The specific heats (C) of the heavy-fermion superconductors, CeCu<sub>2</sub>Si<sub>2</sub>, UPt<sub>3</sub> and UBe<sub>13</sub>, show significant sample-to-sample variations in both the normal and superconducting states (C<sub>n</sub> and C<sub>s</sub>, respectively). For some samples, C<sub>s</sub>/T ≠ 0 at T=0. This has been interpreted as evidence for gapless superconductivity [1-3], and, in the case of UPt<sub>3</sub>, as evidence of a gap over part of the Fermi surface [4], but could also indicate simply that some of the material remains normal. Measurements of C are reported here for four polycrystalline samples of UBe<sub>13</sub> of differing quality, gauged by transition temperature (T<sub>c</sub>) and width (ΔT<sub>c</sub>). There is a strong correlation of C<sub>s</sub>/T at T=0 with T<sub>c</sub> and ΔT<sub>c</sub>. The data also give some information on extrapolation of C<sub>n</sub> to T=0.

Fig. 1 shows C/T below 1K in magnetic fields (H) of 0 and 7.5T. Cubic

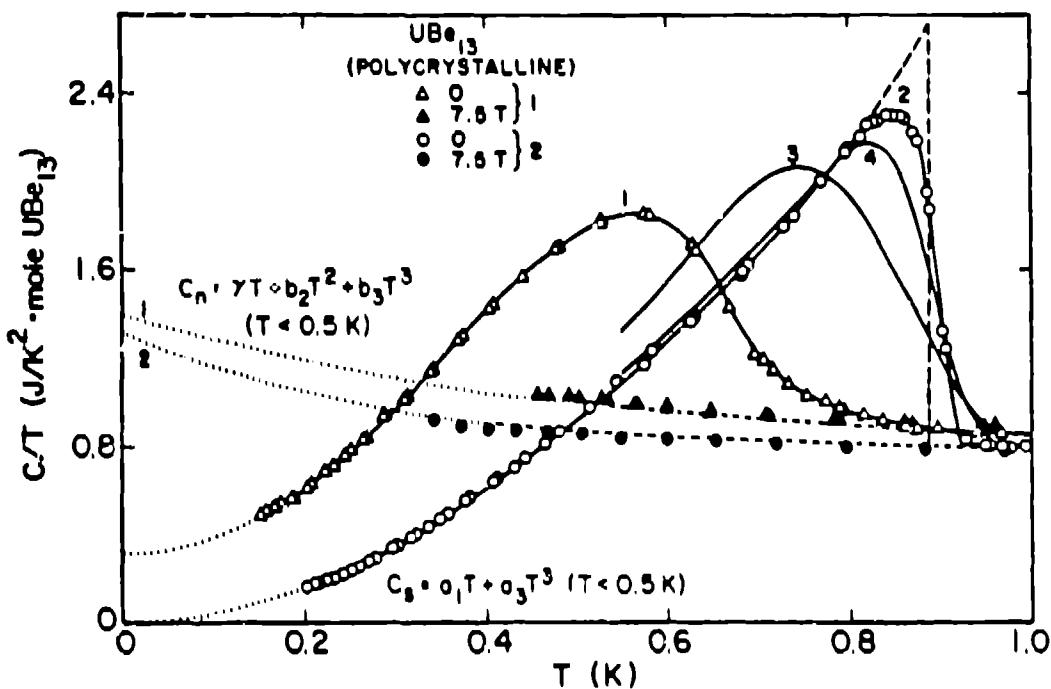

Fig. 1. C for four samples of UBe<sub>13</sub> below 1K.

spline fits of the  $H=0$  data for samples 3 and 4 are displayed near and below  $T_c$ . Above  $T_c$ , 7.5T has only a small effect on  $C$ ; below  $T_c$  it suppresses the transition at the lowest  $T$  investigated, 0.35K. The light dashed curves represent probable values of  $C_n/T$  at  $H=0$ . They are parallel to  $C/T$  at 7.5T, but shifted by the small (barely perceptible) amount necessary to coincide with  $C/T$  at  $H=0$  just above  $T_c$ . The dotted extrapolations to  $T=0$  are by the 3-term polynomials indicated in Fig. 1, with two coefficients chosen to force a match to the dashed curves and the third chosen to give the same high- $T$  entropy as that derived from  $C_g$ . Values of  $\gamma$  derived by this process are given in Table 1 for all four samples. Just above  $T_c$ ,  $C_n/T$  is nearly constant but increases slowly with decreasing  $T$ . The experimental data display a more rapid increase below  $T_c$ , and a still more rapid increase is required below 0.35K (in the region of the extrapolation) to conserve entropy.

