss tangent:  
$$\tan \delta = \frac{\omega \epsilon'' + \sigma}{\omega \epsilon'}$$
- $\epsilon''$  and  $\epsilon'$  are the imaginary and real permittivities, respectively, while  $\sigma$  is conductivity
- Materials with large  $\tan \delta$  either have large  $\epsilon''/\epsilon'$  ratios (like strongly polar materials) or large  $\sigma/\epsilon'$  ratios (like salt solutions or graphite)

# Microwave Heating

## Saving Time in the Lunchroom

Water:  $\tan\delta \sim 0.003$

Dipolar materials have large  $\epsilon''/\epsilon'$  ratio

Much higher  $\tan\delta$  in water than air allows selective heating of dipolar water in the cup

Saltwater:  $\tan\delta \sim 3$   
(5.8M<sub>NaCl</sub>)

Conductivity improvements both raise  $\sigma$  and lower  $\epsilon'$

Salty liquids like soup absorb microwaves much more efficiently

Graphite:  $\tan\delta \sim 0.25-1.5$

Conductivity rises with temperature causing loss tangent to vary

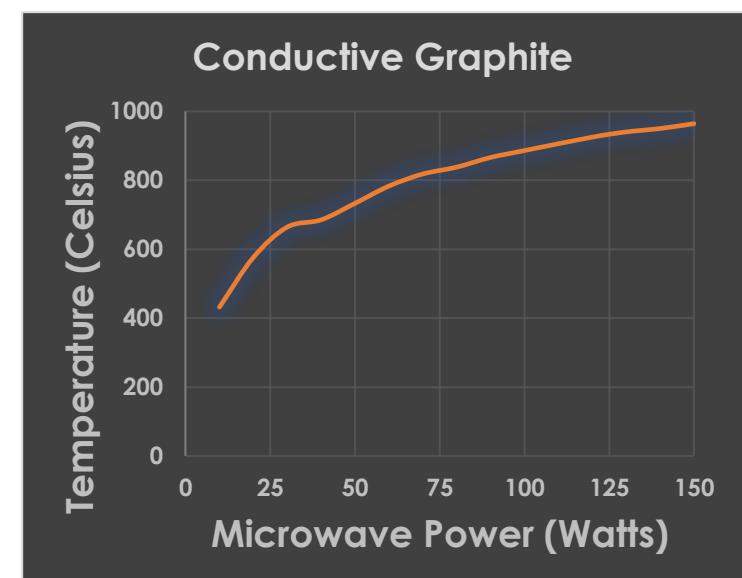

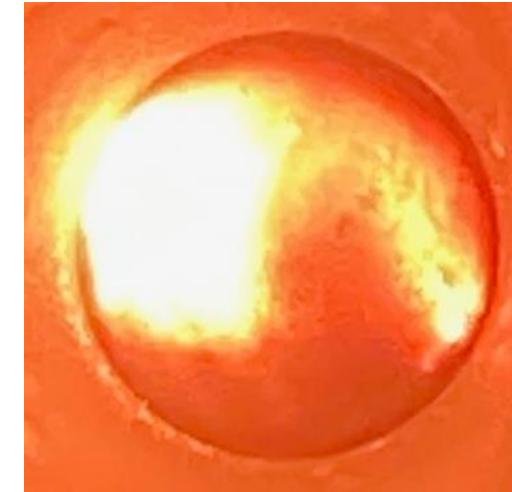

Graphite or other metallic susceptors absorb efficiently and have higher phase transition temperatures than water

# Catalysts/Susceptors

## Putting Microwave Hot Spots to Work

- Catalysis takes place on heterogenous surfaces so those are the only spots that need to be hot
- Metals make excellent microwave absorbers when they are fine enough to absorb instead of reflecting electromagnetic wave
- Once metals sinter or melt, end up with a large metal object in the microwave (which is microwave reflective)
- Want materials that heat like metals but do not sinter or melt like metals
- Graphite heavily used as a microwave susceptor, but conditions that remove coke also remove graphite
- For efficiency, the same material absorbing microwaves should be where catalysis occurs

