The Building Science Series

The Building Science Series disseminates technical information developed at the National Bureau of Standards on building materials, components, systems, and whole structures. The Series presents research results, test methods, and performance criteria related to the structural and environmental functions and the durability and safety characteristics of building elements and systems.

These publications, similar in style and content to the NBS Building Materials and Structures Reports (1938-59), are directed toward the manufacturing, design, construction, and research segments of the building industry, standards organizations, and officials responsible for building codes.

The material for this Series originates principally in the Center for Building Technology of the NBS Institute for Applied Technology. The publications are divided into three general groups: Building Systems and Processes; Health, Safety and Comfort; and Structures and Materials. For further information regarding these publications please contact the Program Planning and Liaison Unit, Center for Building Technology, Institute for Applied Technology, National Bureau of Standards, Washington, D.C. 20234.

Hourly Solar Radiation Data for Vertical and Horizontal Surfaces on Average Days in the United States and Canada

by

Tamami Kusuda and Katsumi Ishii

ABSTRACT

The majority of the available solar radiation data for the United States and Canada are in the form of either monthly averages of daily total radiation on a horizontal surface or hourly values for cloudless days on horizontal, tilted, and vertical surfaces. Hourly solar radiation data for walls and roofs under "average" solar conditions were computed in order to be able to make estimates of the effect that incident solar radiation has on a building and/or its heating and air conditioning system over a heating and/or cooling season. Calculation procedures developed by Liu and Jordan were modified and hourly solar radiation data were compiled for 80 locations in the United States and Canada. Data were also computed and tabulated for a new parameter called "sol-air temperature for glass".

Key Words: Computer; energy; radiation; solar.

Hourly Solar Radiation Data for Vertical and Horizontal Surfaces on Average Days in the United States and Canada

by

Tamami Kusuda and Katsumi Ishii

1. Introduction

There are basically two ways that solar radiation data can be used for design purposes in the building profession. One way is to use past hourly data for the locality or similar locality in question, estimate through mathematical simulation what the performance factors of the building and for its components would have been under those conditions, and base future predictions for performance on that analysis. The second way is to use data that have been derived for specific types of days, either completely clear, "average", or statistically analyzed data for a particular solar process, to calculate the performance of the building and for its components for those types of days.

The first technique has the advantage of easily accounting for the detailed transient nature of the interaction between the solar radiation and the building, and the building and its heating and air conditioning system. This is particularly important when the heating and air conditioning system has been specifically designed to collect the solar energy and utilize it inside the building for heating and/or cooling. ASHRAE has been very active in the recent past in outlining recommended procedures to conduct such hourly calculations for computing heating and cooling loads on buildings [1]*. In the ASHRAE-recommended procedures [1], completely clear day data are predicted using theoretical equations and these data are in turn modified with actual hourly recorded cloud-cover data. Computer programs that have been written for predicting the performance of solar heating and/or cooling systems on an hourly basis use actual recorded hourly solar radiation data [2, 3].

The primary disadvantages of using this first technique are the cost and complexity associated with the use of the computer programs and the lack of good hourly data, particularly for the solar radiation itself.

The major source of solar radiation data in the United States is the National Weather Service and its network of stations. The data collection began in 1902 with the first measurements of the direct component of the solar radiation at normal incidence being made in Asheville, North Carolina. At the present time, there are 86 stations covering the U.S. and the West Indies. Reference 4 gives a complete history of the network. The majority of the present 86 stations record only the total radiation on a horizontal surface. At five of the stations, the direct component is also measured. Of the 86 stations, 67 have their data processed for daily total only, while hourly data are processed at the other 19. Reference 5 describes how the data can be made available either on tape or punched cards.

In addition to the relatively small amount of hourly solar radiation data generally available as described above, the quality of the data has been questioned. Jessup has reported [4] that estimated data errors range from $\pm$ 5 percent to $\pm$ 30 percent. This has been mainly due to insufficient resources in all but the recent past to properly maintain the network. A complete analysis of some of the specific problems with the network instrumentation is included in references 6 and 7.

There is evidence, with the increasing emphasis on the use of solar energy in buildings, that much of the past solar radiation data will be rehabilitated and additional data will be collected in the future; however, it is unlikely that the hourly data to be taken will be extended to cover surfaces other than the horizontal for the majority of the stations. For this and other reasons given above, emphasis will be placed in the foreseeable future on using solar radiation data for specific types of days and orientations for design purposes.

---

* See references at end of text.