The heavy dashed vertical line for sample 2 is the idealized, entropy-conserving construction for a sharp transition at  $T_c$ . (Similar constructions for the other samples are omitted for clarity.) Table 1 lists values of  $T_c$  and  $\delta T_c$ , the difference between  $T_c$  and  $T$  at the onset of superconductivity.

$C_g$  data at  $H=0$  for the four samples are plotted in Fig. 2. From least-squares fits, the straight lines in the insert, it is evident that  $C_g$  for all samples is well represented by  $C_g = a_1 T + a_3 T^3$ . (Table 1 lists  $a_1$  and  $a_3$ .) The positive deviation from this form at low- $T$  for sample 4 has a  $T^{-2}$  dependence and may reflect a contribution from impurities. A small upturn of  $C/T$  at low- $T$  for sample 2 is perhaps also due to impurities, but the effect is too small to permit analysis of the  $T$  dependence. The solid curves in Fig. 2 represent  $a_1 T + a_3 T^3$  plus the additional  $T^2$  term for sample 4. The strongly sample dependent  $a_1$  correlates with  $T_c$  and  $\delta T_c$ : For samples 2 and 4, with the higher  $T_c$  and lower  $\delta T_c$ ,  $a_1 = 0$ . We conclude that the linear term is not an intrinsic property of  $UBe_{13}$ . The  $T^2$  dependence of  $C_g$ , which contrasts with

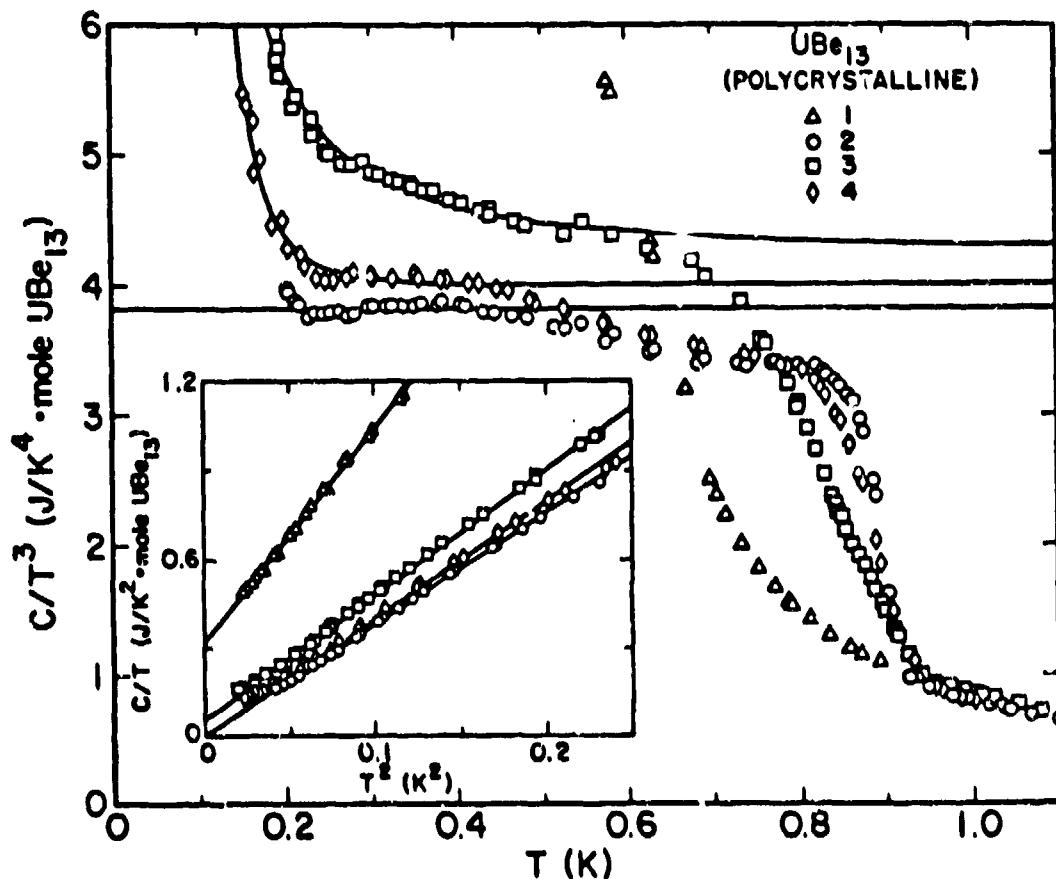

Fig. 2. Limiting low temperature behavior of  $C$  for  $UBe_{13}$ .

