## The $K_L \rightarrow \pi^0 \nu \bar{\nu}$ Decay Beyond the Standard Model\*

Y. Grossman

Stanford Linear Accelerator Center, Stanford University, Stanford CA 94309

### Abstract

The  $K_L \rightarrow \pi^0 \nu \bar{\nu}$  decay is analyzed in a model independent way. When lepton flavor is conserved, this decay mode is a manifestation of CP violating interference between mixing and decay. Consequently, a theoretically clean relation between the measured rate and electroweak parameters holds in any given model.

# The $K_L \rightarrow \pi^0 \nu \bar{\nu}$ Decay Beyond the Standard Model

Yuval Grossman

Stanford Linear Accelerator Center  
Stanford University, Stanford, CA 94309

## Abstract

The  $K_L \rightarrow \pi^0 \nu \bar{\nu}$  decay is analyzed in a model independent way. When lepton flavor is conserved, this decay mode is a manifestation of CP violating interference between mixing and decay. Consequently, a theoretically clean relation between the measured rate and electroweak parameters holds in any given model.

$K_L \rightarrow \pi^0 \nu \bar{\nu}$  is unique among  $K$  decays in several aspects: (a) It is theoretically very clean; (b) it is purely CP violating<sup>1,2</sup>; and (c) it can be measured in the near future<sup>3</sup> even if the rate is as small as the Standard Model prediction. In the Standard Model a measurement of  $\Gamma(K_L \rightarrow \pi^0 \nu \bar{\nu})$  provides a clean determination of the Wolfenstein CP violating parameter  $\eta$  or, equivalently, of the Jarlskog measure of CP violation  $J$  and, together with a measurement of  $\Gamma(K^+ \rightarrow \pi^+ \nu \bar{\nu})$ , of the angle  $\beta$  of the unitarity triangle<sup>2</sup>.

Here we explain what can be learned from the  $K \rightarrow \pi \nu \bar{\nu}$  decay in a model independent way<sup>4</sup>. We define

$$\lambda \equiv \frac{q}{p} \frac{\bar{A}}{A}, \quad (1)$$

where  $p$  and  $q$  are the components of interaction eigenstates in mass eigenstates,  $|K_{L,S}\rangle = p|K^0\rangle \mp q|\bar{K}^0\rangle$ , and  $A(\bar{A})$  is the  $K^0(\bar{K}^0) \rightarrow \pi^0 \nu \bar{\nu}$  decay amplitude. Then, the ratio between the  $K_L$  and  $K_S$  decay rates is<sup>4</sup>

$$\frac{\Gamma(K_L \rightarrow \pi^0 \nu \bar{\nu})}{\Gamma(K_S \rightarrow \pi^0 \nu \bar{\nu})} = \frac{1 + |\lambda|^2 - 2\text{Re}\lambda}{1 + |\lambda|^2 + 2\text{Re}\lambda}. \quad (2)$$

In general, a three body final state does not have a definite CP parity. However, if the light neutrinos are purely left-handed, and if lepton flavor is conserved, the final state is CP even (to an excellent approximation)<sup>4</sup>. If lepton flavor is violated, the final state in  $K_L \rightarrow \pi^0 \nu \bar{\nu}$  is not necessarily a CP eigenstate; specifically,  $K_L \rightarrow \pi^0 \nu_i \bar{\nu}_j$  with  $i \neq j$  is allowed. Here, we concentrate on the

case where the above two conditions are satisfied, so that the final state is purely CP even.

The contributions to the  $K_L \rightarrow \pi^0 \nu \bar{\nu}$  decay from CP violation in mixing ( $|q/p| \neq 1$ ) and from CP violation in decay ( $|\bar{A}/A| \neq 1$ ) are negligibly small. The deviation of  $|q/p|$  from unity is experimentally measured (by the CP asymmetry in  $K_L \rightarrow \pi \ell \nu$ ) and is  $\mathcal{O}(10^{-3})$ . The deviation of  $|\bar{A}/A|$  from unity is expected to be even smaller<sup>4</sup>. Therefore,  $|\lambda| = 1 + \mathcal{O}(10^{-3})$ , and the leading CP violating effect is  $\text{Im}\lambda \neq 0$ , namely interference between mixing and decay. This puts the ratio of decay rates (2) in the same class as CP asymmetries in various  $B$  decays to final CP eigenstates, e.g.  $B \rightarrow \psi K_S$ , where a very clean theoretical analysis is possible<sup>5</sup>.

