Executive Summary

This document defines the contents, format, and methods to be used for the *Hanford Immobilized Low-Activity Tank Waste Performance Assessment* (ILAW PA). This document also provides the data to be used for the supporting calculations. The data are summarized in the main body of the report while the 16 appendices contain the documents used as primary references.

The *Hanford Immobilized Low-Activity Tank Waste Performance Assessment* provides an analysis of the long-term environmental and health impacts of the onsite disposal of Hanford immobilized low-activity tank waste packages. The purpose of the 1998 version[1] was to provide an assessment that would bound the impacts given the limited site-specific and waste-specific data available[2]. The assessment was based on the requirements of DOE Order 5820.2a with the acknowledgment that the order was undergoing revision. This document was conditionally accepted by the Department of Energy and formed part of the basis for the issuance of a Disposal Authorization Statement for the Hanford Site, including the disposal of ILAW.[3]

The next version (known as the 2001 ILAW PA) will use the site-specific and waste form-specific data that have been collected in the past few years. The emphasis of the 2001 ILAW PA will be on how these new data affect the conclusions of the 1998 ILAW PA. These new data and analyses will fulfill the conditions of the DOE headquarters acceptance. The 2001 ILAW PA will also follow the guidance of the new DOE order on radioactive waste management (DOE O 435.1[4]), particularly in the areas of document content and format.

The methods to be used in the performance assessment include the standards (known as performance objectives) against which the impact of the disposal action will be judged, the various scenarios and pathways that will be analyzed, and the tools with which the analyses will be done.

1.0 INTRODUCTION

1.1 PURPOSE AND SCOPE

This document defines the contents, format, and methods to be used for the *Hanford Immobilized Low-Activity Tank Waste Performance Assessment* (ILAW PA) to be issued in 2001. This document also provides the data to be used for the supporting calculations. The data are summarized in the main body of the report while the 16 appendices contain the documents used as primary references.

1.2 BACKGROUND

The Hanford Site, in south-central Washington State has been used extensively for producing defense materials by the Department of Energy (DOE) and its predecessors, the U.S. Atomic Energy Commission and the U.S. Energy Research and Development Administration. Starting in the 1940s, Hanford Site operations were dedicated primarily to producing nuclear weapons materials. In the 1960s, operations were expanded to producing electricity from a dual-purpose reactor, conducting diverse research projects, and managing waste. In the late 1980s, the Site's original mission ended. This mission left a large inventory of radioactive and mixed waste stored in buried single- and double-shell tanks in the Hanford Site 200 Areas.

Today, the Site's missions are environmental restoration, energy-related research, and technology development. As part of its environmental restoration mission, DOE is proceeding with plans to permanently dispose of the waste stored on site. These plans are based on the *Hanford Federal Facility Agreement and Consent Order* (Tri-Party Agreement) (Ecology 1998-1) and the *Record of Decision for the Tank Waste Remediation Systems Environmental Impact Statement* (DOE 1997). These documents call for the waste to be retrieved from the Hanford Site's single- and double-shell tanks, then treated to separate the low-level fraction (now called the low-activity fraction) from the high-level and transuranic fractions. Both fractions will then be immobilized.

The two products (the small volume of high-level immobilized waste and the much larger volume of low-activity waste) will be disposed of in different locations. The high-level waste will be stored on the Hanford Site until sent to a federal geologic repository. The low-activity immobilized waste will be placed in a near-surface disposal system in the 200 East Area of the Hanford Site. On the order of 160,000 m^3 (5,6000,000 ft^3) of low-activity immobilized waste will be disposed of under this plan. This is among the largest amounts of waste in the DOE Complex (DOE 1995) and has one of the largest inventories of long-lived radionuclides at a low-level waste disposal facility.

The DOE is proceeding (DOE-RL 1996a) to procure privatized services for treating and immobilizing the tank waste. In August 1998, DOE placed a contract with BNFL, Inc. (DOE/BNFL 1998) to produce the ILAW with the first delivery currently scheduled in 2008.

The first phase of the effort would extend for about a decade. The contract for the second phase, in which most of the waste will be processed, will be awarded in the second half of the decade.

1.3 PREVIOUS ASSESSMENTS

In 1998, the first version of the *Hanford Immobilized Low-Activity Tank Waste Performance Assessment* (Mann 1998a) was issued and submitted to the Federal Low-Level Waste Review Group (LFRG) for review and action. The Federal Low-Level Waste Review Group has completed their review. Based on this review the DOE has conditionally accepted the ILAW Performance Assessment (DOE 1999f). This acceptance is contingent upon the following actions: providing the LFRG with documentation of the near-term glass activities to provide confidence that the glass performance assumed in the performance assessment can actually be achieved, and addressing the secondary issues identified by the review team in future revisions to the performance assessment.

Most of the data in the 1998 ILAW PA came from the *Data Packages for the Hanford Low-level Tank Waste Interim Performance Assessment (Mann 1995)*, although some data were updated to reflect more current values.

A number of other impact assessments have also been done at the Hanford Site:

- The *Long-Term Performance Assessment of Grouted Phosphate/Sulfate Waste from N Reactor Operations* (Stewart 1987) forms the basis of the environmental assessment (DOE 1986) for the disposal of low-level radioactive waste generated by decontamination operations and other activities associated with N Reactor operations. Because this performance assessment predates the DOE order on radioactive waste management, the DOE review was conducted by reviewing the environmental assessment.

- The *Performance Assessment of Grouted Double-Shell Tank Waste Disposal at Hanford* (Kincaid 1995) dealt with disposing of low-level liquid waste from the double-shell tanks. The waste was to be combined with cement, flyash, and clay to form a grout that would be poured into large subsurface vaults located to the east of the 200 East Area. The Peer Review Panel (Wilhite 1994) approved the grout performance assessment in principle. DOE (Lytle 1995) found that the analysis performed in Kincaid (1995) was "technically adequate and provides reasonable assurance that the selected performance objectives would be met." Noting, however, that the grout project had been canceled, DOE also stated that a new or revised performance assessment would be needed for routine disposal of waste in the Grout Disposal Facility.

- The *Performance Assessment for the Disposal of Low-Level Waste in the 200 West Area Burial Grounds* (Wood 1994) dealt with the solid waste from operations at the Hanford Site and other sites. This waste is placed into trenches in the western part of the 200 West Area and then covered with a *Resource Conservation and Recovery Act of 1976* (RCRA)-compliant barrier. The Peer Review Panel found the performance assessment to

be technically acceptable. The 200 West Area performance assessment has been "conditionally accepted" by DOE-Headquarters (Cowan 1996). The conditions were related to added documentation.

- The *Performance Assessment for the Disposal of Low-Level Waste in the 200 East Area Waste Burial Grounds* (Wood 1996) addresses waste that is similar to that addressed in the 200 West Area performance assessment. However, the disposal trenches for this waste are in the northern part of the 200 East Area. The final performance assessment for this action has also been conditionally approved by DOE-Headquarters (Frei 1997).

- The *Environmental Remediation Disposal Facility Performance Assessment* (Wood 1995) was written to support disposal of waste generated by the cleanup of the Hanford Site. Most of this waste is expected to be contaminated soil. Trenches are planned to be the main means of disposal at the facility. Because the Environmental Remediation Disposal Facility is regulated under the *Comprehensive Environmental Response, Compensation, and Liability Act of 1980* (CERCLA), this performance assessment was not submitted to the Peer Review Panel. However, a remedial investigation and feasibility study report (DOE-RL 1993) was written.

- The *Composite Assessment for Hanford Site* (CA) (Kincaid 1998) was prepared in response to Recommendation 94-2 of the Defense Nuclear Facilities Safety Board to the Secretary of the Department of Energy [DNFSB 1994]. The recommendation noted the need for a risk assessment that investigates the environmental impacts of all radioactive waste disposal actions or leaks at a DOE Site. The CA has undergone headquarters review by the Federal Low-Level Waste Review Group. Based on this review the DOE has conditionally accepted the CA (DOE 1999f). This acceptance is contingent upon the following actions: providing the LFRG by September 30, 2001 with an addendum to the composite analysis that addresses bounding analyses in the 200 Area that include the PUREX tunnels, the chemical separations plants and the CERCLA sites, and resolve the path forward for the Gable Mountain Pond; and address the secondary issues identified in the LFRG review.

- The *Environmental Impact Statement for the Tank Waste Remediation System* (TWRS EIS) (DOE 1996b) analyzed various options to manage the Hanford Site's tank waste with the record of decision issued in 1997 (DOE 1997). Because of the scope of the TWRS EIS, the analyses relied on data less complete and less project-specific than this performance assessment. The record of decision includes the disposal of ILAW in the Hanford Site 200 Areas.

1.4 OTHER RELEVANT HANFORD DATA COLLECTION EFFORTS

Besides the data collection efforts associated with the ILAW PA activity, there are a number of data collection efforts at the Hanford Site that can provide useful data to the ILAW PA activity. Close cooperation with these activities is maintained.

As part of the maintenance program for the Solid Waste Burial Ground Performance Assessments, work on retardation through near-field materials (especially concrete) is being performed.

The maintenance of the Composite Analysis is being undertaken by the Hanford Groundwater / Vadose Zone Integration Project. The Characterization of Systems activity, the Science and Technology activity, and the System Assessment Capability activity will provide (respectively) a centralized data source for Hanford inventory and geotechnical data, improved methods and data, and updated analyses. For the most part, new data will come from other sources.

The Tank Farm Vadose Zone Program has an active program characterizing the vadose zone in and near tank farms. A number of boreholes are planned which will not only provide contaminant concentrations, but also important geologic, geochemical, and hydraulic data in various parts of the 200 Areas.

The 200 Areas Remediation Project will have an active characterization effort in the 200 Areas as it starts planning remediation efforts.

The Hanford Groundwater Project has an active program to monitor groundwater quality at the Hanford Site. This program will be drilling boreholes (in order to replace monitoring wells going dry) from which geotechnical data will be obtained.

1.5 GUIDANCE

Guidance for the performance assessment mainly derives from *Format and Content Guide for U.S. Department of Energy Low-Level Waste Disposal Facility Performance Assessments and Composite Analyses* (DOE 1999a) and *Maintenance Guide for U.S. Department of Energy Low-Level Waste Disposal Facility Performance Assessments and Composite Analyses* (DOE 1999b).

1.6 CONTENTS OF THIS REPORT

Section 2.0 briefly describes the contents and formats of the 2001 ILAW PA. Section 3.0 describes the methods to be used in the PA, including the performance objectives, the scenarios, and the computer codes. Chapter 4.0 summarizes the data to be used, including data on

- Location/geology
- Inventory
- Disposal facility design
- Recharge
- Release rate from the waste form package
- Hydrology

- Geochemistry
- Dosimetry

The appendices contain the documents used as primary references.

This page intentionally left blank.

2.0 CONTENTS AND FORMAT

The contents and format for the 2001 ILAW PA is based on the guidance in Format and Content Guide for U.S. Department of Energy Low-Level Waste Disposal Facility Performance Assessments and Composite Analyses (DOE 1999a). The structure to be used is displayed in Table 2.1.

3.1 OVERVIEW

This section covers the methods to be used in the 2001 ILAW PA. The methods include the standards (known as performance objectives) against which the effect of the disposal action will be judged, the various scenarios and pathways which will be analyzed, and the tools with which the analyses will be done.

3.2 PERFORMANCE OBJECTIVES

Performance objectives are the standards against which the effect of the disposal action will be done. The manual (DOE 1999d –1) for the new DOE order on radioactive waste management, DOE O 435.1 (DOE 1999c) provides performance objectives for a performance assessment as:

The performance objectives are similar to those used in the 1998 ILAW PA. The major differences are the inclusion of chemicals to support RCRA analyses and explicit comparisons to be done at 1,000 years to support the requirements of the DOE order on radioactive waste management.

(1)(a) "25 mrem in a year total effective dose equivalent from all exposure pathways"
(1)(b) "10 mrem in a year total effective dose equivalent " via the air pathway
(1)(c) "Release of radon shall not exceed 10 mrem in a year total effective dose equivalent"
(2)(g) "include an assessment of impacts to water resources"
(2)(h) "The intruder analysis shall use performance measures for chronic and acute exposures, respectively, of 100 mrem in a year and 500 mrem in a year total effective dose equivalent."
(2)(b) "The point of compliance shall correspond to the point of highest projected dose or concentration beyond a 100 meter buffer zone surrounding the disposal waste."
(2) "include calculations for a 1,000 year period after closure"

This performance assessment will also be the technical supporting document for the Resource Conservation and Recovery Act (RCRA) Part B permit and for discussions with the U.S. Nuclear Regulatory Commission (NRC) on the waste classification of ILAW. Therefore, additional items were considered in the establishment of the performance objectives used in the 2001 ILAW PA. Specifically, the RCRA concerns bring in the impacts of hazardous chemicals. The NRC concerns bring in the requirements of 10 CFR 61, which mainly add the requirements for an analysis to 10,000 years after closure.

Therefore, as documented in Appendix A, the various requirements noted above have been merged into an unified set of performance objectives for the 2001 ILAW PA (Mann 1999a). Table 3.1 presents the performance objectives for radionuclides, while Table 3.2 presents the performances objectives for chemicals.

Table 3.1 Radiological Performance Objectives

Protection of General Public and Workers [a, b]	
All-pathways dose from only this facility	25 mrem in a year [d, h]
All-pathways dose including other Hanford Site sources	100 mrem in a year [e, i]
Protection of an Inadvertent Intruder [c, f]	
Acute exposure	500 mrem
Continuous exposure	100 mrem in a year
Protection of Groundwater Resources [b, d, j]	
Alpha emitters	
^{226}Ra plus ^{228}Ra	5 pCi/ℓ
All others (total)	15 pCi/ℓ
Beta and photon emitters	4 mrem in a year
Protection of Surface Water Resources [b, g]	
Alpha emitters	
^{226}Ra plus ^{228}Ra	0.3 pCi/ℓ
All others (total)	15 pCi/ℓ
Beta and photon emitters	1 mrem in a year [k]
Protection of Air Resource [b, f, l]	
Radon (flux through surface)	20 pCi m^{-2} s^{-1}
All other radionuclides	10 mrem in a year

[a] All doses are calculated as effective dose equivalents; all concentrations are in water taken from a well. Values given are in addition to any existing amounts or background.

[b] Evaluated for 1,000 and 10,000 years, but calculated to the time of peak or 10,000 years, whichever is longer.

[c] Evaluated for 500 years, but calculated to 1,000 years.

[d] Evaluated at the point of maximal exposure, but no closer than 100 meters (328 feet) from the disposal facility.

[e] Evaluated at the 200 East Area fence.

[f] Evaluated at the disposal facility.

[g] Evaluated at the Columbia River, no mixing with the river is assumed.

[h] Main driver is DOE Orders on *Radioactive Waste Management* (DOE 1988 and DOE 1999c)

[i] Main driver is DOE Order 5400.5, *Radiation Protection of the Public and the Environment* (DOE 1993).

[j] Main driver is National Primary Drinking Water Regulations (40 CFR 141).

[k] Main driver is Washington State Surface Water Standards (WAC 173-201A)

[l] Main driver is National Emission Standards for Hazardous Air Pollutants (40 CFR 61H and 40 CFR 61Q).

Table 3.2 Performance Goals for Hazardous Materials

Inorganic Compounds/Elements					
Chemical		Groundwater		Surface Waters	
Ammonia				4.0	mg/l
Antimony		0.006	mg/l	0.006	mg/l
Arsenic		0.00005	mg/l	0.05	mg/l
Barium		1.0	mg/l	2.0	mg/l
Beryllium		0.004	mg/l	0.004	mg/l
Cadmium		0.005	mg/l	0.00077	mg/l
Chlorine		250.	mg/l	230.	mg/l
Chromium		0.05	mg/l	0.011	mg/l
Copper		1.0	mg/l	0.0078	mg/l
Cyanide		0.2	mg/l	0.0052	mg/l
Fluoride		4.0	mg/l	4.0	mg/l
Iron		0.3	mg/l		
Lead		0.05	mg/l	0.0015	mg/l
Manganese		0.05	mg/l		
Mercury		0.002	mg/l	0.000012	mg/l
Nickel				0.115	mg/l
Nitrate as N		10.	mg/l	10.	mg/l
Nitrite as N		1.0	mg/l	1.0	mg/l
Nitrite plus Nitrate		10.	mg/l	10.	mg/l
Selenium		0.01	mg/l	0.005	mg/l
Silver		0.05	mg/l		
Sulfate		250.	mg/l		
Thallium		0.002	mg/l		
Zinc		5.0	mg/l	0.072	mg/l
Organic Compounds					
CAS #	Constituent (a)	Groundwater		Surface Waters	
56-23-5	Carbon tetrachloride	0.0003	mg/l	0.005	mg/l
67-66-3	Chloroform	0.007	mg/l		
71-43-2	Benzene	0.001	mg/l	0.005	mg/l
71-55-6	1,1,1-Trichloroethane	0.003	mg/l	0.2	mg/l
75-09-2	Dichloromethane (Methylene Chloride)	0.005	mg/l	0.005	mg/l
79-00-5	1,1,2-Trichloroethane	0.005	mg/l	0.005	mg/l
79-01-6	1,1,2-Trichloroethylene	0.005	mg/l	0.005	mg/l
95-47-6	o-Xylene	0.7	mg/l	0.7	mg/l
100-41-4	Ethyl benzene	0.1	mg/l	0.1	mg/l
106-46-7	1,4-Dichlorobenzene	0.004	mg/l	0.075	mg/l
108-88-3	Toluene	1.0	mg/l	1.0	mg/l
127-18-4	1,1,2,2-Tetrachloroethene	0.005	mg/l	0.005	mg/l

No entry in a cell indicates that no limit was found.

3.3 SCENARIOS AND PATHWAYS

3.3.1 Introduction

The scenarios and pathways are basically unchanged from the 1998 ILAW PA.

The selection of scenarios and pathways for the 2001 ILAW PA is more fully described in Appendix B (Mann 1999b). Possible scenarios were suggested by analyzing the performance objectives given in Section 3.2 and determining which parameters could lead to exposure which is given by the performance objective. The pathways to be analyzed are groundwater, air, and inadvertent intruder. Finally, probable natural events are identified in Section 3.3.5.

In 1992, the Hanford Future Site Uses Working Group (consisting of local, state, and federal officials, representatives of tribal nations, people from agriculture and labor, as well as members of environmental and special interest groups) was charged to determine potential future uses of the various parts of the Hanford Site. Their summary report (HFSUWG 1992-1) states

> *"In general, the Working Group desires that the overall cleanup criteria for the Central Plateau should enable general usage of the land and groundwater for other than waste management activities in the horizon of 100 years from the decommissioning of waste management facilities and closure of disposal areas."*

The DOE along with the U.S. Department of Interior, local governments, and affected tribal nations have recently issued a comprehensive land use plan for the Hanford Site for at least the next 50 years (DOE 1999e). The plan outlines that the 200 Areas (or Central Plateau) would be used exclusively as a waste management area.