Table 1. Properties Characterizing Four  $\text{UBe}_{13}$  Samples below  $T_c$ . Units:  $a_1$  and  $\gamma$  in  $\text{J/K}^2\cdot\text{mole}$ ;  $a_3$  in  $\text{J/K}^4\cdot\text{mole}$ ;  $C(1\text{K})$  and  $S(1\text{K})$  in  $\text{J/K}\cdot\text{mole}$ .

the BCS exponential dependence on  $T$ , has been observed previously for  $\text{UBe}_{13}$ , and has been interpreted in terms of p-wave pairing [5]. Power laws in  $T$  for  $C_g$  have also been found for  $\text{CeCu}_2\text{Si}_2$  and  $\text{UPt}_3$  and have been interpreted as arising from points or lines on the Fermi surface with zero gap [1-3]. In addition to the power law for  $C_g$ , there is a new feature for samples 2 and 4 -- a small but significant departure from  $T^3$  behavior near 0.5K, corresponding approximately, especially for sample 2, to a change in the value of  $a_3$ . This effect is also present for a sample studied by the Darmstadt group [2] (Fig. 7b). The fact that the same effect is seen in three samples from two separate sources, and in two laboratories with independent measuring techniques, demonstrates that it is a real, intrinsic property of  $\text{UBe}_{13}$ . (Samples 1 and 3 do not show this "transition" region, perhaps because of a lowered quality.) An intriguing possibility is that this feature is related to the second transition [6] in  $(\text{U, Th})\text{Be}_{13}$  that persists for  $\text{UBe}_{13}$ .

BCS theory gives  $r \approx [(C_g - C_n)/C_n(T_c)] = 1.43$ . Taking "ideal" values of  $C_g - C_n$  (derived from constructions like that for sample 2 in Fig. 1),  $r = 2.4$  for sample 2, close to reported values [2,5] and typical for strong coupling superconductors. For sample 4,  $r = 2.1$ . For samples 1 and 3,  $r < 2$ , but, assuming the  $a_1 T$  term in  $C_g$  is due to material remaining normal,  $r$  would be corrected to 2.0 for both. The superconducting fraction of the sample at  $T=0$ ,  $f_s \approx 1-a_1/\gamma$ , and corrected values of  $r$  are given in Table 1.

Fig. 3 shows  $C_g/T$  vs.  $T$  from 1 to 20K for samples 1 and 2 at  $T=0$ , and sample 2 at 7.5K. In the region of the broad maximum in  $C_g$  (1-5K) the samples differ somewhat, while above 5K,  $C_g$  is nearly the same for each. Between 5