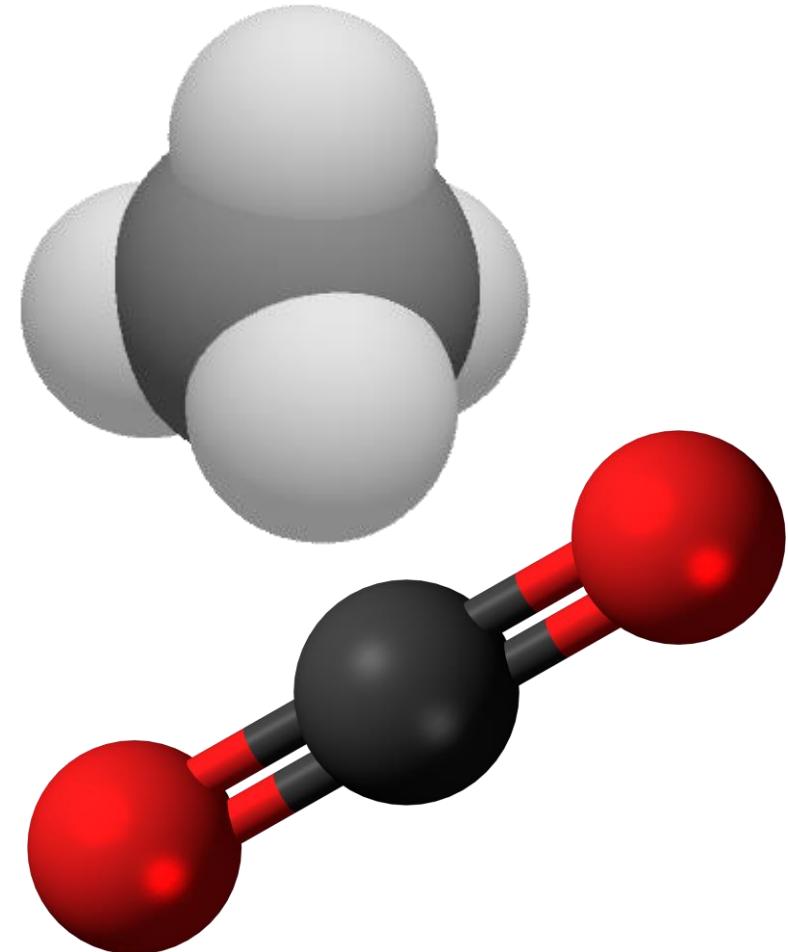

# Methane Reforming Catalysts

## Bringing Molecules Together

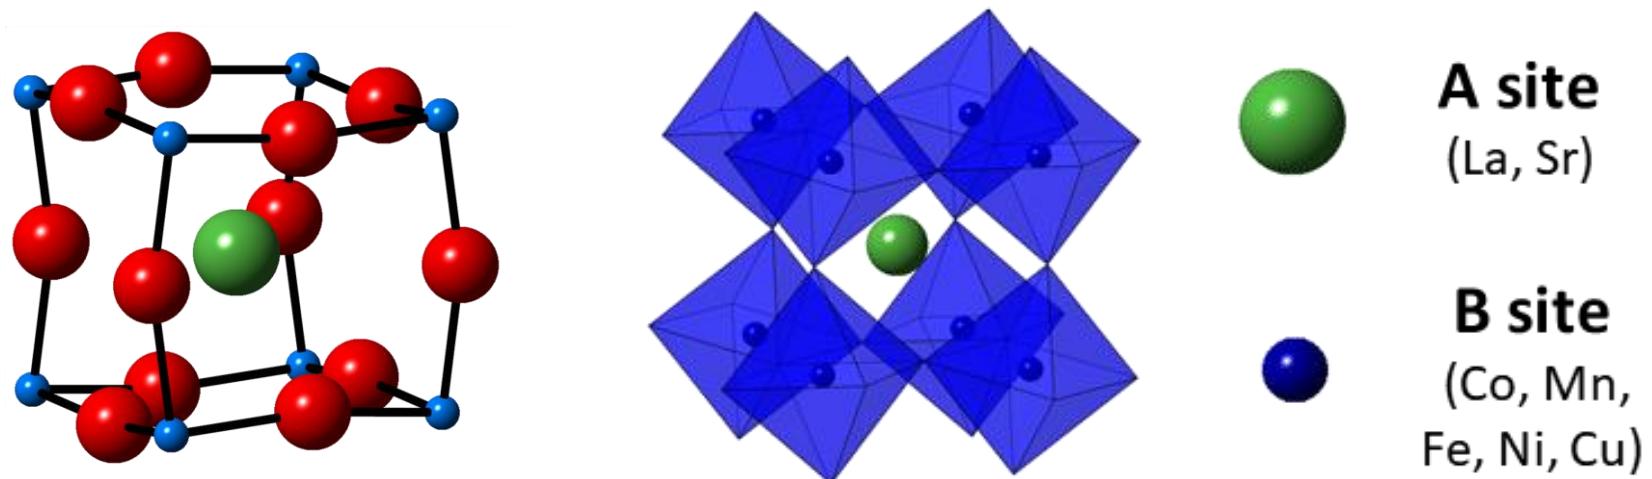

- $\text{CH}_4$  is symmetric and tough to crack
  - Generally, metals are used as active sites for  $\text{CH}_4$  to bind to
- $\text{CO}_2$  is also symmetric, but does present Lewis acid sites
  - Basic oxides are often used as active sites for  $\text{CO}_2$
- Typical methane reforming catalysts are metals (Pt, Ru, Ni, Co, etc.) on oxide supports with base sites (Na, Ca, Sr, etc.) to promote  $\text{CO}_2$  interaction

# Conductive Perovskites

## Making Oxygen Share

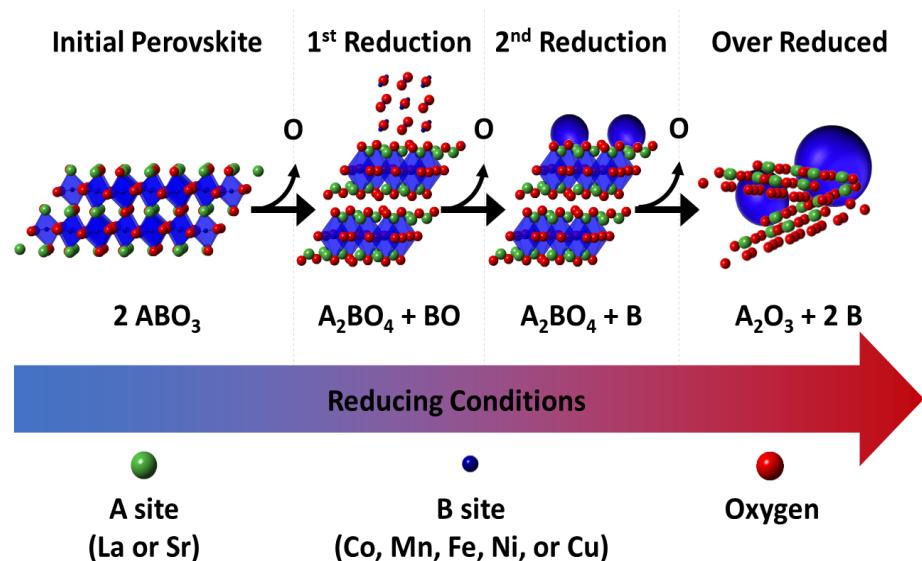

- The highest high temperature oxide conductivities belong to the perovskite family
- Perovskites have general form  $ABO_3$  with A sites generally alkaline or rare earths and B sites generally transition metals
- B sites make up the structure backbone with each metal octahedrally coordinated with vertex sharing oxygen
- In the case of Sr doped  $LaCoO_3$ , highest known oxide conductivity  $\sim 4,400$  S/cm and a melting point of 1700 °C

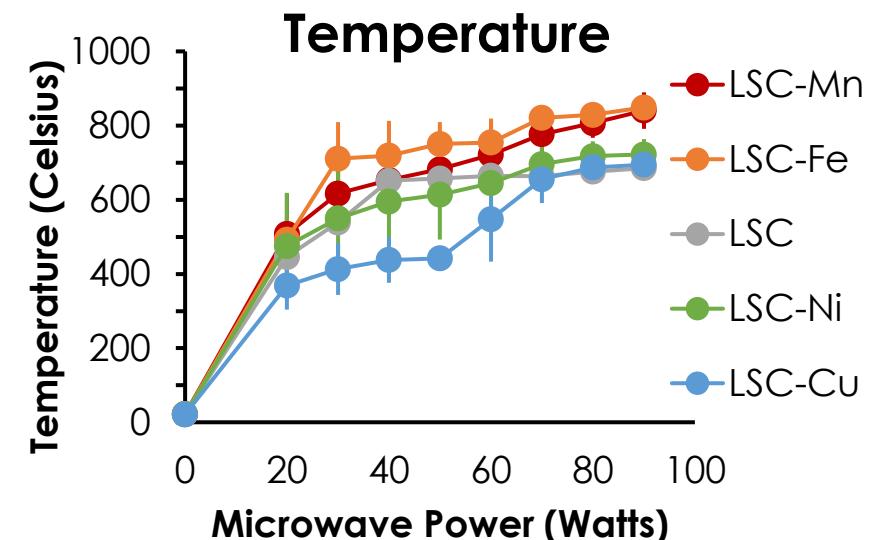

# DRM with LSC

That's  $\text{CO}_2 + \text{CH}_4 \rightarrow 2\text{CO} + 2\text{H}_2$  with  $\text{La}_{0.8}\text{Sr}_{0.2}\text{CoO}_3$

