Introduction to Optically Pumped Magnetometers (OPMs)

Peter D. D. Schwindt

Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

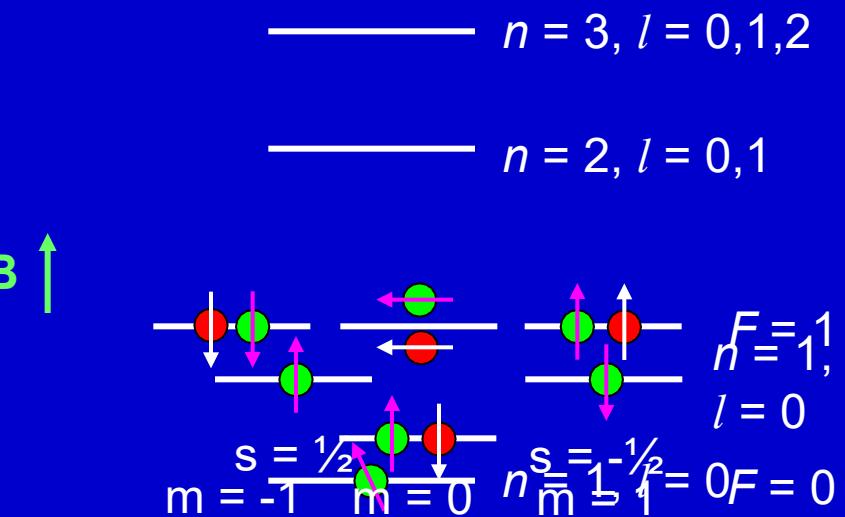

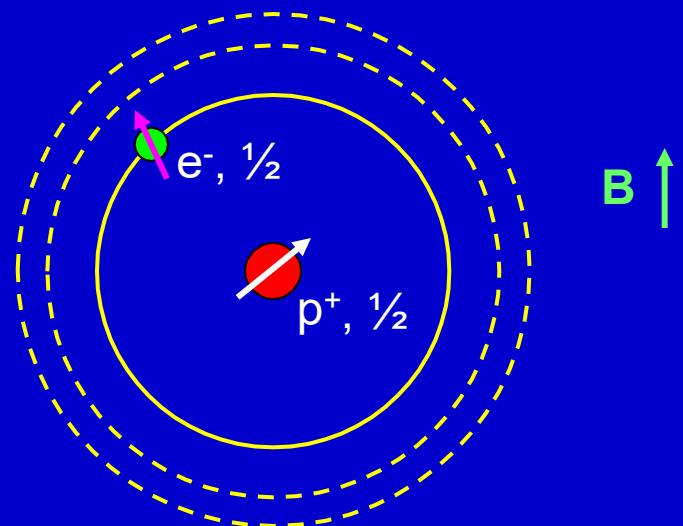

Properties of a Neutral Atom

- Quantized energy levels

Properties of a Neutral Atoms

- Spin and magnetic moment
 - Electron spin
 - Nuclear spin

Zeeman effect

Atoms Used in OPMs

The Rubidium-87 Ground State

Clock—measure hyperfine frequency

Magnetometer—measure Zeeman splitting

Gyromagnetic Ratio = $2\pi 7 \text{ Hz} / \text{nT}$

$$F = 2$$

$$F = I + S$$

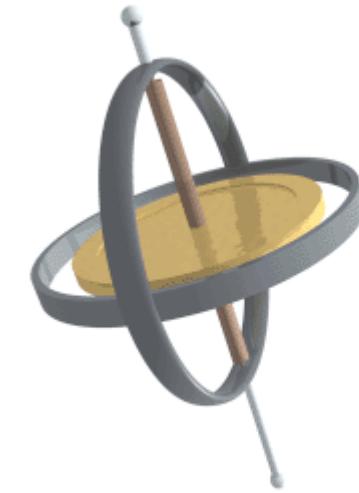

$$I = 3/2, S = 1/2$$

$$F = 1$$

Bloch Equations for an OPM

$$\frac{d\mathbf{P}}{dt} = D\nabla^2\mathbf{P} + \gamma\mathbf{P} \times \mathbf{B} + R_{OP}(\mathbf{s} - \mathbf{P}) - \frac{\mathbf{P}}{T_1, T_2} - R_{PR}\mathbf{P}$$

1. Atoms diffuse through inert buffer gas (limits atom-wall depolarization)
2. Atoms precess under influence of magnetic field \mathbf{B} at rate given by the gyro magnetic ratio $\gamma = \frac{g_F\mu_B}{\hbar}$
3. Electrons are oriented along circularly polarized pump beam (photon spin \mathbf{s}) via optical pumping at rate R_{OP}
4. Optical pumping causes depolarization of the collective magnetic moment
5. Collisions cause atomic depolarization (T_1) and decoherence (T_2)
6. Probing the atoms causes depolarization of the collective magnetic moment at a rate R_{PR}

What is SERF?

Spin Exchange Relaxation Free

T_2 often limited by spin exchange collisions.

Near zero field and at high density, spin exchange rate \gg spin precession frequency

- More $F = 2$ states, so on average atoms precess in $F = 2$ direction
- Precession rate is slowed down by nuclear spin and incomplete optical pumping

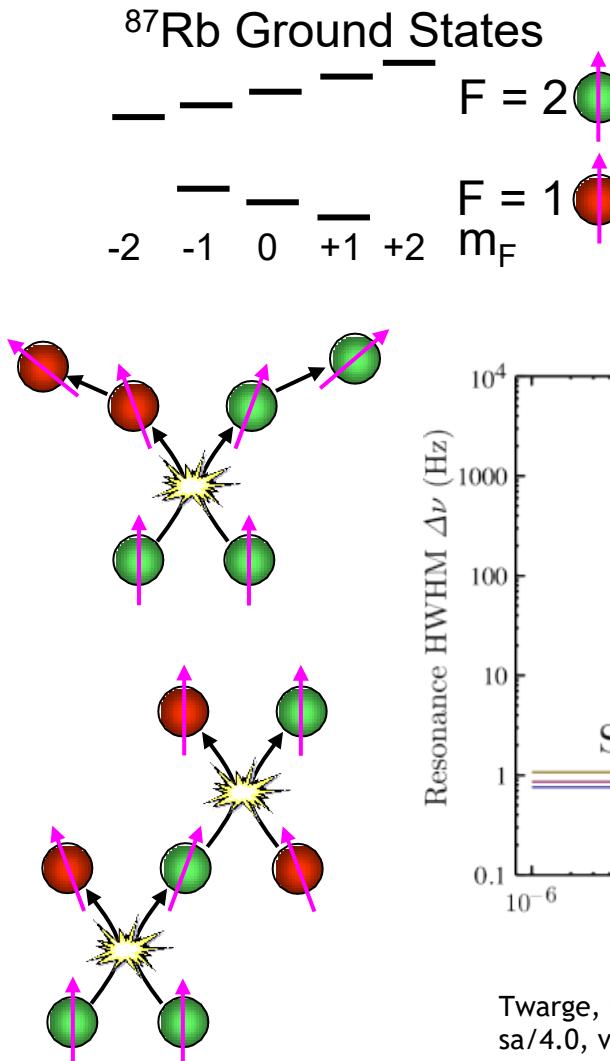

Record sensitivity: $160 \text{ aT} / \text{Hz}^{1/2}$

- Atom shot noise: $\sim 0.1 \text{ fT} / \text{Hz}^{1/2}$

SERF in a $\sim 6 \text{ mm}^3$ scale cell: $5 \text{ fT} / \text{Hz}^{1/2}$

Rubidium relaxation cross sections

$$\sigma_{\text{SE}} = 2 \times 10^{-14} \text{ cm}^2$$
$$\sigma_{\text{SD}} = 9 \times 10^{-18} \text{ cm}^2$$