The 1977 ASHRAE Handbook of Fundamentals [8] will include tables of solar heat gain factors for all combinations of six different northern latitudes, sixteen primary compass orientations plus the horizontal, for the 21st day of each month of the year and for each hour of that day. This enables one to calculate the amount of solar energy passing through a unit area of reference glazing (single sheet of 0.3 cm (1/8 in.) thick double-strength window glass) on a completely clear day, and is based on a calculation procedure developed by Stephenson [9]. Recently Morrison and Farber [10] have extended this type of calculation and have produced tables of incident solar radiation for all combinations of six different northern latitudes, five different south-facing surfaces tilted up at angles ranging from latitude minus 10 degrees to the vertical plus the horizontal, for the 21st day of each month of the year and for each hour of that day. Both of these above sets of data can be used for design purposes to determine the maximum effect that the solar radiation is likely to have for a given condition or in a given situation. However, it is felt desirable to also have similar tables of data for "average" conditions so that estimates can be made for the long-term effect that incident solar radiation has on a building and for its heating and air conditioning system.

References 11 and 12 contain a series of 12 monthly maps showing isoclines of daily total radiation on a horizontal surface for the United States and the world, respectively. The data were gathered from a large number of sources and can be used to indicate general trends and to predict areas of potential solar energy applications.

Liu and Jordan [13, 14, 15] conducted extensive analyses during the early 1960's on the available solar radiation data and developed several empirical correlations that can be used to estimate the available solar radiation on "average" days for each month of the year and for a large number of locations in the United States and Canada. Using the correlations, it is possible to take the monthly average daily total radiation on a horizontal surface, divide the daily total into direct and diffuse components, convert each component into hourly values, and then compute the hourly value of either component on a surface of any orientation desired.

This report outlines the technique that was used to compute and tabulate the monthly "average" incident radiation on an hourly basis during the day for each month of the year, and each of eight different vertical orientations. The data was tabulated for 80 different locations in the United States and Canada. A minor modification was made to the basic technique recommended in the Liu, Jordan procedure [14, 15] in order to eliminate what was believed to be erroneous results near the sunrise and sunset hours. An additional parameter called "sol-air temperature for glass" was also computed and tabulated for each of the locations. An explanation of the meaning of this parameter is included in Section 7 of the report.

2. Calculation Procedure of Liu and Jordan

The pertinent correlations developed by Liu and Jordan [13, 14, 15] were for:

a. the monthly average daily diffuse radiation on a horizontal surface as a function of the monthly average daily total radiation on a horizontal surface,

b. the ratio of the hourly diffuse radiation to the daily diffuse radiation (both on a horizontal surface) as a function of the number of daylight hours, and

c. the ratio of the hourly total radiation to the daily total radiation (both on a horizontal surface) as a function of the number of daylight hours.

The correlations were based on available solar radiation data from Blue Hill, Massachusetts; Nice, France; Helsingfors, Finland; and Kew Observatory, London, England.

Liu and Jordan [15, 16] also compiled for each of twelve months at 80 different locations in the United States and Canada, the "average" daily total radiation on a horizontal surface ($\overline{H}$) and the ratio $\overline{K}_T = \overline{H}/H_o$, where H_o is the daily total extraterrestrial radiation on a horizontal surface calculated for the 15th or 16th of each month. The ratio $\overline{K}_T$ represents the fraction of extraterrestrial radiation that is transmitted through the atmosphere and thus provides a useful index for the solar climate of a particular location.

The correlations described in a, b, and c above are included herein as Table 2, Figure 1, and Figure 2, respectively. $\overline{K}_d$ in Table 2 is defined as $\overline{D}/H_o$, where $\overline{D}$ is the "average" daily diffuse radiation on a horizontal surface. The step-by-step technique for using the correlations to compute the "average" incident solar radiation on a horizontal or vertical surface is as follows:

a. Daily total extraterrestrial radiation on a horizontal surface for a given latitude and declination angle is calculated as follows:

$$H_o = \frac{24}{\pi} r I_{sc} (\cos L \cos S \sin W_s + W_s \sin L \sin S) \quad (1)$$

where

r = ratio of solar radiation intensity at normal incidence outside the earth's atmosphere to the solar constant (monthly average values are given in Table 1)

I_{sc} = solar constant, 1,393 W/m^2 (442 Btu/(h · ft^2))*

L = latitude, radians

S = solar declination angle, radians, monthly values are given in Table 1

W_s = sunrise hour angle, radians, obtained from:

$$\cos W_s = - \tan L \tan S \quad (2)$$

b. Obtain the monthly average daily total radiation on a horizontal surface, $\overline{H}$, from references 15 and 16 or other available sources.