- Under reducing conditions,  $\text{La}_{0.8}\text{Sr}_{0.2}\text{CoO}_3$  kicks out Co metal sites and adopts a layered perovskite structure
- Under oxidizing conditions, catalyst can be converted back to parent perovskite
- When over-reduced, phase separation to microwave inactive  $\text{La}_2\text{O}_3$  and  $\text{SrO}$  leads to sintering and to a catalyst that no longer heats efficiently
- Control of B site dopants effective for moderating phase transition temperatures

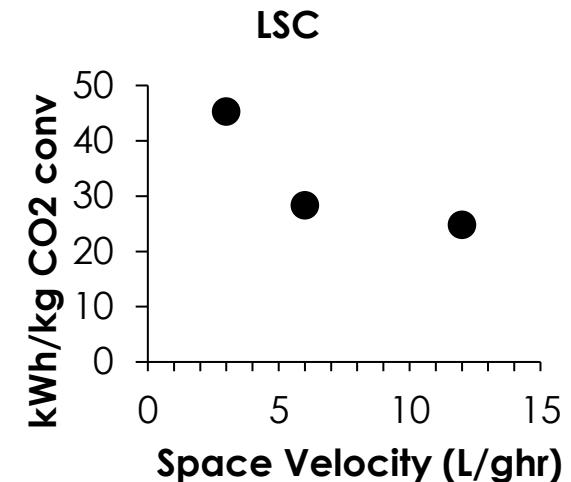

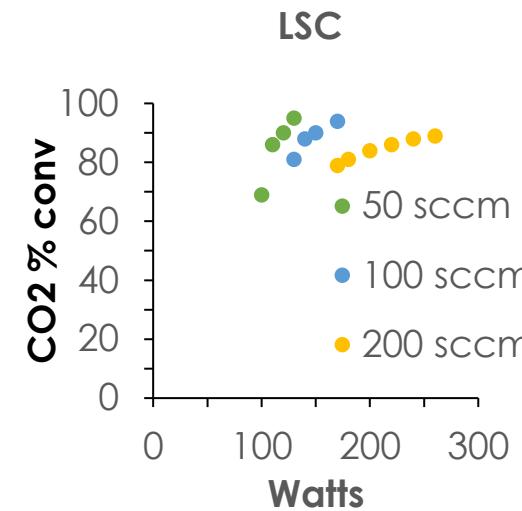

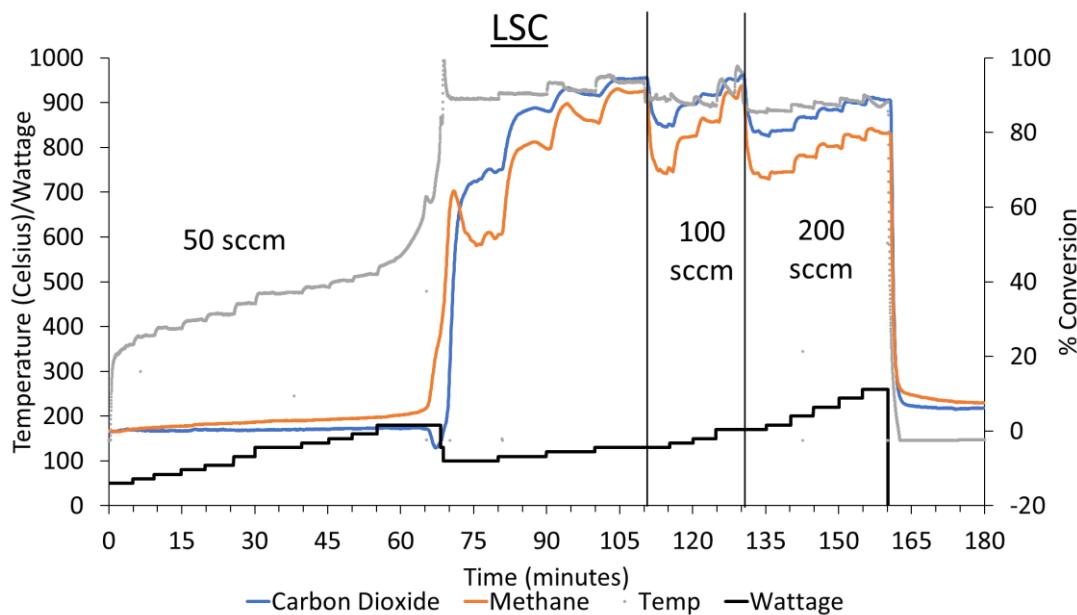

Marin et al. Applied Catalysis B 284 (2021) 119711

# Fast Failure Performance Screening

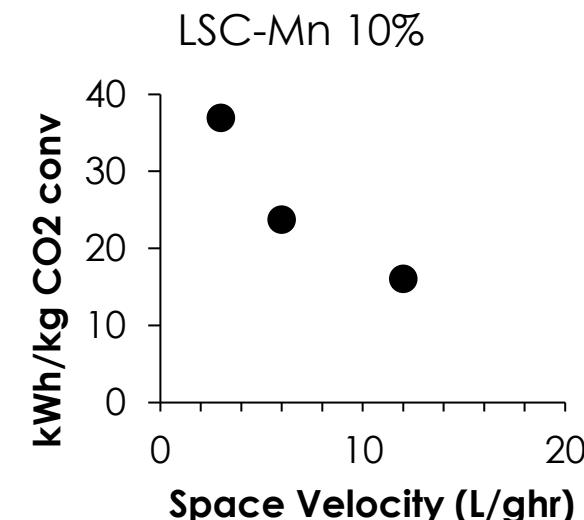

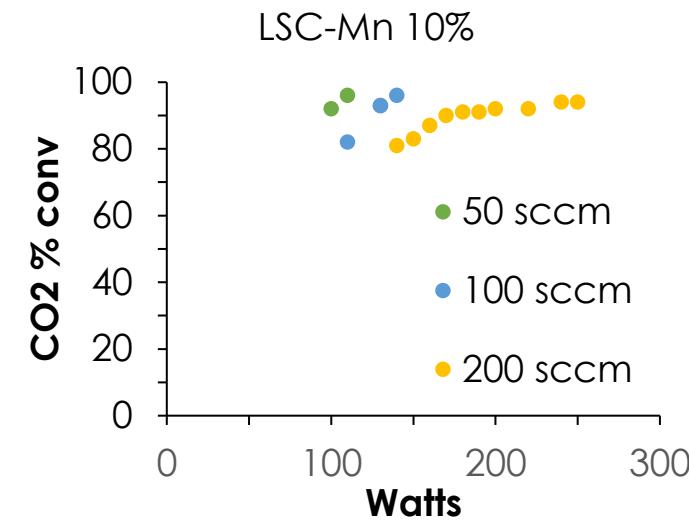

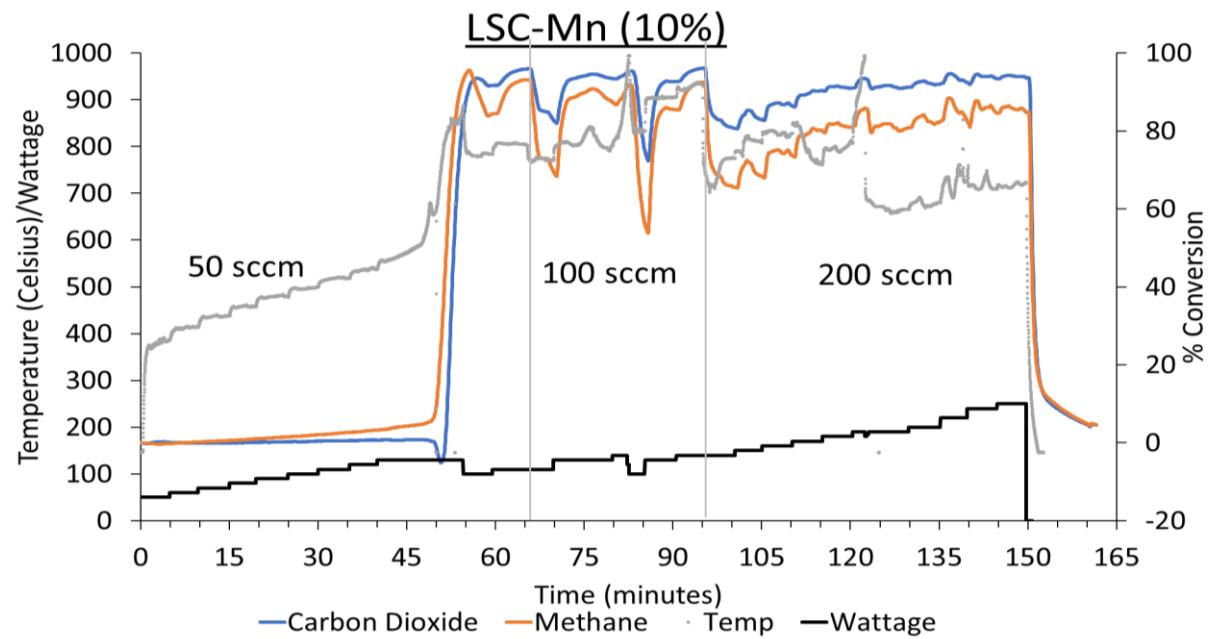

# If at First You Succeed, Try-Try Again

- Starting with 1g  $\text{La}_{0.8}\text{Sr}_{0.2}\text{CoO}_3$  (LSC) and testing with 50:50  $\text{CO}_2:\text{CH}_4$
- Trying to find the least energy to convert a kg of  $\text{CO}_2$  at 80-90% conversions
- If conversions below 90% of both  $\text{CO}_2$  and  $\text{CH}_4$ , applied power raised
- If conversions of  $\text{CO}_2$  and  $\text{CH}_4 \geq 90\%$ , increase the flow rates and repeat