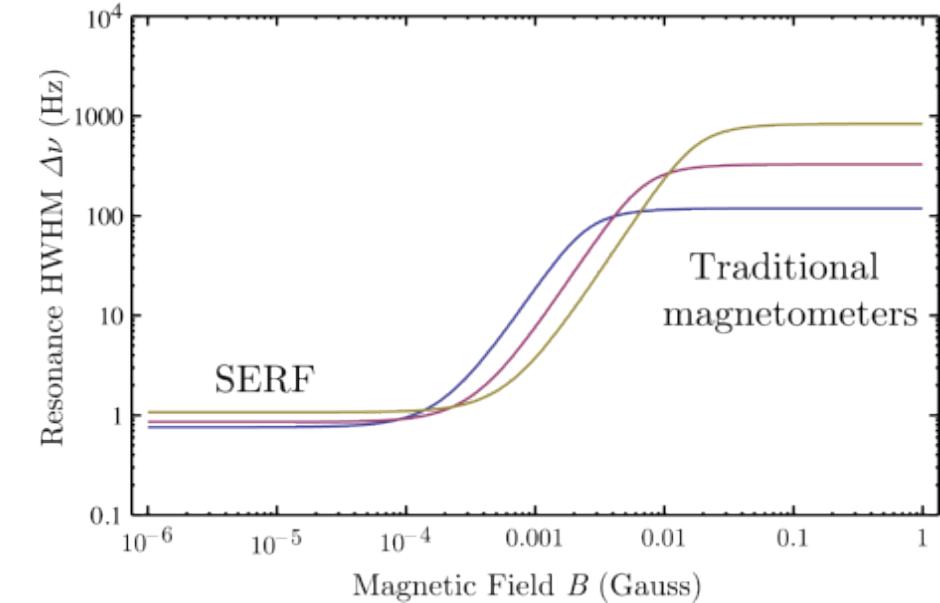

$$\delta B = \frac{1}{\gamma \sqrt{NT_2\tau}}$$

γ = gyromagnetic ratio

$T_2 = \frac{1}{\pi \Delta\nu}$ = transverse coherence time

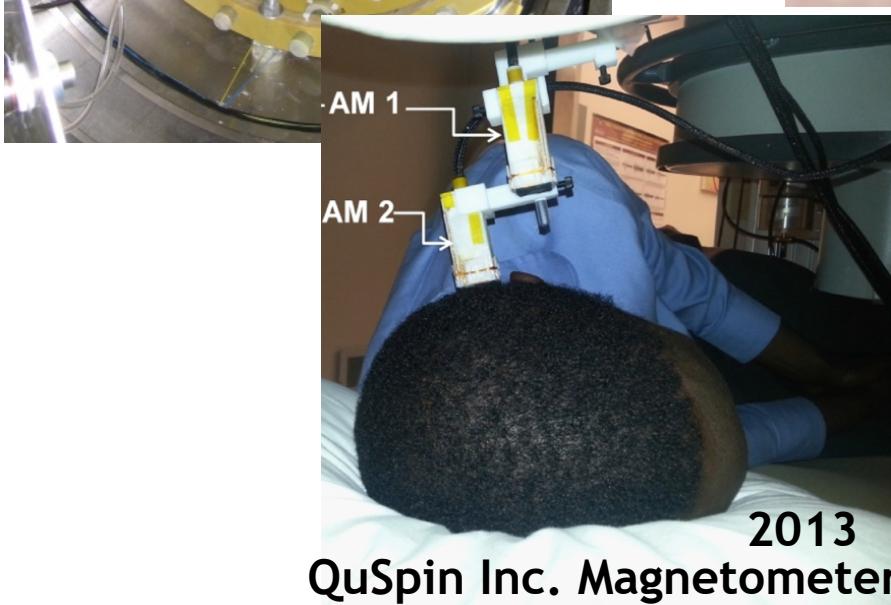

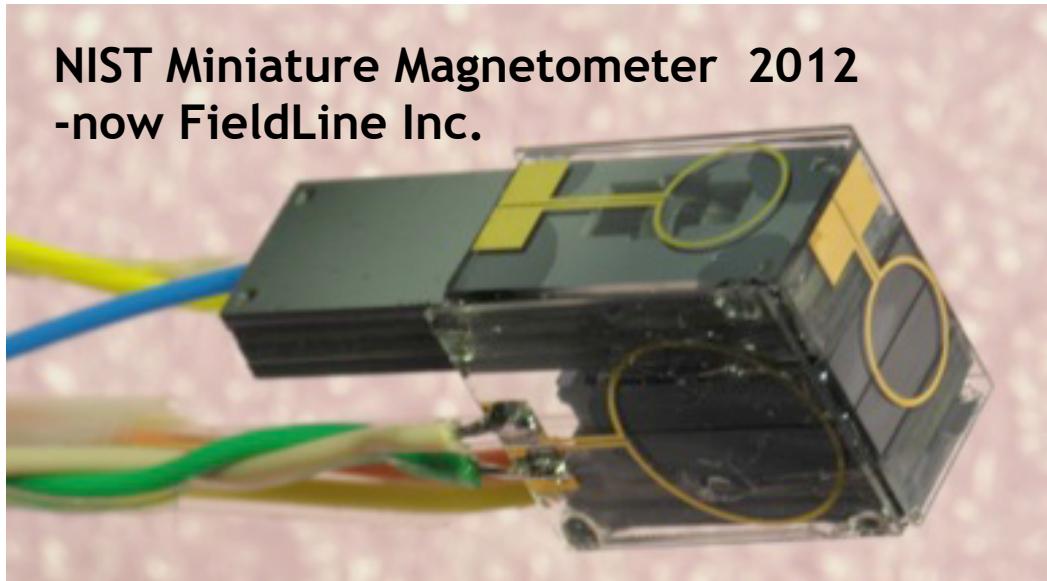

N = number of atoms

τ = measurement time

*Assuming this is a zero-field/SERF OPM

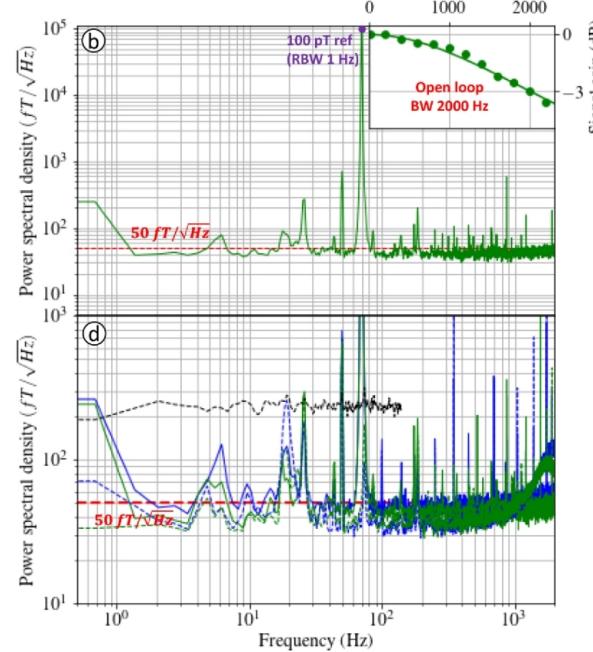

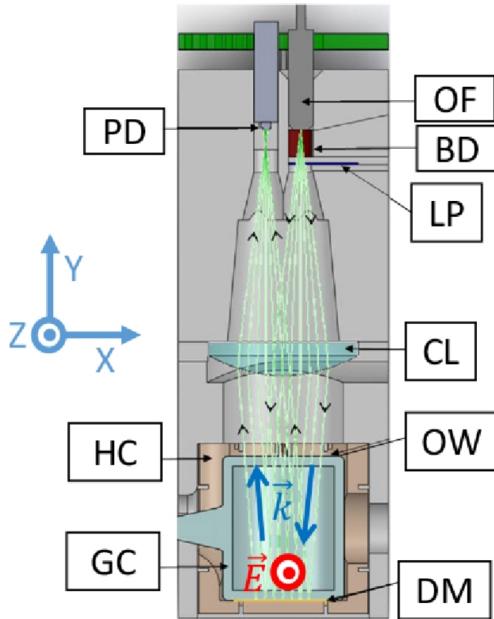

Other types of OPM

Helium-4 OPM

Sensitivity: 50 fT/rt-Hz

Closed-loop, triaxial operation

No cell heating: 10 mW RF discharge

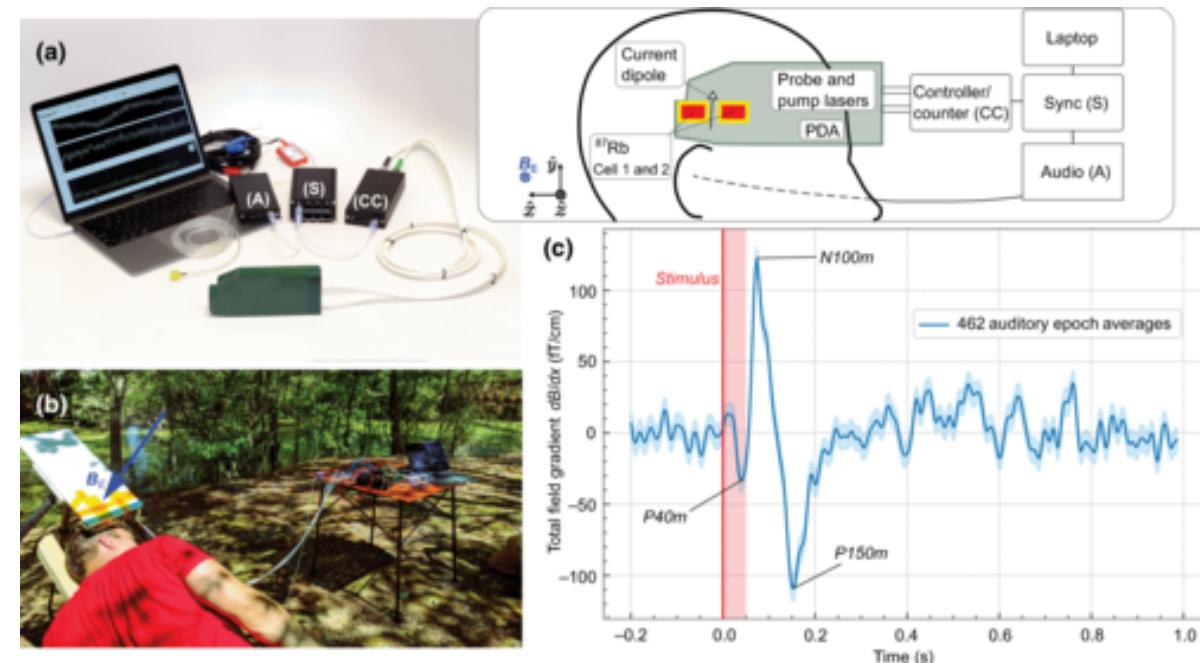

Unshielded MEG using scalar OPM

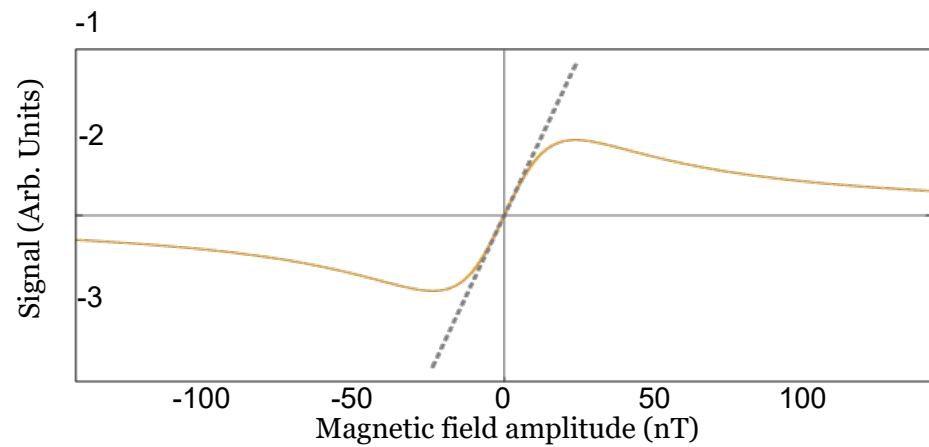

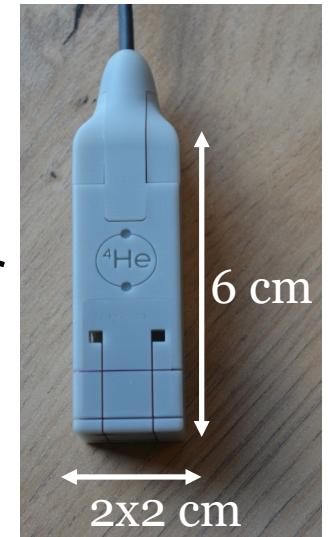

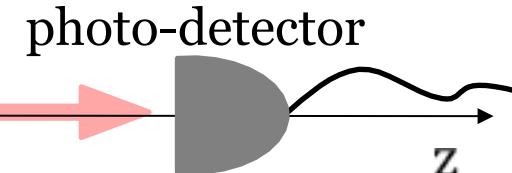

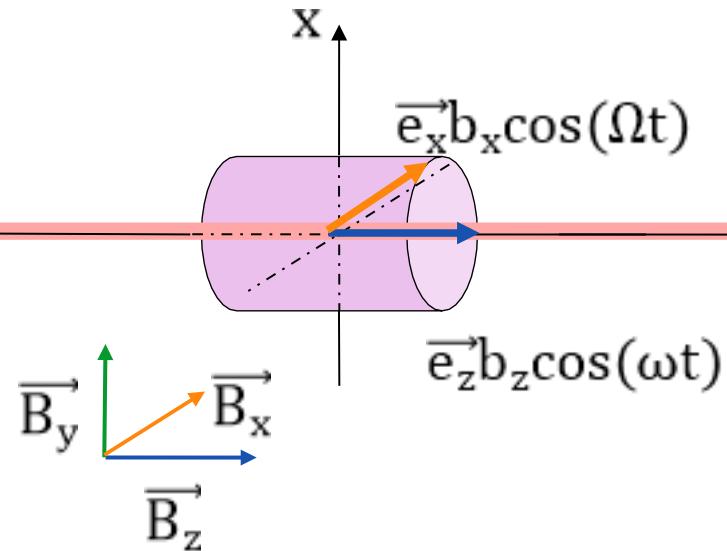

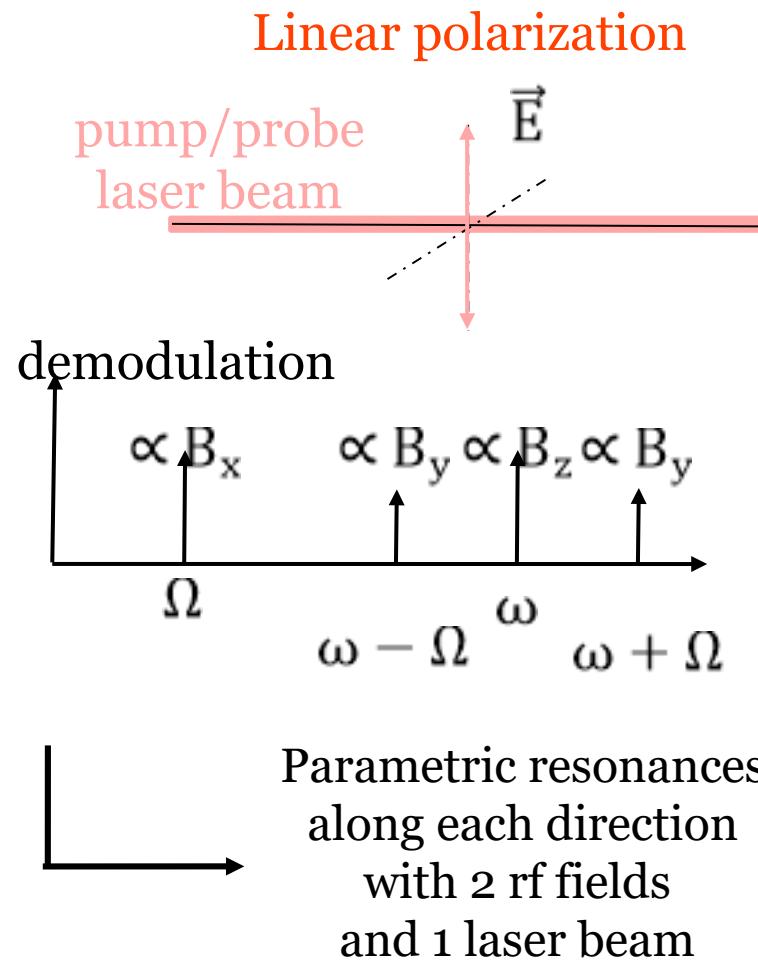

Gradiometric Sensitivity: 15 fT/cm/rt-Hz

Measure field component parallel to ambient field

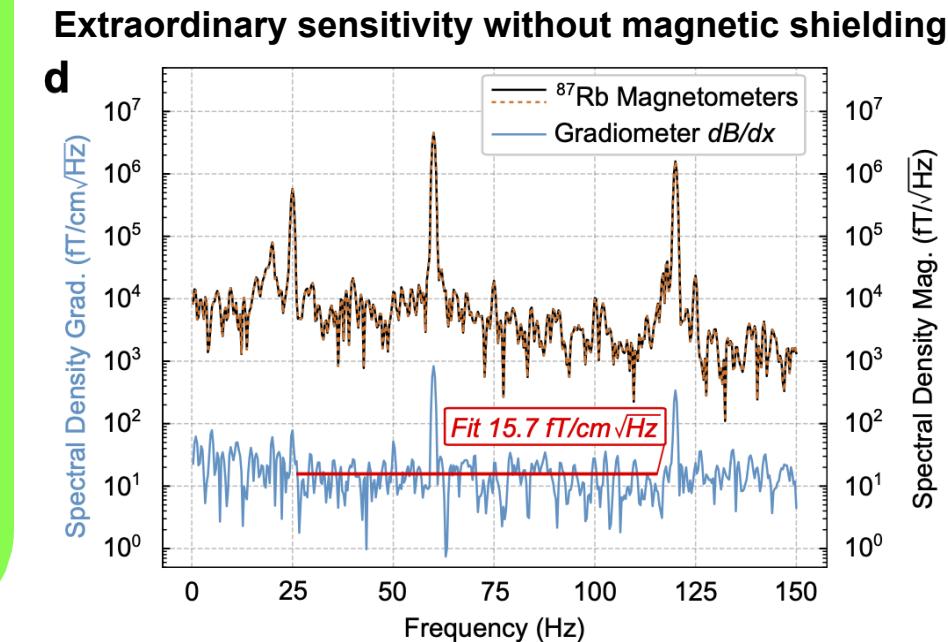

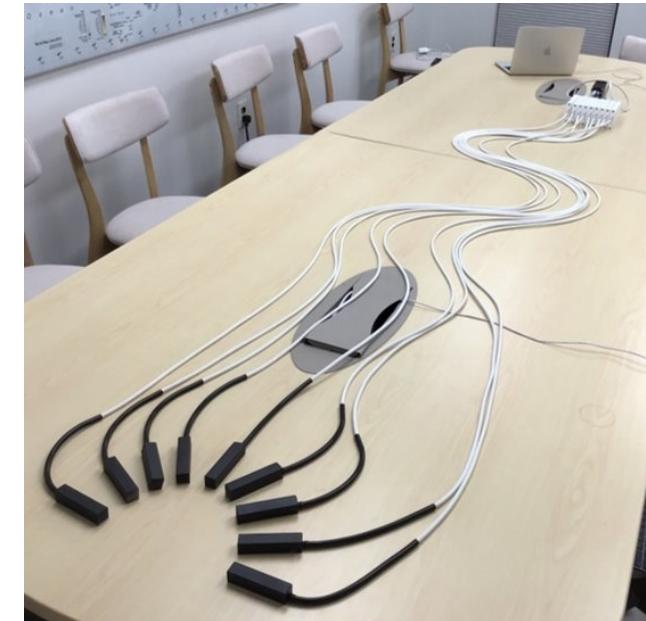

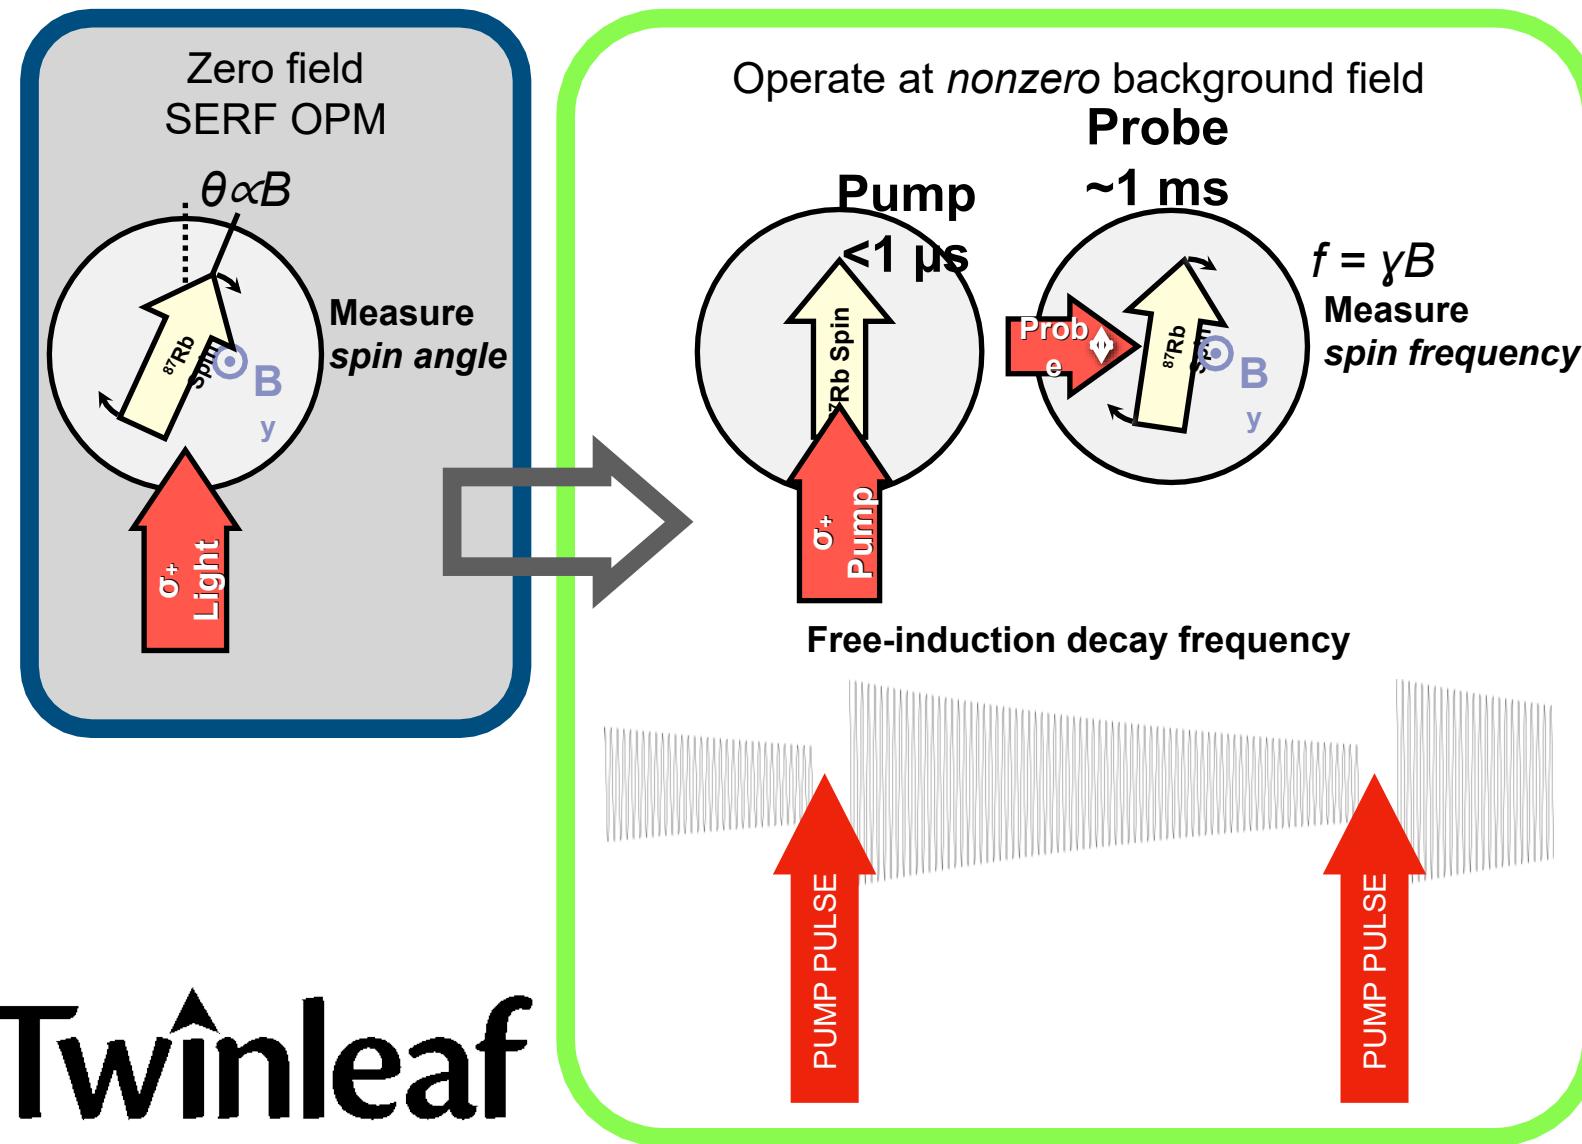

No crosstalk / magnetically silent

Helium-4 OPM - principle

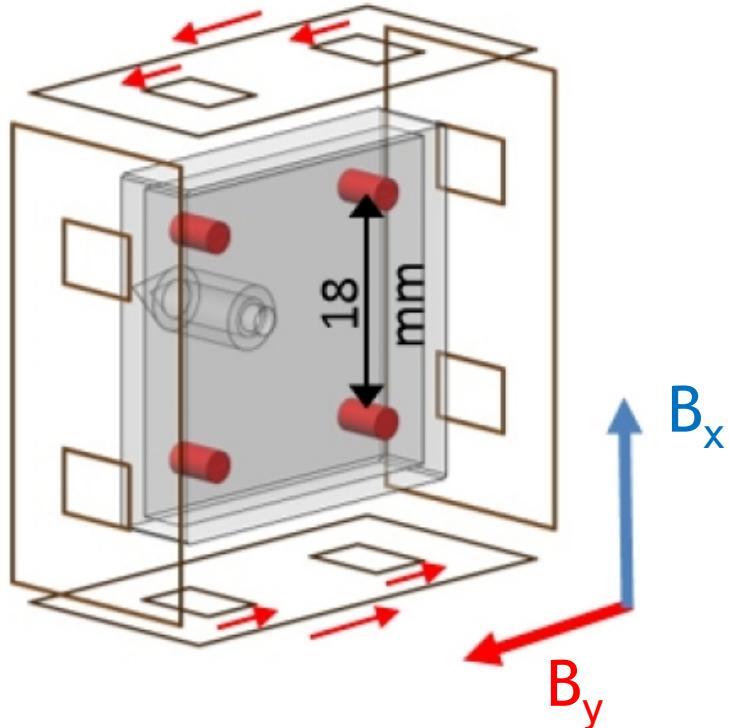

Pulsed Pump Magnetometer

SQUID vs OPM

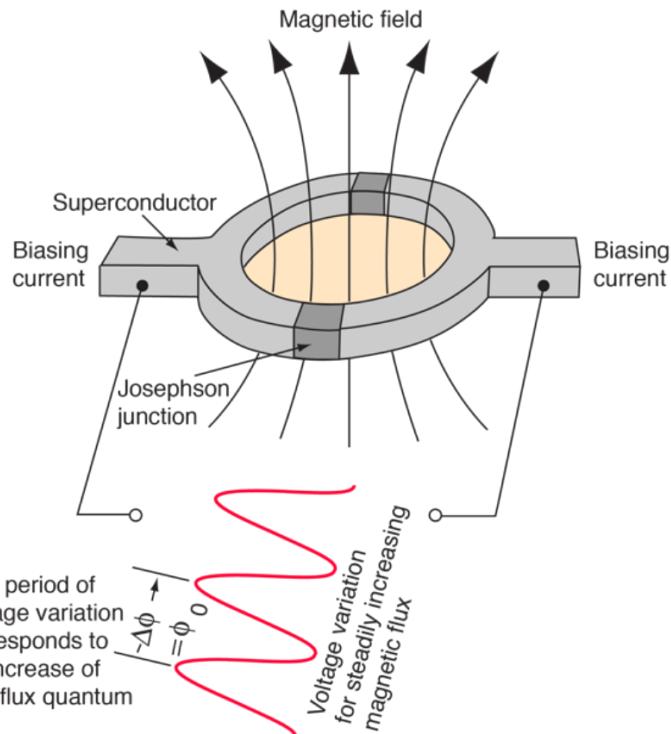

SERF OPM

- Integrates over volume of laser beam
- Sensitive axis determined by field modulation (Some SERF designs use laser beam geometry to define sensitivity axis.)

SQUID

