## **DISCLAIMER**

**This report was prepared as an account of work sponsored by an agency of the United States Government. Neither the United States Government nor any agency Thereof, nor any of their employees, makes any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness, or usefulness of any information, apparatus, product, or process disclosed, or represents that its use would not infringe privately owned rights. Reference herein to any specific commercial product, process, or service by trade name, trademark, manufacturer, or otherwise does not necessarily constitute or imply its endorsement, recommendation, or favoring by the United States Government or any agency thereof. The views and opinions of authors expressed herein do not necessarily state or reflect those of the United States Government or any agency thereof.**

## **DISCLAIMER**

**Portions of this document may be illegible in electronic image products. Images are produced from the best available original document.**

The facilities of Argonne National Laboratory are owned by the United States Government. Under the terms of a contract (W-31-109-Eng-38) among the U. S. Department of Energy, Argonne Universities Association and The University of Chicago, the University employs the staff and operates the Laboratory in accordance with policies and programs formulated, approved and reviewed by the Association.

ACTINIDE 5f SYSTEMS: EXPERIMENTAL DETERMINATION  
OF THE MAGNETIC RESPONSE FUNCTION\*

G. H. Lander

Materials Science Division  
Argonne National Laboratory  
Argonne, IL 60439

INTRODUCTION

The advent ten years ago of neutron spectroscopy to identify excited crystal-field (cf) states in lanthanide type materials has greatly added to our understanding of the microscopic interactions in these compounds.<sup>1,2</sup> For example, once the cf scheme is known, one can calculate the magnetization at any field and temperature, compare with experiment, and thus derive exchange terms.<sup>3</sup> If the material orders then the easy axis, details of the spin-wave spectrum, and value of the ordered moment all depend on the cf terms.<sup>4</sup> Indeed, the very presence or absence of magnetic order may depend on whether or not a singlet is the ground state.<sup>5</sup> Despite the difficulty of calculating the cf potential from first principles, its measurement represents a necessary step forward in describing a material. In this respect, one may say it is as necessary as knowing the lattice parameter. In the study of actinide compounds the first step therefore was to determine the cf states.

Early Experiments and Expectations

The first experiments with neutron spectroscopy were those of Wedgwood<sup>6</sup> on UX (X = C, N, P, S, and Se) and Lander et al.<sup>7</sup> on USn<sub>3</sub>. Both attempts failed to see any discrete cf levels.

Before proceeding further along this experimental line, let us return to the simple question of whether or not we expect to observe transitions between cf states in actinide materials with

\*Work supported by the U. S. Department of Energy.

neutron inelastic spectroscopy. We may first look at investigations of ionic solids with optical techniques. Here the answer is clear, cf states are well defined, as we would expect from the highly correlated  $f$  nature of the outer electrons,<sup>8</sup> and the overall energy is roughly a factor of 2 to 5 greater than in the  $4f$  series.<sup>9</sup> If we now turn to the metallic compounds, the first study to discuss cf states was by Grunzweig-Genossar et al.<sup>10</sup> They considered the UX compounds and concluded that the stable configuration is  $5f^2$  with a  $\Gamma_1$  singlet ground state. The ordering then develops through a strong exchange mixing. Such a model should be immediately verifiable by neutron spectroscopy, especially on compounds diluted with thorium to weaken the exchange interactions. In 1974 Chan and Lam<sup>11</sup> developed a more complete theory including the effects of  $J$  mixing, but this still assumes well-defined cf levels. Unless the energies between the ground and excited states are always greater than  $\sim 12$  THz ( $\approx 50$  meV  $\approx 400$  cm $^{-1}$   $\approx 576$  K) cf levels should be observable with neutron spectroscopy. For example, by fitting high-temperature susceptibility data Troc and Lam<sup>12</sup> proposed that UAs had a  $5f^3$  configuration with a  $\Gamma_8^{(1)}$  ground state and excited  $\Gamma_6$  and  $\Gamma_8^{(2)}$  states at 1.44 and 52.5 THz, respectively. The first transition  $\Gamma_8^{(1)} - \Gamma_6$  is exactly in the right region for neutron spectroscopy and evidence for such a transition was reported by Furrer and Murasik<sup>13</sup> using a polycrystalline sample, but our recent experiments on single crystals show this to be a wrong analysis of the data.