- 24.8 kWh/kg CO<sub>2</sub> conversion at 12 Lg<sup>-1</sup>hr<sup>-1</sup>

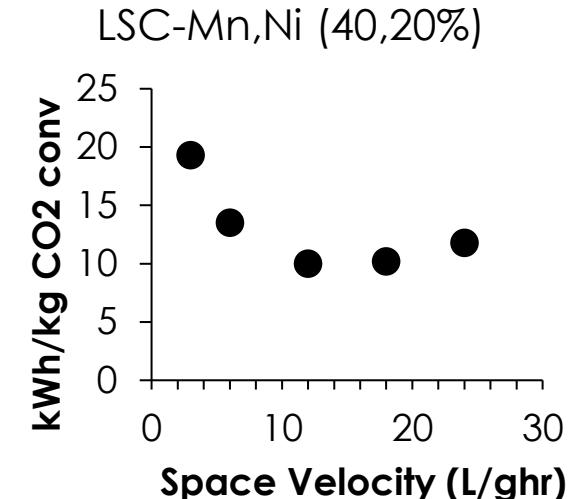

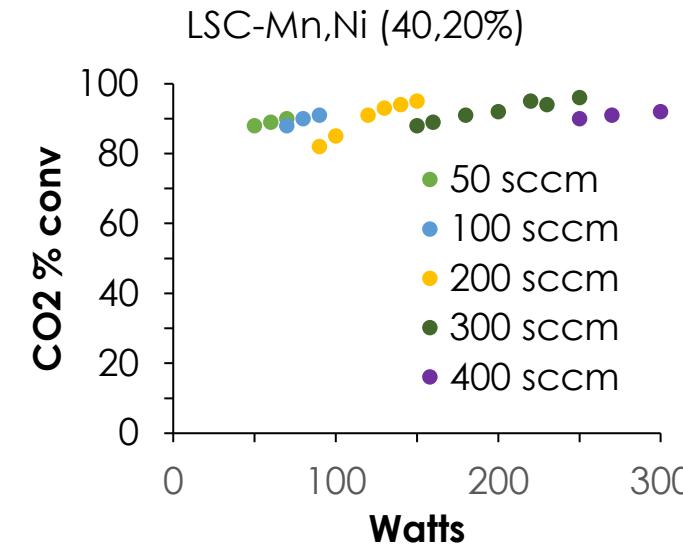

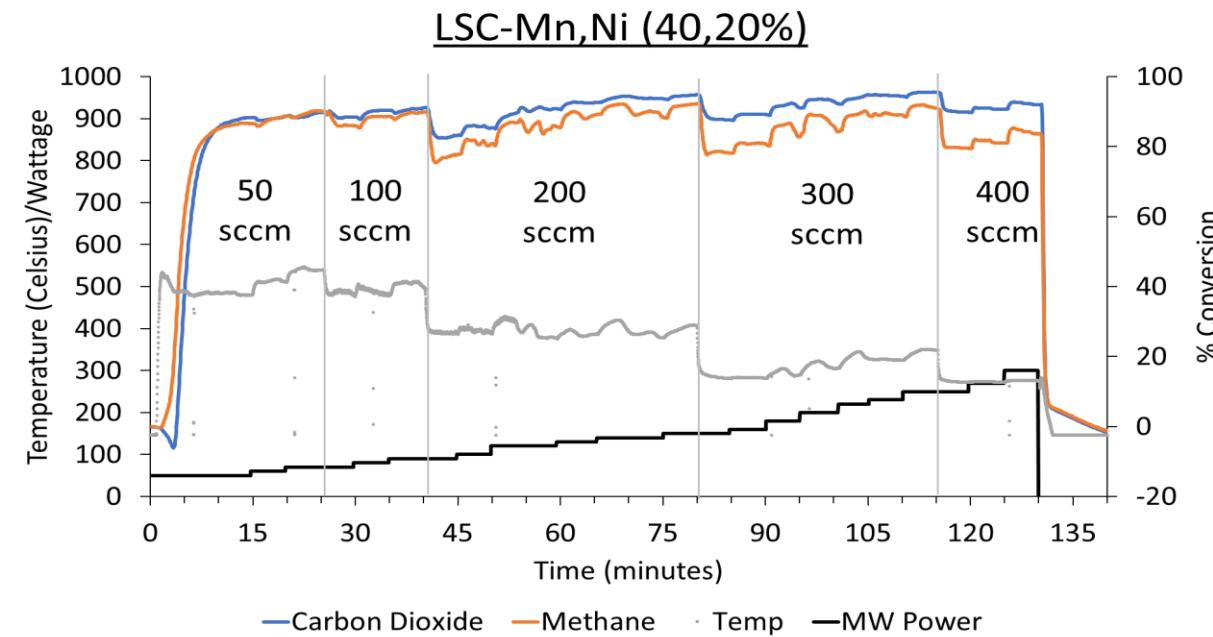

# Fast Failure Performance Screening

- 16.0 kWh/kg CO<sub>2</sub> conversion at 12 Lg<sup>-1</sup>hr<sup>-1</sup>

# Fast Failure Performance Screening

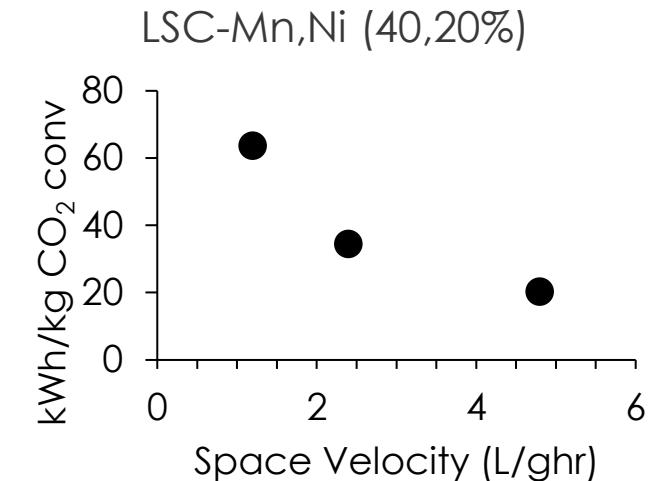

