## Abstract

Work involving the synthesis of monometallic transition metal carbides supported on alumina is described. The catalysts have excellent initial activity in the hydrodechlorination of  $\text{CCl}_2\text{F}_2$  (CFC 12), but deactivate with time by the deposition of carbon. Initial work on the preparation of unsupported bimetallic oxynitrides is also described.

## **Executive Summary**

Several supported transition metal carbides and nitrides were prepared and tested in the catalytic dechlorination of the freon CFC 12 ( $\text{CCl}_2\text{F}_2$ ). The catalysts had excellent initial activity compared to noble metal catalysts, but deactivated due to the deposition of carbon. Good progress was made with the preparation of bimetallic oxynitrides, and several stable compositions were obtained.

## **Introduction**

In the previous quarterly report we described the synthesis and characterization of a series of unsupported transition metal carbides and nitrides. The catalysts had excellent activity in hydrodenitrogenation (HDN) of a model coal-liquid feed. Because of the exceptional hydrogenation activity it was decided to test them for the dechlorination of  $\text{CCl}_2\text{F}_2$  (freon 12), a chlorofluorocarbon. Dechlorination of freons to hydrofluorocarbons is an important environmental objective which warranted examination.

In the first quarterly report it was shown that the best catalysts were molybdenum and tungsten carbide. It was decided to prepare these compounds in supported form on an alumina substrate. Also, because of the positive initial results and the good prospects for developing the carbides and nitrides, it was also decided to prepare new compositions based on combining two different metals. Such bimetallic alloys could be prepared by the same temperature-programmed techniques used to synthesize the monometallic compounds.

## **Results and Discussion**

### **Preparation of Supported Compounds**

Supported carbide catalysts were prepared by temperature-programmed reaction of supported oxide precursors. These precursors were made by impregnating  $\text{Al}_2\text{O}_3$  (Degussa Aluminum Oxide C) with ammonium molybdate and ammonium metatungstate (20% loading of oxide). The precursors were pelletized and reacted with a stream of 20%  $\text{CH}_4$  in  $\text{H}_2$ . X-ray diffraction analysis of the compounds showed the presence of  $\text{Mo}_2\text{C}$  and  $\text{W}_2\text{C}$ . These supported carbides were also themselves impregnated with 1% Pd, to test for synergy between the carbides and a noble metal. The catalysts were characterized by chemisorption of CO and BET measurements.

### **Testing of Catalysts**

The catalysts were tested for the conversion of  $\text{CCl}_2\text{F}_2$  (CFC 12) in a medium pressure reactor system consisting of two stainless steel reactors in parallel. The reaction products were analyzed by on-line gas-chromatography (Varian, Model 3700) using a PoraPLOT Q column (Chrompack, Inc.). The catalysts were compared to a standard palladium catalyst. The results are summarized in Table 1. It was found that the initial activities of the carbides were high, rivaling those of the palladium catalyst, but that the activity deteriorated with time. Examination of the spent catalysts by XPS indicated that they had substantial contents of carbon. Evidently, some cracking had occurred to cause coke deposition. The work has been published and is reported in Ref. 1.

**Table 1**  
**Initial Activities of Catalysts at a Space Velocity of 1800 h<sup>-1</sup>**

| Catalyst   | Temp (K) | Conv of CFC (%) | Selectivity to HFC 32 (%) | Turnover rate (s <sup>-1</sup> ) |
|--|----------|-----------------|---------------------------|----------------------------------|
| 0.1% Pd-Mo <sub>2</sub> C/Al <sub>2</sub> O <sub>3</sub> | 573      | 13              | 100                       | 0.055                            |
| 1% Pd-Mo <sub>2</sub> C/Al <sub>2</sub> O <sub>3</sub>   | 623      | 43              | 100                       | 0.183                            |
| Mo <sub>2</sub> C/Al <sub>2</sub> O <sub>3</sub>         | 623      | 46              | 100                       | 0.196                            |
| W <sub>2</sub> C/Al <sub>2</sub> O <sub>3</sub>          | 623      | 73              | 100                       | 0.310                            |
| Mo <sub>2</sub> C  | 623      | 4               | 100                       | 0.017                            |
| WC   | 623      | 6               | 100                       | 0.026                            |
| 1% Pd/activated C  | 523      | 47              | 45                        | 0.200                            |

### Preparation of Bimetallic Compounds

A new class of materials, M<sub>I</sub>-M<sub>II</sub>-O-N (where M<sub>I</sub>, M<sub>II</sub> = V, Mo, W, and Nb) were synthesized by nitriding bimetallic oxide precursors with ammonia gas via a temperature programmed reaction. The oxide precursors were prepared by conventional solid state reaction between two appropriate monometallic oxides. The synthesis of the oxynitrides involved passing NH<sub>3</sub> gas over the oxide precursors at a flow rate of 6.80 x 10<sup>2</sup> μmol s<sup>-1</sup> (1000 cm<sup>3</sup> min<sup>-1</sup>) and raising the temperature at a rate of 5 K min<sup>-1</sup> to a final temperature which was held constant for a short period of time. The oxynitrides thus obtained were pyrophoric and needed to be passivated before exposing them to air. All these new bimetallic oxynitrides had a face centered cubic metal arrangement and high values of surface area. They had good CO uptakes and are likely to be surface active. Their XRD patterns are reported in Figure 2 and indicate pure substances. The work has been published (Ref. 2,3).

### Conclusions

The supported carbides and nitrides show good activity in hydrodechlorination, but deactivate. This may be due to the acidity of the alumina support. The bimetallic oxynitrides

can be made in a homologous series and are promising for hydroprocessing.