Except for the inadvertent intruder scenario, the scenarios described here assume that some controls remain in place to prevent public intrusion into the disposal site. That is, the barriers and markers that have been left are effective in preventing open use of the land directly over the disposal site.

3.3.2 Groundwater Pathway

Past Hanford Site performance assessments (see Section 1.3) have shown that the groundwater pathway to be the most restrictive for the vast majority of radionuclides. Previous assessments have not analyzed the effect of chemicals. Figure 3-1 shows the details of the groundwater pathway. The eight steps are

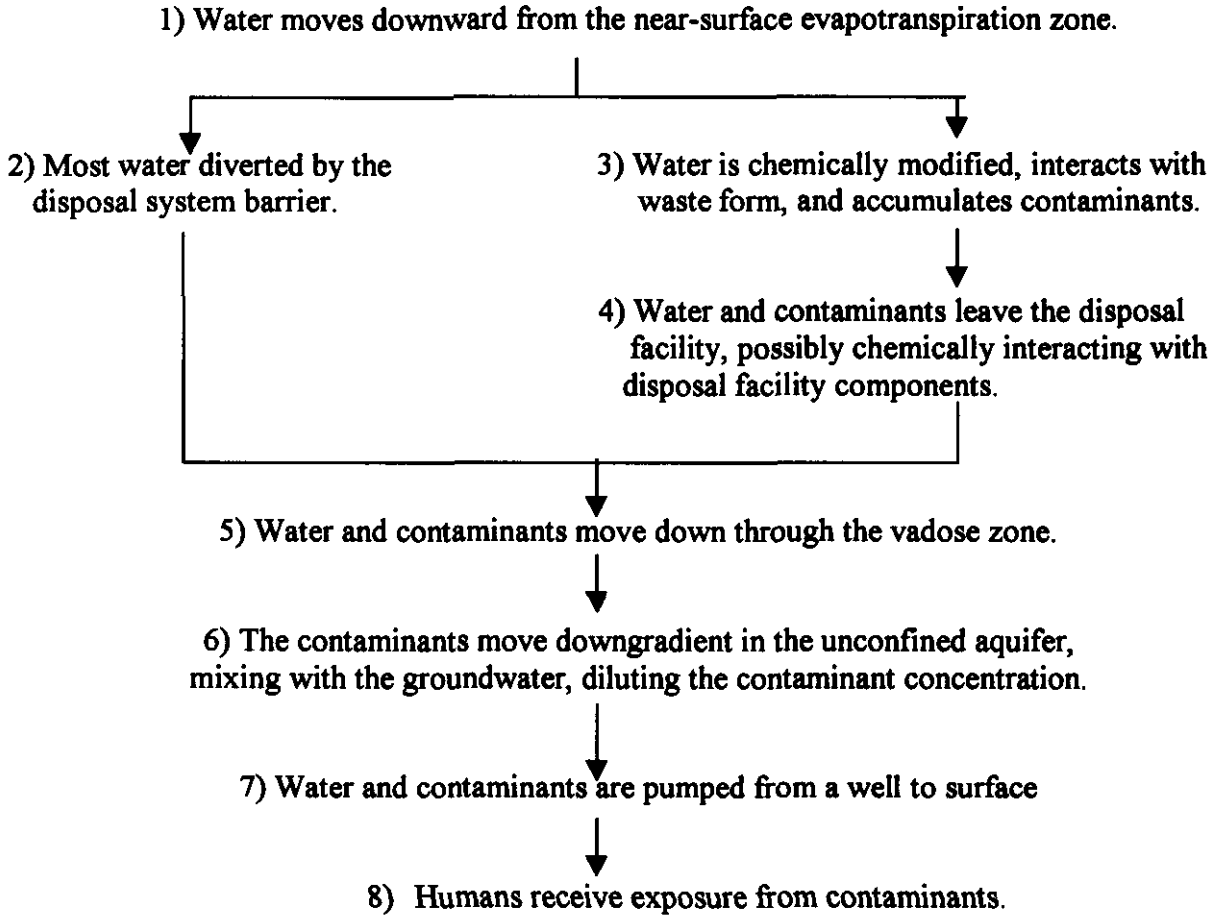
1) Precipitation (rain or snow) enters the soil. Much of this water returns to the atmosphere by evaporation from the soil surface or transpiration through plant leaves. The remaining water moves down below the surface evapotranspiration zone at a very low rate.

2) The deep water continues to move downward, but some of the water is diverted by any intact sand-gravel capillary barrier.

3) The water that is not diverted away from the waste may be chemically modified by the local environment, interacts with the waste form, and accumulates contaminants.

4) The water (possibly a reduced amount because waste form dissolution and mineral formation consume water) leaves the disposal facility carrying contaminants with it. Some contaminants may interact with the material in the disposal facility, slowing the release of contaminants to the surrounding natural environment.

5) Contaminated water moves through the undisturbed, unsaturated zone (vadose zone) below the disposal facility down to the unconfined aquifer. The contaminants may interact with soil sediments causing further retardation. Changes to the properties of the natural system are considered, but are not major.



6) The water and contaminants move and mix with the water in the unconfined aquifer until they are extracted from the aquifer and brought to the surface or until they reach the Columbia River.

7) Contaminants are extracted by being carried to the surface with groundwater being pumped through a well.

8) The contaminants result in human exposure through a variety of exposure pathways (ingestion, inhalation, dermal contact, and external radiation).

The 1998 ILAW PA (Mann 1998a) showed that the second most mobile radionuclides (such as uranium and its daughters) peaked at about 50,000 years, a time at which the most mobile radionuclides (technetium, selenium, and many chemicals) were still significant. Explicit numerical simulations will be performed from the present to 100,000 years in the future (i.e., twice the time for the peak all-pathways dose) using best-estimate values for all parameters. Comparisons to the performance objectives will be made at 1,000 years and at 10,000 years after closure of the ILAW disposal facility (which is assumed to be in 2030).

Figure 3-1. Eight Sequential Steps for the Groundwater Pathway

3.3.3 Air Pathway

The previous performance assessment (Mann 1998a) showed that using conservative assumptions that releases to the atmosphere are many orders of magnitude (four in the case of radon releases and nine for other gases) less than performance objectives. As in the 1998 ILAW PA, diffusion of gaseous species will be treated.

3.3.4 Inadvertent Intruder Scenarios

Following the practice of the Nuclear Regulatory Commission (NRC 1988, NRC 1997), three scenarios were considered:

- A basement is excavated which extends into the waste and hence contaminants are brought to the surface,

- A well is drilled through the waste, bringing contaminants to the surface,
- Contaminants that have been brought to the surface are mixed with the surrounding soil as a residential farmer works the soil.

Because the waste will be below (> 5 meters) the levels that basement excavations are dug in the Columbia Basin region, the first scenario (basement excavation) is not treated. The other two scenarios are treated.

3.3.5 Natural Event Scenarios

The main natural events to be expected are 1) erosion of the surface above this disposal units due to wind, 2) subsidence of the engineered barriers or facilities, 3) earthquakes, and 4) flooding due to post-glacial events. As in the 1998 ILAW PA, the first three events will be treated as part of the degradation of the disposal facility, while a simple calculation will estimate the effect of post-glacial flooding.

3.4 COMPUTER CODES

3.4.1 Introduction

Computer codes will be used for four purposes:

Selection processes resulted in newer codes than used in the 1998 ILAW PA.

- calculate contaminant release rates from the waste packages and from the disposal facility,
- calculate moisture flow and contaminant transport in the vadose zone,
- calculate moisture flow and contaminant transport in groundwater, and
- merge the results of the other codes.

For the first three codes, the code selection criteria, code selection, and verification packages have been published and are described below. The code that merges the results will be discussed in the 2001 ILAW PA itself.

3.4.2 Waste Form Release and Near-Field Contaminant Transport Code

The 1998 ILAW PA showed that a key intermediate result is the waste form release rate, which is calculated over thousands of years. The code selection criteria and selection process is documented in *Selection Of A Computer Code For Hanford Low-Level Waste Engineered-System Performance Assessment* (McGrail 1998a), which is included as Appendix C of this document. The needed capabilities were identified from an analysis of the important physical and chemical processes expected to affect LAW glass corrosion and the mobility of radionuclides. The available computer codes with suitable capabilities were ranked in terms of

the feature sets implemented in the code that match a set a physical, chemical, numerical, and functional capabilities needed to assess release rates from the engineered system. The highest ranked computer code was found to be the STORM code developed at PNNL for the U.S. Department of Energy for evaluation of arid land disposal sites. The verification studies for STORM are documented in *Subsurface Transport Over Reactive Multiphases (STORM): A General, Coupled, Nonisothermal Multiphase Flow, Reactive Transport, and Porous Medium Alteration Simulator, Version 1.09, User's Guide* (Bacon et. al. 2000), which is included as Appendix D.

3.4.3 Vadose Zone Moisture Flow and Contaminant Transport Code

The selection process for the vadose zone code was more formal. The code selection criteria were determined (Mann 1998b) and vendors formally submitted proposals which were formally evaluated (Voogd 1999). These latter documented which includes the code selection criteria is attached as Appendix E. The code selection criteria were heavily based on those used in the code selection for the earlier ILAW PAs (Mann 1996) which themselves were based on DOE and NRC criteria. The VAM3DF code, an earlier version of which has been approved by the DOE, EPA, and Washington State Department of Ecology for vadose zone calculations (TPA Milestone 29-2) was selected. Documentation on verification of VAM3DF (Finfrock 2000) can be found in Appendix F.

3.4.4 Groundwater Flow and Contaminant Transport Code

The Richland Operations Office (DOE-RL 1996b) has directed the Hanford Groundwater Program to establish a single groundwater model for the Hanford Site. As a followup to this directive, RL initiated a project in FY 1997 to consolidate multiple groundwater models at the Hanford Site into a single consolidated site-wide groundwater model. The overall recommendations made by RL to select the site-wide groundwater model in the initial phase of the consolidation process are documented in DOE-RL (2000). In this effort, RL initiated an evaluation of computer codes for implementation with the consolidated site-wide groundwater model. Only two computer codes were reviewed in this initial phase of the model-consolidation process: 1) the VAM3D-CG code developed by Hydrogeologic, Inc., in Herndon, Virginia, and 2) the CFEST-96 code developed by the CFEST Co. in Irvine, California. The GWRS model is implemented based on the VAM3D-CG code. The HGWP model is based on the CFEST-96 code. In a qualitative comparison of the two computer codes, both VAM3D-CG and CFEST-96 were found to be technically acceptable because they

- were included in the list of accepted groundwater flow and transport codes identified in Milestone M-29-01 (DOE/RL 1991)
- met the technical capabilities and administrative requirements outlined in the original Milestone M-29-01 document and generally met the technical capabilities and administrative requirement in this report.

In the interest of minimizing initial cost and potential schedule impacts, RL selected the CFEST-96 code as an interim code for implementing the consolidated site-wide groundwater model since it was already implemented with the selected conceptual and numerical model. Documentation of the specific application of the CFEST code to the selected site-wide groundwater flow and transport model at Hanford is provided in Wurstner et al. (1995), Cole et al. (1997), and Kincaid et al. (1998).

RL deferred decisions on final selection of the code until the external peer review of the consolidated site-wide groundwater model and the resulting final refinements and modifications have been completed. When this first phase of the model-consolidation process is completed, RL may consider more in-depth testing and benchmarking of the CFEST-96, VAM3D-0CG, and other applicable codes using the refined and modified site-wide groundwater model before reaching a final decision on selection of a code.

3.5 CALCULATIONAL STRATEGY

The calculational strategy adopted for this performance assessment has been to provide the best estimate for the performance of this disposal action against the performance assessment objectives outlined in section 3.2 of this report. This best estimate calculation is based on the best estimates for the data used in the computer codes to calculate the transport of contaminants from the waste site to the receptors for the various scenarios calculated within this performance assessment.

The authors recognize that there are uncertainties associated with these calculations and the calculational approach. In a broad sense these uncertainties are associated with our understanding of the physical system performance, uncertainty in the models used to approximate the physical system, uncertainty in the codes used to model the transport, and uncertainty in the data input into these codes. An estimate for uncertainty in the data input to the code calculations is provided within the data reports summarized in section 4.0. The other uncertainties are explored through a set of sensitivity calculations where bounding values are used in the calculations for different physical system assumptions. This approach is undertaken in an attempt to convince both the regulators and the public that the proposed disposal action is "acceptable."

4.0 DATA

4.1 INTRODUCTION

The data to be used in the calculations of the 2001 ILAW PA are described in this section. For most of the topics, the ILAW PA activity has maintained an energetic data gathering and interpretation activity. For other activities (for example, disposal facility design and dosimetry) closely coupled interfaces were developed with those responsible for the information either at the ILAW project level or at the Hanford Site level.

In each subsection, the methods used to generate the values are described and the values for the most important parameters are given. Full details are given in appendices G through N which contain the reports on which this chapter is based. These reports have all undergone Hanford review and several reports (Appendices J, L, M, and N) have undergone external review.

4.2 LOCATION/GEOLOGY

The current plan (Burbank 1999, Taylor 1999a) is to construct new facilities in the south central part of the 200 East Area (Rutherford 1997). Although the existing disposal vaults at the central eastern edge of the 200 East Area are not planned to be used, they will be analyzed as they may be used in the future.

The current plan is to use new facilities in the south-central part of Hanford's 200 East Area. The geology of this area is based on a new borehole as well as reexamining samples from previous holes. The resulting geologic data are more detailed and believed to be more accurate.

The geology of the two disposal sites is given in *Geologic Data Package for the 2001 ILAW PA* (Reidel 1999) which is attached as Appendix G. The Hanford Site lies in the Pasco Basin of the Columbia Plateau. The Columbia Plateau consists of a sequence of thick basalt flows that occurred 5 to 7 million years ago. Overlying the basalt flows are sediments of the late Miocene, Pliocene, and Pleistocene ages, known as the Ringold Formation and (nearer the surface) the Hanford formation. The Hanford formation arises from deposits from post-glacier flooding (between 780,000 years ago and 13,000 years ago) and consists mainly of unconsolidated sand and sandy gravel layers. The unconfined aquifer is near the interface between the Hanford formation and Ringold Formation throughout the Hanford Site and at the disposal sites is about 80-95 meters (262-312 feet) below the surface. Clastic dikes have been observed at the existing disposal site are assumed to exist at the new ILAW site as well.

Data used in the (Reidel 1999) report compilation was obtained from surface geologic studies and from borehole data. The surface geology and geomorphology of the Hanford Site has been mapped and published by Reidel and Fecht (1994a, 1994b). Borehole data consisting of drilling logs, archived samples and geophysical logs are the principal data sets used to interpret the subsurface at the existing disposal site and the new ILAW disposal site. In addition, numerous

reports describing the geology of the area and vicinity are available and are a valuable source of information (e.g., Tallman et al. 1979; DOE 1988; Connelly et al. 1992; Lindberg et al. 1993, Lindsey et al. 1992, 1994b). During the course of this study, archived natural gamma geophysical logs from boreholes at the new ILAW site and surrounding area were located and the logs were incorporated into the interpretations. Geophysical logs include boreholes from surrounding waste disposal sites obtained prior to discharge of effluent and provide a valuable source of information for stratigraphic correlations.

Elevation information were obtained from well completion reports or as-built diagrams if available, or from Chamness and Merz (1993). Because the boreholes are from so many vintages and because several different surveys have been used at the Hanford Site over the years, no attempt was made to assure consistency in the elevation survey data. However, differences among surveys are generally small (<3 feet; 1 m) with respect to other uncertainties associated with the data and, except for water levels in areas with a relatively flat water table, will not affect significantly the information presented in this database.

The methodology used in the process of building the data package followed a series of steps that were designed to insure the data were used properly. First, the main stratigraphic units and contacts were identified in boreholes with geologist's logs and geophysical data. Gross gamma-ray logs were examined with respect to the geologist's logs for geophysical signatures of the stratigraphy. For many boreholes from both sites, chip samples from the Hanford Geotechnical Sample Library were examined to help control the location of contacts and lithologies of stratigraphic units and lateral changes in the percentage of silt, sand, and gravel. Next, boreholes with driller's logs and gross gamma-ray logs were examined and compared to nearby wells and boreholes. At the new ILAW site, the stratigraphy was built out from borehole 299-E17-21 using boreholes with geologist's logs and geophysical logs. Boreholes for which only driller's logs were available were given the least priority for constructing the geologic models.

The stratigraphy at the existing disposal vaults site has the top of the Columbia River Basalt Group at an elevation (above sea level) of approximately 91 m (300 ft). The top of the Ringold Formation ranges between 113-128 m (370-420 ft). The average thickness of the Unit A sequence within the Ringold Formation is 23.7 m (78 ft). The average thickness of the Ringold Formation fine-grain sequence above the Unit A sequence is 5.5 m (18 ft). In some areas beneath the existing disposal site this formation is not present. The Hanford Formation gravel sequence is approximately 31m (102 ft) thick; and the Hanford Formation sand sequence varies from 41 to 67 m (134-220 ft). Finally, recent surface deposits range in thickness between 1.5-4.5 m (5-15 ft). The current water table is in the Ringold Formation fine-grain sequence or in the Hanford Formation gravel sequence.

The stratigraphy at the new ILAW disposal site has the top of the Columbia River Basalt Group at an elevation (above sea level) of approximately 84 m (275 ft). The top of the Ringold Formation ranges between 91-122 m (300-400 ft). The Hanford Formation gravel sequence thickness is approximately 27-46m (88-150 ft) thick; and the Hanford Formation sand sequence varies from 64 to 76 m (210-250 ft). Within the sandy sequence three paleosols were identified. Finally, Eolian deposits cover the southern part of the new ILAW disposal site and range in

thickness between 3 to 15 m (10-50 ft). The current water table is in the Hanford Formation gravel sequence below the new disposal site.

4.3 INVENTORY

The environmental or health impact of each radionuclide or chemical is proportional to the amount of the material at the point of impact. However, normally it is the sum of these impacts over materials at the point of impact that is important. Thus, as shown by the previous Hanford Site performance assessments (see Section 1.3), particularly the last version of the ILAW PA, the significant materials are the most mobile due to the long travel times of the other materials. This section summarizes the data in the *Immobilized Low-Activity Tank Waste Inventory Data Package* report (Wootan 1999) that is included as Appendix H in this document.