Quite clearly the subject is confused. Our initial (5 years ago) expectation was that in most metallic systems we would find cf levels with neutron spectroscopy. Now we find them hardly at all, and the review I wrote<sup>14</sup> in 1976 marks the point at which our naive expectation gave way to reality. Since that time a number of important developments have taken place. First, cf levels have been seen in the U-Pd system,<sup>15,16</sup> thus disselling the myth that they never can be seen in metallic systems. Second, experiments on  $4f$  systems with intermediate valence have shown that the neutron spectrum consists of a broad Lorentzian response, the energy width of this response being almost independent of temperature. In such systems cf transitions are rarely seen. Third, experiments on single crystals of UX ( $X = N, As, Sb, S$ , and  $Te$ ) have shown that the nature of the response function in these compounds, which all order at relatively high temperatures (50-250 K), is much more complex than in the analogous lanthanide systems.

#### Neutron Cross Section

To prepare the discussion for both ordered and nonordered system we need to consider the fundamental expressions for the thermal neutron cross section, which can be written,<sup>17</sup>

$$\begin{aligned}
 \frac{d^2\sigma}{d\Omega d\omega} = & \left\{ \left( \frac{\gamma e^2}{m_e c^2} \right)^2 \left[ \frac{1}{2} g f(\vec{Q}) \right]^2 \frac{k_f}{k_i} \exp[-2W(\vec{Q})] \right\} \\
 & \times \sum_{\alpha\beta} (\delta_{\alpha\beta} - \hat{Q}_\alpha \hat{Q}_\beta) \frac{1}{2\pi\hbar} \int_{-\infty}^{\infty} [\exp(-i\omega t) \\
 & \times \langle \hat{S}_Q^\alpha(0) \hat{S}_{-Q}^\beta(t) \rangle dt] \quad (1)
 \end{aligned}$$

We have written down the full expression [Eq. (8.26) in Ref. 18] so as to make some important points.

- (i) The section  $\{ \}$  contains constants, the magnetic form factor  $f(\vec{Q})$ , and the Debye-Waller factor. We have assumed that the spatial part of the wavefunction is factorizable from the spin operator  $\hat{S}_Q^\alpha(t)$  so that the  $|\vec{Q}|$  dependence appears in this section only.
- (ii) The term  $(\delta_{\alpha\beta} - \hat{Q}_\alpha \hat{Q}_\beta)$  reminds us that magnetic scattering takes place between components perpendicular to the momentum transfer. This will be important later in ordered systems, although in paramagnets a simple average value of  $2/3$  enters into the expression.
- (iii) The time integral of the spin correlation function enters directly into the cross section.

Two other forms of the cross section are also of importance

$$\frac{d^2\sigma}{d\Omega d\omega} = \{ \} \times S(\vec{Q}, \omega) \quad (2)$$

where

$$S(\vec{Q}, \omega) = \frac{N}{\pi(g\mu_B)^2} [n(\omega) + 1] \sum_{\alpha\beta} (\delta_{\alpha\beta} - \hat{Q}_\alpha \hat{Q}_\beta) \text{Im}\chi^{\alpha\beta}(\vec{Q}, \omega) \quad (3)$$

and through the Kramers-Kronig relationship

$$\text{Im}\chi(\vec{Q}, \omega) = \omega \chi(\vec{Q}) F(\vec{Q}, \omega) \quad (4)$$

where the fluctuation spectrum is defined by

$$\int_{-\infty}^{+\infty} F(\vec{Q}, \omega) d\omega = 1$$

If the spin dynamics are purely relaxational, i.e.,  $F(\vec{Q}, t) \sim \exp(-\Gamma(\vec{Q}) \times t)$  then

$$F(\vec{Q}, \omega) = \frac{1}{\pi} \frac{\Gamma(\vec{Q})}{\Gamma^2(\vec{Q}) + \omega^2}. \quad (5)$$