c. Calculate $\overline{K}_T$ by:

$$\overline{K}_T = \frac{\overline{H}}{H_o} \quad (3)$$

or obtain the value from references 15 and 16 for any of 80 locations.

d. Determine the value of $\overline{K}_d$ from Table 2.

e. Calculate the monthly average daily diffuse radiation on a horizontal surface, $\overline{D}$, by:

$$\overline{D} = \overline{K}_d \cdot H_o \quad (4)$$

f. Calculate the value of a factor, r_d, from the following equation or determine from Figure 1:

$$r_d = \frac{\pi}{24} \frac{\cos W - \cos W_s}{\sin W_s - W_s \cos W_s} \quad (5)$$

where

W = hour angle corresponding to a given hour of the day (solar time), radians

---

* This was the value used by Liu and Jordan. A value of 1,353 W/m^2 (428 Btu/(h · ft^2)) is the value currently recommended by a number of governmental agencies and technical societies in the U.S. [17].

g. Calculate the average hourly diffuse radiation on a horizontal surface ($\bar{I}_{dh}$) by:

$$\bar{I}_{dh} = r_d \bar{D} \tag{6}$$

h. Determine the value of a factor, r_T, from Figure 2.

i. Calculate the average hourly total radiation on a horizontal surface ($\bar{I}_{Th}$) by:

$$\bar{I}_{Th} = r_T \bar{H} \tag{7}$$

j. Calculate the average hourly direct radiation on a horizontal surface ($\bar{I}_{Dh}$) by:

$$\bar{I}_{Dh} = \bar{I}_{Th} - \bar{I}_{dh} \tag{8}$$

k. Calculate the angle of incidence between the sun's direct beam and a horizontal (θ_H) or vertical surface (θ_v) by:

$$\cos \theta_H = \cos L \cos S \cos W + \sin L \sin S \tag{9}$$

or

$$\cos \theta_v = \cos ALT \cos SAZM \tag{10}$$

where

ALT = solar altitude angle, the angle between the sun's direct beam and the horizontal, radians

SAZM = the difference between the solar azimuth angle (AZM) and the wall azimuth angle (WAZ), radians

Figure 3 shows the relationship between the various angles.

l. Calculate the average hourly direct radiation on a given vertical surface ($\bar{I}_{Dv}$) by:

$$\bar{I}_{Dv} = \frac{\bar{I}_{Dh}}{\cos \theta_H} \cdot \cos \theta_v \tag{11}$$

m. Approximate the average hourly diffuse radiation on a given vertical surface ($\bar{I}_{dv}$) by:

$$\bar{I}_{dv} = \frac{\bar{I}_{dh}}{2} \tag{12}$$

n. Approximate the average hourly reflected radiation from the ground on a given vertical surface ($\bar{I}_{gv}$) by:

$$\bar{I}_{gv} = \frac{\rho_g I_{Th}}{2} \tag{13}$$

where

ρ_g = ground reflectance

o. Calculate the average hourly total radiation incident on a given vertical surface by:

$$\bar{I}_{Tv} = \bar{I}_{Dv} + \bar{I}_{dv} + \bar{I}_{gv} \tag{14}$$

3. Anomalous Calculated Values Using the Liu and Jordan Calculation Procedure

The procedure described in the previous section was used to generate the hourly solar radiation values incident on vertical surfaces oriented in the eight primary directions (S, SW, W, NW, N, NE, E, and SE) as well as the horizontal surface. Upon analyzing the data, exceptionally large values of incident solar radiation were observed near the sunrise and sunset hours. A close examination of the calculation procedure revealed that the large peak resulted from the use of equation (11) where cos θ_H is very close to zero at the sunrise and sunset hours. This phenomenon is illustrated in Figure 3 where the value of the direct component of the solar radiation ($\bar{I}_{DN}$) is computed for a vertical surface oriented directly facing the sun (equation (11) with cos θ_v = 1) on February 22 in Miami, Florida:

$$\bar{I}_{DN} = \bar{I}_{Dh}/\cos\ \theta_H \tag{15}$$

The inconsistency appeared to arise as a result of the sensitive empirical relationship between $\bar{K}_T$, r_T, $\bar{K}_d$, and r_d. Upon discussions with one of the authors of [15, 16]*, it is felt that the inconsistency is mainly due to the inaccuracy of the empirical relationship for r_T (Figure 2).