Both radionuclide and chemical inventory are given. The radionuclide and inorganic material inventory is based on the current best basis estimates of what is the tank waste inventory corrected for the separation that will occur during the treatment phase as well as contract limits. The organic material inventory is based on RCRA disposal limits.

The ^{99}Tc inventory (5,790 Ci) is lower than in the 1998 ILAW PA because 80% of the Tc will be removed according to the current contract with BNFL.

Both radionuclides and chemicals are considered in this performance assessment. Although DOE O 435.1 only requires performance assessments for radionuclides, the Office of River Protection of DOE along with the Washington State Department of Ecology have determined that the technical analyses should support the Resource Conservation and Recovery Act (RCRA) permitting requirements as well. Thus, one technical analysis will serve as the basis for protection of the public under the requirements of the Atomic Energy Act and RCRA.

Forty-six radionuclides and twenty-five chemicals are explicitly treated in the best basis tank inventories. These materials were selected by the TWRS Characterization Program (Kupfer 1999) as those important for safety, disposal, and processing requirements. This set includes all the radionuclides identified as significant in the 1998 ILAW PA (Mann 1998a) as well as those identified in the screening studies for the ILAW PAs (Schmittroth 1995). The chemicals identified in the 2001 ILAW PA performance objectives (Mann 1999a) that are not listed in the tank inventories should not survive the vitrification process. Therefore, their upper bound concentrations in the waste form were set equal to the concentration limits for land disposal (40 CFR 268).

The nominal ILAW inventories for all the materials explicitly included are based on the *Tank Waste Remediation System Operation and Utilization Plan* (Kirkbride 1999), also known as the TWRSO&UP. The best basis tank by tank inventories (BBI) as of October 1, 1998 were adjusted for waste transfers not accounted for in the BBI, and for non-BBI analytes that are in the waste treatment contract. The BBI inventories were adjusted to a common date (October 1, 1998). The BBI values are based on a tank by tank evaluation of measurements from tank samples as well as modeling results of transfers to and from the tank. The retrieval and feed

delivery process was modeled by estimating liquid and solid partitioning (Hendrickson 1998) and by following the April 1, 1999 DOE guidance (Taylor 1999b) on schedules and contract requirements. Vitrification losses were explicitly included in the model and are described in Kirkbride 1999).

As noted in the 1998 ILAW PA, the previously accepted half-lives of ^{79}Se and ^{126}Sn are now thought to be underestimates. This underestimate for ^{126}Sn has been confirmed (Brodzinski 1999). Thus, inventories for ^{79}Se and ^{126}Sn in the TWRSO&UP have been multiplied by 0.08 and 0.40, respectively.

Table 4.1 provides the total inventory in the tanks and in the ILAW packages as well as the expected average and maximum concentration in the ILAW packages for each radionuclide and chemical considered. The following provide short descriptions of key materials:

- ^{3}H: No tritium is expected to survive the vitrification process to end up in ILAW packages (Kirkbride 1999).
- ^{14}C: No ^{14}C is expected to survive the vitrification process and end up in the ILAW packages (Kirkbride 1999).
- ^{79}Se: Results are based on models, but are considered conservative, since the model neglects previous removals such as disposals to cribs.
- ^{90}Sr: Values are constrained by the current contract (DOE/BNFL 1998) and assumption that this constraint applies to all ILAW waste.
- ^{99}Tc The values are felt to be conservative because the shipments to off-site are neglected. Values are also constrained by the current contract (DOE/BNFL 1998) and assumption that this constraint applies to al ILAW waste.
- ^{126}Sn Results are based on models that overestimate the distribution in tanks 241-AZ-101 and 241-AZ-102.
- ^{129}I The values are felt to be conservative since no credit was taken for losses of iodine to the atmosphere during processing.
- ^{137}Cs Values are constrained by the treatment contract (DOE/BNFL 1998).
- U Many of the values are based on total uranium analysis of samples.
- ^{237}Np The BBI inventory is 30% higher than the global estimate. Two tanks (241-An-103 and 241-AN-105) are thought to have the bulk of the Np, but only "bounding value estimates" are available for those two tanks.
- Pu Values are primarily based on accountability records and samples.

Table 4.1 ILAW Package Inventories (Ci for radionuclide and kg for chemical) and Concentrations (Ci/m^3 for radionuclide and kg/m^3 for chemical)

Material	Tank Inventory	ILAW Inventory	Average Package Concentration	Maximum Upper Bound Package Concentration
3-H	2.46E+04	0.00E+00	0.00E+00	4.66E-01
14-C	4.38E+03	0.00E+00	0.00E+00	8.00E+00
59-Ni	8.58E+02	1.67E+02	1.06E-03	6.20E-02

Material	Tank Inventory	ILAW Inventory	Average Package Concentration	Maximum Upper Bound Package Concentration
60-Co	1.99E+04	4.18E+03	2.64E-02	4.39E+00
63-Ni	8.45E+04	1.62E+04	1.02E-01	7.00E+02
79-Se	5.74E+01	4.80E+01	3.03E-04	2.55E-02

Footnotes:

Inventories for radionuclides are as of 10/1/98.

NA entries refer to components where inventory information is not available.

The ^{90}Sr will have ^{90}Y daughter in equilibrium. The ^{137}Cs will have ^{137m}Ba daughter in equilibrium.

Tank inventories of specific organics are not available. Organics are not expected to survive the vitrification process.

4.4 DISPOSAL FACILITY DESIGN

The design for the ILAW disposal facility (trenches with surface barrier) is based on the mixed waste disposal facility at the Hanford Site. This is a major change from the 1998 ILAW PA which is based on a pre-conceptual design using concrete vaults. Also, conceptual designs have been published for the use of concrete vaults for ILAW.

This section summarizes the data given in *Disposal Facility Data for the Hanford Immobilized Low-Activity Tank Waste* (Puigh 1999), which is included as Appendix I of this document.

The Immobilized Low-Activity Waste (ILAW) disposal planning was to utilize the existing disposal vaults from the grout program suitably modified to receive ILAW packages and new disposal facilities currently in their early design phase. In December 1999 the Department of Energy identified the remote handled trench as the baseline concept for ILAW disposal at Hanford (Taylor 1999a). The 2001 ILAW PA will consider both concepts in assessing long term environmental impacts from the proposed disposal action.

The existing disposal vaults were originally constructed in the late 1980's and early 1990's. These vaults were designed to contain a liquid low-level waste (LLW) grout mixture during the curing and solidification period, and to serve as a disposal structure for the resulting grouted waste monolith. Five vaults were constructed. One vault was filled before termination of the program leaving four empty vaults available for use.

Each vault is 37.6 m (123.5 ft) long and 15.4 m (50.5 ft) wide, with a roof clearance of 10.4 m (34.0 ft), providing 579 m^2 (6,236 ft^2) of floor space. The vaults are constructed of reinforced concrete, and were designed and constructed in compliance with RCRA requirements for both hazardous waste surface impoundments and land disposal units. Each vault is built above a RCRA-compliant leak detection and collection system. The leak detection system consists of a sealed concrete slab sloped to a collection sump fitted with a riser pipe to the surface. The system is capable of collecting, detecting, sampling, and removing any leachate that might escape from the primary vault structure.

A conceptual design activity has been performed to modify the existing disposal vaults to accept and ultimately serve as a disposal facility for the ILAW from the Hanford waste tanks (Pickett 1998a). The existing asphalt layer and concrete "topping" layer above the precast concrete roof slabs will be removed from the four available vaults. For each vault, side wall and end wall extensions 1.8 m (6.0 ft) high will be added to the original top of the side and end walls,

respectively. To support the unloading of ILAW packages from the transportation vehicles, rails for a gantry crane are to be placed on top of the side wall extensions and will run the full length of the vaults.

A conceptual design for the new ILAW disposal facilities (Pickett 1998b) utilizes a long concrete vault concept divided into cells. Each vault will be an underground, open-topped, concrete vault approximately 23 m (76 ft) wide, 207.8 m (686 ft) long, and 8.1 m (26.7 ft) deep below grade. The top of the vault walls will extend 1 m (3.3 ft) above grade. Each vault will be divided into 11 cells, separated by concrete partition walls.

Each vault is built above a RCRA-compliant leak detection and collection system. It consists of a cast-in-place reinforced concrete basin approximately 209.5 m (687.0 ft) long, 24.7 m (81 ft) wide with walls 1.07 m (3.5 ft) high. The basin floor is 0.6 m (2 ft) thick and contains steel reinforcing bars within. The catch basin is lined with two flexible membrane liners, and on top of these lie a layer of gravel with perforated collection pipe routed to sumps, one at each end of a vault. Liquids entering the sump can be removed by use of a portable pump lowered down a riser pipe.

Interim closure for each filled cell in the new disposal facility will consist of using inert backfill material followed by a "controlled density fill," unreinforced concrete. A waterproof membrane will be placed above the "controlled density fill." After all cells in the vault have been filled and interim closed, a closure cap consisting of a capillary break followed by a modified RCRA Subtitle C cap will be placed over the entire vault. A similar closure is assumed for the existing disposal vaults. Each vault will be interim closed using the process used for the cell closure for the new disposal facility. After all vaults have been filled and interim closed, a similar closure cap will be placed over all four vaults.

One trench concept that is receiving additional consideration is the Remote Handled (RH) trench concept. Under the ILAW disposal alternative described below, the disposal facility is a Resource Conservation and Recovery Act (RCRA) compliant landfill (i.e., double lined trench with leachate collection system). Many operational aspects and ancillary activities of the landfill (e.g., leachate collection and disposition, storm water control, installation of surface barrier at closure, etc.) would be similar to that incorporated into the Radioactive Mixed Waste Burial Trench, which was designed and constructed under the Solid Waste Program. However, operational activities related to ILAW package receipt and emplacement in the trench would be modified to accommodate the potentially higher radiation dose rate from remote-handled ILAW.

The RH trench complex would be constructed in the same location as the new ILAW disposal facility. The RH trench internal dimensions 260 m long by 80 m wide by 10 m deep. The trench sides have a 3:1 slope.

The current waste package design consists of a cubic, stainless steel package having outer dimensions of 1.4 m on each side. The package is filled to within 85% capacity with the remaining volume filled with silicate sand. The void volume will be less than 5% (by volume). Current plans for waste loading into each disposal facility design is as follows. Each existing disposal vault would contain seven layers of waste packages with 25 x 10 packages on each

layer. Each cell within the new ILAW disposal facility vault would contain six layers of waste packages with 12 x 14 packages on each layer. Finally, each remote handled trench would have the packing characteristics outlined in Table 4.2.

Table 4.2 Trench Packing Characteristics

Layer	Cells per layer	Matrix size per cell	Packages per layer
1	2	6 x 132	1,584
2	3	6 x 140	2,520
3	4	7 x 150	4,200
4	6	6 x 160	5,760
		Total packages per trench	14,064

The design for the ILAW disposal facilities has not yet been finalized. Facility uncertainty cases have been identified that may impact disposal performance. For example, the following sensitivity cases have been identified: waste form geometry and waste loading into the glass, new facility vault layout with respect to geometry and groundwater flow, different options for closure, inclusion of a capillary break or side wall diverter into the design, and early failure of the system.

4.5 RECHARGE

Recharge rates are based on lysimetry and tracer measurements as well as computer simulations. The recharge rate for the surface barrier (0.1 mm/year) is reduced from the 0.5 mm/year value in the 1998 ILAW PA. Two natural rates (0.9 and 4.2 mm/year) are given based on the type of surface soil. These rates straddle the value used in the 1998 ILAW PA (3.0 mm/year).

The term recharge is used to denote the rate at which moisture flows past the root zone (that is, very near surface) into a region where moisture flow follows simpler models. Recommendations for recharge rates are taken from *Recharge Data Package for the Immobilized Low-Activity Waste 2001 Performance Assessment* (Fayer 1999), that is reproduced in Appendix J of this document. Long-term estimates of moisture flux through the ground surface are needed for a fully functional surface cover, the cover sideslope, the immediate surrounding terrain (Pre-Hanford), as well as for degraded cover conditions. The estimates were derived from lysimeter and tracer measurements collected by the ILAW PA activity and by other projects combined with a modeling analysis.

Values for the recharge are given in Table 4.3. Values are given for two separate surface soils, Rupert sands and Burbank loamy sands. The Rupert sands are located at the site of the existing grout vaults and at the southernmost 60% of the new ILAW disposal site. The Burbank loamy sand is located at the northernmost 40% of the new ILAW disposal site. Impacts from degradation of the barrier, vegetation change, climate change, and irrigation were considered in establishing the best estimate and bounding values.

Table 4.3 Recharge Rate Estimates (mm/year) [a]

Surface feature	Pre-Hanford	Construction	Cover design Life	Post Cover Design Life
Surface cover	na	na	0.1 (0.01, 4.0)	0.1 (0.01,4.0)
Cover sideslope	na	na	50 (4.2, 86.4)	50 (4.2, 86.4)
Rupert sand	0.9 (0.16, 4.0)	0.9 (0.16, 4.0)	0.9 (0.16, 4.0)	0.9 (0.16, 4.0)
Burbank Loamy sand	4.2 (2.8, 5.5)	4.2 (2.8, 5.5)	4.2 (2.8, 5.5)	4.2 (2.8, 5.5)
Construction	na	55.4 (50, 86.4)	na	na
na = not applicable				

a best estimate case given, with values for reasonable bounding cases given in parentheses.

4.6 RELEASE RATE FROM THE WASTE FORM PACKAGE

4.6.1 Introduction

The 1998 ILAW PA showed that the release rate from the waste form was one of the key parameters in the performance assessment. This rate is a major determinant of the impact of disposal as well as setting the temporal structure of that impact. The data for determining the waste form release rate are given in *Waste Form Release Data Package for the 2001 Immobilized Low-Activity Waste Performance Assessment* (McGrail 1999) which is also included as Appendix K to this document.

Key parameters needed to calculate waste form release rates are based on an extensive series of measurements of glasses thought to be in the compositional space of the ILAW product. Data for other needed reaction rates are taken from standard chemical databases. In contrast, the release rate assumed in the base case of the 98 ILAW PA was based on a release rate of 4.4 ppm/year.

The release rate is a function of both the release rate from the glass as well as retardation because of the formation of secondary phases. Because these rates depend on a variety of parameters (amount of moisture, amount of silic acid [the main by-product of dissolved glass] in solution, pH, amount and type of secondary phases) which will vary with time, the release rate must be calculated. However, in order for the calculations to be believed they must be based on an accepted paradigm and an extensive database.

4.6.2 Paradigm for Waste Release

The paradigm for the calculations and the data to support the calculations are given in A Strategy to Conduct an Analysis of the Long-Term Performance of Low-Activity Glass in a Shallow Subsurface Disposal System at Hanford (McGrail 1998b). This document has been favorably reviewed (Wicks 1999) by an internationally known set of experts (Dr. Bernd Grambow, Dr. Etienne Vernaz, Prof. Werner Lutze, Dr. Elmer Wilhite, and Dr. George Wicks) who were selected by the DOE Environmental Science Program.

The main thrust of the paradigm is that there are a few equations, which define the rate-determining step in waste form release. Over the last few decades, a general rate equation has been fashioned to described the dissolution of glass (and more ordered materials) into aqueous solution:

$$k_i = \overset{\mathbf{v}}{k} \nu_i a_{H^+}^{-\eta} e^{\frac{-E_a}{RT}} \left[1 - \left(\frac{Q}{K}\right)^{\sigma}\right] \prod_j a_j \qquad (1)$$

where: k_i = dissolution rate, g/m²/d
$\overset{\mathbf{v}}{k}$ = intrinsic rate constant, g/m²/d
ν_i = the stoichiometric coefficient of element i in the glass (dimensionless)
a_{H^+} = hydrogen ion activity
a_j = activity of the j^{th} aqueous species that acts as an inhibitor or as a catalyst of dissolution
E_a = activation energy, kJ/mol
R = gas constant, kJ/mol·K
T = temperature, K
Q = ion activity product
K = pseudoequilibrium constant
η = pH power law coefficient
σ = Temkin coefficient.

As glass is metastable, the reaction proceeds one way (i.e. glass dissolves).

However, there are a number of reactions, that depending on the amount of constituents and other environmental parameters could go either way. The most important of these are the ion exchange reaction and the formation of secondary phases. The waste form will contain high concentrations of sodium (up to 25 weight percent). At the temperatures of interest, the exchange of sodium in the glass with hydrogen in the water is important as the reaction effectively increases the pH of the solution. Secondary reactions are important because they can strip chemicals from the aqueous solution, affecting the glass corrosion rate or trapping important contaminants.

4.6.3 Waste Form Experiments

The parameters in these equations are established by a set of various experiments, performed at various temperatures and pHs:

- single-pass flow-through test
- product consistency test
- vapor hydration test
- pressurized unsaturated flow-through test.

4.6.3.1 Single-Pass Flow-Through Test

The single-pass flow-through test has solutions of known chemistry flow (at various rates) through a container with glass samples at various temperatures. Such tests determine the intrinsic rate constant (k) of the glass as a function of the various conditions. Many experiments have shown that this rate (also known as the forward rate) is the maximum rate at which glass can dissolve for the given conditions. A limitation of this test is that only very short-term behavior can be determined.

4.6.3.2 Product Consistency Test

The product consistency test was established to compare glasses produced over periods of time (i.e., the consistency of the glass making process). The test, which involves placing a crushed glass in a solution at a fixed temperature, allows long-term testing of glasses to determine how they will behave as the environment surrounding them changes (although in an uncontrolled manner). The major limitations of this test are that the environment changes in an uncontrolled manner and (for ILAW disposal) the test is conducted under saturated conditions.

4.6.3.3 Vapor Hydration Test

The vapor hydration test involves moisture attack at high temperatures (i.e. vapors) which accelerates the dissolution of glasses and the formation of secondary phases. The major limitation of this test is that being performed at much higher temperatures (> 100 °C) than those of interest (14 °C), this test could be emphasizing processes not important at lower temperatures and missing processes important at the lower temperatures.

4.6.3.4 Pressurized Unsaturated Flow-Through Test

The pressurized unsaturated flow-through test involves flowing unsaturated water with known chemistry through glass samples (which may be crushed, fractured, or in some other form). This test can be used to investigate a variety of conditions as the chemical environment can be monitored and controlled. The major limitations of this test are its newness and its complexity. However, this test comes closest to what will happen in the disposal facility.

4.6.4 Other Data Sources

Data for the reactions other than the main glass reactions come mainly from the literature. However, the test conditions described above were used to establish reaction rate constants for the ion exchange reaction and for the important secondary phases.