The experimental intensity is therefore proportional to the product of  $S(\vec{Q}, \omega)$  and a function that takes out the dependence on  $|\vec{Q}|$ . We may immediately extract  $\text{Im}\chi(\vec{Q}, \omega)$ , via Eq. (3). Spin waves (or crystal-field excitons) correspond to peaks in the function  $\text{Im}\chi(\vec{Q}, \omega)$ , which can be expressed as a delta function in one or both of  $\vec{Q}$  and  $\omega$ . This treatment is not particularly useful in extracting the physics from a spin-wave spectrum of something such as  $\text{MnF}_2$ , but for more complex situations Eq. (3) is a useful form.<sup>18</sup> For paramagnetic systems we can use Eqs. (4) and (5) to see that  $S(\vec{Q}, \omega)$  is given by an overall scale factor  $\chi(\vec{Q})$  and a Lorentzian energy distribution, which has a full-width at half maximum (FWHM) of  $2\Gamma(\vec{Q})$ .

### Non-ordered Systems

Although experiments on  $\text{U}_{0.15}\text{Th}_{0.85}\text{Se}$  and other diluted U systems have been performed,<sup>14</sup> no careful data analysis has been presented other than the statement that sharp cf transitions do not exist. The same is true for a very rapid experiment performed some years ago at Brookhaven National Laboratory by S. Shapiro and myself on  $\text{Np}_{0.02}\text{Y}_{0.98}$ . We do, however, have results on  $\text{UAI}_2$  by Loewenhaupt et al.,<sup>17</sup> who also present qualitative results on  $\text{USn}_3$  in the same paper.

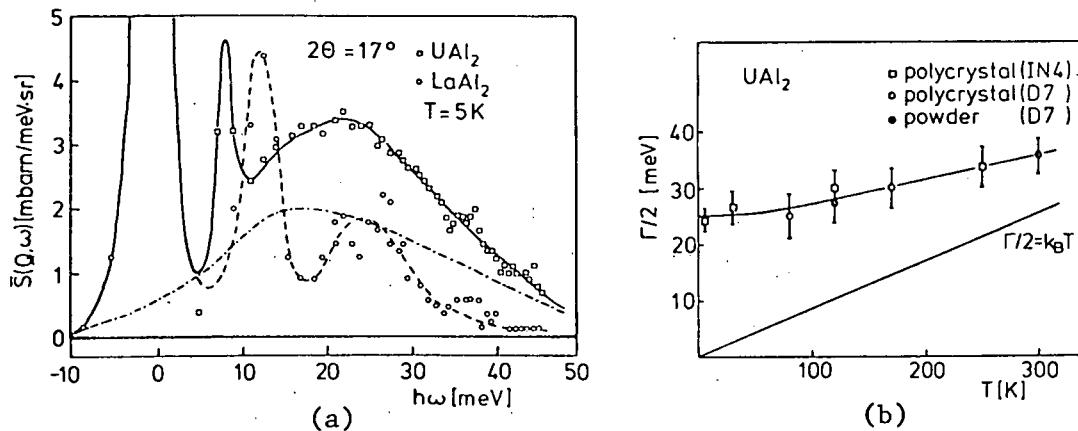

Fig. 1. (a) Energy loss spectra of  $\text{UAI}_2$  and  $\text{LaAl}_2$  at 5 K. Solid line represents fit for  $\text{UAI}_2$ , dashed line for  $\text{LaAl}_2$ . Dashed dotted line shows quasielastic magnetic contribution distorted by detail balance factor  $[n(\omega) + 1]$ . (b) Temperature dependence of half-line width (4.13 meV = 1 THz) in  $\text{UAI}_2$ . (From Loewenhaupt et al., Ref. 17)

