Optimization of GaInP<sub>2</sub>/GaAs dual and GaInP<sub>2</sub>/GaAs/Ge triple junction cells, and development of future generation monolithic multi-junction cells will involve the development of suitable high bandgap tunnel junctions. There are three criteria that a tunnel junction must meet. First, the resistance of the junction must be kept low enough so that the series resistance of the overall device is not increased. For AM0, 1 sun operation, the tunnel junction resistance should be below  $5 \times 10^{-2} \Omega\text{-cm}$ . Secondly, the peak current density for the tunnel junction must also be larger than the  $J_{sc}$  of the cell so that the tunnel junction I-V curve does not have a deleterious effect on the I-V curve of the multi-junction device. Finally, the tunnel junction must be optically transparent, i.e., there must be a minimum of optical absorption of photons that will be collected by the underlying subcells.

We have looked at four "high" bandgap tunnel junctions, Al<sub>0.4</sub>Ga<sub>0.6</sub>As:C/In<sub>0.5</sub>Ga<sub>0.5</sub>P:Si, Al<sub>0.4</sub>Ga<sub>0.6</sub>As:C/In<sub>0.5</sub>Ga<sub>0.4</sub>Al<sub>0.1</sub>P:Te, Al<sub>0.9</sub>Ga<sub>0.1</sub>As:C/In<sub>0.5</sub>Ga<sub>0.3</sub>Al<sub>0.2</sub>P:Si, and Al<sub>0.9</sub>Ga<sub>0.1</sub>As:C/In<sub>0.5</sub>Ga<sub>0.3</sub>Al<sub>0.2</sub>P:Te. The bandgap of Al<sub>0.9</sub>Ga<sub>0.1</sub>As and Al<sub>0.4</sub>Ga<sub>0.6</sub>As are 2.1 eV and 1.9 eV, respectively, while the bandgap of In<sub>0.5</sub>Ga<sub>0.3</sub>Al<sub>0.2</sub>P and In<sub>0.5</sub>Ga<sub>0.4</sub>Al<sub>0.1</sub>P are 2.1 eV and 2.0 eV, respectively. Each active layer of the tunnel junction is 250 Å thick, sandwiched by GaAs layers. All of the tunnel junctions were grown by metal-organic chemical vapor deposition (MOCVD), the growth method of choice for commercial production of III-V space solar cells. All of the devices have the p-on-n structure, and were processed as 100 μm x 100 μm diodes. The maximum electron density achieved for Si doping of both compositions of InGaAlP is  $5 \times 10^{18} \text{ cm}^{-3}$ . With Te, an electron carrier density of  $1.5 \times 10^{19} \text{ cm}^{-3}$  is achievable. Both

Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under Contract DE-AC04-94AL85000.

compositions of AlGaAs are doped with C, with a maximum hole density of  $1.5 \times 10^{19}$  cm<sup>-3</sup> being attained.

The I-V curves for the different tunnel junctions are shown in the Figures 1 through 4, along with the peak current and series resistance for each structure. Only the Al<sub>0.9</sub>Ga<sub>0.1</sub>As:C/In<sub>0.5</sub>Ga<sub>0.3</sub>Al<sub>0.2</sub>P:Te tunnel junction meets the criteria mentioned previously, with  $J_p$  being 1,500 mA/cm<sup>2</sup>, and  $R_s$  being  $2.5 \times 10^{-2}$  Ω-cm<sup>2</sup>. While it is possible to degenerately dope In<sub>0.5</sub>Ga<sub>0.5</sub>P with Si, the level is not high enough to reduce the series resistance to the values needed for a multijunction device. With In<sub>0.5</sub>Ga<sub>0.3</sub>Al<sub>0.2</sub>P, however, degeneracy cannot be achieved with Si doping, as can be seen from Fig. 3. Compensation occurs before degeneracy is reached, with increased amounts of Si above a certain point reducing the n-type carrier density.

Because of concern about a Te memory effect, an iteration of the In<sub>0.5</sub>Ga<sub>0.3</sub>Al<sub>0.2</sub>P:Te/Al<sub>0.9</sub>Ga<sub>0.1</sub>As:C tunnel junction was grown with reduced amounts of Te. Unfortunately, the series resistance of the junction is increased to an unacceptable level. The precise growth conditions have a significant effect on the final device results.

A SIMS analysis was done on the sample shown in Fig. 4, to determine how abrupt the doping profiles are, and to see any Te memory effect. The results indicate that within 0.1 μm the Te doping level drops to the background level. The Te memory effect is minimal, and should have no effect on a multijunction device that would use the In<sub>0.5</sub>Ga<sub>0.3</sub>Al<sub>0.2</sub>P:Te/Al<sub>0.9</sub>Ga<sub>0.1</sub>As:C tunnel diode.

To our knowledge, the Al<sub>0.9</sub>Ga<sub>0.1</sub>As:C/In<sub>0.5</sub>Ga<sub>0.3</sub>Al<sub>0.2</sub>P:Te tunnel junction is the highest bandgap tunnel junction made to date. The tunnel junction has the necessary optical and electrical properties such that it could be used in a AM0, 1-sun monolithic multijunction solar cell.

