The quasi 2-dimensional square-lattice antiferromagnet  $\text{Ba}_2\text{CuGe}_2\text{O}_7$  was studied by neutron scattering and bulk magnetic techniques. An incommensurate magnetic spiral structure with the propagation vector  $(1+\xi, 1+\xi, 0)$  ( $\xi=0.027$ ) was observed below  $T_N=3.26$  K. The spin dynamics can be adequately described by conventional spin-wave theory with two exchange constants: nearest-neighbor in-plane antiferromagnetic coupling  $J_1\approx 0.48$  meV and interplane ferromagnetic interaction  $J_2\approx 0.013$  meV. This set of exchange parameters apparently fails to explain the spiral order. The non-centrosymmetric crystal structure suggests that the incommensurate phase may be the result of a Dzyaloshinskii-Moriya instability of the Neel ground state.

AF arrangement) by an angle  $\phi=9.7^\circ$  in spin space ( $\phi=0$  would corresponds to Neel order).  $\xi$  is given by  $\xi=\phi/(2\pi)$ .

As a rule, spiral order is caused by competing exchange interactions [4]. To verify the applicability of this hypothesis to  $\text{Ba}_2\text{CuGe}_2\text{O}_7$  we performed inelastic neutron scattering measurements of the spin wave dispersion relation, that was measured in constant-Q scans along the  $(1,0,0)$ ,  $(1,1,0)$  and  $(0,0,1)$  directions. We have worked out the classical spin-wave dispersion law assuming the relevant Heisenberg exchange parameter are 1-nn and 2-nn in-plane AF coupling constants  $J_1$  and  $J_2$ , as well as the 1-nn interplane FM exchange  $J_3$ . The model produces good fits to our data with  $J_1=0.482$  (0.003) meV,  $J_2/J_1=0.01$  (0.04) and  $J_3=0.013$  (0.001) meV. Two immediate conclusions can be drawn: i) the system is indeed strongly 2-dimensional with  $J_1/J_3=37$  and ii) 2-nn interactions in the Cu-planes are negligible. The Neel ground state for a 2-D square-lattice AF is known to be stable in a wide range of  $J_2/J_1$  [5] and thus *competing interactions can not explain the spiral order* in  $\text{Ba}_2\text{CuGe}_2\text{O}_7$ .

So, what causes the spiral phase? We believe the answer lies in the non-centric nature of the crystal structure, as is the case for MnSi [6,7] and FeGe [7], for example. The absence of inversion center allows Dzyaloshinskii- Moriya (DM) terms [8] in the Hamiltonian. These are proportional to the *vector* product of nearest-neighbor spins. A symmetry analysis by S. Maslov and P. Bak shows that it is exactly the observed type of spiral structure that must be stabilized by DM interactions in the particular symmetry of  $\text{Ba}_2\text{CuGe}_2\text{O}_7$ . Additional valuable information on the DM transition was obtained in high-field experiments, that are beyond the scope of this paper.

This study was supported in part by NEDO International Joint Research Grant and the U.S.-Japan Cooperative Program on Neutron Scattering. Work at Brookhaven National Laboratory was carried out under Contract No. DE-AC02-76CH00016, Division of Material Science, U.S. Department of Energy.