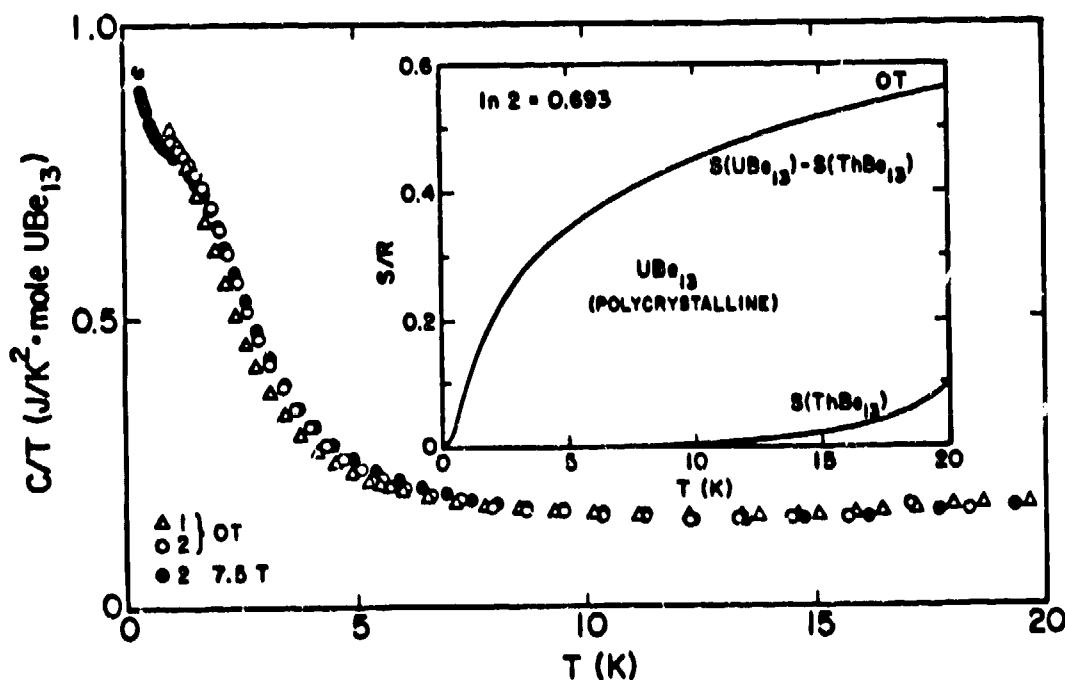

Fig. 3.  $C$  and  $S$  for  $\text{UBe}_{13}$  at 0 and 7.5T to 20K.

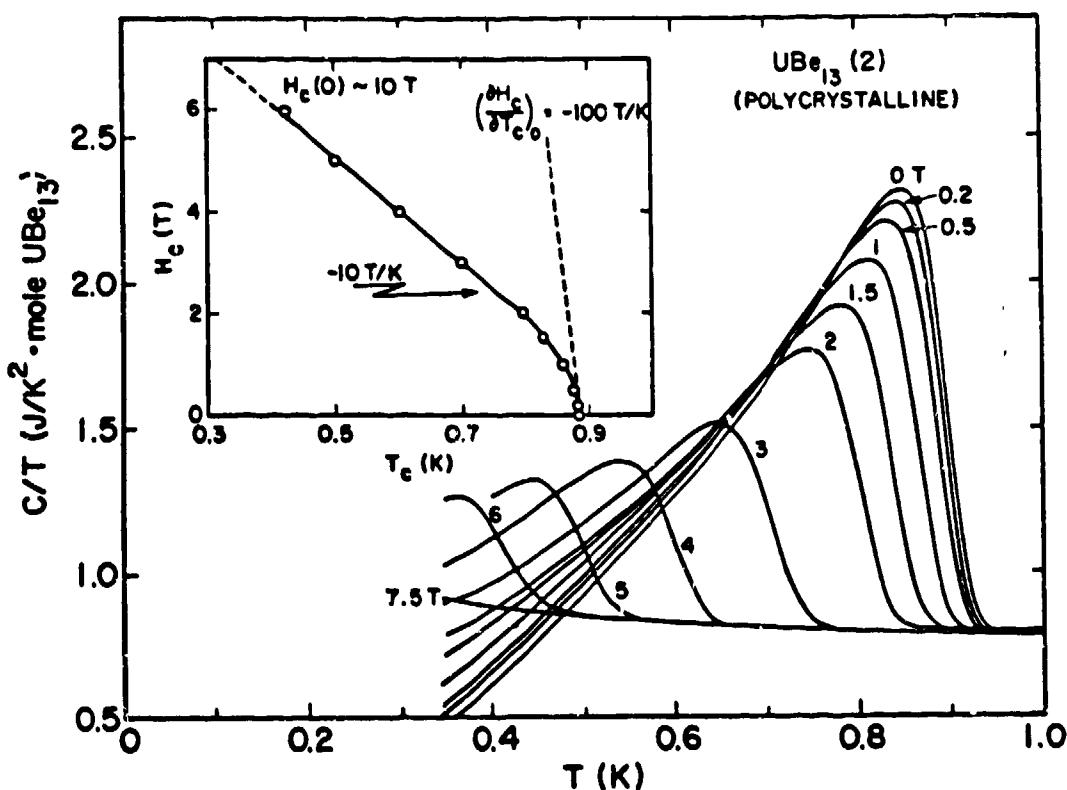

Fig. 4.  $H_c$  vs.  $T_c$  for  $UBe_{13}$  as measured by C in fields to 7.5T.

and 20K,  $C_n/T$  has a weak T dependence with a minimum near 12K. Stewart [1] has reviewed measurements of C in this T-range. The insert shows the electronic entropy calculated by subtracting the entropy for  $TlBe_{13}$  [7].

Fig. 4 shows cubic spline fits of  $C/T$  vs. T for sample 2 in fields to 7.5T. (Precision of the data is similar to that in Fig. 1.)  $T_c$  vs.  $H_c$  is shown in the insert --  $T_c$  was taken as T at the midpoint of the transition, and these values of  $T_c$  are not equal to those in Table 1. Initially  $(\partial H_c / \partial T_c)$  is  $-100T/K$  (at least) and for higher H is linear at  $-10T/K$ . At T=0,  $H_c$  extrapolates to 10T. Similar calorimetric results have been reported [8].