Figure 1 shows the energy loss spectra (incident energy 51.4 meV = 12.4 THz) for  $UAl_2$  and  $LaAl_2$  at 5 K. In addition to the elastic line arising from incoherent nuclear scattering, two inelastic phonon lines are observed. The most important feature is that for  $UAl_2$  additional scattering appears spread over a wide energy range. This additional scattering is well described by Eqs. (2) - (5) where the static bulk susceptibility  $\chi(\vec{Q} = 0)$  is an overall (T dependent) scale factor and the energy dependence is given by a Lorentzian. The variation of the half width is shown in Fig. 1(b). Such a general magnetic scattering function was found<sup>20</sup> for the intermediate valent system  $CePd_3$ , and has been found for other non-stable 4f configurations,<sup>18</sup> and forces us at least to consider that many metallic uranium compounds should best be considered in terms of intermediate valence theory.

### Ordered Systems

Studies of ordered systems began with Wedgwood<sup>6</sup> who noted that the magnetic scattering appeared over a wide energy range and was approximately represented by a gaussian centered at  $\omega = 0$ . These experiments were performed in the paramagnetic state, where most materials show inelastic contributions around  $\omega = 0$ , but the half widths are seldom more than 0.5 THz,<sup>20</sup> whereas for the UX materials the half widths were clearly of the order of 3 - 5 THz.

#### (i) Measurements on UN

Uranium nitride (NaCl structure,  $a_0 = 4.89 \text{ \AA}$ ) orders antiferromagnetically with the simple type I structure at 53 K. The ordered moment is  $0.75 \mu_B$  at 0 K. The neutron inelastic scattering experiment failed to find any evidence for discrete excitations.<sup>21</sup> Instead, in the ordered phase the magnetic response at the (110) reciprocal lattice point, which is the magnetic zone center, is a broad (FWHM = 5 + 1 THz) distribution peaked at  $\sim 4$  THz. One may think of this as a strongly overdamped spin wave with very steep dispersion. Two important points, which will recur in other investigations, is that (a) the response function is primarily longitudinal in nature and (b) the anisotropy gap at the X point [110] is close to that defined by the phonon branches. To understand (a) we must refer back to the orientational factor in Eqs. (1) and (3). In the type I structure the domain symmetry is such that the scattering around [110] and [001] come from a single domain, that with  $\mu \parallel [001]$ . We may then separate out<sup>22</sup> the response into transverse  $\chi^{xx}$  (or  $\chi^{yy}$ ) and longitudinal components  $\chi^{zz}$ .

Further analysis and experiments are now in progress. Of particular interest will be how the high-temperature broad response function, seen by both Wedgwood<sup>6</sup> and the Chalk River Group,<sup>21</sup> changes on cooling through  $T_N$ . Another question is whether a

Lorentzian distribution of magnetic scattering exists even in the ordered phase.

(ii) Measurements on UAs

Uranium arsenide (NaCl structure,  $a_0 = 5.78 \text{ \AA}$ ) orders with type I antiferromagnetism at 127 K, but has a first order transition to the type IA structure<sup>23</sup> at 63 K. The ordered moment is  $2.2 \mu_B$  at 5 K. Neutron inelastic scattering experiments have only just been completed,<sup>24</sup> so that the results are very preliminary. Nevertheless, some simple statements are possible. First, no collective excitation has been observed in the ordered state. Second, the scattering may be characterized by a scale factor  $\chi(Q)$  and a Lorentzian energy spectrum centered about  $\omega = 0$  in the ordered state.