<http://hyperphysics.phy-astr.gsu.edu/hbase/Solids/Squid.html>

- Integrates over the area of pickup loop
- Sensitive axis determined by loop geometry

SQUID vs OPM

	Sensitivity	Bandwidth	Sensitive axis	Dynamic range (Max field)
Zero field, SERF OPM	5-20 fT/rt-Hz	80-150 Hz (open loop) 350 Hz (closed loop)**	1, 2, or 3 axis (3 rd axis from 2 nd OPM)	±2 nT (80 nT) open loop* ±150 nT (150 nT) closed loop**
He OPM	50 fT/rt-Hz	2 kHz (open loop) 1.35 kHz (closed loop)	3 axis (3 rd axis 6x worse sensitivity)	±300 nT (unknown)
Scalar OPM gradiometer—Unshielded	15 fT/cm/rt-Hz	300 Samples/s (adjustable)	Parallel to ambient bias field	Unknown (Earth's field)
SQUID	2-3 fT/rt-Hz	1-5 kS/s (adjustable)	Normal to pickup loop	±20 nT (Unshielded operation possible)

SERF OPMs: Formulating Gain/Sense-Angle Error

C. Cohen-Tannoudji, J. Dupont-Roc, S. Haroche, F. Laloë. Diverses résonances de croisement de niveaux sur des atomes pompés optiquement en champ nul. I. Théorie. Revue de Physique Appliquée, 1970, 5 (1), pp.95-101. 10.1051/rphysap:019700050109500 . jpa-00243381

$$B_x = \widehat{B_{xs}}(t) + B_m \sin(\omega_m t)$$

$$P_z \approx \frac{R_{op}}{R_{op} + R_{rel}} J_0 \left(\frac{\gamma B_m}{q \omega_m} \right) J_1 \left(\frac{\gamma B_m}{q \omega_m} \right) \sin(\omega_m t) \left[\frac{\frac{\gamma \widehat{B_{xs}}(t)}{(R_{op} + R_{rel})}}{1 + \left(\frac{\gamma \widehat{B_{xs}}(t)}{(R_{op} + R_{rel})} \right)^2} - J_0^2 \left(\frac{\gamma B_m}{q \omega_m} \right) \left\{ \frac{\frac{\gamma^2 B_y B_z}{(R_{op} + R_{rel})^2}}{1 + \left(\frac{\gamma \widehat{B_{xs}}(t)}{(R_{op} + R_{rel})} \right)^2} + \frac{\frac{\gamma \widehat{B_{xs}}(t)}{(R_{op} + R_{rel})}}{\left(1 + \left(\frac{\gamma \widehat{B_{xs}}(t)}{(R_{op} + R_{rel})} \right)^2 \right)^2} \left(\left(\frac{\gamma B_y}{(R_{op} + R_{rel})} \right)^2 + \left(\frac{\gamma B_z}{(R_{op} + R_{rel})} \right)^2 \right) \right\} \right]$$

$$G_{OPM}$$

$$G_2$$

$$G_3$$

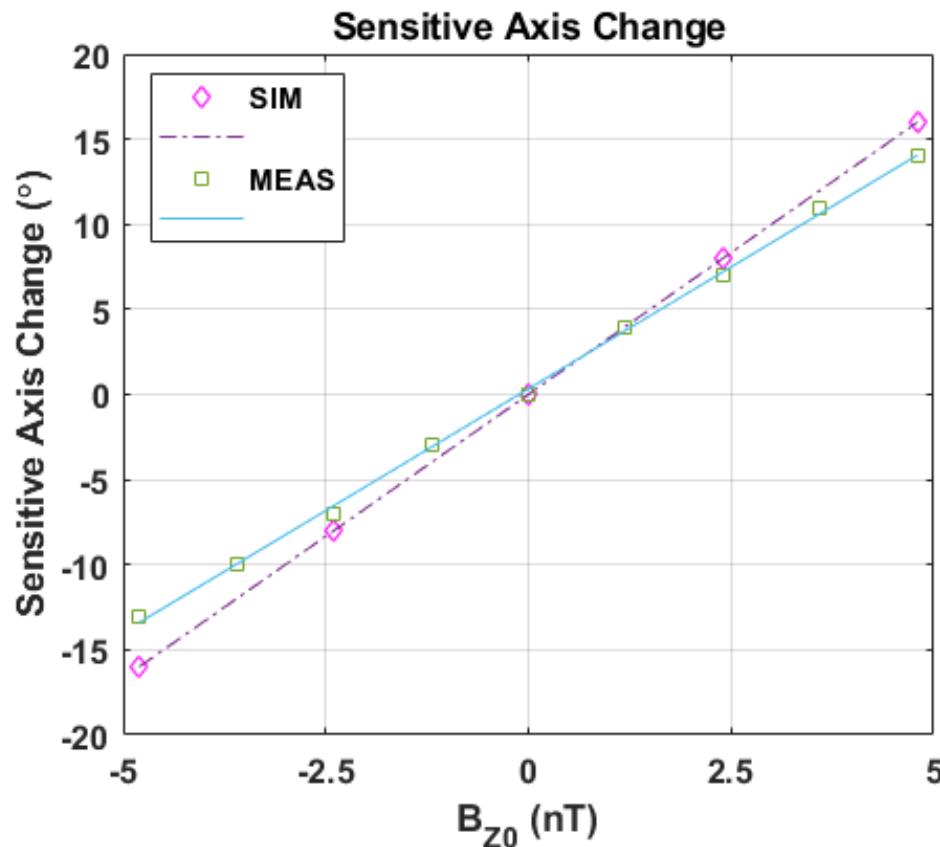

Cross Axis Projection Error (CAPE) Effects

→ $\left\{ \begin{array}{l} \varphi_i \approx \arctan \left(\frac{-G_2 B_i}{G_{OPM}} \right), i = y \text{ or } z \rightarrow \text{Rotation of the sensitive axis} \\ G_\varphi \approx \left(G_{OPM} - G_3 (B_y^2 + B_z^2) \right) \rightarrow \text{Reduction of gain} \end{array} \right.$

Phase errors

Amir Borna, Joonas Iivanainen, Tony R. Carter, Jim McKay, Samu Taulu, Julia Stephen, Peter D.D. Schwindt, "Cross-Axis projection error in optically pumped magnetometers and its implication for magnetoencephalography systems," *NeuroImage*, 247, 118818 (2022).

Sensitive Axis Rotation: Simulation vs. Measurement

$$\varphi_z \approx \arctan\left(\frac{-G_2 B_z}{G_{OPM}}\right)$$

- CAPE rotates the sensitive axis by $2.86 \text{ } ^\circ/\text{nT}$ (measured) and $3.33 \text{ } ^\circ/\text{nT}$ (simulated).
- The slight difference between the two is attributed to different relaxation rates.