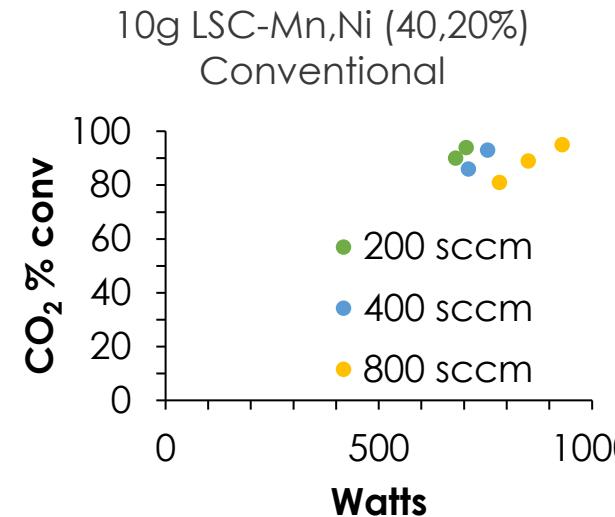

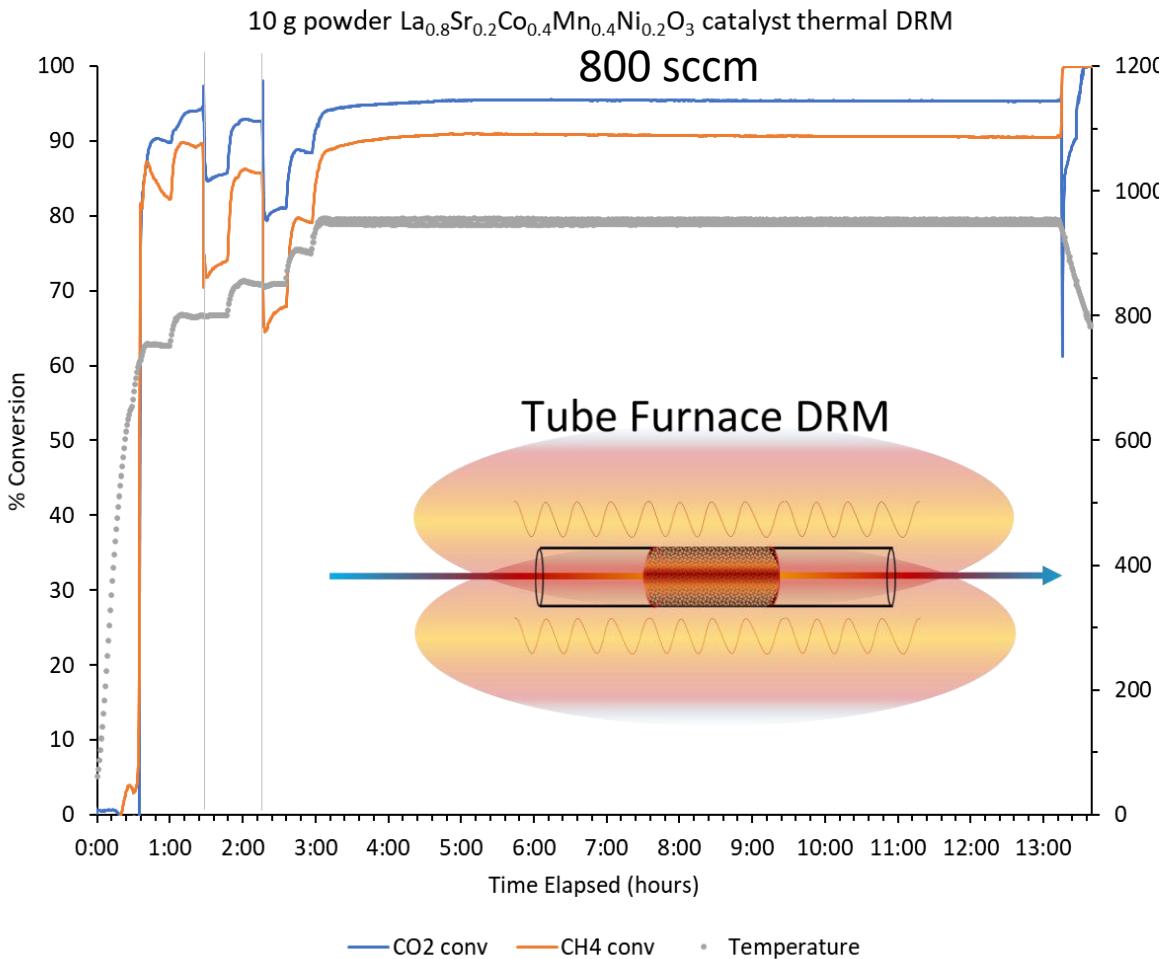

- 10.0 kWh/kg CO<sub>2</sub> conversion at  $12 \text{ Lg}^{-1}\text{hr}^{-1}$

# Test Results $\text{La}_{0.8}\text{Sr}_{0.2}\text{Co}_{0.4}\text{Mn}_{0.4}\text{Ni}_{0.2}\text{O}_3$

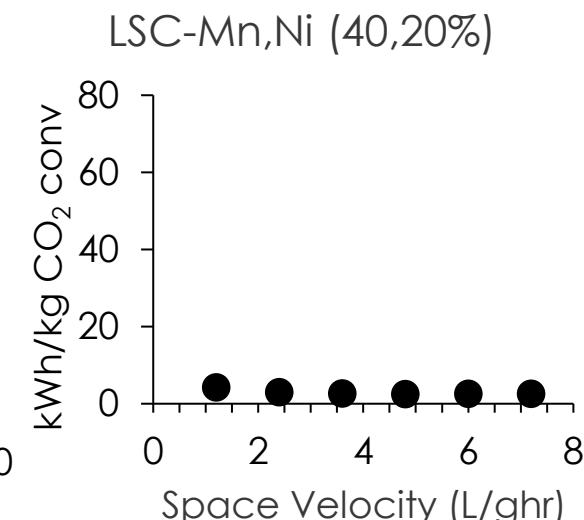

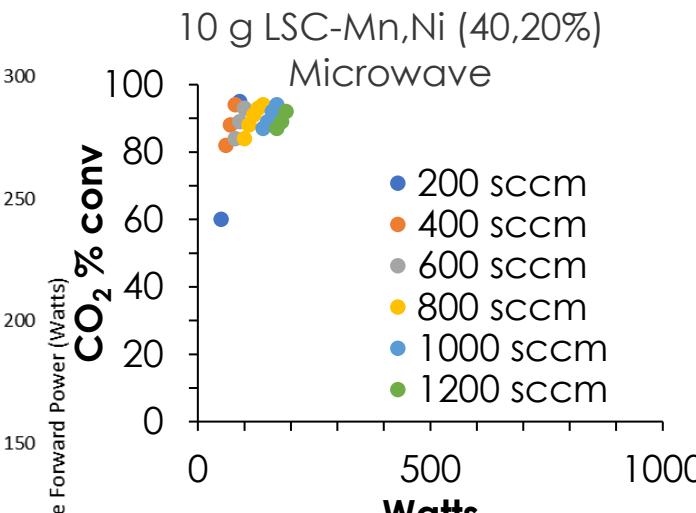

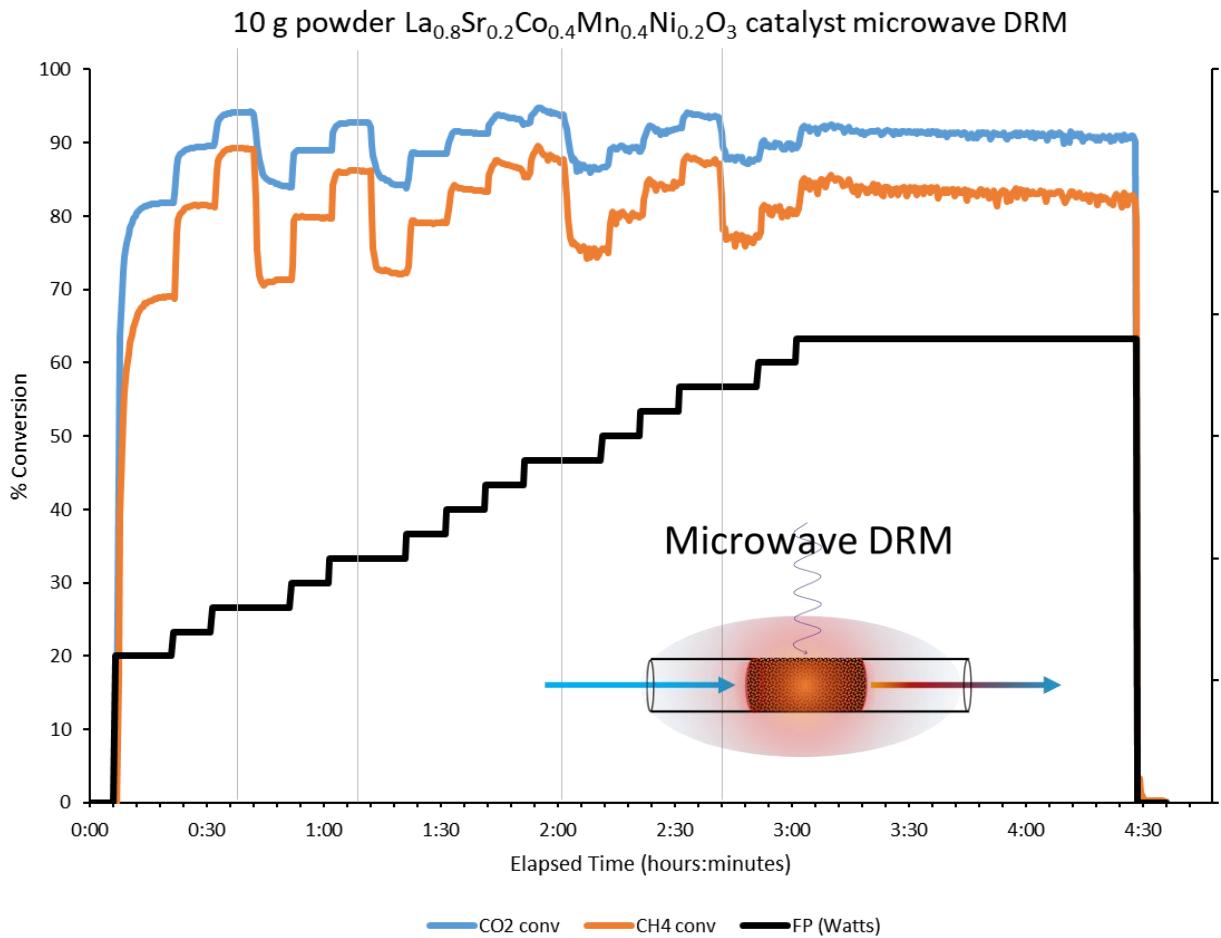

## Conventional (Indirect) Heating

- In a conventional tube furnace reactor, only 20.3 kWh/kg CO<sub>2</sub> conversion at  $4.8 \text{ Lg}^{-1}\text{hr}^{-1}$
- Efficiency improves with flow rate, but faster flow rates require much hotter side walls to keep catalyst bed at temperature
- Back pressure gradually rose forcing a test end after 10 hours with catalyst heavily sintered and coked up