As a result of this cleanliness, the CP violating phase can be extracted almost without any hadronic uncertainty, even if this phase comes from New Physics. Defining  $\theta$  to be the relative phase between the  $K - \bar{K}$  mixing amplitude and the  $s \rightarrow d \nu \bar{\nu}$  decay amplitude, namely  $\lambda = e^{2i\theta}$ , we get from eq. (2)

$$\frac{\Gamma(K_L \rightarrow \pi^0 \nu \bar{\nu})}{\Gamma(K_S \rightarrow \pi^0 \nu \bar{\nu})} = \frac{1 - \cos 2\theta}{1 + \cos 2\theta} = \tan^2 \theta. \quad (3)$$

In reality, however, it will be impossible to measure  $\Gamma(K_S \rightarrow \pi^0 \nu \bar{\nu})$ . We can use the isospin relation,  $A(K^0 \rightarrow \pi^0 \nu \bar{\nu})/A(K^+ \rightarrow \pi^+ \nu \bar{\nu}) = 1/\sqrt{2}$ , to replace the denominator by the charged kaon decay mode:

$$a_{CP} \equiv r_{is} \frac{\Gamma(K_L \rightarrow \pi^0 \nu \bar{\nu})}{\Gamma(K^+ \rightarrow \pi^+ \nu \bar{\nu})} = \frac{1 - \cos 2\theta}{2} = \sin^2 \theta, \quad (4)$$

where  $r_{is} = 0.954$  is the isospin breaking factor<sup>6</sup>. The ratio (4) may be experimentally measurable as the relevant branching ratios are  $\mathcal{O}(10^{-10})$  in the Standard Model<sup>2</sup> and even larger in some of its extensions.

Eq. (4) implies that a measurement of  $a_{CP}$  will allow us to determine the CP violating phase  $\theta$  without any information about the magnitude of the decay amplitudes. Also, using  $\sin^2 \theta \leq 1$  and  $\tau_{K_L}/\tau_{K^+} = 4.17$ , we get the model independent bound

$$\text{BR}(K_L \rightarrow \pi^0 \nu \bar{\nu}) < 1.1 \times 10^{-8} \left( \frac{\text{BR}(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{2.4 \times 10^{-9}} \right). \quad (5)$$

This bound is much stronger than the direct experimental upper bound<sup>7</sup>  $\text{BR}(K_L \rightarrow \pi^0 \nu \bar{\nu}) < 5.8 \times 10^{-5}$ .

New Physics can modify both the mixing and the decay amplitudes.  $\varepsilon = \mathcal{O}(10^{-3})$  implies that any new contribution to the mixing amplitude carries almost the same phase as the Standard Model one. On the other hand, the

upper bound<sup>8</sup>  $\text{BR}(K^+ \rightarrow \pi^+ \nu \bar{\nu}) < 2.4 \times 10^{-9}$ , which is much larger than the Standard Model prediction<sup>2</sup>, allows New Physics to dominate the decay amplitude (with an arbitrary phase). We conclude that a significant modification of  $a_{CP}$  can only come from New Physics in the decay amplitude. For example, in models with extra quarks, the decay amplitudes can be dominated by tree level  $Z$ -mediated diagrams<sup>4</sup>.

In superweak models, all CP violating effects appear in the mixing amplitudes. Then, CP violation in  $K_L \rightarrow \pi^0 \nu \bar{\nu}$  should be similar in magnitude to that in  $K_L \rightarrow \pi \pi$ . In models of approximate CP symmetry, all CP violating effects are small. Both scenarios predict then  $a_{CP} = \mathcal{O}(10^{-3})$ , in contrast to the Standard Model prediction,  $a_{CP} = \mathcal{O}(1)$ . In other words, a measurement of  $a_{CP} \gg 10^{-3}$  (and, in particular,  $\text{BR}(K_L \rightarrow \pi^0 \nu \bar{\nu}) \gtrsim \mathcal{O}(10^{-11})$ ) will exclude these two scenarios of New Physics in CP violation.

In the Standard Model there are two clean ways to determine the unitarity triangle: (1) CP asymmetries in  $B^0$  decays<sup>5</sup>; and (2) the combination of  $\text{BR}(K_L \rightarrow \pi^0 \nu \bar{\nu})$  and  $\text{BR}(K^+ \rightarrow \pi^+ \nu \bar{\nu})$ <sup>2</sup>. In general, New Physics will affect both determinations. Moreover, it is very unlikely that the modification of the two methods will be the same. Consequently, a comparison between these two clean determinations will be a very powerful tool to probe CP violation beyond the Standard Model. Because of the very small theoretical uncertainties in both methods even a small new physics effect can be detected. In practice, we will be limited only by the experimental sensitivity.

In conclusion: a measurement of  $\text{BR}(K_L \rightarrow \pi^0 \nu \bar{\nu})$  is guaranteed to provide us with valuable information. It will either give a new clean measurement of CP violation or indicate lepton flavor violation.