4. ASHRAE Methodology for the Computation of the Direct Component of the Solar Radiation

In order to circumvent the anomaly described in the previous section, it was decided to replace equation (15) with an equation similar to one used in reference 18:

$$\bar{I}_{DN} = \bar{A}\ e^{-\left[\frac{B}{\cos\ \theta_H}\right]} \tag{16}$$

The original equation was developed by Stephenson [9] for completely clear sky conditions. It has been assumed in this work that the same basic form of the equation is valid for "average" day solar radiation. A modified multiplying coefficient has been adapted, denoted in equation (16) as $\bar{A}$ (as opposed to A in reference 9).

The monthly values of B for equation (16) are given in Table 1. In order to develop appropriate values of $\bar{A}$, it was necessary to calculate the average daily direct radiation over a horizontal surface, $\bar{H}_{Dh}$ by:

$$\bar{H}_{Dh} = \int_{\text{sunrise}}^{\text{sunset}} \bar{I}_{DN} \cos\ \theta_H\ dt \tag{17}$$

where t denotes time. Combining equations (16) and (17):

---

* Private communication with Dr. Liu.

$$\bar{H}_{Dh} = \frac{24}{\pi} \bar{A} \int_0^{W_s} e^{-\left[\frac{B}{\cos \theta_H}\right]} \cos \theta_H \, dW \qquad (18)$$

By denoting the integral of the above equations by G, and by using $\bar{K}_T$ and $\bar{K}_d$ of the Liu and Jordan procedure, equation (18) can be written:

$$\bar{H}_{Dh} = \frac{24}{\pi} \bar{A} \cdot G = (\bar{K}_T - \bar{K}_d) H_o \qquad (19)$$

By substituting equation (1) into equation (19), the value of $\bar{A}$ can be calculated as follows:

$$\bar{A} = (\bar{K}_T - \bar{K}_d) f \qquad (20)$$

where

$$f = \frac{r I_{sc}}{G} (\cos L \cos S \sin W_s + W_s \sin L \sin S) \qquad (21)$$

Table 3 lists the values of f which were computed using the above equations. The values are tabulated for latitudes of 0 through 50 degrees in one-degree increments and for each of the 12 months. The monthly values are plotted in Figure 5.

The concept of f is convenient since its value is independent of the specific local climate. As an example, both Hatteras, North Carolina and Albuquerque, New Mexico are at a latitude of 35° N. Table 3 indicates the value of f in January to be 644.5 at this latitude. The Liu and Jordan tabulated data [15, 16] show the following values of $\bar{K}_T$ and $\bar{K}_d$ for these two cities.

	Hatteras	Albuquerque
$\bar{K}_T$	0.634	0.704
$\bar{K}_d$	0.166	0.147

Using these data, $\bar{A}$ for Hatteras and Albuquerque were determined as 302 and 359 respectively, whereas the cloudless sky value of A developed by Stephenson [9] was 390.

5. Modification of the Liu and Jordan Procedure to Eliminate the Anomalous Calculated Solar Radiation Values

With the relationship between equation (16), the constant $\bar{A}$, and the constants $\bar{K}_T$ and $\bar{K}_d$ established, a modified hourly calculation procedure was developed as follows:

a. Same as before.

b. Same as before.

c. Same as before.

d. Same as before.

e. Same as before.

f. Same as before.

g. Same as before.

h. Determine the value of f from Table 3 for a given month and latitude.

i. Calculate $\overline{A}$ using equation (20).

j. Calculate the hourly value of $\overline{I}_{DN}$ using equation (16).

k. Same as before.

l. Calculate the average hourly direct radiation on a horizontal surface by:

$$\overline{I}_{Dh} = \overline{I}_{DN} \cos \theta_H \tag{22}$$

m. Calculate the average hourly total radiation on a horizontal surface by:

$$\overline{I}_{Th} = \overline{I}_{Dh} + \overline{I}_{dh} \tag{23}$$

n. Calculate the average hourly direct radiation on a vertical surface by:

$$\overline{I}_{Dv} = \overline{I}_{DN} \cos \theta_v \tag{24}$$

o. Same as m. in Section 2.

p. Same as n. in Section 2.

q. Same as o. in Section 2.

6. Computation and Tabulation of Data for Eighty Locations

A computer program was written for carrying out the calculation procedure described in the previous section. A listing of the program is given at the end of this report. Complete tables of total solar radiation values are also included at the end of the report in Table 4 for 80 different locations in the United States and Canada [15, 16]. The tabulated solar radiation data are all in units of either Btu/(h · ft^2) (= 3.152 W/m^2) or Btu/ft^2 (= 11,348.9 J/m^2).