4.6.5 Data Values for Glasses

The exact glass composition that BNFL, Inc will used for ILAW has not been determined. The ILAW PA activity has worked with BNFL, Inc and the DOE Environmental Science program to investigate a set of glasses in the BNFL, Inc. processing space. For the 2001 ILAW PA, the base analysis case uses LAWABP1 as the reference glass. This glass has the most extensive database of any glass in its compositional space. The composition of LAWABP1 is based on the composition of preliminary BNFL, Inc. glasses. BNFL, Inc. has indicated that the composition of LAWABP1 remains in their design space. Table 4.4 provides a summary of the best-estimate values for parameters important in calculating contaminant release from the LAWABP1 glass waste form.

Table 4.4 Summary of Best Estimate Parameters for LAWABP1 Glass

Parameter	Meaning	Value	Test Method	Evaluation Method
Kinetic Rate Law Parameters				
$\overset{v}{k}$	intrinsic rate constant	3.5×10^{5} g m^{-2} d^{-1}	SPFT	Substitution of regressed coefficients
K_g	apparent equilibrium constant for glass based on activity product $a[AlO_2^-] \cdot a[SiO_2(aq)]$	3.6×10^{-10}	SPFT	Linear regression
η	pH power law coefficent	0.5	SPFT	Linear regression
E_a	activation energy of glass dissolution reaction	75 kJ/mol	SPFT	Nonlinear regression
σ	Temkin coefficient	1		LD6-5412 data
r_x	Na ion-exchange rate	3.5×10^{-6} mol/(m^2·d)	SPFT	Linear regression
Secondary Mineral Phases				
$\log_{10} K_1$	$Al(OH)_3$(am)	-13.10	PCT[a]	log K adjusted to fit PCT data

(b) Solid phases identified from direct observation of reacted solids

4.7 HYDROLOGY

4.7.1 Overview

Hydrologic processes describe how moisture moves through the subsurface. Because there are distinct regions associated with subsurface flow and transport at the ILAW disposal facilities, the system has been divided into three parts: near-field, far-field, and groundwater.

4.7.2 Near-Field Hydrology Data

The best-estimate and bounding values for the near-field hydrologic parameters were based on literature values as well as measurements done especially for this activity. The values are similar to those of the 1998 ILAW PA.

The processes and data important for moisture flow in the near-field, that is, the zone between the surface and the bottom of the engineered disposal facility is described in *Near-Field Hydrology Data Package for the Immobilized Low-Activity Waste 2001 Performance Assessment* (Meyer 1999), which is reproduced as Appendix L. Physical and hydraulic properties (particle size distribution, particle density, bulk density, porosity, water retention, and hydraulic conductivity as a function of moisture content) and associated transport parameters (dispersivity and effective diffusion

coefficient) are given for materials of the surface cover, the vault structure, diversion layers, the water conditioning layer, and the backfill materials. Table 4.5 presents best-estimate parameter values for near-field materials. Best estimate values for transport parameters can be found in chapter 5 of *Near-Field Hydrology Data Package for the Immobilized Low-Activity Waste 2001 Performance Assessment* and are not repeated here because of their length.

Table 4.5 Best-Estimate Hydraulic Parameter Values For Near-Field Materials

Material	ρ_p (g/cm^3)	ρ_b (g/cm^3)	θ_s	θ_r	α (cm^{-1})	n	K_s (cm/s)
Silt Loam-Gravel admixture	2.72	1.48	0.456	0.0045	0.0163	1.37	8.4×10^{-5}
Compacted Silt Loam	2.72	1.76	0.353	0.0035	0.0121	1.37	1.8×10^{-6}
Sand Filter	2.755	1.88	0.318	0.030	0.538	1.68	8.58×10^{-5}
Gravel Filter	2.725	1.935	0.290	0.026	8.1	1.78	1.39×10^{-2}
Gravel Drainage	2.725	1.935	0.290	0.006	17.8	4.84	2.0
Asphaltic Concrete	2.63	2.52	0.04	0.000	1.0×10^{-7}	2.0	1×10^{-11}
Vault Concrete	2.63	2.46	0.067	0.00	3.87×10^{-5}	1.29	1.33×10^{-9}
Vault Filler Material	2.63	1.59	0.397	0.005	0.106	4.26	3.79×10^{-2}
Glass Waste	2.68	2.63	0.02	0.00	0.2	3	0.01
Diversion Layer Sand	2.8	1.65	0.371	0.045	0.0683	2.08	3.00×10^{-2}
Diversion Layer Gravel	2.8	1.38	0.518	0.014	3.54	2.66	1.85
Backfill	2.76	1.89	0.316	0.049	0.035	1.72	1.91×10^{-3}
Conditioning layer	2.73	1.59	0.397	0.005	0.106	4.26	3.79×10^{-2}

ρ_p = particle density ρ_b = dry bulk density θ_s = saturated water content
θ_r = residual water content α,n = van Genutchen fitting parameters
K_s = saturated hydraulic conductivity

A discussion of uncertainty in the estimated parameter values and reasonable bounds for parameter values are also presented in the document.

4.7.3 Far-Field Hydrology

The best-estimate and bounding values for the far-field hydrologic parameters were based on samples from the ILAW boreholes as well as other boreholes in the 100 Area. Laboratory measured data were upscaled using stocastic theory. The values are similar to those of the 1998 ILAW PA.

The processes and data important for moisture flow and contaminant transport in the far-field, that is, the region between the bottom of the engineered disposal facility and the water table are described in *Far-Field Hydrology Data Package for the Immobilized Low-Activity Waste Performance Assessment* (Khaleel 1999), which is reproduced as Appendix M. This document summarizes the hydraulic parameter estimates based on data from the ILAW borehole and data on gravelly samples from the 100 Area boreholes. The document also describes the processes for upscaling such small-scale laboratory measurements to field-scale applications, and provides recommendation for parameter estimates

to be used at that scale. Table 4.6 provides the best estimate values for parameters impacting moisture flow. Best estimate values for transport parameters (bulk density, diffusivity, and dispersivity) are also described in *Far-Field Hydrology Data Package for the Immobilized Low-Activity Waste Performance Assessment*. The document also presents an overall approach for sensitivity and uncertainty analysis for far-field flow and transport predictions.

Table 4.6 Best-Estimate Hydraulic Parameter Values For Far-Field Layers

Formation	Number of samples	θ_s	θ_r	α (1/cm)	n	ℓ	K_s (cm/s)
Sandy	20	0.375	0.041	0.057	1.768	0.5	2.88E-03
Gravelly	15	0.138	0.010	0.021	1.374	0.5	5.60E-04

θ_s = saturated water content
θ_r = residual water content
α,n = van Genutchen fitting parameters
ℓ = pore size distribution factor
K_s = saturated hydraulic conductivity

4.7.4 Groundwater

Groundwater hydrology is an integral part of the Hanford Sitewide model. As was noted in Section 3.4.4, this model is mandated for Hanford Site use. Information on the hydrology used can be found in Cole 1997.

4.8 GEOCHEMISTRY

Geochemical values (solubilities and K_ds) are based on site-specific samples for the most part, but in a few cases depend on literature values or chemical similarity. Values are given for 5 zones (having different soil properties and impacts from released waste). These values are similar to the values used in the 1998 ILAW PA.

Geochemical effects are based on the discussion and values presented in *Geochemical Data Package for the Hanford Immobilized Low-Activity Tank Waste Performance Assessment* (Kaplan 1999), provided in Appendix N of this document. The geochemistry is described using two parameters, the distribution coefficient (K_d value) and the solubility product of a specified solid. The distribution coefficient is a thermodynamic construct. It is the ratio of the concentration of a species reversibly adsorbed/exchanged to a geomedia's surface site divided by the concentration of the species in solution. Parameters are given for five zones:

1) Near-Field: inside the disposal facility (K_d and solubility values)
2) Degraded Concrete Vault (K_d and solubility values)
3) Chemically Impacted Far-Field in Sand Sequence (K_d values only)
4) Chemically Impacted Far-Field in Gravelly Sequence (K_d values only)

5) Far Field in Gravel Sequence (K_d values only).

Values are based on site-specific samples for the most part, but in a few cases depend on literature values or chemical similarity. The document describes corrections due to the amount of gravel or moisture present. Since the tables are quite extensive, the only full table displayed is the one for K_d values in the gravel sequence of the far-field zone (see Table 4.7). Other important geochemical data (e.g., near-field field values for important radionuclides) are displayed in Table 4.8. Other information is provided in *Geochemical Data Package for the Hanford Immobilized Low-Activity Tank Waste Performance Assessment.*

Table 4.7 Best-Estimate K_d Values For Far-Field Gravel Sequence (a)

Radionuclide	Reasonable Conservative Kd_{gc} (mL/g)	"Probable" Kd_{gc} (mL/g)	Kd_{gc} Range (mL/g)
Ac	6.	30.	6. to 130.
Am	6.	30.	6. to 130.
C	0.05	0.5	0.05 to 100.
Ce	6.	30.	6. to 130.
Cl	0.	0.	0. to 0.06
Cm	6.	30.	6. to 130.
Co	100.	200.	100. to 1250.
Cs	50.	200.	50. to 400.
Eu	6.	30.	6. to 130.
^3H	0.	0.	0. to 0.06
I	0.	0.01	0.0 to 1.5
Nb	5.	30.	5. to 250.
Ni	5.	30.	5. to 250.
Np	0.2	1.5	0.2 to 2.5
Pa	0.2	1.5	0.2 to 2.5
Pb	800.	600.	800. to 8000.
Pu	5.	15.	5. to 200.
Ra	0.5	1.4	0.5 to 20.
Ru	1.	2.	1. to 100.
Se	0.3	0.7	0.3 to 1.5
Sn	5.	30.	5. to 250.
Sr	0.5	1.4	0.5 to 20.
Tc	0.	0.	0. to 0.06
Th	4.	100.	4. to 250.
U	0.05	0.06	0.01 to 8.
Zr	4.	100.	4. to 250.

(a) The aqueous phase is untainted Hanford groundwater except for trace levels of radionuclides; the solid phase is composed of the unaltered gravel-dominated sequence material. Kd_{gc} is the gravel-corrected K_d value.

Table 4.8 Other Important Geochemical Values

Element	Reasonable Conservative	"Best" Value	Range	Zone
Tc	0.1	1	0.1 to 1.2	Zone 1: Near-Field K_d (mL/g)
U	5	20	10 to 800	Zone 1: Near-Field K_d (mL/g)
U	1×10^{-6}	1×10^{-7}		Zone 1: Near Field Solubility (M)
I	1	2	1 to 5	Zone 2: Degraded Aged Concrete K_d (mL/g)
U	70	100	70 to 250	Zone 2: Degraded Aged Concrete K_d (mL/g)
U	1×10^{-6}	1×10^{-7}		Zone 2: Degraded Aged Concrete Solubility (M)

4.9 DOSIMETRY

Dosimetry values are based on Hanford Site standards and have been approved by the Hanford Environmental Dose Oversight Panel.

Dosimetry scenarios and parameter values are based on the discussion and values presented in *Dosimetry Data Package for the Hanford Immobilized Low-Activity Tank Waste Performance Assessment* (Rittmann 1999), also Appendix O of this document. The scenarios for human exposure to the hazardous materials associated with the ILAW glass are defined in Appendix B (Mann 1999b). Table 4.9 provides the unit dose factors for the intrusion scenario where a post-intrusion resident lives near the exhumed waste associated with a well drilled through the disposal site. Internal and external contributions are separated because the glass matrix will prevent a portion of the exhumed waste from contributing to the internal dose. All of the exhumed activity contributes to the external dose.

Table 4.10 provides unit dose factors for exposure scenarios that use contaminated groundwater. The first four columns of unit dose factors are based on a well near the disposal facility. The last column is based on groundwater entering the Columbia River.

The first column of unit dose factors," HSRAM Industrial," are for employees of a business that uses well water for drinking and showering. The second column of numbers," HSRAM Residential," are for people in a suburban setting who obtain a portion of their diet from a garden that is irrigated with well water. The third column of numbers, "All Pathways Farmer," adds animal products, such as milk and meat to the exposure scenario. The fourth column of numbers, "Native American Subsistence Resident," can be considered a bounding case in that all intake parameters are maximized. The last column of numbers, "Columbia River Population," give the collective dose to 5 million people living near the Columbia River between the Hanford Site and the Pacific Ocean.

Table 4.9 Unit Dose Factors for Post-Intrusion Resident (mrem per Ci exhumed)

4.10 AGRICULTURE USE

The future application of Hanford land for potential agriculture use is presented and described in *Determining Reasonable Future Agriculture Land Use on the Hanford Site* (Evans 2000), also Appendix P of this document.

Potential land use and economic scenarios on the Hanford Site favor intensive, large-scale agricultural development growing high-value orchard, vineyard, and vegetable crops. Such large enterprises would be able to afford to import clean water and use high-level water management to minimize deep drainage. It is highly probable that any future irrigation development on the Hanford Site would be pressurized irrigation systems because of the site's very sandy soils and undulating topography. Water would be supplied to the fields by pressurized pipelines rather than canals or ditches. Because of the light soils and widely variable topography of the Hanford Site, new advances in micro-irrigation and self-propelled irrigation (i.e., linear move and center pivot systems) will probably have the most promise for future irrigation.

A reasonable estimate of deep percolation in 50 years would be the current best achievable levels of the best technology: from 2% to 15% of the applied water, not including water applied for frost protection or other non-irrigation uses. Recharge from irrigation would probably range from 50 to 500 mm/yr compared to historical estimated natural recharge rates, even with the expected improved technologies and systems. Wine grapes would have the least recharge, while field crops would potentially have the greatest deep percolation losses. Small acreage, irrigated ranchette development would probably contribute about twice the recharge to the unconfined aquifer systems as large scale irrigation.

Washington State Department of Ecology well data records were reviewed for the area surrounding the Hanford Site. Average screened lengths for the wells in the region ranged from 4.6 to 9.7 m.

1.0 OVERVIEW

The purpose of the next version of the *Hanford Immobilized Low-Activity Tank Waste* (ILAW) *Performance Assessment* (ILAW PA) is to provide an updated estimate of the long-term human health and environmental impact of the disposal of ILAW and to compare these estimates against performance objectives. Since the previous performance assessment (Mann 1998) was issued, considerable additional data on waste form behavior and soil geotechnical properties have been collected. Such a radiological performance assessment is required by U.S. Department of Energy (DOE) Orders on radioactive waste management (DOE 1988a and DOE 1999a).

The ILAW PA will also support other activities necessary for the disposal of ILAW. The Nuclear Regulatory Commission (NRC) has required (Paperiello 1997) that the original ILAW PA (Mann 1998) and updates be supplied in order to support DOE's request that ILAW be classified as incidentalwaste, that is, wastethat is produced in association with reprocessing and meets three criteria (Paperiello 1997):

1) the "wastes have been processed (or will be further processed) to remove key radionuclides to the maximum extent that is technically and economically practical,"

2) the "waste will be incorporated in a solid physical form at a concentration that does not exceed the applicable concentration for Class C [low-level waste] as set out in 10 CFR 61," and

3) the "wastes are managed, pursuant to the Atomic Energy Act, so that safety requirements comparable to the performance objectives set out in 10 CFR Part 61, Subpart C are satisfied."

The NRC expects that the analyses in the ILAW PAs show that the disposal system will meet performance requirements at least as protective as those required by the NRC. In their review of the *Hanford Low-Level Tank Wastes Interim Performance Assessment* (Mann 1997a), the staff of the NRC (Paperiello 1997) indicated that meeting the performance objectives in the interim performance assessment (which are the same as the ones in this document) would indeed meet the performance objectives of the NRC regulations (10 CFR 61).

DOE will also use the 2001 ILAW PA as part of the technical basis for permits required by the State of Washington in its regulation of the disposal of mixed waste. Mixed waste is waste that is both radioactive and dangerous (or radioactive and hazardous if federal terminology is used). The previous version of the ILAW PA only estimated long-term impacts from radionuclides. It must be emphasized that this document provides the performance objectives for the 2001 ILAW PA and that the standards to be used in the permits issued by the State of Washington may have a different basis.

The initial step in performing an assessment of the long-term impact of disposing of low-level waste from Hanford tanks is the determination of criteria by which success or failure will be judged. These criteria, known as performance objectives, are based on

- DOE requirements (primary source),
- NRC requirements,
- EPA land disposal restrictions,
- State of Washington requirements,
- Programmatic requirements, and
- Public involvement

The DOE requirements not only include the regulation directing the creation of the PA, but also regulations that are directly and indirectly cited in that regulation. In addition, other PAs produced in the DOE Complex and "case law" offer precedents that indicate what may constitute a successful performance assessment.

This document updates the performance objectives (Mann 1995) created for the *Hanford Low-Level Tank Wastes Interim Performance Assessment* (Mann 1997) and the *Hanford Immobilized Low-Activity Tank Waste Performance Assessment* (Mann 1998). These performance objectives will be used in the next revision of the performance assessment which is scheduled for 2001.

These performance objectives are only for the long-term assessment of the public health and environmental impacts from the disposal of immobilized low-activity tank waste. The TWRS Immobilized Waste Program, of which the ILAW performance assessment activity is a part, has additional objectives that relate to other parts of the Immobilized Waste Program. Thus, for example, worker and public safety during construction and active facility operation are not considered here. Although reviewed by others performing Hanford Site assessments, it must be emphasized that these performance objectives deal only with the ILAW disposal effort and not with the performance objectives of other Hanford Site disposal actions.

As described in the following sections,

2. Introduction
3. Regulations and Other Performance Assessments
4. Programmatic Requirements
5. Public Involvement,

performance objectives have been determined for both radioactive and chemical species. The radiological objectives are shown in Table 1.0 and are unchanged from those radiological performance objectives (Mann 1995) defined for the earlier ILAW PAs. Because the DOE orders on radioactive waste management specify only radiological performance objectives, the chemical goals are displayed in the appendix, Appendix A.