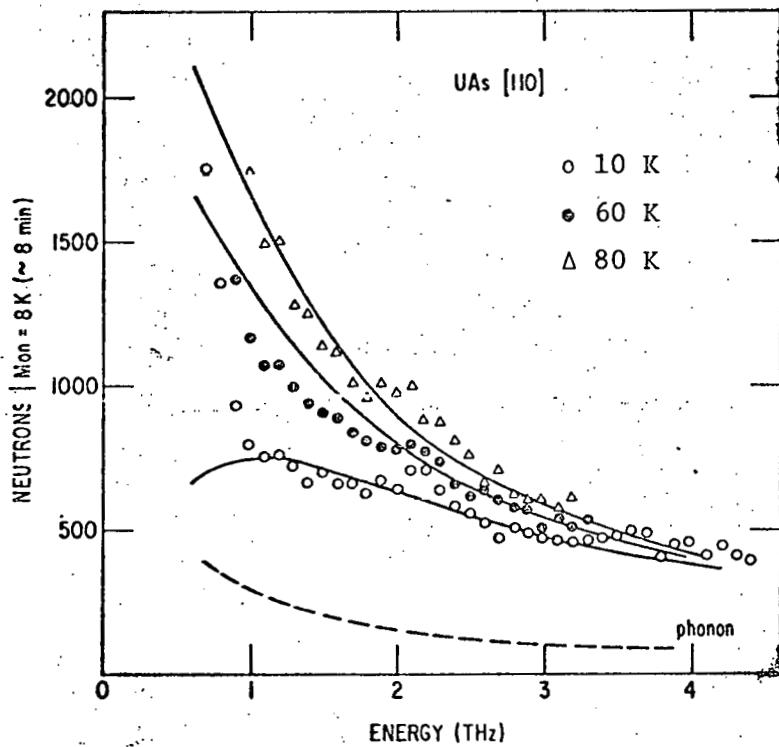

Fig. 2. Experimental scans ( $k_f = 3.6 \text{ \AA}^{-1}$ ) from a single crystal of UAs at different temperatures. The phonon contribution (shown for  $T = 80 \text{ K}$ ) is obtained from the  $Q^2$  dependence of the scattering. The lines represent the variation in scattering expected if  $\chi(110) = 700$  and  $\Gamma(110) = 1.1 \text{ THz}$ . The change in shape is simply a feature of the thermal population and detail balance factor. We have not subtracted the tail of the incoherent scattering, hence the upturn in experimental intensity for  $\omega < 1 \text{ THz}$  and  $T = 10 \text{ K}$  is not significant.

We show in Fig. 2 scattering from UAs. To fit the data we have separated the nuclear and magnetic parts by the  $Q$  dependence (for example, at each temperature scans were done at both the [110] and [330] zone centers) and then used the expression derived from Eqs. (3) - (5). Similar curves for  $\vec{Q} = [001]$  are shown in Fig. 3.

Without going into great length, we can note the following:

- (a) The magnetic scattering is very strong. The incoherent phonon contribution is small (<20%), as also is the instrumental background of ~40 counts on this scale, and which has not yet been subtracted.
- (b) Since  $\chi(\vec{Q} = [001]) = 2 \chi^{xx}$  and  $\chi(\vec{Q} = [100]) = \chi^{xx} + \chi^{zz}$ , then we can roughly deduce that  $\chi^{zz} \approx 2\frac{1}{2} \chi^{xx}$ .
- (c) Above  $T_N$  (= 127 K) the spectra (not shown) indicate a drop in  $\chi(Q)$  but rather little change in  $\Gamma(Q)$ . This is exactly what is expected if we believe the response function is a measure of the fluctuation time, and therefore insensitive to ordering, whereas the staggered susceptibility  $\chi(\vec{Q})$  must be greater in the ordered state.
- (d) In the [110] scans the collective excitation possibly begins to coalesce at ~2.1 THz (this small peak has been also seen with  $k_f = 3.36 \text{ \AA}^{-1}$ ) but line-broadening effects prevent its observation away from this point.