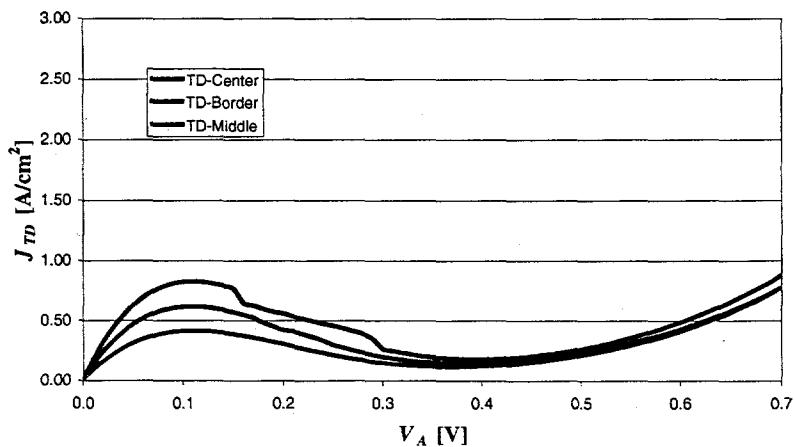

Figure 1. I-V curve for the In<sub>0.5</sub>Ga<sub>0.5</sub>P:Si/Al<sub>0.4</sub>Ga<sub>0.6</sub>As:C tunnel diode. The  $J_p$  is 600 mA/cm<sup>2</sup>, and the  $R_s$  is  $7.5 \times 10^{-2}$  Ω-cm<sup>2</sup>.

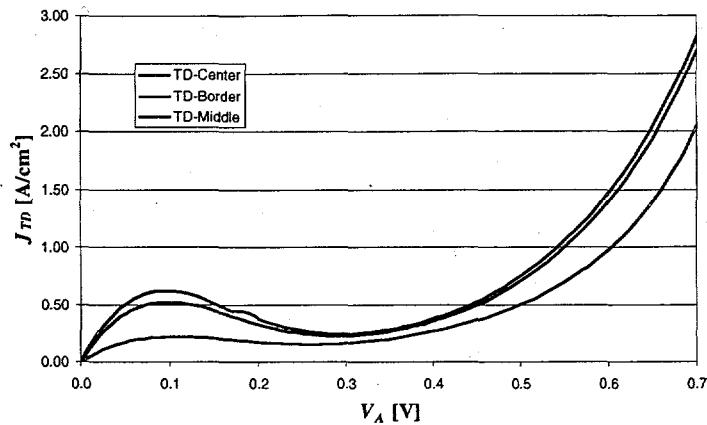

Figure 2. I-V curve for the  $\text{In}_{0.5}\text{Ga}_{0.4}\text{Al}_{0.1}\text{P:Te}/\text{Al}_{0.4}\text{Ga}_{0.6}\text{As:C}$  tunnel diode. The  $J_p$  is  $500 \text{ mA/cm}^2$ , and the  $R_s$  is  $7.5 \times 10^{-2} \Omega\text{-cm}^2$ .

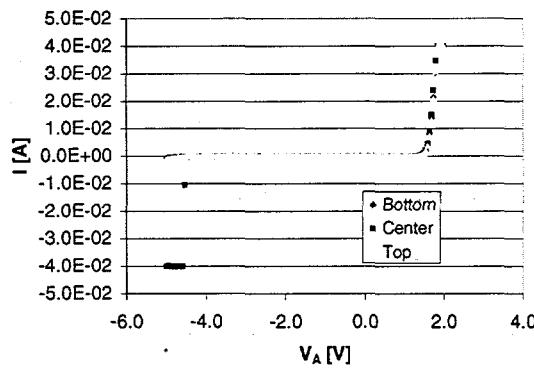

Figure 3. I-V curve for the  $\text{In}_{0.5}\text{Ga}_{0.3}\text{Al}_{0.2}\text{P:Si}/\text{Al}_{0.9}\text{Ga}_{0.1}\text{As:C}$  junction. No tunneling action is seen because the  $\text{In}_{0.5}\text{Ga}_{0.3}\text{Al}_{0.2}\text{P:Si}$  is not degenerate.

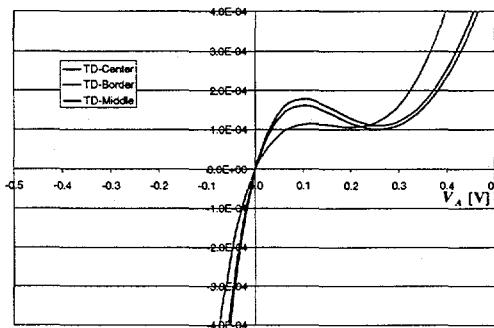

Figure 4. I-V curve for the  $\text{In}_{0.5}\text{Ga}_{0.3}\text{Al}_{0.2}\text{P:Te}/\text{Al}_{0.9}\text{Ga}_{0.1}\text{As:C}$  tunnel diode. The  $J_p$  is  $1,500 \text{ mA/cm}^2$ , and the  $R_s$  is  $2.5 \times 10^{-2} \Omega\text{-cm}^2$ .