Mitigation of CAPE

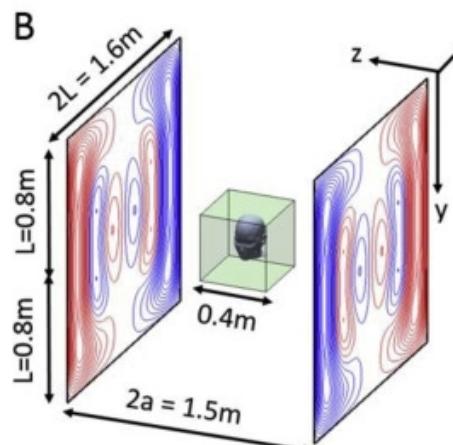

Zero the fields (easier)

- Zero the field at each sensor (< nT)
- Zero the field in the shield

Closed-loop, 3-axis OPM (harder)

- Upside: It's a 3-axis measurement!
 - Can we maintain good sensitivity?
- Upside: Fixed gain. Sensors are always calibrated.
- Downside: cross-talk between sensors.

NeuroImage, 252, 119027 (2022)

Sandia
Person-Sized
Shield Coils

Interference and crosstalk

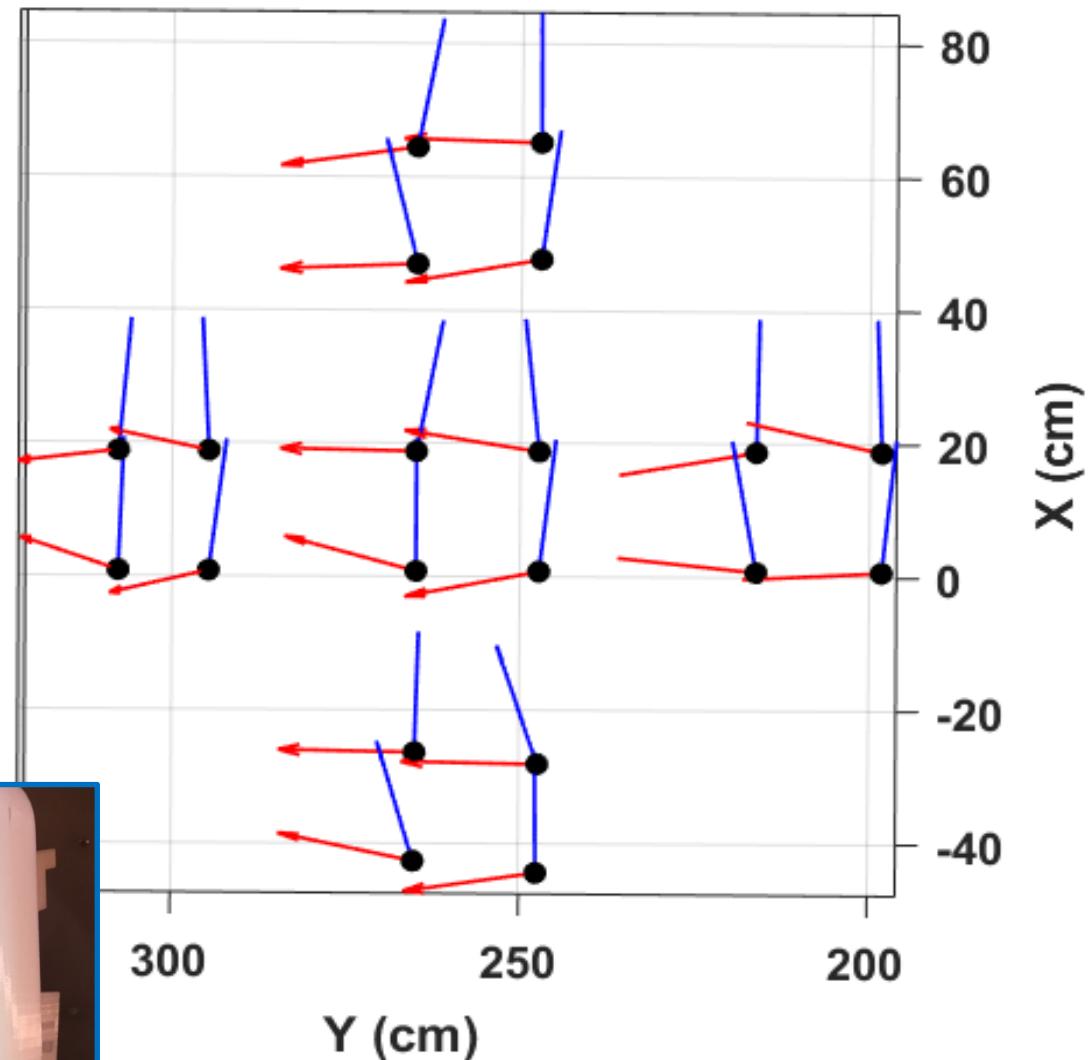

Interference

- Leakage of the modulation field from one sensor to another
- Can easily be ameliorated through sensor calibration

Crosstalk in closed loop system

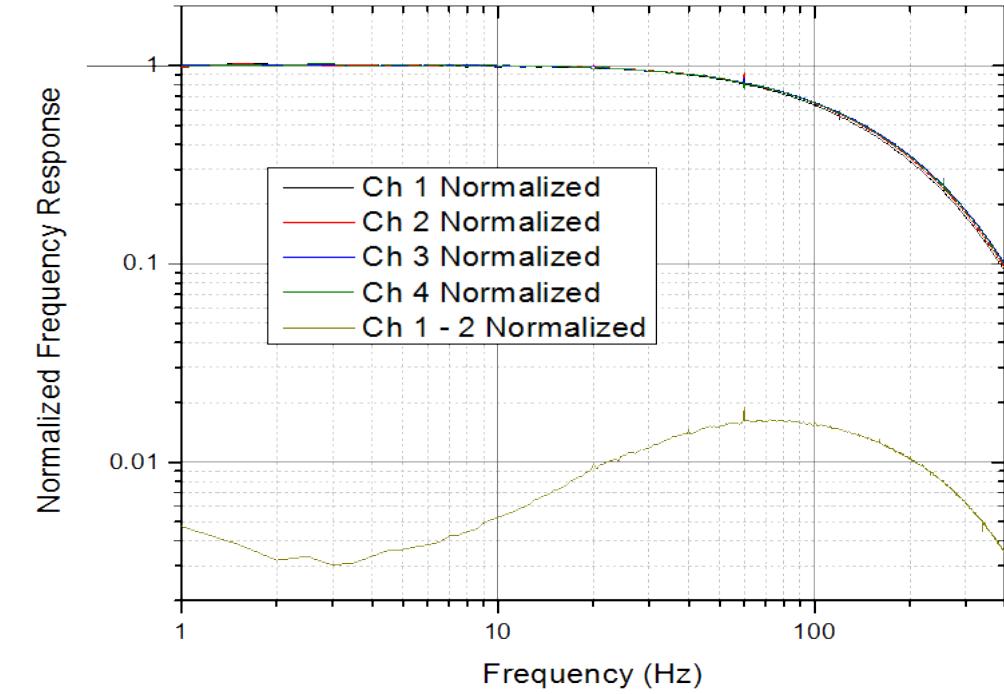

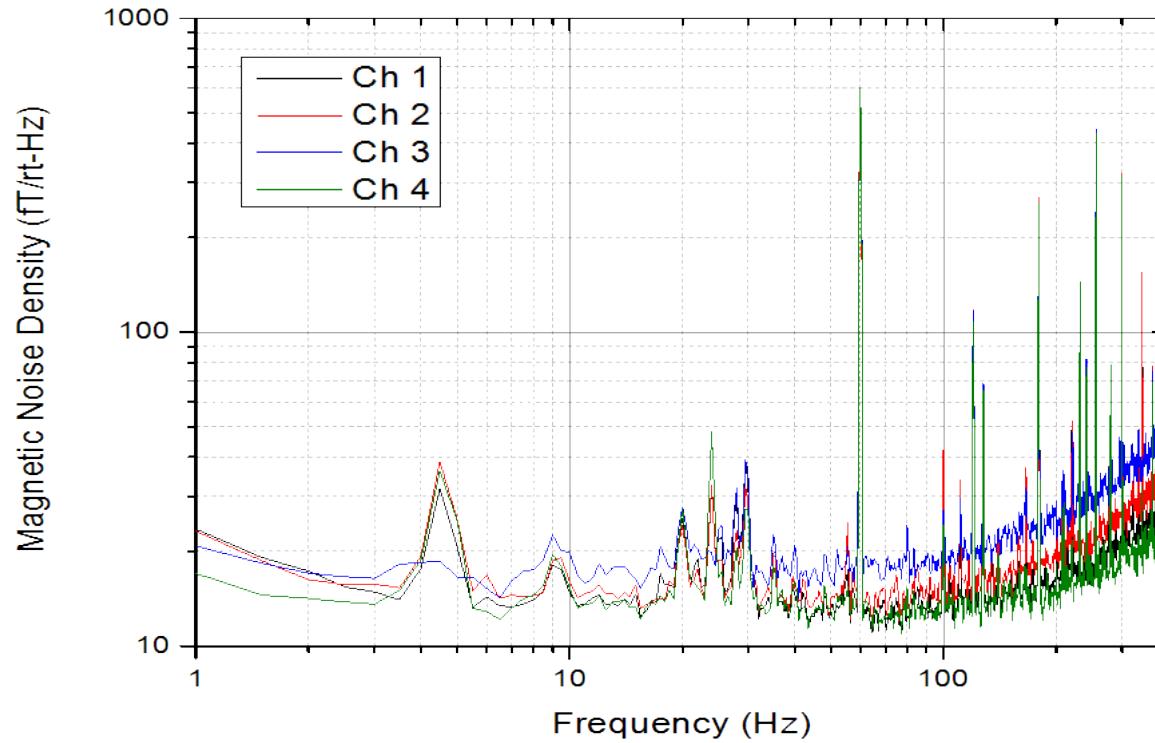

- Cancelling field at one sensor is sensed by another sensor
- Mitigation: Design feedback coils that minimize cross talk.
- Mitigation: A cross-talk matrix may need to be measured for each sensor configuration.