Table 1.0 Radiological Performance Objectives
(These are Unchanged from Mann 1995)

Protection of General Public and Workers [a, b]	
All-pathways dose from only this facility	25 mrem in a year [d, h]
All-pathways dose including other Hanford Site sources	100 mrem in a year [e, i]
Protection of an Inadvertent Intruder [c, f]	
Acute exposure	500 mrem
Continuous exposure	100 mrem in a year
Protection of Groundwater Resources [b, d, j]	
Alpha emitters	
^{226}Ra plus ^{228}Ra	5 pCi/ℓ
All others (total)	15 pCi/ℓ
Beta and photon emitters	4 mrem in a year
Protection of Surface Water Resources [b, g]	
Alpha emitters	
^{226}Ra plus ^{228}Ra	0.3 pCi/ℓ [j]
All others (total)	15 pCi/ℓ [j]
Beta and photon emitters	1 mrem in a year [k]
Protection of Air Resource [b, f, l]	
Radon (flux through surface)	20 pCi m^{-2} s^{-1}
All other radionuclides	10 mrem in a year

[a] All doses are calculated as effective dose equivalents; all concentrations are in water taken from a well. Values given are in addition to any existing amounts or background.
[b] Evaluated for 1,000 and 10,000 years, but calculated to the time of peak or 10,000 years, whichever is longer.
[c] Evaluated for 500 years, but calculated to 1,000 years.
[d] Evaluated at the point of maximal exposure, but no closer than 100 meters (328 feet) from the disposal facility.
[e] Evaluated at the 200 East Area fence.
[f] Evaluated at the disposal facility.
[g] Evaluated at the Columbia River, no mixing with the river is assumed.

[l] Main driver is National Emission Standards for Hazardous Air Pollutants (40 CFR 61H and 40 CFR 61Q).

2.0 INTRODUCTION

2.1 General Requirements

Before low-level waste may be disposed of, a performance assessment must be written and then approved by the DOE (DOE 1988a, DOE 1999a). The performance assessment is to determine whether "reasonable assurance" exists that the performance objectives of the disposal facility will be met. The DOE requirements for waste disposal (DOE 1988a, DOE 1999a) require (see Appendix B)

- The protection of public health and safety; and
- The protection of the environment.

Although quantitative limits are sometimes stated (for example, the all-pathways exposure limit is 25 mrem/year), usually the requirements are stated in a general nature. Quantitative limits were established by:

- investigating all potentially applicable regulations as well as interpretations of the review panels which DOE has established to review performance assessments,
- interacting with program management to establish the additional requirements of the program, and
- interacting with the public (i.e., the Hanford Advisory Board members; as well as affected Tribal Governments) to understand the values of residents in the Pacific Northwest.

Because of space considerations, not all radionuclides and dangerous chemicals are listed in this document. The radionuclides listed here are those which were explicitly treated in the ILAW PA (Mann 1998). The dangerous chemicals listed here are those most often detected in Hanford tank waste as documented in the *Regulatory Data Quality Objectives Supporting Tank Waste Remediation System Privatization Project* (Wiemers 1998).

2.2 1998 ILAW PA

Presently, there are about 54 million gallons of high-level waste stored in underground tanks located in the central plateau area of the Hanford Site. The present plans are to retrieve these wastes, separate the wastes into streams, and then vitrify each stream. The high-level waste stream would contain relatively little volume, but it would contain the bulk of the radionuclides. The vitrified high-level waste will be stored onsite until it is shipped to a federally approved geological repository. The low-activity waste stream will contain most of the material, but relatively few radionuclides. The vitrified (or immobilized) low-activity waste is planned to be disposed of in near-surface underground vaults in the 200 East Area (which is part of Hanford's central plateau).

The 1998 ILAW PA (Mann 1998) only analyzed the impacts of radionuclides. The most restrictive performance objective was for beta and gamma emitters in groundwater (estimated impact = 2.0 mrem/yr compared to a performance objective of 4.0 mrem/yr). The main radionuclides contributing to this result was ^{99}Tc and ^{79}Se. The next most restrictive performance objective was the all-pathways scenario (estimated impact = 6.4 mrem/yr compared to a performance objective of 25 mrem/yr). The performance objective for alpha emitters in ground water (15 pCi/liter) was more easily met (estimated impact = 1.7 pCi/liter). Performance objectives for surface water protection, air emissions, and protection of inadvertent intrusion were all met by at least a factor of ten.

2.3 Programmatic Uses of the ILAW PA

The TWRS Immobilized Waste Program will use the ILAW PA in a variety of ways. The design of the disposal facilities is in the conceptual model stage. The results of the PA (particularly the sensitivity cases) will be used to optimize the design using subsequent design stages in order to keep doses as low as reasonable achievable. Similarly, the selection of the waste form formulation and processing are in the early stages. The ILAW PA data collection activities as well as the analyses for the document are aiding DOE and BNFL, Inc. in optimizing waste form performance. As the total cost of the retrieval, separation, vitrification, and disposal activities is many 10's of billions of dollars, optimization can have large financial impacts.

3.0 REGULATIONS AND OTHER PERFORMANCE ASSESSMENTS

3.1 Introduction

A number of federal and state regulations are potentially applicable to the determination of how well the public health, safety and the environment must be protected. Table C.1 in Appendix C lists the regulations that were reviewed and that were judged potentially relevant to this proposed disposal action. Quantitative limits from such regulations are contained in the remaining tables of Appendix C.

Other regulations and general environmental acts were not included in Table C.1 because:

- Requirements fall under other parts of the TWRS Immobilized Waste Program (i.e., the National Environmental Policy Act – NEPA);
- Requirements are for different environmental actions (for example, the Comprehensive Environmental Response, Compensation, and Liability Act – CERCLA);
- Requirements deal with general environmental concerns (e.g., Endangered Species Act) and such concerns are thought to be adequately addressed for the long-term by regulations presented here; or
- The regulations are only at a preliminary stage and are likely to change. Examples are the Radiation Site Cleanup Regulation (proposed 40 CFR 196) and Environmental Radiation Standards for Management and Disposal of Low-Level Waste (proposed 40 CFR 193) from the U.S. Environmental Protection Agency. The development of these proposals will be closely followed.

This is not the first performance assessment concerning the disposal of low-level waste in the DOE complex. In fact, it is not the first one concerning Hanford wastes. Such prior assessments provide "case law" interpretations. Table D.1 in Appendix D lists the performance objectives of the other performance assessments in the DOE complex.

3.2 Protection of the General Public

For this assessment, the performance objective for the protection of the general public is 25 mrem (effective dose equivalent [EDE]) in a year. This value is used consistently in the regulations (DOE 1988a, DOE 1999a, and 10 CFR 61) and was used in the past performance assessments. However, the EnvironmentalProtection Agency has issued a guidance for CERCLA cleanup actions (EPA 1997) that 15 mrem/yr should be used. Although other methods are available for determining body dose (Mann 1995), the effective dose equivalent method was selected because regulations normally use this method.

The Defense Nuclear Facilities Safety Board (DNFSB 1994) noted that a member of the public could receive exposures from several sources at a DOE site. Guidance from DOE-Headquarters (DOE 1996a) is that protection of the general public from multiple sources should be based on *Radiation Protection of the Public and the Environment*, DOE Order 5400.5 (DOE 1993-1). This order sets a limit of 100 mrem in a year from all sources. In addition, the order requires that if the dose is above 30 mrem in a year, then an additional analysis is required. For the Hanford Site, this is considered to be a fence surrounding the present Hanford Site 200 Areas. The *Composite Analysis for the Low-Level Waste Disposal in the 200 Area Plateau of the Hanford Site* (Kincaid 1998) shows compliance with this requirement.

Little guidance is provided on the interpretation of ALARA (as low as reasonably achievable). The philosophy of the new DOE Order on Radioactive Waste Management is that results from the performance assessment are to be used to minimize potential impacts by better disposal facility designs and better disposal operational practices. The Immobilized Waste Program is integrating design and safety (including environmental considerations) into a single program so that the exposure effects can be minimized. The iterative approach uses environmental and safety analyses of preconceptual designs (see Mann 1996), followed by preliminary and detailed designs using the results of those analyses, followed by more complete environmental and safety analysis (for example, successors to this document). Disposal facility components will be incorporated whenever their inclusion significantly adds protection to human health or to the environment.

The compliance time for this performance assessment is 10,000 years. (The compliance time is the time starting 100 years from the time of closure over which the predicted dose must remain below the performance objectives.) However, the calculation will be carried out to the time of maximum impact if that time is longer than 10,000 years. This compliance time is significantly longer than that included in the guidance for draft DOE Order 435.1 (1,000 years).

The compliance time used is, however, consistent with the compliance time used by the NRC [see, for example, the *Branch Technical Position on a Performance Assessment Methodology for Low-Level Radioactive Waste Disposal Facilities* (NRC 1997)]. Because the waste being disposed of is derived from high-level waste, the NRC has indicated that DOE must protect the public and the environment consistent with NRC standards (Paperiello 1997). Thus, the more conservative time of compliance is used in this performance assessment. The time of compliance used here is consistent with that used in the other Hanford Site performance assessments: the Grout Performance Assessment (Kincaid 1995), the 200 West Area Solid Waste Performance Assessment (Wood 1995), and the 200 East Area Solid Waste Performance Assessment (Wood 1996). Results at 1,000 years will also be presented to compare the impacts to the performance objectives at the DOE time of compliance.

The point of compliance will be the point of maximum exposure at least 100 meters down gradient from the disposal facilities. This follows the requirements of the new DOE manual on radioactive waste management (DOE 1999b). Under the Resource Conservation and Recovery Act (RCRA), the point of compliance for a disposal facility is at the fenceline for the facility. However, no fenceline has yet been established. Moreover, as shown in the previous

ILAW PA (Mann 1998), because of the physical extent of the disposal facilities, doses at closer locations are not significantly higher than at a point of compliance at 100 meters.

3.3 Protection for Workers

For this performance assessment, as for others performed under DOE orders on radioactive waste management, worker health is not explicitly addressed. Rather , the more restrictive requirements for the general public are used. Protection for workers during construction and operations will be addressed in the safety analysis report that will be prepared for the Immobilized Waste Program.

3.4 Protection of the Inadvertent Intruder

The exposure limits for protecting a hypothetical inadvertent intruder are consistent with the regulations (DOE 1988a, DOE 1999a, and 10 CFR 61) and with earlier performance assessments. As shown in Table D.1. These limits are 500 mrem (EDE) for a one-time (acute) exposure and 100 mrem (EDE)/year for a continuous exposure.

The compliance time for protecting an inadvertent intruder is defined differently from the time of compliance for protecting the general public or the environment. The inadvertent intrusion time of compliance differs slightly between regulations. Current DOE guidance (Alm 1997) is that active institutional control shall occur for at least 100 years, but notes that longer times can be used if justified. DOE intends to control the Hanford Site 200 Areas as long as necessary to protect the public (DOE 1996b). The Hanford Site grout performance assessment (Kincaid 1995) used the 500-year compliance time based on the assumption that passive barriers and markers would be present. The performance assessments for the disposal of solid radioactive waste on the Hanford Site (Wood 1995 and Wood 1996) also have used a compliance time of 500 years. This is consistent with the NRC requirement for Class C waste (10 CFR 61) that inadvertent intruders be protected for 500 years.

Following the precedent of the other Hanford Site performance assessments, the 500-year compliance time was used in this assessment because passive barriers and markers are planned for this proposed disposal action. Therefore, protection of an inadvertent intruder shall be considered met if the exposure limits are met at 500 years after closure. Calculations will be run from 100 years to 1,000 years after the time of disposal to obtain the doses as a function of time.

3.5 Protection of Ground Water Resources

The protection of ground water resources is the most complicated requirement to determine. The level of protection for groundwater is usually based on its intended use. However, predicting future groundwater use is highly subjective given the long time frames involved in a performance assessment. The quantities being limited (decay rate and dose) differ

in the various regulations. Moreover, different regulatory agencies approach the protection of groundwater resources using a variety of methods. In addition, earlier DOE performance assessments have taken different approaches. The guidance under the new DOE order on radioactive waste management (see Appendix B) is to use the site's groundwater protection management plan. However, the Hanford Site's plan (DOE-RL 1995) focuses only on short-term activities and does not address the metrics to apply for the long-term protection of groundwater.

Previous performance assessments have generalized the requirements from the "National Primary Drinking Water Regulations" (40 CFR 141) for determining if the disposal action meets the groundwater protection requirement. The scenario used is based on a public drinking water system serving at least 25 people and located at the point of compliance of the disposal facility. The previous performance assessments set a limit for the total exposure from all radionuclides for an individual drinking the water at less than 4 mrem (EDE) in a year. The "National Primary Drinking Water Regulations," however, use the limit of 4 mrem in a year not for all radionuclides, but for just beta and gamma emitters. The distance of 100 meters from the disposal facility is given in the manual for the new DOE order on radioactive waste management (DOE 1999b). Four mrem (EDE) in a year was chosen for two reasons. First, the value corresponds to the risk-based limit found in the "National Primary Drinking Water Regulations." Second, for most of the radionuclides, the value is more restrictive (see Table C.9) than decay rate concentration limits specified in the Washington State regulations (WAC 173-200).

The requirements for alpha emitters are the same in both the Washington State (WAC 173-200) and Federal (10 CFR 141) regulations. Both regulations limit alpha emitters by decay rate concentration limits, not annual dose. In addition, both sets of requirements limit the same subsets of alpha emitters (^{226}Ra, total radium, and other) and set the same quantitative limits. These decay rate concentration limits (Table 1.0) are used for this performance assessment.

Washington State's requirements for beta emitters are based on a screening level previously used by the EPA. These screening levels were selected because the requirements are easily verified in the field. (The current EPA regulations are based on risk limitation.) The current state screening level ensures that even for beta emitters emitting high-energy gamma radiation, the dose limit will be met. However, for low-energy beta emitters, the state screening level is conservative by a factor of about 100. This high degree of conservatism exists for radionuclides, such as ^{99}Tc, that are important in this performance assessment.

For this performance assessment, the Federal standards are used. This means that the current EPA regulation governing drinking water (40 CFR 141) is used to protect groundwater. The "Maximum Contaminant Level Goals" subpart of 40 CFR 141 (40 CFR 141, Subpart F) and the "National Secondary Drinking Water Standards" (40 CFR 143) were not used because they are stated only as goals. This follows the precedent set in the *Tank Waste Remediation System Environmental Impact Statement* (TWRS EIS) (DOE 1996c), a joint publication of the Washington State Department of Ecology and DOE. Thus, the performance objective is an EDE of 4 mrem in a year for beta/photon emitters and a concentration of 15 pCi per liter for

alpha emitters. Although uranium is not restricted by the regulations, for this analysis it is included under other alpha emitters. The values are displayed in Table 1.0. A dose of 4 mrem (EDE) in a year for 70 years corresponds to an incremental health risk of 0.0001 (EPA 1989b).

To ensure compliance with the intent of Federal and State groundwater regulations, the limits shown in Table 1.0 are applied to a well 100 meters downgradient from the disposal facility for a time period of 10,000 years after closure (the same time of compliance as for protection of the general public). Calculations will also be done for a location at the future Hanford Site boundary (DOE 1996b) and for 1,000 years after closure to compare the results at the DOE time of compliance. The hypothetical well from which the water is drawn is sized to provide the minimum public drinking water system that serves 25 people (40 CFR 141).

Performance goals for chemicals were chosen by selecting the most restrictive of the Federal and State groundwater regulations. All inorganic chemicals found in the regulations are included in Table A.1. However, for organic chemicals only those organic chemicals that have been detected frequently in tank waste (Wiemers 1998) are included in Table A.2.

3.6 Protection of Surface Water Resources

Federal (40 CFR 141) and State requirements (WAC 173-201A) for surface water protection are similar in scope and objectives. Both are directed at preventing degradation of surface water quality and preservation of highest priority water uses. The point of compliance for performance assessment purposes is where the groundwater is predicted to reach the Columbia River. The concentration of radionuclides in the groundwater at the point where it enters the Columbia River should meet all the standards listed in Table 1.0.

The 1.0 mrem (EDE) dose in a year (one quarter of the EPA drinking water standard) value is used because it meets the Washington State regulation while minimizing reporting requirements. The Washington State regulation (WAC 173-201A) mandates a dose limit that is the lesser of the EPA drinking water standard and explicit limits for each radionuclide contained in the State regulation. For the major radionuclides of interest, the explicit limits when converted to dose are greater than 1.3 mrem in a year. Using 1.0 mrem in a year for the sum of all beta/photon emitters is restrictive.

The compliance time for protecting surface water resources is selected as 10,000 years, the same compliance time as for protecting groundwater resources. Calculations will also be done for 1,000 years after closure to compare the results at the DOE time of compliance.

Performance goals for chemicals were chosen by selecting the more restrictive of the Federal and State groundwater regulations. All inorganic chemicals found in the regulations are included in Table A.1. However, for organic chemicals only those organic chemicals that have been detected frequently in tank waste are included in Table A.2.

3.7 Protection of Air Resources

Air emissions limits were taken from the draft DOE manual on radioactive waste management (DOE 1999b) which are the same limits found in Parts H and Q of the "National Emissions Standards for Hazardous Air Pollutants" (40 CFR 61H and 40 CFR 61Q). Based on these standards, emissions (except radon) are limited to 10 mrem (EDE) in a year with radon emissions limited to 20 pCi/m^2s.

4.0 PROGRAMMATIC REQUIREMENTS

The TWRS Immobilized Waste Program has mandated that all wastes to be disposed of and/or stored in the facility shall meet NRC Class C concentration limits (10 CFR 61). In addition, the immobilized waste form will meet Resource Conservation and Recovery Act [RCRA] (40 CFR 261, 40 CFR 264, and 40 CFR 268) concentration limits as well as the requirements of the ILAW treatment contract (BNFL 1998). Table C.8 lists these limits in the immobilized waste form.

Although the ILAW performance assessment is being created to meet the DOE Order (DOE 1988a, DOE 1999a) requirement to prepare a radiological performance assessment, the TWRS Immobilized Waste Program will also use the ILAW PA to support permits required by the Washington State Department of Ecology and the Washington State Department of Health. Therefore, performance goals for concentrations of chemicals have also been established (using the same procedures as for the radionuclides). These performance goals are shown in Appendix A.

5.0 PUBLIC INVOLVEMENT

It is important that Hanford stakeholders have the opportunity to affect the scenarios analyzed in the ILAW performance assessment. Public comments were requested on the original version of this document (Mann 1994) as well as revision 2 (Mann 1999).

A summary of the initial version of the scenarios was sent to each member and alternate of the Hanford Advisory Board, to selected Hanford Site contractor employees, and to selected members of the DOE's Peer Review Panel and Performance Assessment Task Team. Their comments and corresponding responses to the previous version of this document are available for review (Murkowski 1995).

Revision 2 of this document was made available for public review following the public involvement procedures established by the Hanford Groundwater / Vadose Zone Integration Project (that is, announcements were made at biweekly meetings, the review period was noted on the published list of Integration Project activities, and the documents were available on the Integration Project's web site). Only the Oregon Office of Energy submitted comments (Blazek 1999) and these mainly dealt with waste classification, the extent of public announcement, and other general program activities. Because of the nature of the comments, no changes were made to revision 2 based on these comments. The comments from the Oregon Office of Energy as well as the responses (Taylor 1999) to them by the Department of Energy's Office of River Protection are available on request.