# Test Results $\text{La}_{0.8}\text{Sr}_{0.2}\text{Co}_{0.4}\text{Mn}_{0.4}\text{Ni}_{0.2}\text{O}_3$

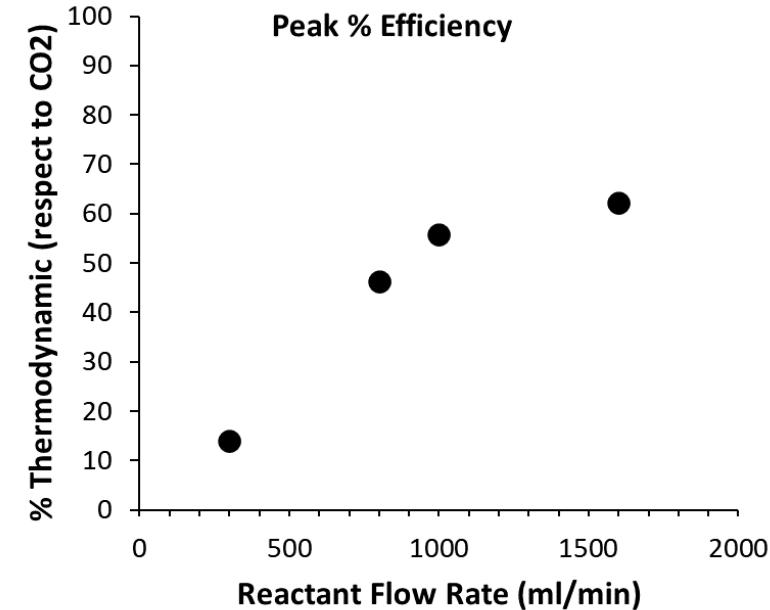

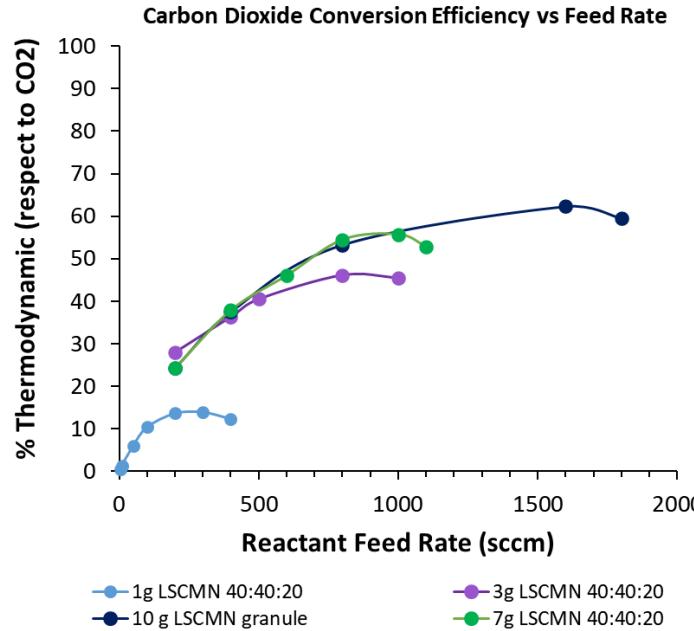

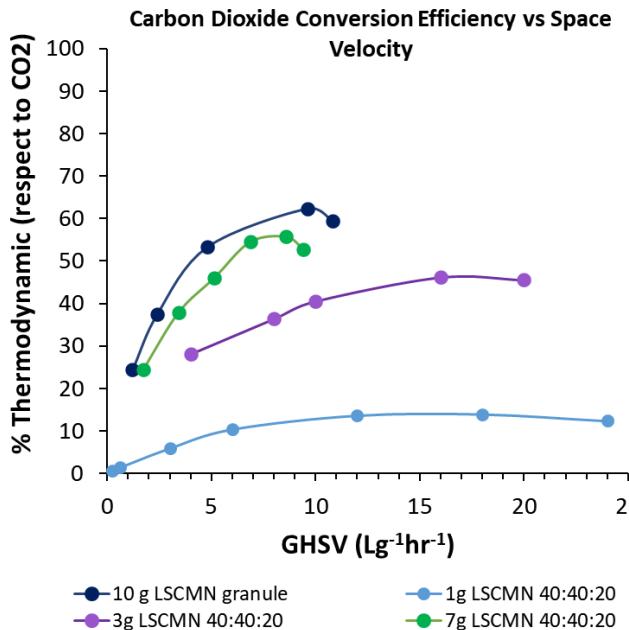

## Microwave (Direct) Heating

- In a microwave reactor, only 2.4 kWh/kg CO<sub>2</sub> conversion at  $4.8 \text{ Lg}^{-1}\text{hr}^{-1}$  **~10x better efficiency**
- Efficiency improves with flow rate and higher flow rates were achievable with internally heated catalyst
- Ran catalyst for over 40 hours on stream before back pressure ran high

# Efficiency

Working Smarter, Not Harder

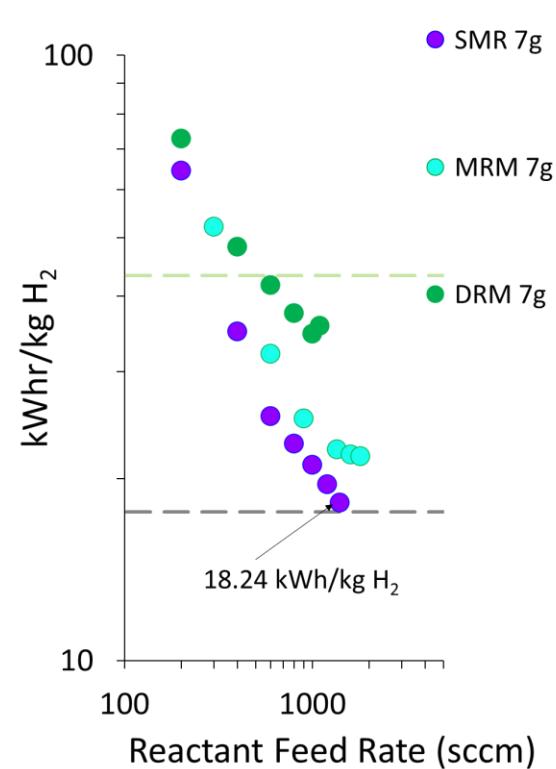

- Thermodynamic efficiency calculated assuming that at 100% only energy used is for dry reforming reaction enthalpy (+247 kJ/mol CO<sub>2</sub>)
- Like other internally heated endothermic reactions, efficiency improving with flow rate
- Efficiency improving with flow rate even while keeping within the same space velocity range