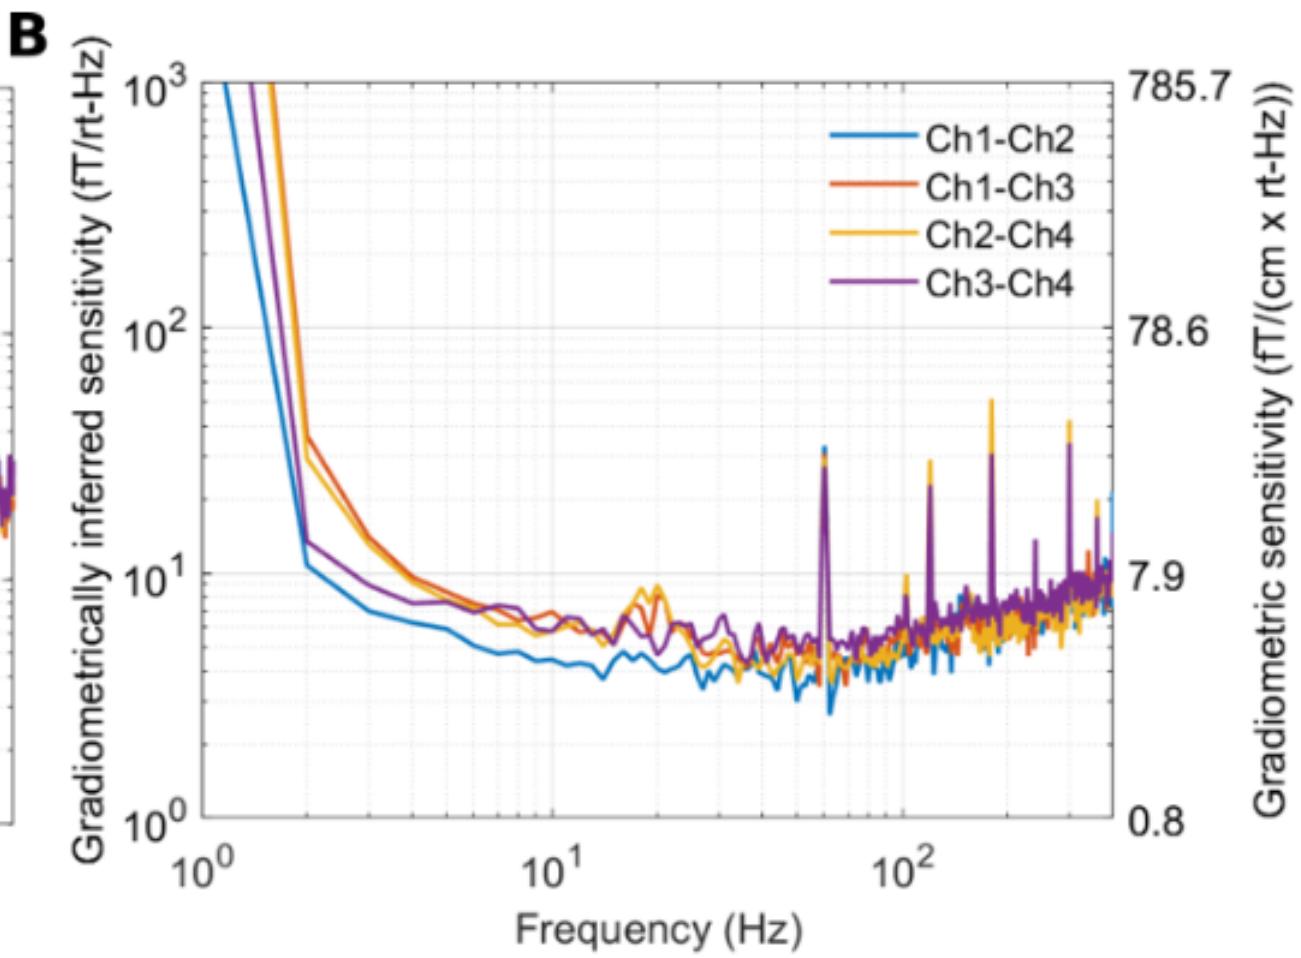

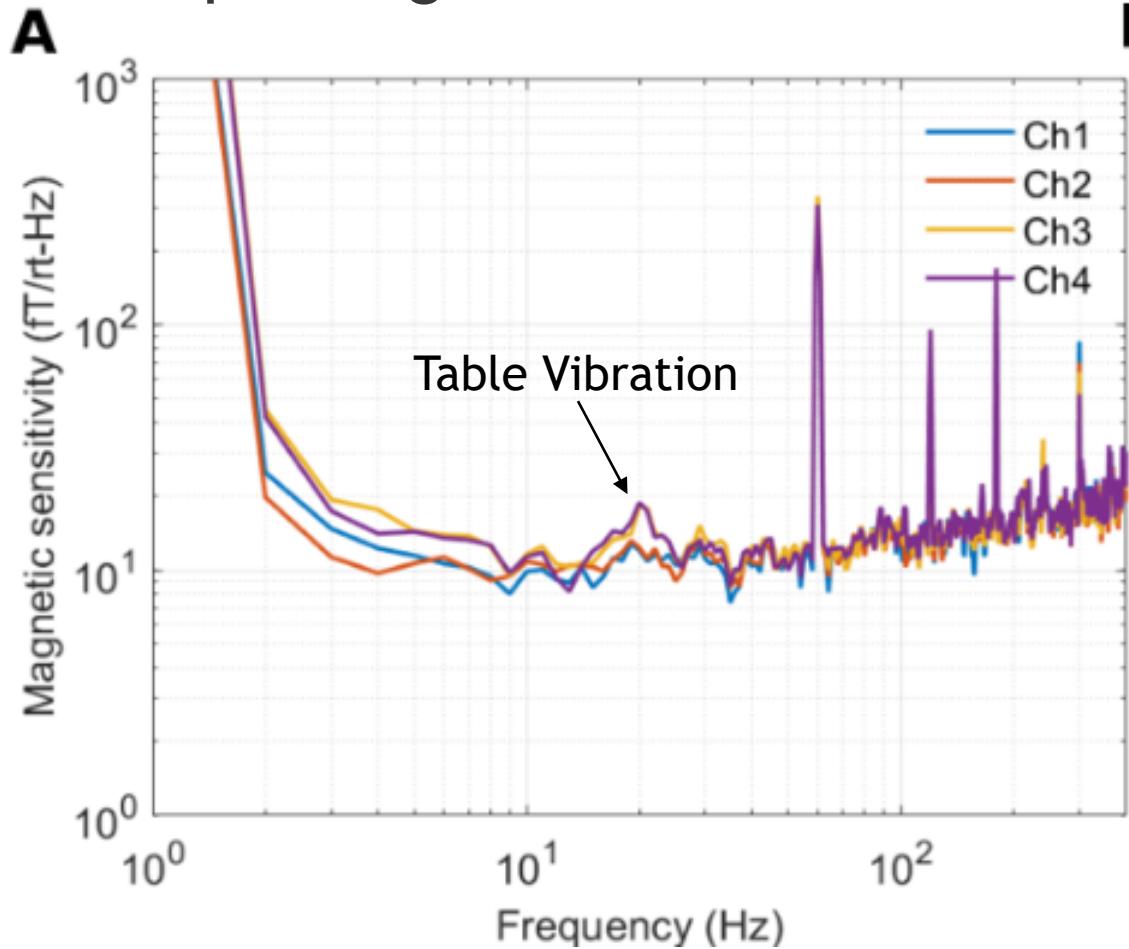

Reporting results

Sensitivity results should be normalized by the bandwidth.

Reporting results

$$\text{Gradiometrically inferred sensitivity} = (Ch1 - Ch2)/\sqrt{2}$$

$$\text{Gradiometer sensitivity} = (Ch1 - Ch2)/1.8 \text{ cm}$$

1.8 cm = gradiometer baseline

Conclusions

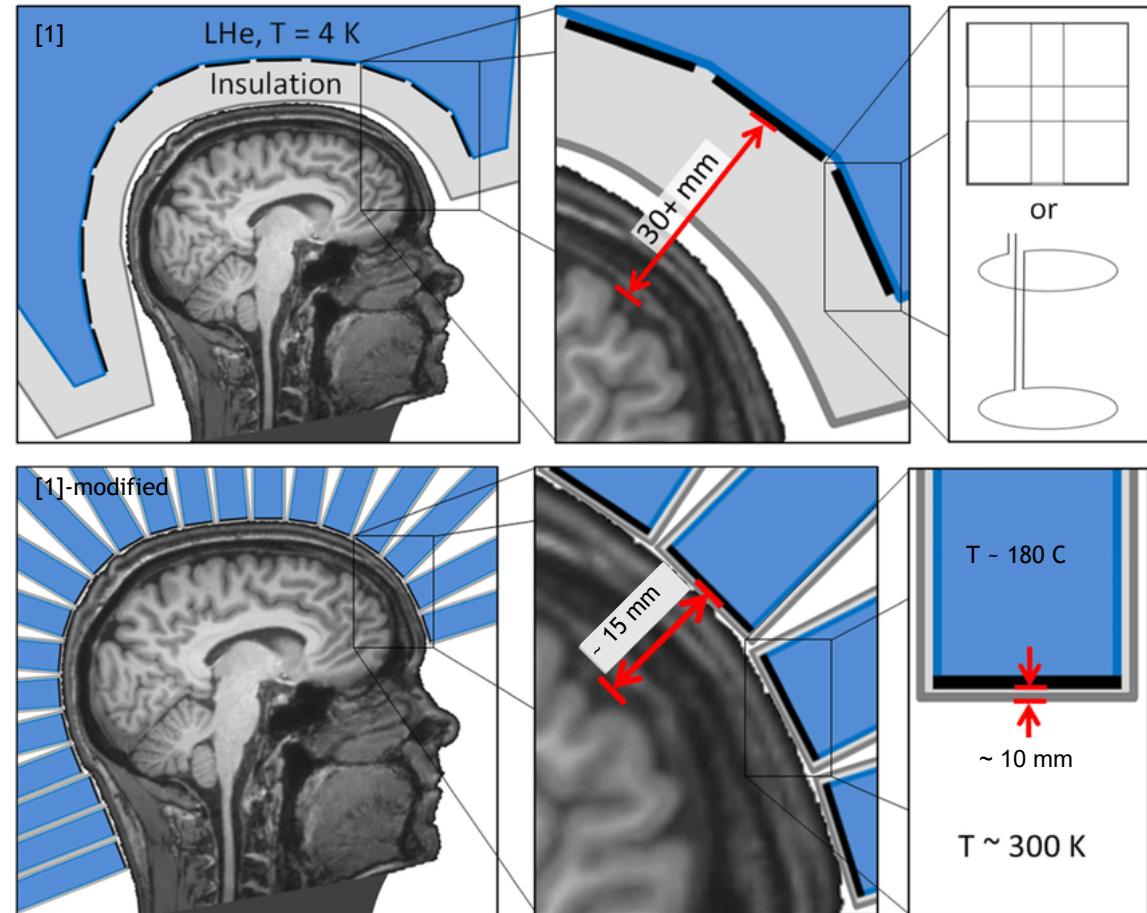

OPMs are fundamentally different than SQUID sensors

- OPMs integrate field over a volume, not an area
- Bandwidth reduced compared to SQUID, at least for SERF OPMs
- Sensitivity of today's OPM are reduced compared to SQUIDs
 - Mitigated by being closer to the head
 - Prospects for better OPM sensitivity: Best OPM 0.16 fT/rt-Hz
- OPM respond to all components of the field
 - “Vectorization” methods needed to read out specific field components
 - Three-axis detection possible
 - Systematic errors arise from offset field