Comments on this version of the document should be sent to:

Frederick M. Mann
Fluor Daniel Northwest
Mail Stop H0-22
Post Office Box 1050
Richland, Washington 99352

Since calculations for the performance assessment will begin in October 1999, to be effective the comments should be sent as soon as possible.

Appendix A Dangerous Materials Performance Goals

Chemical concentration limits for groundwater protection and surface water protection are determined by identifying the Federal and State regulations dealing with chemicals in the environments and applying the most restrictive limit. Although organic compounds are not expected to be measurably present in the immobilized product resulting from a vitrification process, organic compounds are listed here.

Table A.1 Performance Goals for Inorganic Materials

Chemical	Groundwater	Surface Waters
Ammonia		4.0 mg/l
Antimony	0.006 mg/l	0.006 mg/l
Arsenic	0.00005 mg/l	0.05 mg/l
Barium	1.0 mg/l	2.0 mg/l
Beryllium	0.004 mg/l	0.004 mg/l
Cadmium	0.005 mg/l	0.00077 mg/l
Chlorine	250. mg/l	230. mg/l
Chromium	0.05 mg/l	0.011 mg/l
Copper	1.0 mg/l	0.0078 mg/l
Cyanide	0.2 mg/l	0.0052 mg/l
Fluoride	4.0 mg/l	4.0 mg/l
Iron	0.3 mg/l	
Lead	0.05 mg/l	0.0015 mg/l
Manganese	0.05 mg/l	
Mercury	0.002 mg/l	0.000012 mg/l
Nickel		0.115 mg/l
Nitrate as N	10. mg/l	10. mg/l
Nitrite as N	1.0 mg/l	1.0 mg/l
Nitrite plus Nitrate	10. mg/l	10. mg/l
Selenium	0.01 mg/l	0.005 mg/l
Silver	0.05 mg/l	
Sulfate	250. mg/l	
Thallium	0.002 mg/l	
Zinc	5.0 mg/l	0.072 mg/l

No entry in a cell indicates that no limit was found.

Table A.2 Performance Goals for Organic Materials

CAS #	Constituent (a)	Groundwater	Surface Waters
56-23-5	Carbon tetrachloride	0.0003 mg/l	0.005 mg/l
67-66-3	Chloroform	0.007 mg/l	
71-43-2	Benzene	0.001 mg/l	0.005 mg/l
71-55-6	1,1,1-Trichloroethane	0.003 mg/l	0.2 mg/l
75-09-2	Dichloromethane (Methylene Chloride)	0.005 mg/l	0.005 mg/l
79-00-5	1,1,2-Trichloroethane	0.005 mg/l	0.005 mg/l
79-01-6	1,1,2-Trichloroethylene	0.005 mg/l	0.005 mg/l
95-47-6	o-Xylene	0.7 mg/l	0.7 mg/l
100-41-4	Ethyl benzene	0.1 mg/l	0.1 mg/l
106-46-7	1,4-Dichlorobenzene	0.004 mg/l	0.075 mg/l
108-88-3	Toluene	1.0 mg/l	1.0 mg/l
127-18-4	1,1,2,2-Tetrachloroethene	0.005 mg/l	0.005 mg/l

(a) Greater than 100 analytical detects in tank waste or greater than 20 analytical detects in TWINS Solid/Liquid Hits. Taken from Wiemers 1998.

Appendix B. DOE Orders on Low-Level Waste Disposal

B.1 DOE Order 5820.2A (DOE 1988a) (effective 09/26/88)

This is the DOE Order currently governing the disposal of low-level waste (5820.2A). A new order (435.1 [see section B.2 below]) will replace this order. Chapter III, Section 3a states that the objectives are to

1) "Protect public health and safety in accordance with standards specified in applicable EH orders and other DOE orders.
2) Assure that external exposure to the waste and concentrations of radioactive material which may be released into surface water, ground water, soil, plants, and animals results in effective dose equivalent that does not exceed 25 mrem/yr to any member of the public. Releases to the atmosphere shall meet the requirements of 40 CFR 61. Reasonable effort should be made to maintain releases of radioactivity in effluents to the general environment as low as is reasonably achievable.
3) Assure that the committed effective dose equivalents received by individuals who inadvertently may intrude into the facility after the loss of active institutional control (100 years) will not exceed 100 mrem/year for continuous exposure or 500 mrem for a single acute exposure.
4) Protect ground water resources, consistent with Federal, State, and local requirements."

B.2 DOE Order 435.1 (DOE 1999a)

B.2.1 DOE Order 435.1 (*Radioactive Waste Management*)

DOE Order 435.1 is the DOE order on radioactive waste management which should be effective when the next version of the *Hanford Immobilized Low-Activity Tank Waste Performance Assessment* is prepared and submitted.

DOE Order 435.1 requires

(4a) "DOE radioactive waste management activities shall be systematically planned, documented, executed, and evaluated."

(4b). "Radioactive waste shall be managed to

(1) Protect the public from exposure to radiation from radioactive materials. Requirements for public protection are in DOE O 5400.5, *Radiation Protection of the Public and the Environment.*
(2) Protect the environment. Requirements for environmental protection are in DOE O 5400.1, *General Environmental Protection Program,* and DOE O 5400.5, *Radiation Protection of the Public and the Environment.*
(3) Protect the work force. Requirements for radiation protection of workers are in 10 CFR 835; requirements for industry safety are in DOE O 440.1, *Worker Protection Management for DOE Federal and Contractor Employees.*
(4) Comply with applicable Federal, state, and local laws and regulations. These activities shall also comply with applicable Executive Orders and other DOE directives."

(4c) "All radioactive waste shall be managed in accordance with the requirements in DOE M 435.1, *Radioactive Waste Management Manual.*" [DOE 1999b]

B.2.2 *Radioactive Waste Management Manual* (DOE M 435.1)

The document that implements DOE Order 435.1 is DOE M 435.1, *Radioactive Waste Management Manual* (DOE 1999b). This manual requires (Chapter I, 1D) the following regulations and DOE directives for all DOE radioactive waste management facilities, operations, and activities.

(1D) **"Analysis of Environmental Impacts**. Radioactive waste management facilities, operations, and activities shall meet the requirements of 10 CFR 1021, *National Environmental Policy Act Implementing Procedures*; and DOE O 451.1A, National Environmental Policy Act Compliance Program."

(1E10) "**Mixed Waste**. Radioactive waste that contains a hazardous waste component is also subject to the *Resource Conservation and Recovery Act* (RCRA) as amended." Note hazardous waste is termed "dangerous waste" in Washington State requirements.

(1E13) **"Radiation Protection.** Radioactive waste management facilities, operations, and activities shall meet the requirements of 10 CFR 835, *Occupational Radiation Protection,* and DOE O 5400.5, *Radiation Protection of the Public and the Environment.*"

(1E18) **"Site Evaluation And Facility Design.** New radioactive waste management facilities, operations, and activities shall be sited and designed in accordance with DOE O 420.1, *Facility Safety*, and DOE O 430.1, *Life Cycle Asset Management.*"

(1E21) **"Worker Protection.** Radioactive waste management facilities, operations, and activities shall meet the requirements of DOE O 440.1, *Worker Protection Management for DOE Federal and Contractor Employees.*"

Section P of Chapter IV of the DOE *Radioactive Waste Management Manual* has additional requirements for low-level waste disposal facilities.

(1) **"Performance Objectives**. Low-level waste disposal facilities shall be sited, designed, operated, maintained, and closed so that reasonable assurance exists that the following performance objectives will be met for waste disposed of after September 26, 1988:

(a) Dose to representative members of the public shall not exceed 25 mrem (0.25 mSv) in a year total effective dose equivalent from all exposure pathways, excluding the dose from radon and its progeny in air.
(b) Dose to representative members of the public via the air pathway shall not exceed 10 mrem (0.10 mSv) in a year total effective dose equivalent, excluding the dose from radon and its progeny.
(c) Release of radon shall be less than an average flux of 20 $pCi/m^2/s$ (0.74 $Bq/m^2/s$) at the surface of the disposal facility. Alternatively, a limit of 0.5 pCi/l (0.185 Bq/l) of air may be applied.

(2) **Performance Assessment**. A site-specific radiological performance assessment shall be prepared and maintained for DOE low-level waste disposal facilities which received waste after September 26, 1988. The performance assessment shall include calculations of potential dose to representative future members of the public and potential releases from the facility to provide reasonable expectation that the performance objectives identified in this Chapter will not be exceeded over a period of 1,000 years after facility closure.

(a) Analyses performed to demonstrate compliance with the performance objectives in this chapter, and to establish limits on performance measures for inadvertent intruders in this chapter shall be based on reasonable activities in the critical group of exposed individuals. Unless otherwise specified, the assumption of average living habits and exposure conditions in representative critical groups of individuals projected to receive the highest dose is appropriate. ...
(b) The point of compliance shall correspond to the point of highest projected dose or concentration beyond a 100 meter buffer zone surrounding the disposed waste. A larger or smaller buffer zone may be used provided adequate justification is provided.
(c) Performance assessments shall address reasonably foreseeable natural processes that might disrupt barriers against release and transport of radioactive materials.

(d) Performance assessments shall use DOE-approved dose coefficients (dose conversion factors) for internal and external exposure of reference adults.

(e) The performance assessment shall include an estimate of the maximum projected dose, flux, or concentration and the time of the maximum, in the sensitivity/uncertainty analysis.

(f) Performance assessments shall include a demonstration that projected releases of the radionuclides to the environment shall be maintained as low as reasonably achievable (ALARA).

(g) For the purpose of establishing limits on radionuclides that may be disposed near-surface, the performance assessment shall include an assessment of impacts to water resources.

(h) For purposes of establishing limits on concentration of radionuclides that may be disposed of near-surface, the performance assessment shall include an assessment of impacts calculated for a hypothetical person assumed to inadvertently intrude into the low-level waste disposal facility. For intruder analyses, institutional controls shall be assumed to be effective in deterring intrusion for at least 100 years following closure. The intruder analyses shall use performance measures of 100 mrem (1 mSv) in a year total effective dose equivalent for chronic exposure and 500 mrem (5 mSv) total effective dose equivalent for acute exposure."

B.2.3 *Implementation Guide for DOE M 435.1* (DOE G 435.1)

The Department of Energy has also issued an implementation guide (DOE 1999c) on how the *Radioactive Waste Management Manual* is to be used.

Section IV.P(1) provides guidance on the performance objectives.

(1) The use of the phrase 'representative members of the public' is "to indicate that overly conservative assumptions such as age, sex, or assumed activities of persons, are not made."

(2) The air-pathway objective (10 mrem in a year) "is for all sources on the DOE site, not just the disposal facility."

(3) Sources of radon include the "constituent of waste at the time of disposal or produced by radioactive decay following disposal."

- "In most cases, the ground surface emanation limit for radon of 20 $pCi/m^2/s$ should be used. However, in cases where the disposed waste radiologically resembles uranium or thorium mill tailings, the limit on air concentration may be warranted. The radon dose can also be calculated as part of the total air dose, in which case, radon does not need to be addressed separately."

Section IV.P.(2) provides guidance on the performance assessment. "Detailed guidance on conducting performance assessments has been developed and is contained in *Format and Content Guide for U.S. Department of Energy Low-Level Disposal Facility Performance Assessments and Composite Analyses*" (DOE 1999d). Guidance explicitly in the implementation guide includes

(1) The compliance time period is 1,000 years after the disposal facility has been closed. "This time was selected to encompass rates of processes likely to govern migration of radiochemical species most likely to contribute to calculated dose. Longer times of assessments are not to be used to assess compliance because of the inherent large uncertainties in extrapolating calculations over long time frames."

(2) "Performance assessment analyses should be based on reasonable activities of the portion of the exposed population likely to receive the highest dose (i.e., the critical group). The performance assessment analyses should not be based on "worst case" assumptions. Rather, the analyses should be based on scenarios that represent reasonable actions of a typical group of individuals performing activities that are consistent with regional social customs, work, and housing practices, and expected regional environmental conditions at the time of the exposure scenario."

(3) "The concept of a buffer zone is inherent in defining a low-level waste disposal facility. The disposal facility is comprised of a number of disposal units." "Setting the extent of the buffer zone at 100 meters is somewhat arbitary, but 100 meters is considered to be sufficient, but not unreasonably large, for the stated purposes." "In certain cases, e.g. if the disposal facility is located adjacent to the current DOE site boundary, it may be more appropriate to use a smaller buffer zone. In other cases, e.g., where the disposal facility is located far from the DOE site boundary, and the site's land use planning does not envision relinquishing control of the site, a larger buffer zone could be considered."

(4) Natural processes "might disrupt the intended performance of the disposal facility, but such consideration should be limited to those processes which are foreseeable." Examples of such natural processes are corrosion which "will, in time, breach most containers; environmental conditions, will, in time, consume the capacity of chemical buffers, and burrowing animals and root intrusion will eventually breach disposal facility caps." "Other processes or events, although not regularly occurring, are, nonetheless, reasonably foreseeable. Such events would include severe weather such as flooding (e.g., 100 year flood, probable maximum flood), and seismic events. Other processes, such as climate change, are considered to be too speculative for consideration in the performance assessment."

(5) Dose calculations are "for adults (i.e., Reference Man). The actual dose to a particular individual from a given exposure to radioactive material is dependent on a number of characteristics, including age and sex. However, doses are not to be predicted for specific individuals or classes of persons. Rather, the calculations are to represent potential exposures to hypothetical future members of the public."

(6) "Performance assessments should include ALARA assessment that focus on alternatives for low-level waste disposal. The alternatives considered might consider the use of different disposal unit covers, waste forms, containers, or other alternatives (e.g. concrete vaults versus earthen trenches) consistent with the situation being addressed. The rigor of the ALARA assessment and its analysis of alternatives should be commensurate with the magnitude of the risk and decisions to be made."

(7) "The hierarchy for establishing water resource protection performance measures is:

- First, the DOE LLW disposal facility must comply with any applicable State or local law, regulation, or legally applicable requirements for water resource protection.

- Second, the DOE LLW disposal facility should comply with any formal agreement applicable to water resource protection that is made with appropriate State or local officials.
- Third, if neither the above conditions apply, the site should select assumptions for use in the performance assessment based on criteria established in the site groundwater protection management program and any formal land-use plans.
- If none of the above conditions apply, the site should identify a performance measure for protection of water resources that is consistent with the use of water as a drinking water source. Examples of this type of performance measure would be the assumption of the concentration limits in 40 CFR 141 or a dose limit of 4 mrem per year above background from the ingestion of water."

(8) "Although DOE is committed to retaining control of land containing residual radioactive material, such as disposed low-level waste, it is nonetheless appropriate to consider the impacts of potential inadvertent intrusion. Intrusion can be considered either as an accident scenario which could occur during lapses of institutional control or as a hypothetical situation assumed simply to provide a basis for establishing control over the concentration of radioactive material acceptable in a near-surface disposal facility."

"Institutional control should be assumed to be effective in preventing intrusion for 100 years following disposal facility closure. Longer periods may be assumed with justification (e.g. land-use planning, passive controls)."

"Development of intruder scenarios should be based on the following assumptions

- Intruders could carry out activities for no more than about a year before discovery.
- An intruder performs reasonable activities consistent with regional social customs and well drilling, excavation, and construction practices, and the regional environmental conditions projected for the time that intrusion is assumed to occur.
- Intrusion events involve random contact with waste.
- An intruder will take reasonable, investigative actions upon discovery of unusual materials.
- Intrusion events that contact waste should normally be assumed to be limited to drilling or simple extraction scenarios involving use of relatively unsophisticated tools and commonplace machinery.
- Doses calculated for an intruder will depend on waste disposal facility design and operating practices, and may be reduced by practices such as disposal below depths normally associated with common construction activities, use of intruder barriers or durable waste forms or containers, or distributed disposal of higher activity waste."

"The inadvertent intruder assessment should, at a minimum, include consideration of an acute construction scenario, an acute well drilling scenario, and a chronic agricultural scenario."

B.2.4 *Technical Basis for DOE M 435.1*

Further information is given in the *Technical Basis for DOE M 435.1* (DOE 1999e). In particular, the sections on the performance objectives and performance assessment given justification for the approach taken and the values used.

1) The requirement of an all-pathways effective dose equivalent "is consistent with established radiation protection practice that allocates a fraction of the 100 mrem/yr public dose to a particular practice or activity. It is also consistent with the regulatory practice of the NRC to require all-pathways assessments, and this is consistent with the NRC low-level waste disposal facility licensing regulations at 10 CFR 61."

2) The requirement on groundwater protection "provides defense in depth to the all pathways performance objective." "Guidance developed for this requirement describes a tiered structure for its application. The guidance is based on a recognition that at the current time, there are no applicable Federal regulations. Therefore, the emphasis is to be consistent with the site's groundwater protection

management program. Also, the role of future use commitments between DOE and other authorities in the management of water resources may provide a sound basis for making decisions."

3) The time period for compliance (1,000 years after closure) "was selected after consideration of the times used in other regulations (e.g. 10 CFR 191, 40 CFR 192), and recognition of the uncertainties and hypothetical nature of long-term projections." "based on the study, *Comparison of Low-Level Waste Disposal Programs of DOE and Selected International Countries* (DOE/LLW-236) [DOE 1996d] two countries (Canada and Sweden) have established a time of compliance of 10,000 years. The other two countries (France and the United Kingdom) have not specified a time of compliance. Similarly, to date, DOE, NRC, and EPA have not specified a time of compliance for low-level waste disposal facility performance assessments. A team composed of primarily of DOE contractor performance assessment staff evaluated the options for a time of compliance. In its progress report, *Performance Assessment Task Team Progress Report* (DOE/LLW-157, Rev. 1) [Wood 1994], the team recommended a time of compliance of 10,000 years. This time was consistent with the time specified on 10 CFR 191 for high-level and transuranic waste disposal, and was considered to be conservative in that no longer times had been seriously proposed. This time or longer times had been used in DOE disposal facility performance assessments conducted up to that time. Subsequently, EPA asked agency reviewers for their opinions on the use of 10,000, 1,000, or some other time frame as the time of compliance for low-level waste disposal facility performance assessments. DOE responded that its position was that 1000 years was an appropriate time."