Sample results are shown in Figures 6 through 12 for the horizontal and different vertical orientations in February in Miami, Florida. Shown in these figures are the hourly radiation values calculated by Liu and Jordan, the authors' modification of the Liu and Jordan procedure, and the data for completely clear skies [10].

7. Calculation of "Sol-Air Temperature for Glass"

In general, energy is transferred through glazing both by transmitted solar radiation and by conduction and convection as a result of a temperature difference between the outside and the inside air. The governing equation for the net heat transfer, q (W), across the glazing into a building space is:

$$q = A \left[\overline{\tau} \, I + U \, (t_o - t_i) \right] \tag{25}$$

where

A = cross-sectional area of the glazing, m^2

$\bar{\tau}$ = effective transmittance of the glazing to short-wave radiation

I = incident total solar radiation on the glazing, W/m^2

U = overall heat transfer coefficient for the glazing, $(W/(m^2 \cdot °C))$

t_o = outside air temperature, °C

t_i = inside air temperature, °C

If the first term in equation (25) is multiplied and divided by U, the equation can be rearranged to:

$$Q = U\,A\left[\frac{\bar{\tau}\,I}{U} + t_o - t_i\right] \tag{26}$$

or

$$q = U\,A\left[SATG - t_i\right] \tag{27}$$

where

$$SATG = \frac{\bar{\tau}\,I + t_o}{U} = \text{sol-air temperature for glass, °C}$$

Values of SATG are useful in assessing the net heat transfer through glazing into the building. In other words, for those periods of time when SATG > t_i, there is a net heat gain into the building and when SATG < t_i, there is a net heat loss.

Equation (26) is written on an instantaneous basis and can be used for computing hourly values. The equation can also be written to be valid for a period covering a number of hours N:

$$Q = U\,A\left[\frac{\bar{\tau}\sum_{i=1}^{N} I}{U} + N\,(\bar{t}_o - t_i)\right] \tag{28}$$

where

Q = net heat transfer over the time period N, W

N = number of hours

$\bar{t}_o$ = average outdoor air temperature over the time period N, °C

The indoor air temperature, t_i, has been assumed to be constant for the time period N. Equation (28) can be rearranged as was done with equation (25):

$$Q = U\,A\,N\left[\frac{\bar{\tau}\sum_{i=1}^{N} I}{UN} + \bar{t}_o - t_i\right] \tag{29}$$

$$Q = U\,A\,N\left[SAG - t_i\right] \tag{30}$$

where

$$SAG = \frac{\bar{\tau} \sum_{i=1}^{N} I}{UN} + \bar{t}_o, \ ^\circ C \qquad (31)$$

The values of SAG were computed for each month of the year, for each of the eight primary vertical orientations and the horizontal, and for each of the 80 locations in the United States and Canada. The values are tabulated in Table 4 in units of °F along with the average hourly radiation values discussed previously.

Four different values of SAG were computed. Two values were for a 24-hour period (N = 24), one for single glazing (SATGS) and a second for double glazing (SATGD). The other two computations were also for single and double glazing, but the time period N was shortened to include only the daylight hours. In all cases, the radiation values $\sum_{i=1}^{N} I$ were the total incident radiation under "average" conditions discussed previously. The values of $\bar{\tau}$ used in the computations were 0.87 for single glazing and 0.78 for double glazing. The overall heat transfer coefficients were 6.4 W/(m^2 · °C) (1.13 Btu/(h · ft^2 · °F)) and 6.0 W/(m^2 · °C) (1.06 Btu/(h · ft^2 · °F) for single glazing and for winter and summer, respectively. The values used for double glazing were 3.1 W/(m^2 · °C) (0.55 Btu/(h · ft^2 · °F)) and 3.1 W/(m^2 · °C) (0.54 Btu/(h · ft^2 · °F), respectively. The value of $\bar{t}_o$ was either the average over the 24-hour period or daylight hours only, depending on the time period N.

The intent in calculating and compiling the data was to permit computation, for a given glazing size and orientation, of the net heat transfer into the space of a building for "average" solar conditions and for any period of months desired. By repeating the calculation for all the glazing in a given building, the total net effect for the entire building could be determined.

8. Summary

The Liu and Jordan method for calculating the incident hourly solar radiation on a surface of any tilt and orientation under "average" conditions was modified and used to compute the average hourly incident total radiation on the eight primary vertical orientations and the horizontal for each month of year and for each of 80 locations in the United States and Canada. In addition, a new parameter was introduced and computed for the 80 locations called "sol-air temperature for glass". The tabulated values enable one to easily compute the net heat transfer through single or double glazing under "average" solar conditions for any of the eight primary vertical orientations or on a horizontal surface.