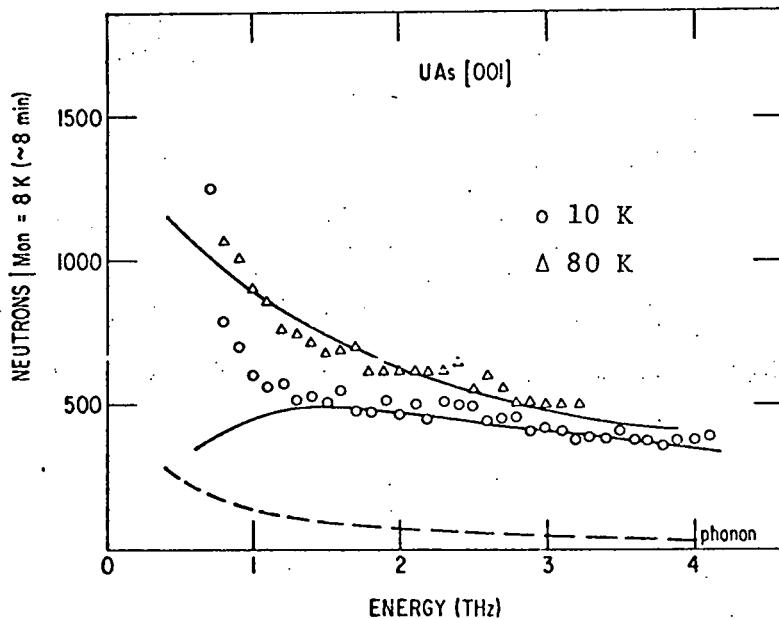

Fig. 3. Experimental scans ( $k_f = 3.6 \text{ \AA}^{-1}$ ) and preliminary fits at the [001] point in UAs. The solid curves are as in Fig. 2 except that  $\chi(001) = 400$  and  $\Gamma(001) = 1.6 \text{ THz}$ . The phonon function, again shown for  $T = 80 \text{ K}$ , is the same as in Fig. 2.

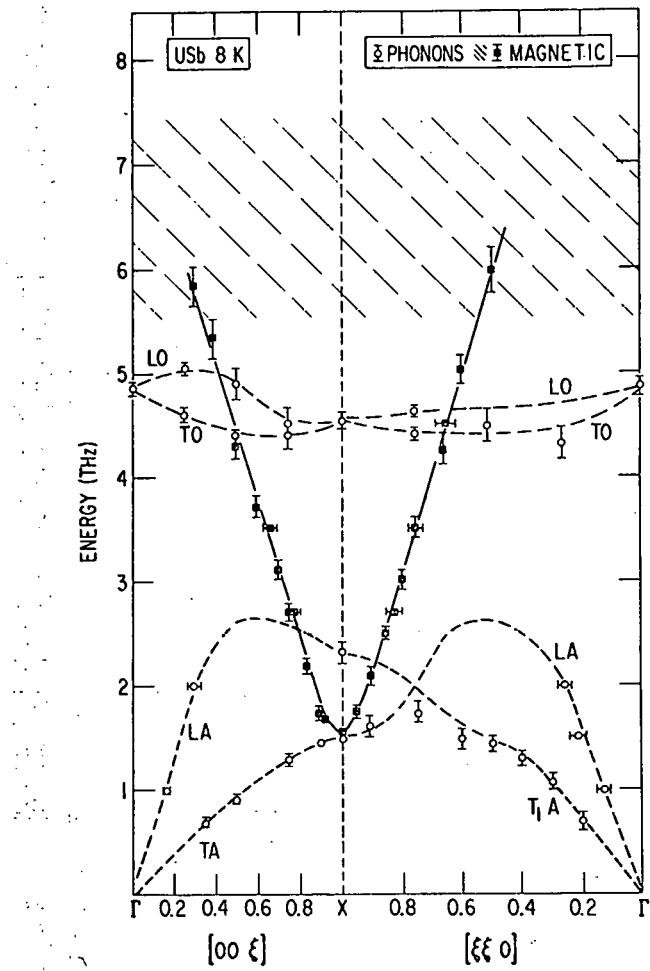

Fig. 4. The dispersion curves for USb; energy plotted against wave-vector transfer  $\vec{Q}$  (in units of  $2\pi/a$ ). The dashed lines represent the phonons. The magnetic modes are represented by solid squares (the collective excitation) and the hatched area (excitonic level).