4) The "point of compliance is consistent with regulatory positions included in 40 CFR 192.32 and 40 CFR 264.95. The NRC regulation at 10 CFR 61.52(a)(8) states that a 'buffer zone of land must be maintained between any buried waste and the disposal site boundary ...' In NUREG-1200, section 4.3.6 [NRC 1988] it is recommended that this buffer be at least 30 m wide. The Performance Assessment Task Team recommended a point of compliance of 100 meters in the *Performance Assessments Task Team Progress Report* (DOE/LLW-157, Rev. 1). [Wood 1994] In the *Draft Recommendations on Prospective Assessments for Long-Term Management of Low-Level Radioactive Waste* (memorandum, R. Beube, dated September 5, 1996) [DOE 1996e], the DOE Office of Environment recommended that the point of compliance should be at the point of public access. Therefore the point of compliance would be the site boundary. The Office of Environment recommendations further acknowledged that it may be prudent to use a closer point of assessment if there is uncertainty about the future location of the site boundary. 40 CFR 192.32 permits the establishment of alternative concentration limits that are as low as reasonable and meet the standards of 40 CFR 264.94(a) at all points at a greater distance than 500 meters from the edge of the disposal area and/or outside the site boundary."

5) "The rationale for using standard adult dose conversion factors comes from the fact that in a performance assessment one is calculating a postulated dose to a hypothetical future person assumed to be engaged in a set of 'normal' activities over a period of years. Consequently, performing calculations as if real people of known age were being impacted by releases from the facility is not reasonable."

6) "in addition to calculations over the time of compliance (1000 years), performance assessments also are to present calculations of maxima relative to each of the performance objectives. The results of these calculations are part of the sensitivity and uncertainty analysis which would support a conclusion that the model is providing a reasonable projection. These longer calculations address the need to ensure that there are no unexpected significant increases shortly after the time of compliance and provide a mechanism for understanding the model performance and significance of modelling parameters. The calculation of maxima does present the possibility that there may be results that exceed the performance objectives. The significance of these results must be handled with caution and judgement. The further out in time that the maxima occurs, the less significant is the relationship to the performance objective."

"This requirement represents a DOE policy decision; it derives in part from IAEA Fundamental Principles of Radioactive Waste Management."

7) "The use of the ALARA concept in long-term assessments is a best management practice that contributes defense-in-depth to the possible exposures from a disposal facility. Application of the ALARA principle for managing current operational exposures has practical and measurable merit in that real doses are being avoided or reduced. This concept is extended here by addressing projected releases of materials well into the future which may result in doses."

8) "The concept of protection of inadvertent intrusion is consistent with national and international practice (NRCP, ICRP, IAEA). The NRC included the protection of inadvertent intruders as one of the performance objectives in 10 CFR 61. Other international and national organizations have and continue to include the protection of inadvertent intruders as one of the elements of radiation protection."

"Since the intent of the Department is to control the use of the land where low-level waste is disposed until the land can be released, inadvertent intruder calculations provide defense-in-depth by limiting the concentration of waste that can be disposed of in the near surface. With each performance assessment evaluating and developing limits for near-surface disposal, DOE is more cost-effective in managing waste and is consistent with the philosophy of using performance based requirements."

Appendix C Supporting Tables

Table C.1 List of Relevant Regulations

REGULATION	COMMENT
Radioactive Waste Management (DOE Order 5820.2A) [DOE 1988a]	Current DOE order covering disposal of low-level waste.
Radioactive Waste Management (DOE Order 435.1) [DOE 1999a]	New DOE order covering disposal of low-level waste, released July 9, 1999.
Licensing Requirements for Land Disposal of Radioactive Wastes (10 CFR 61)	Requirements of the Nuclear Regulatory Commission for the land disposal of low-level radioactive waste
Radioactive Waste – Licensing and Disposal (WAC 246-250)	Sets requirements for disposal of low-level radioactive wastes in the State of Washington
General Environmental Protection Program (DOE Order 5400.1) (DOE 1990)	Lists executive orders, laws, and regulations which DOE actions must meet
Radiation Protection of the Public and the Environment (DOE Order 5400.5) (DOE 1993)	Provides exposure limits for general activities
Department of Energy Radiological Health and Safety Policy (DOE 1996a)	Establishes basis of DOE's radiological control programs
Occupational Radiation Protection (10 CFR 835)	Establishes radiation protection standards, limits, and programs for protecting individuals from ionizing radiation from the conduct of DOE activities
Standards for Protection Against Radiation (10 CFR 20)	Establishes standards for protection against ionizing radiation resulting from activities conducted under licenses issued by the NRC.
Radiation Protection Standards (WAC 246-221)	Sets radiation protection standards for the state of Washington
National Emission Standards for Emissions of Radionuclides Other than Radon from Department of Energy Facilities (40 CFR 61.192)	Establishes maximum exposure to public via air pathway for non-radon radionuclides
National Emission Standards for Radon Emissions from Department of Energy Facilities (40 CFR 61.192)	Establishes maximum exposure to public of Ra-222 via air pathway
Ambient Air Quality Standards and Emission Limits for Radionuclides (WAC 173-480)	Sets emission standards into air for radionuclides in the state of Washington
Radiation Protection – Air emissions (WAC 246-247)	Sets radioactive air emissions standard
National Primary Drinking Water Regulations (40 CFR 141)	Sets drinking water standards
Water Quality Standards for Ground Waters of the State of Washington (WAC 173-200)	Sets standards for ground waters in the State of Washington

REGULATION	COMMENT
Water Quality Standards for Surface Waters of the State of Washington (WAC 173-201A)	Sets standards for surface waters in the State of Washington
Identification and Listing of Hazardous Waste (40 CFR 261)	Establishes which wastes are subject to RCRA
Land Disposal Restrictions (40 CFR 268)	Limits disposal options for hazardous wastes
Dangerous Waste Regulations (WAC 173-303)	Implements RCRA in the State of Washington

Table C.2 Requirements Of Relevant General Radioactive Waste Regulations

DOE Order 5820.2a: (DOE 1988a)	
All pathways	25 mrem/year
ALARA	See footnote
Intruder (100 years)	100 mrem/year (continuous)
Intruder (100 years)	500 mrem (single event)

DOE M 435.1 (DOE 1999b)	
All pathways (<1,000 years)	25 mrem/year
ALARA	See footnote
Intruder (> 100 years or larger)	100 mrem/year (continuous)
Intruder (> 100 years or larger)	500 mrem (single event)

DOE Order 5400.5 (DOE 1993)	
All pathways (from all DOE facilities at the site)	100 mrem/year (analysis performed by a separate document)

WAC 246-221-060	
All pathways	2 mrem/hour
All pathways	100 mrem/year

10 CFR 61. 41	
All pathways (whole body)	25 mrem/year
All pathways (thyroid)	75 mrem/year
All pathways (other organs)	25 mrem/year
Only Class C disposal	See Table C.8

WAC 246-250-170	
All pathways (whole body)	25 mrem/year
All pathways (thyroid)	75 mrem/year
All pathways (other organs)	25 mrem/year

Following DOE Order 435.1 guidance, ALARA restrictions are taken to require sensitivity studies showing the significance of various design options.

Table C.3 Requirements of Relevant Worker Protection Regulations

10 CFR 835	
All pathways (effective dose equivalent)	5,000 mrem/year
Sum of deep dose equivalent for external exposures and the committed dose equivalent to any organ or tissue other than the lens of the eye	50,000 mrem
Lens of the eye (dose equivalent)	15,000 mrem
Shallow dose equivalent to the skin or any extremity	50,000 mrem
WAC 246-221-010	
All-Pathways	5,000 mrem/year
Sum of deep dose equivalent for external exposures and the committed dose equivalent to any organ or tissue other than the lens of the eye	50,000 mrem
Lens of the eye (annual limit)	15,000 mrem
Shallow dose equivalent to the skin or any extremity (annual limit)	50,000 mrem

Table C.4 Requirements of Relevant Air Regulations

DOE O 435.1	
Air emissions (except radon)	10 mrem/year
Air emissions (radon)	20 pCi/m^{2}s

DOE Order 5400.5 (DOE 1993)	
Air emissions (except radon)	10 mrem/year

40 CFR 61.92	
Air emission (except radon)	10 mrem/year

40 CFR 61.192	
Air emissions (radon)	20 pCi/m^{2}s

WAC 173-480-040	
Air emissions (except radon) (whole body)	25 mrem/year
Air emissions (except radon) (critical organ)	75 mrem/year

WAC 173-480-060
Best available radionuclide control technology

WAC 246-247-040
References WAC 173-480 and 40 CFR 61

Table C.5 Requirements of Relevant Drinking Water Regulations

DOE Order 5400.5 (DOE 1993)	
Radionuclides	4 mrem/year
Ra-226 plus Radium-228	$5x10^{-9}$ μCi/ml (= 5 pCi/l)
Alpha emitters (but not Rn nor U)	$1.5x10^{-8}$ μCi/ml (=15 pCi/l)

40 CFR 141.11	
Arsenic	0.05 mg/l

40 CFR 141.12	
Trihalomethanes	0.10 mg/l

40 CFR 141.15	
Ra-226+Ra-228	5 pCi/l
Alpha activity (except Ra and U)	15 pCi/l

40 CFR 141.16	
Beta and photon activity (2 L/d)	4 mrem/year
H-3	20,000 pCi/l
Sr-90	8 pCi/l

40 CFR 141.61		
CAS #	Constituent (a)	Limit
56-23-5	Carbon tetrachloride	0.005 mg/l
71-43-2	Benzene	0.005 mg/l
71-55-6	1,1,1-Trichloroethane	0.2 mg/l
75-09-2	Dichloromethane (Methylene Chloride)	0.005 mg/l
79-00-5	1,1,2-Trichloroethane	0.005 mg/l
79-01-6	1,1,2-Trichloroethylene	0.005 mg/l
95-47-6	o-Xylene	0.7 mg/l
100-41-4	Ethyl benzene	0.1 mg/l
106-46-7	1,4-Dichlorobenzene	0.075 mg/l
108-88-3	Toluene	1.0 mg/l
127-18-4	1,1,2,2-Tetrachloroethene	0.005 mg/l

40 CFR 141.62			
Antimony	0.006 mg/l	Barium	2.0 mg/l
Beryllium	0.004 mg/l	Cadmium	0.005 mg/l
Chromium	0.1 mg/l	Cyanide	0.2 mg/l
Fluorine	4.0 mg/l	Mercury	0.002 mg/l
Nitrate (as N)	10. mg/l	Nitrite (as N)	1. mg/l
Nitrate + Nitrite (as N)	10. mg/l	Selenium	0.05 mg/l
Thallium	0.002 mg/l		

a Greater than 100 analytical detects in tank waste or greater than 20 analytical detects in TWINS Solid/Liquid Hits. Taken from Wiemers 1998.

Table C.6 Requirements of Relevant Groundwater Regulations

40 CFR 264.94			
Arsenic	0.005 mg/l	Barium	1.0 mg/l
Cadmium	0.01 mg/l	Chromium	0.05 mg/l
Lead	0.05 mg/l	Mercury	0.002 mg/l
Selenium	0.01 mg/l	Silver	0.05 mg/l

WAC 173-200-040	
Alpha emitters	15 pCi/l
Beta emitters	50 pCi/l
H-3	20,000 pCi/l
Sr-90	8 pCi/l
Ra 226 plus Ra-228	5 pCi/l
Ra 226	3 pCi/l

Chemical	**WAC 173-200-040**	**WAC 173-303-645**
Arsenic	0.00005 mg/l	0.05 mg/l
Barium	1 mg/l	1 mg/l
Cadmium	0.01 mg/l	0.01 mg/l
Chlorine	250. mg/l	
Chromium	0.05 mg/l	0.05 mg/l
Copper	1. mg/l	
Fluorine	4. mg/l	
Iron	0.30 mg/l	
Lead	0.05 mg/l	0.05 mg/l
Manganese	0.05 mg/l	
Mercury	0.002 mg/l	0.002 mg/l
Selenium	0.01 mg/l	0.01 mg/l
Silver	0.05 mg/l	0.05 mg/l
Zinc	5. mg/l	
Sulfate (SO_4)	250. mg/l	
Nitrate (as N)	10. mg/l	

CAS #	Constituent (a)	**WAC 173-200-040**
56-23-5	Carbon tetrachloride	0.0003 mg/l

1.0 OVERVIEW

The purpose of the next version of the *Hanford Immobilized Low-Activity Tank Waste* (ILAW) *Performance Assessment* (ILAW PA) is to provide an updated estimate of the long-term human health and environmental impact of the disposal of ILAW and to compare these estimates against performance objectives displayed in Tables 1, 2, and 3 (Mann 1999a). Such a radiological performance assessment is required by U.S. Department of Energy (DOE) Orders on radioactive waste management (DOE 1988a and DOE 1999a). This document defines the scenarios that will be used for the next update of the PA that is scheduled to be issued in 2001. Since the previous performance assessment (Mann 1998) was issued, considerable additional data on waste form behavior and site-specific soil geotechnical properties have been collected. In addition, the 2001 ILAW PA will benefit from improved computer models and the experience gained from the previous performance assessment. However, the scenarios (that is, the features, events, and processes analyzed in the performance assessment) for the next PA are very similar to the ones in the 1998 PA.

The scenarios analyzed as part of the base case studies are chosen to represent likely situations to demonstrate compliance with the performance objectives. Other scenarios are chosen to represent situations that demonstrate the uncertainties or sensitivities of key parameters surrounding the best case. Finally, reasonably bounding scenarios are chosen to provide an understanding of the limits of performance.

The scenarios are based on guidance from the Department of Energy (1999a, 1999b, 1999c, 1999d, and 1999e) and from the U.S. Nuclear Regulatory Commission (NRC 1988 and NRC 1997). The scenarios are also based on those used in the 1998 ILAW PA (Mann 1998) and other Hanford Site performance assessments (Kincaid 1995, Wood 1995, and Wood 1996). This document updates the document (Mann 1994) which defined the scenarios used in the 1998 ILAW PA.

This document provides a general description of the scenarios that will be analyzed. A series of documents (data packages) [Fayer 1999, Kaplan 1999, Khaleel 1999, Meyer 1999, McGrail 1999, Prosser 1999, Puigh 1999, Reidel 1999, Rittmann 1999, and Wootan 1999] that cover each of the various data areas important to the performance assessment will be published later this year. These data packages will provide the values for all of the parameters used in the analyses as well as the associated uncertainty information. Each of these data packages will have a formal review plan that will include external review.

Chapter 2 provides background information about the ILAW disposal. The next three chapters,

3. All-Pathways and Groundwater
4. Releases to the Atmosphere
5. Inadvertent Intruder,

define the scenarios for each set of performance objectives. Since contamination transport to surface water (such as the Columbia River) will be through the groundwater pathway, that

pathway is also described in Chapter 3. Chapter 6 describes the public involvement process used for this document.

Table 1.1 Radiological Performance Objectives

Protection of General Public and Workers [a, b]	
All-pathways dose from only this facility	25 mrem in a year [d, h]
All-pathways dose including other Hanford Site sources	100 mrem in a year [e, i]
Protection of an Inadvertent Intruder [c, f]	
Acute exposure	500 mrem
Continuous exposure	100 mrem in a year
Protection of Groundwater Resources [b, d, j]	
Alpha emitters	
$^{226}Ra + ^{228}Ra$	5 pCi/ℓ
All others (total)	15 pCi/ℓ
Beta and photon emitters	4 mrem in a year
Protection of Surface Water Resources [b, g]	
Alpha emitters	
$^{226}Ra + ^{228}Ra$	0.3 pCi/ℓ [j]
All others (total)	15 pCi/ℓ [j]
Beta and photon emitters	1 mrem in a year [k]
Protection of Air Resource [b, f, l]	
Radon (flux through surface)	20 pCi m^{-2} s^{-1}
All other radionuclides	10 mrem in a year

[a] All doses are calculated as effective dose equivalents; all concentrations are in water taken from a well. Values given are in addition to any existing amounts or background.
[b] Evaluated for 1,000 and 10,000 years, but calculated to the time of peak or 10,000 years, whichever is longer.
[c] Evaluated for 500 years, but calculated to 1,000 years.
[d] Evaluated at the point of maximal exposure, but no closer than 100 meters (328 feet) from the disposal facility.
[e] Evaluated at the 200 East Area fence.
[f] Evaluated at the disposal facility.
[g] Evaluated at the Columbia River, no mixing with the river is assumed.
[h] Main driver is DOE Orders on *Radioactive Waste Management* (DOE 1988a and DOE 1999a)
[i] Main driver is DOE Order 5400.5, *Radiation Protection of the Public and the Environment* (DOE 1993).
[j] Main driver is "National Primary Drinking Water Regulations (40 CFR 141).
[k] Main driver is "Washington State Surface Water Standards (WAC 173-201A)
[l] Main driver is "National Emission Standards for Hazardous Air Pollutants (40 CFR 61H and 40 CFR 61Q)

Table 1.2 Performance Goals for Inorganic Materials

Chemical	Groundwater	Surface Waters
Ammonia		4.0 mg/l

BACKGROUND

To better understand the scenarios selected, some background information is presented for

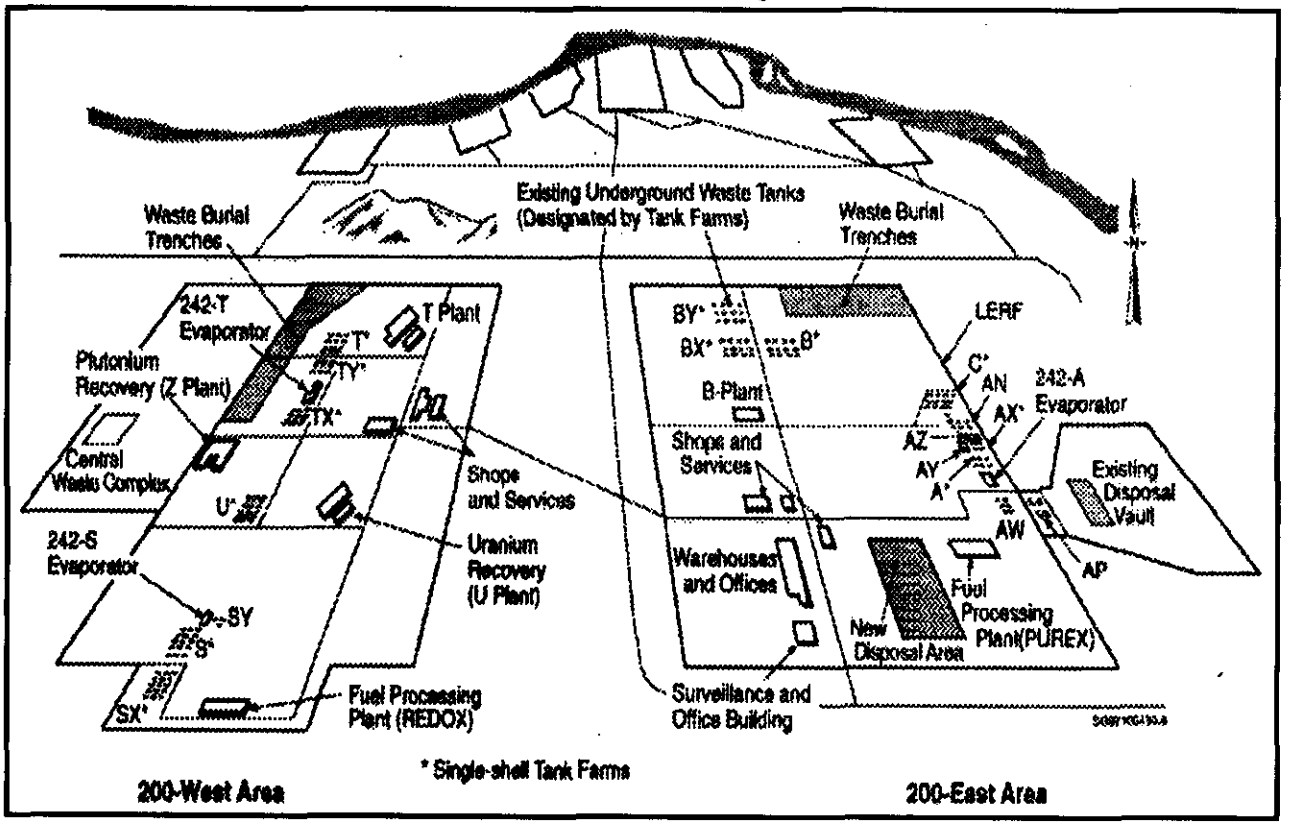
- the disposal action,
- the Hanford Site,
- the expected future land use.