SERF and He OPM need a low-field environment

Scalar gradiometer operates in Earth's field

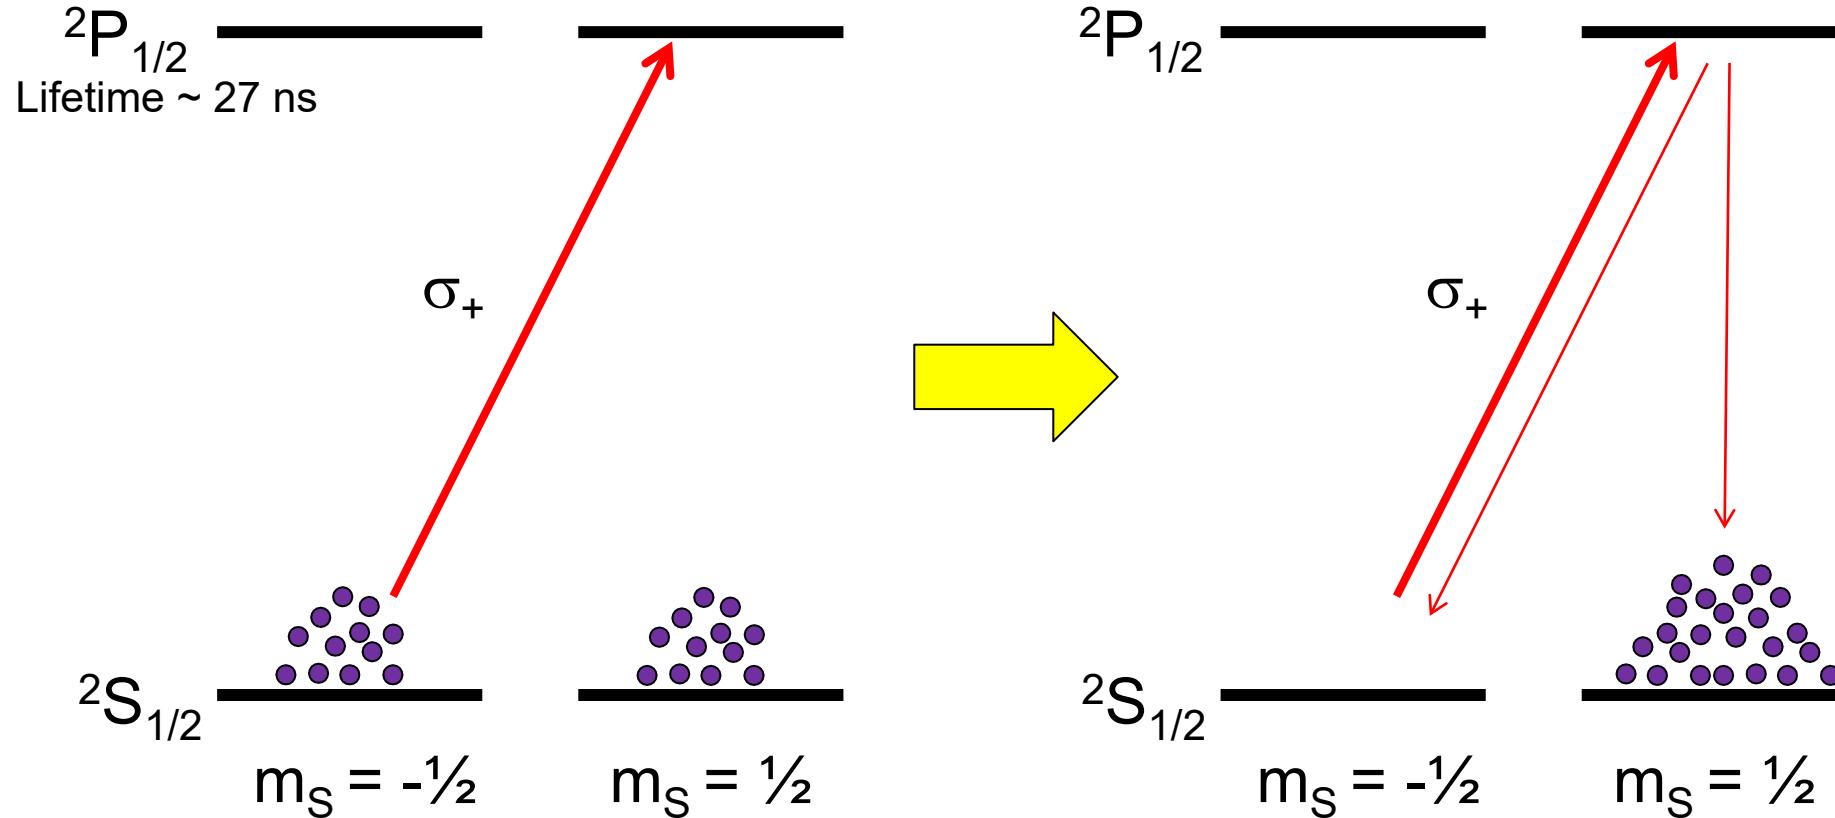

Back up slides

Optical Pumping

Hyperfine Ground State

Ground State Hamiltonian:

- Spin angular momentum \mathbf{S}
- Nuclear angular momentum \mathbf{I}
- Total angular momentum $\mathbf{F} = \mathbf{S} + \mathbf{I}$
- $H_{HF} = \mu_B g_S \mathbf{S} \cdot \mathbf{B} + \mu_B g_I \mathbf{I} \cdot \mathbf{B} + A_{HF} \mathbf{I} \cdot \mathbf{S}$
- $g_S = 2.002, g_I = -0.000995$ (^{87}Rb), -0.000399 (^{133}Cs)
- $E_{HF} = \frac{1}{2} A_{HF} (F(F+1) - I(I+1) - S(S+1))$
- ^{87}Rb : $\Delta E_{HF}/h = 6.835\text{GHz}$, $I = 3/2$
- ^{133}Cs : $\Delta E_{HF}/h = 9.192\text{GHz}$, $I = 7/2$

At low field the nuclear and electron spins are combined,

- $H_B = \mu_B g_F \mathbf{F} \cdot \mathbf{B}, \Delta E_{mF} = g_F m_F \mu_B B$
- $g_F \approx \pm \frac{1}{2F_{max}}, -F \leq m_F \leq F$
- $\frac{g_S \mu_B}{h} = 2.8 \text{ MHz/G}$ or 28 Hz/nT (gyromagnetic ratio)
- ^{87}Rb : $g_F = \pm \frac{1}{4}, \frac{g_F \mu_B}{h} = 700 \text{ kHz/G}$ or 7 Hz/nT
- ^{133}Cs : $g_F = \pm \frac{1}{8}, \frac{g_F \mu_B}{h} = 350 \text{ kHz/G}$ or 3.5 Hz/nT

Sensitivity Limits

Magnetic Sensitivity

$$\delta B = \frac{S_{noise}}{dS/dB}$$

Atom shot noise limit

$$\delta B = \frac{1}{\gamma \sqrt{N T_2 \tau}}$$

γ = gyromagnetic ratio

T_2 = transverse coherence time

N = number of atoms

τ = measurement time

Decoherence limits noise to $1/N^{1/2}$ scaling

Sensitivity improved by increasing T_2 or N

Most AMs do not operate at this limit.