### (iii) Measurements on USb

Uranium antimonide (NaCl structure,  $a = 6.20 \text{ \AA}$ ) orders with the type I structure at 240 K. The ordered moment is  $2.8 \mu_B$  at 0 K. In contrast to the rather featureless spectra discussed above for UN and UAs, the excitation spectra for USb has a number of most intriguing features.<sup>25</sup>

The dispersion curves are shown in Fig. 4. The most important point of the USb experiment concerns the observation of a longitudinally polarized magnetic excitation, centered at the X-point, with steeply rising branches. As the temperature is raised the intensity of this collective mode decreases so that by  $T_N/2$  it is unobservable. Second, we see a dispersionless exciton (cf level) at  $\sim 6\frac{1}{2} \text{ THz}$ . Third, we observe a broad response function which is centered on zero energy and (experimentally) appears to increase in intensity as the temperature is raised.

Let us examine these in the context of the UN and UAs experiments. The broad response function is clearly similar to that shown in Figs. 2 and 3 and experimentally in USb we also find a much stronger signal at [110] than [001]. The cf level in USb at  $\sim 6\frac{1}{2}$  THz is in excellent agreement with predictions based on form-factor measurements,<sup>26</sup> so that this can be reasonably assigned to a transition between states of different symmetry. If the splitting  $\Delta E$  is proportional to  $a_0^{-5}$ , as expected from cf considerations, then  $\Delta E \sim 9$  THz in UAs and  $\sim 21$  THz in UN. Both values are rather large for neutron spectroscopy and might well be missed, especially as the matrix element in USb is small. Finally, we come to the collective longitudinal mode. Where has this gone in UN and UAs? We cannot, of course, answer this question unambiguously. It seems highly probable though that the response is strongly overdamped in UN and UAs, but would like to appear at approximately the acoustic phonon X-point frequency, which is what happens in USb (see Fig. 4). The most plausible suggestion is that the strong indirect 5f-5f interaction through the anions and/or conduction electrons leads to suppression of the longitudinal fluctuation. We might expect this to be a function of lattice parameter, and its absence in those materials with small U separation is at least consistent with this view.

## CONCLUSIONS

We have discussed at some length the neutron cross section to draw attention to the fact that more than just cf levels can be seen with neutron spectroscopy. Progress since 1976<sup>14</sup> has been substantial -- at least from an experimental view, but it is also clear that we have a long way to go before we can claim an understanding. We have shown that the broad magnetic response function seen in intermediate valence 4f compounds is also present in many U compounds, independent of whether they order or not. In one material, USb, an unusual longitudinal excitation has been observed. This corresponds to a correlated fluctuation in the magnitude of  $\langle J_z \rangle$ , and one might therefore speculate that it is a collective valence fluctuation, although such a highly provocative statement is not yet supported by quantitative theory. The conventional spin-wave (transverse) response in these materials is clearly at very high energies, as a consequence of the uniaxial anisotropy,<sup>22</sup> and has not been seen with neutron experiments. The inability of the neutrons to see the longitudinal mode in UN and UAs is probably because of lifetime broadening effects, arising from interaction with the conduction electrons, or a widening of the 5f band width if we choose to consider a band structure approach.

In this paper I have suggested that the difficulties and challenge of neutron spectroscopy in U compounds is because many of them show characteristics of intermediate valence. Since the

two ground states,  $5f^2$  and  $5f^3$ , may both support magnetic ordering, these systems may well turn out to be as interesting as TmSe, a compound of much current interest. The next few years will show to what extent these suggestions are valid.

#### ACKNOWLEDGMENTS

Discussions with W. J. L. Buyers, B. R. Cooper, T. M. Holden, S. K. Sinha, and W. G. Stirling are much appreciated. These colleagues should not be held responsible for the possibly controversial views expressed here! Finally, the cooperation, and continued enthusiasm of Oscar Vogt of ETH, Zurich in growing the crystals involved in these studies is of immeasurable importance.