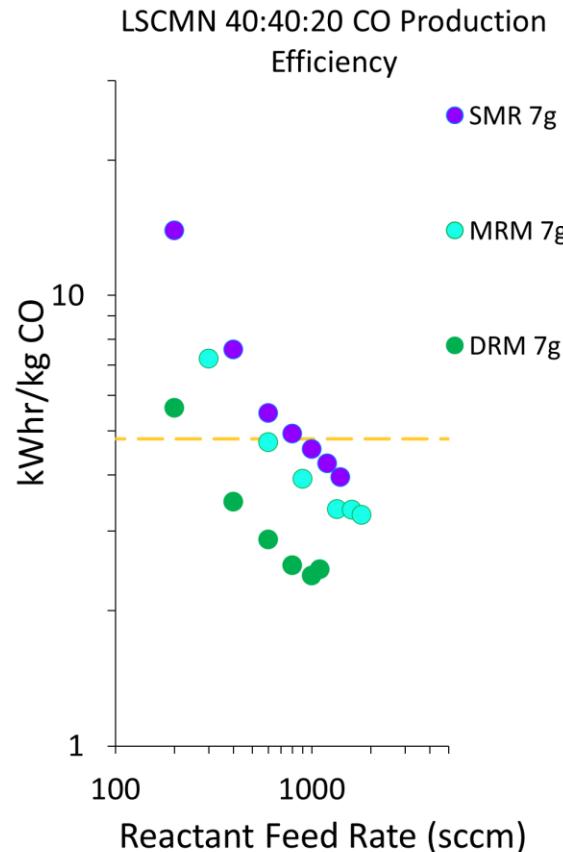

# Variable Methane Reforming

## 1:1 to 3:1 Syngas Ratios

LSCMN 40:40:20 Hydrogen Production Efficiency

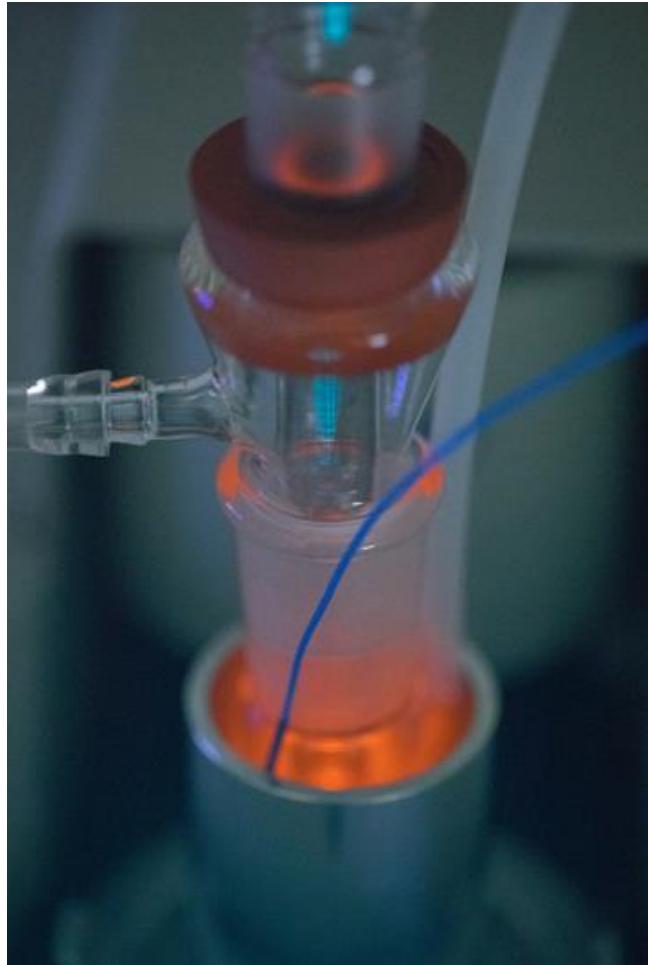

LSCMN 40:40:20 CO Production Efficiency

- As LSC-Mn,Ni (40,20%) was developed for performance with dry reforming methane, catalyst also suitable for mixed and steam reforming
- Dry Reforming Methane ( $\text{CO}_2 + \text{CH}_4 \rightarrow 2\text{CO} + 2\text{H}_2$ ) **1:1 syngas**
- Mixed Reforming Methane (in our case,  $\text{CO}_2 + 2\text{H}_2\text{O} + 3\text{CH}_4 \rightarrow 8\text{H}_2 + 4\text{CO}$ ) **2:1 syngas**
- Steam Methane Reforming ( $\text{CH}_4 + \text{H}_2\text{O} \rightarrow 3\text{H}_2 + \text{CO}$ ) **3:1 syngas**
- For all 3, efficiency has been improving with reactant feed rate

# Conclusions

- High temperature endothermic reactions such as dry reforming methane run more efficiently with higher flow rates
- Directly heating of catalyst bed from within allows for better temperature uniformity and stability at high gas flow rates
- LSC optimized for microwave absorption and dry reforming stability with incorporation of Mn and Ni for overall formula  $\text{La}_{0.8}\text{Sr}_{0.2}\text{Co}_{0.4}\text{Mn}_{0.4}\text{Ni}_{0.2}\text{O}_3$
- Catalyst found to be suitable for microwave dry, mixed, and steam reforming conditions

- Methane reforming composed of many elementary steps to strip  $\text{H}_2$  from  $\text{CH}_4$  and oxidize carbon back into a leaving group (CO and  $\text{CO}_2$ )
- $\text{CO}_2$  and  $\text{H}_2\text{O}$  closely interrelated by the water-gas shift reaction  $\text{CO} + \text{H}_2\text{O} \rightleftharpoons \text{CO}_2 + \text{H}_2$ 
  - Note: WGSR also not an elementary reaction
- Ratio of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  oxidizers use control the ratio of  $\text{H}_2:\text{CO}$  in product mix but elementary steps are the same either way
- Very complex microkinetics: thermodynamics treatment relied on for reforming reactions

Changming Ke, Reaction Chemistry & Engineering 2020(5) 10.1039/C9RE00460B