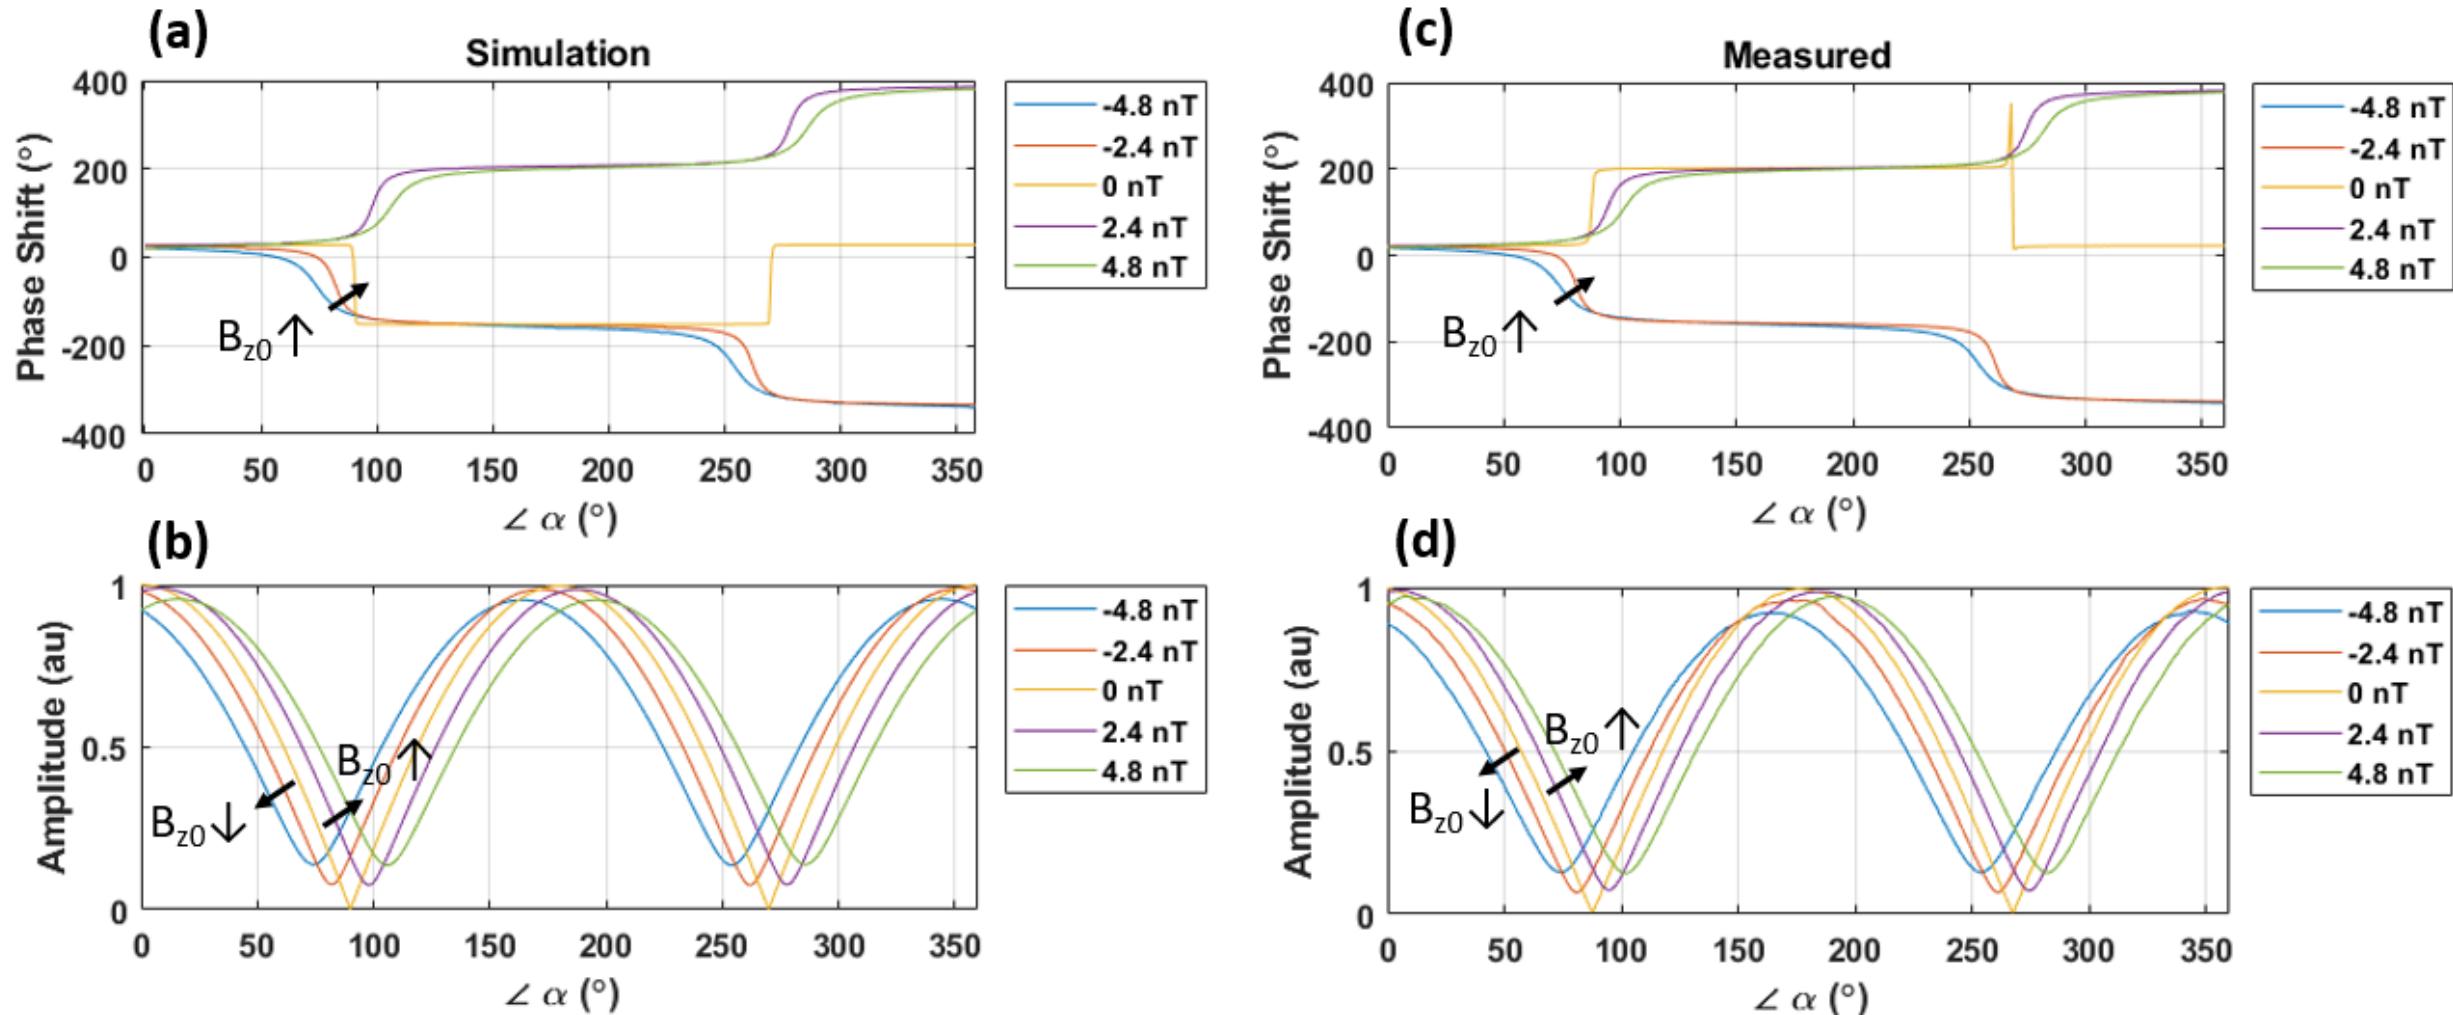

Photon shot noise limit

$$\delta B = \frac{\sqrt{2N_{ph}}}{dS(N_{ph})/dB} \propto \frac{1}{\sqrt{N_{ph}}}$$

Most AMs operate at or near the photon shot noise limit

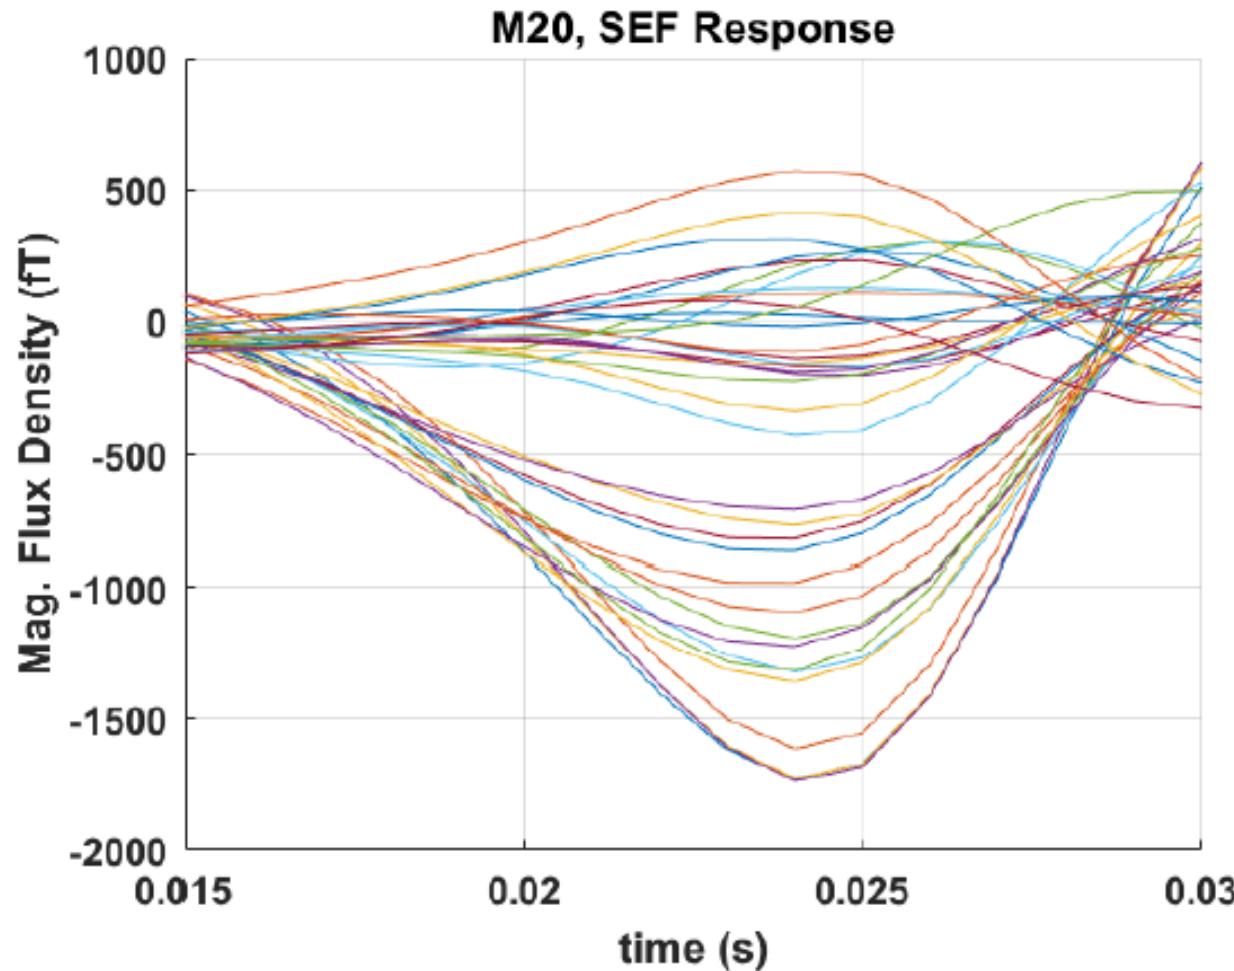

Probe intensity contributes to T_2 so N_{ph} cannot be made arbitrarily high.

Simulation vs. Measurement, CAPE

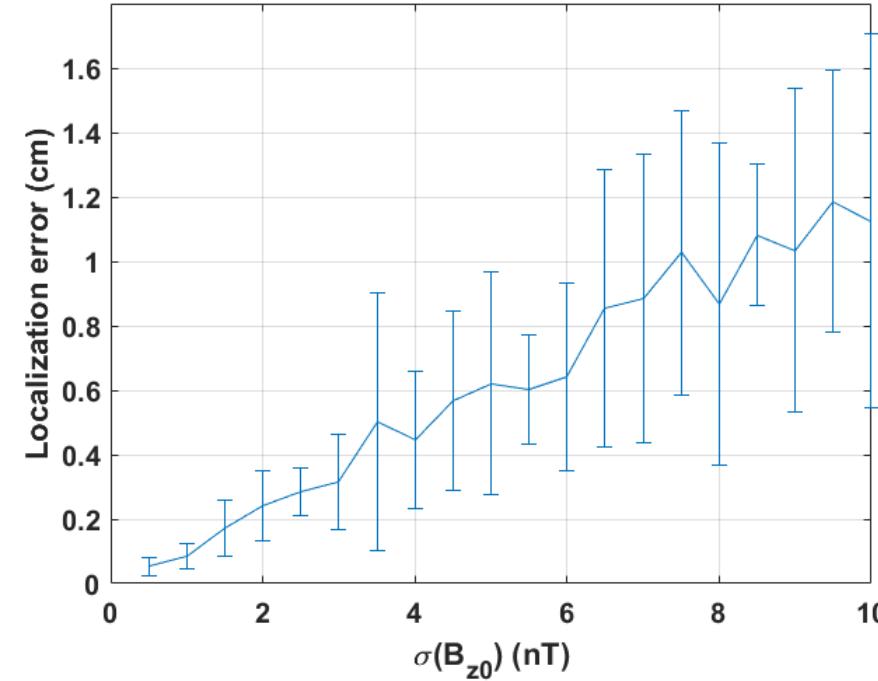

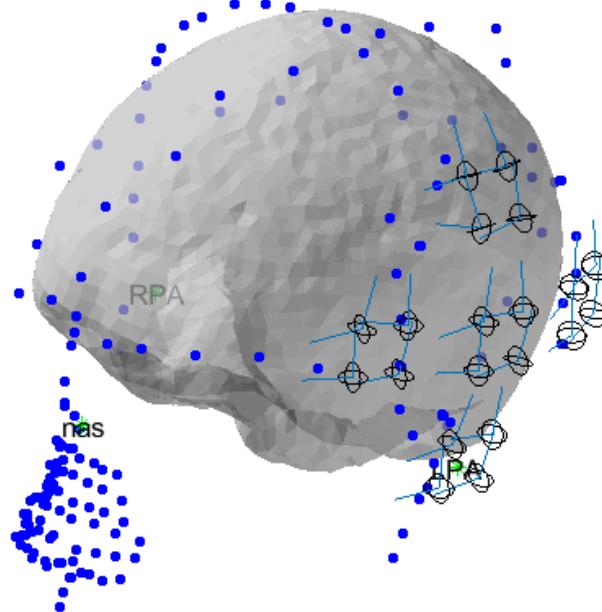

OPM's cross-axis projection error for a 25 Hz, sinusoidal signal with an amplitude of 0.33 nT.

Impact of CAPE on MEG Signals: M20 Median Nerve Response