Only a summary is given here. More information is provided in the *Hanford Immobilized Low-Activity Tank Waste Performance Assessment* (Mann 1998).

2.1 ILAW Disposal Action

In the 200 Areas of the Hanford there are presently 54 million gallons of high-level radioactive and hazardous waste stored in 177 underground tanks (See Figure 1). These wastes are the by-products of the production of special nuclear material for the U.S. defense effort. The inventory in the underground tanks (Kupfer 1998) for the radionuclides found most important in the 1998 ILAW PA is displayed in Table 2.1.

Table 2.1 Most Important Radionuclides in Tanks (from Kupfer 1998)



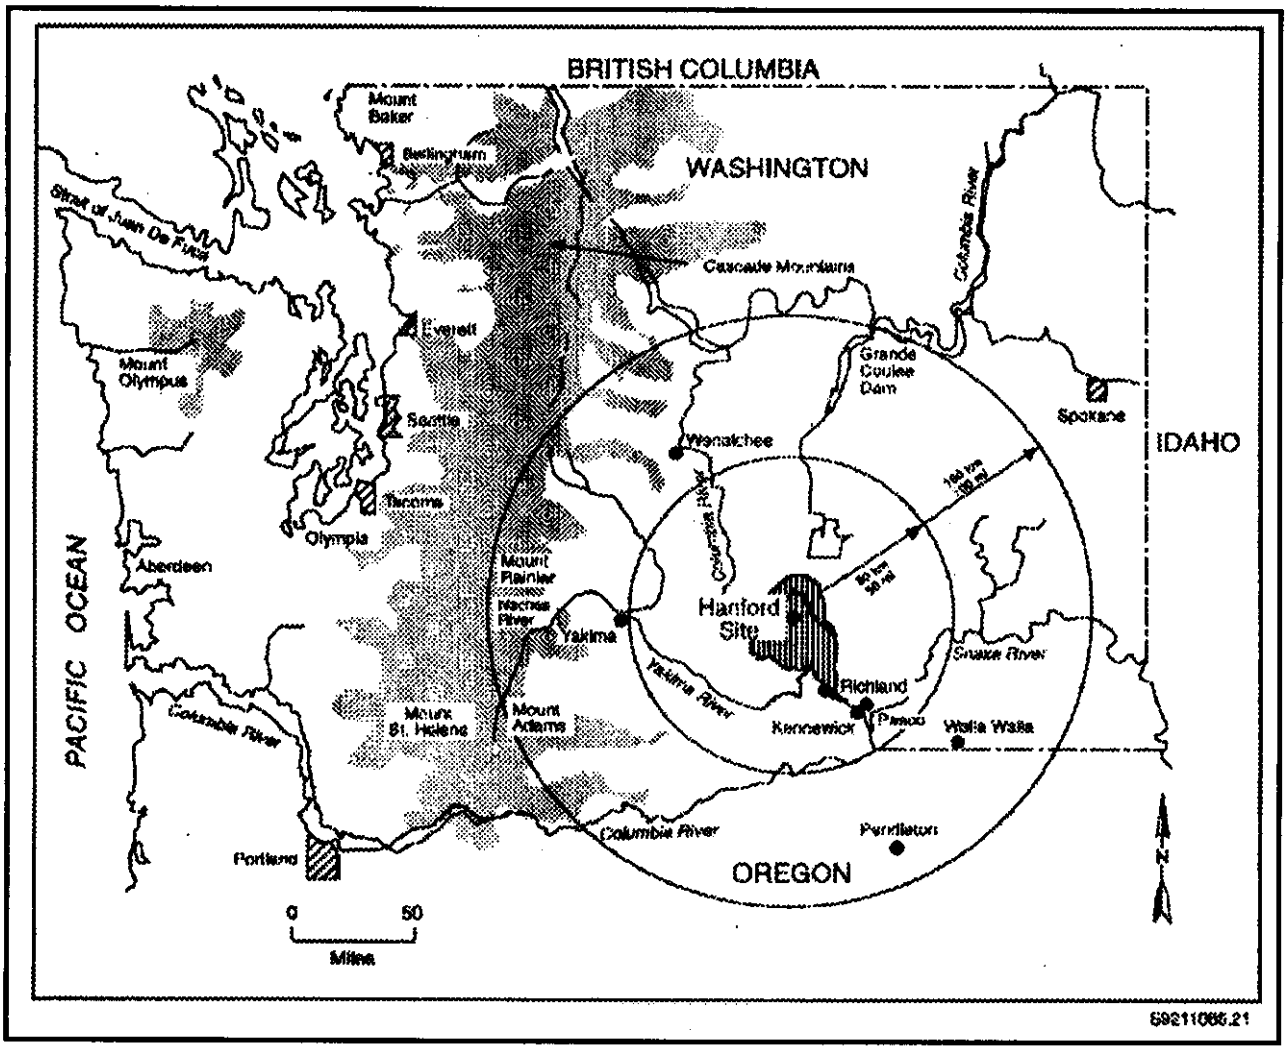
Radionuclide	Amount (Curies) (Decayed to 1/1/1994)
H - 3	34,000
Se- 79	773
Sr - 90	71,600,000
Tc - 99	32,600
Sn- 126	1,190
I - 129	63
Cs -137	46,400,000
U -235	15
U - 238	322
Pu - 239	39,000

Over the next 30 years, it is planned to retrieve the waste from the tanks and separate it into two waste streams, which will then be immobilized (TPA 1996). The high-level waste stream will contain most of the radionuclides. The immobilized high-level waste will be stored at the Hanford Site until it is transferred to a federally licensed geologic repository. The low-activity waste will contain most of the non-radioactive chemical constituents of the tank waste. The immobilized low-activity waste (about 200,000 cubic meters) will be disposed of on site in steel containers.

The Department of Energy (DOE) has entered into a contract with BNFL, Inc. (BNFL/DOE 1998) for tank waste treatment and immobilization services. Vitrification is the required method of immobilization for both the high-level and low-activity waste streams. However, the initial glass formulations have not yet been determined. The ILAW steel containers (about a meter in length in each dimension) are to last a minimum of 50 years. The long-term contaminant release rate is expected to be a few parts per million per year.

The current plans are to dispose of the ILAW containers in large underground concrete vaults (on the order of 20 to 40 meters long by 10 meters wide by 10 meters high). A surface barrier will be placed over the vault with the top of the waste being about 5 meters below the resulting ground surface. Four vaults, constructed as part of the Double-Shell Tank Waste Grout Disposal Program and are located at the eastern edge of the 200 East Area, could store about 4% of the ILAW. The remaining waste is planned to be disposed in new facilities in the south central part of the 200 East Area (Rutherford 1997) (See Figure 2.1). However, on-going engineering studies may indicate the benefits of other disposal options.

Figure 2.1 Location of the Disposal Vaults



(The four existing disposal vaults are located at the just east of the AP Tank. The new disposal facility is located in the south-central part of the 200 East Area. The tank farms are identified by their letter names, e.g. AP)

2.2 Hanford Site

The Hanford Site is located in south central Washington State (See Figure 2.). Because this site lies in the rain shadow of the Cascade Mountains, there is little precipitation most of which is removed from the soil by evaporation and plant transpiration. Thus, the Hanford Site is characterized by having a very small average moisture infiltration rate to the water table.

Figure 2.2 Location of the Hanford Site

The Hanford Site lies in the Pasco Basin of the Columbia Intermontane Province. This province is the product of the Miocene continental flood, basalt volcanism, and regional deformation that occurred 6 to 17.5 million years ago. Glacier-related flooding has had a major impact on the physical geography. Cataclysmic flooding occurred when ice dams in western Montana and northern Idaho were breached, allowing large volumes of water to spill across eastern and central Washington. The last series of major floods occurred about 13,000 years ago, during the late Pleistocene Epoch. Interconnected flood channels, giant current ripples, and giant flood bars are among the landforms created by the floods. These formations resulted in heterogeneous and discontinuous characteristics for sediments ranging in size from silts to coarse gravels.

The top three geologic strata at the disposal site locations (the Holocene deposits, the Hanford formation, and, the Ringold Formation) have important roles in the performance assessment. More details are given in Mann 1998.

During the Holocene Epoch (the last 11,000 years), winds have locally reworked the flood sediments. The winds deposited dune sands in the lower elevation and loess (very fine wind-blown silts) around the margins of the Pasco Basin. Generally, anchoring vegetation has stabilized sand dunes. There is little potential for landslides, flooding, volanicism, or earthquakes at the disposal sites.

The Hanford formation was deposited by the catastrophic ice age flooding. The formation consists of pebble-to-boulder sized gravel, fine- to coarse-grained sand, and silt. It can be divided into two main facies: coarse-grained or gravelly deposits and fine-grained or sandy and silty deposits. The gravelly facies consists of coarse-grained sand and granule-to-boulder sized gravel. These gravels often lack matrix material and have an open framework appearance. The gravelly facies was deposited by high-energy floodwaters in flood bars and along channelways. The sand and silt facies consist of silt and fine- to coarse-grained sand that commonly display normally graded rhythmites a few centimeters to several tens of centimeters thick in outcrop (Myers 1979, DOE 1988b). These sediments were deposited under slackwater conditions and in backflooded areas (DOE 1988b). Clastic dikes are vertical features occasionally seen in the Hanford formation. In clastic dikes coarser Hanford formation materials surround a vertical hexagonal structure of very-fine grained sand. At the location of the disposal facilities, the Hanford formation is about 90 to 105 m (300 to 345 ft) thick and consists predominantly of sands and gravelly sands. The sandy sequence is interpreted to lie between a slightly gravelly sand and a lower sandy gravel to gravelly sand. The Hanford formation thickens both to the north and south of the site of the new disposal facilities.

The Ringold Formation is assigned to a late Miocene to Pliocene age (Fecht 1987, DOE 1988b) and consists of clay, silt, compacted mud, fine- to coarse-grained sand, and granular to cobble gravel. In general, it tends to be finer-grained, or siltier, in the upper parts just below the Hanford formation. At the existing vaults site, the Ringold Formation starts about 90 meters (300 feet) below the unperturbed surface. At this location, the Ringold Formation is about 25 to 32 meters (82 to 105 feet) thick. At the site of the new disposal facilities, the Formation begins at about 100 meters (330 feet) and is about 30 to 38 meters (100

to 125 feet) thick. In both cases the Ringold Formation lies atop the Columbia River Basalt Group.

2.3 Future Land Use

In 1992, DOE, EPA, and Ecology gathered a group of stakeholders to study future land use of the Hanford Site. This Hanford Future Site Uses Working Group issued a summary (HFSUWG 1992a) and a detailed report (HFSUWG 1992b) of its findings. The draft *Hanford Remediation Action Environmental Impact Statement and Comprehensive Land Use Plan* (DOE 1996) is heavily based on the work of the Hanford Future Site Uses Working Group. However, DOE's land use planning extends for only 50 years instead of the 100 years forecast by the working group.

HFSUWG (1992a) contains the following statement about near-term use of the 200 Areas, called the Central Plateau in the report.

> "The presence of many different types of radionuclides and hazardous constituents in various forms and combinations throughout the site poses a key challenge to the Hanford cleanup. To facilitate cleanup of the rest of the site, wastes from throughout the Hanford site should be concentrated in the Central Plateau...Waste storage, treatment, and disposal activities in the Central Plateau should be concentrated within this area as well, whenever feasible, to minimize the amount of land devoted to, or contaminated by, waste management activities. This principle of minimizing land used for waste management should specifically be considered in imminent near-term decisions about utilizing additional uncontaminated Central Plateau lands for permanent disposal of grout."

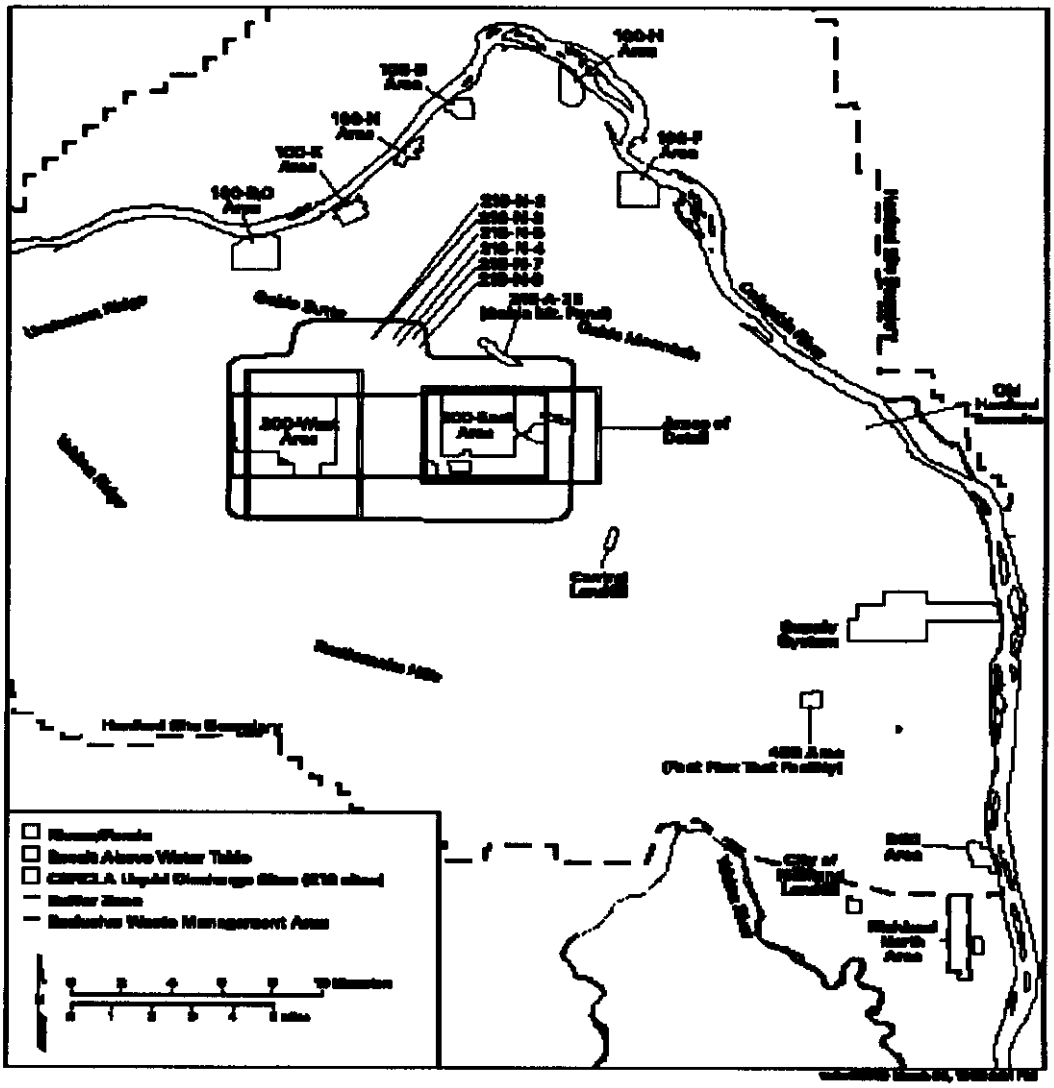
The report continues on the subject of future use options (HFSUWG 1992a),

> "In general, the Working Group desires that the overall cleanup criteria for the Central Plateau should enable general usage of the land and groundwater for other than waste management activities in the horizon of 100 years from the decommissioning of waste management facilities and closure of waste disposal areas."

Based on conversations of the working group, no definition of "general use" could be agreed on. For the "foreseeable future" the working group developed options involving waste treatment, storage, and disposal of DOE low-level radioactive waste. The differences among the options are whether offsite waste (radioactive and/or hazardous) would be allowed to be disposed of on the Hanford Site.

Finally (HFSUWG 1992a),

> "The working group identified a single cleanup scenario for the Central Plateau. This scenario assumes that future uses of the surface, subsurface and groundwater in and immediately surrounding the 200 West and 200 East Areas would be exclusive...Surrounding the exclusive area would be a temporary surface and subsurface exclusive buffer zone composed of at least the rest of the Central Plateau...As the risks from the waste management activities decrease, it is expected that the buffer zone would shrink commensurately."



For nearer term land use planning, as part of the Washington State Growth Management Act of 1991, Benton County is identifying land uses for the Hanford Site. This plan treats the 200 Areas as industrial areas surrounded by "critical areas." By state law, "critical areas" are defined as land to be protected from use because of wildlife habitat or geologic or environmental conditions. Only the following areas were found suitable for development:

> The McGee Ranch area to the northwest of the 200 West Area (at least 6 km [4 mi] away), where farming would be allowed
>
> The area to the east of the 200 East Area (a minimum of 5 km [3 mi] away), where research and development activities would be allowed.

However, any formal land use planning is not expected to be accurate over the hundreds to hundreds of thousands of years covered in this analysis.

The future site boundary is shown in Figure 2.3.

Figure 2.3 Location of the Future Site Boundary

3.0 ALL-PATHWAYS AND GROUNDWATER

Previous Hanford Site performance assessments (Kincaid 1995, Mann 1998, Wood 1995, Wood 1996) have shown that the main pathway that results in exposure will involve the following eight steps

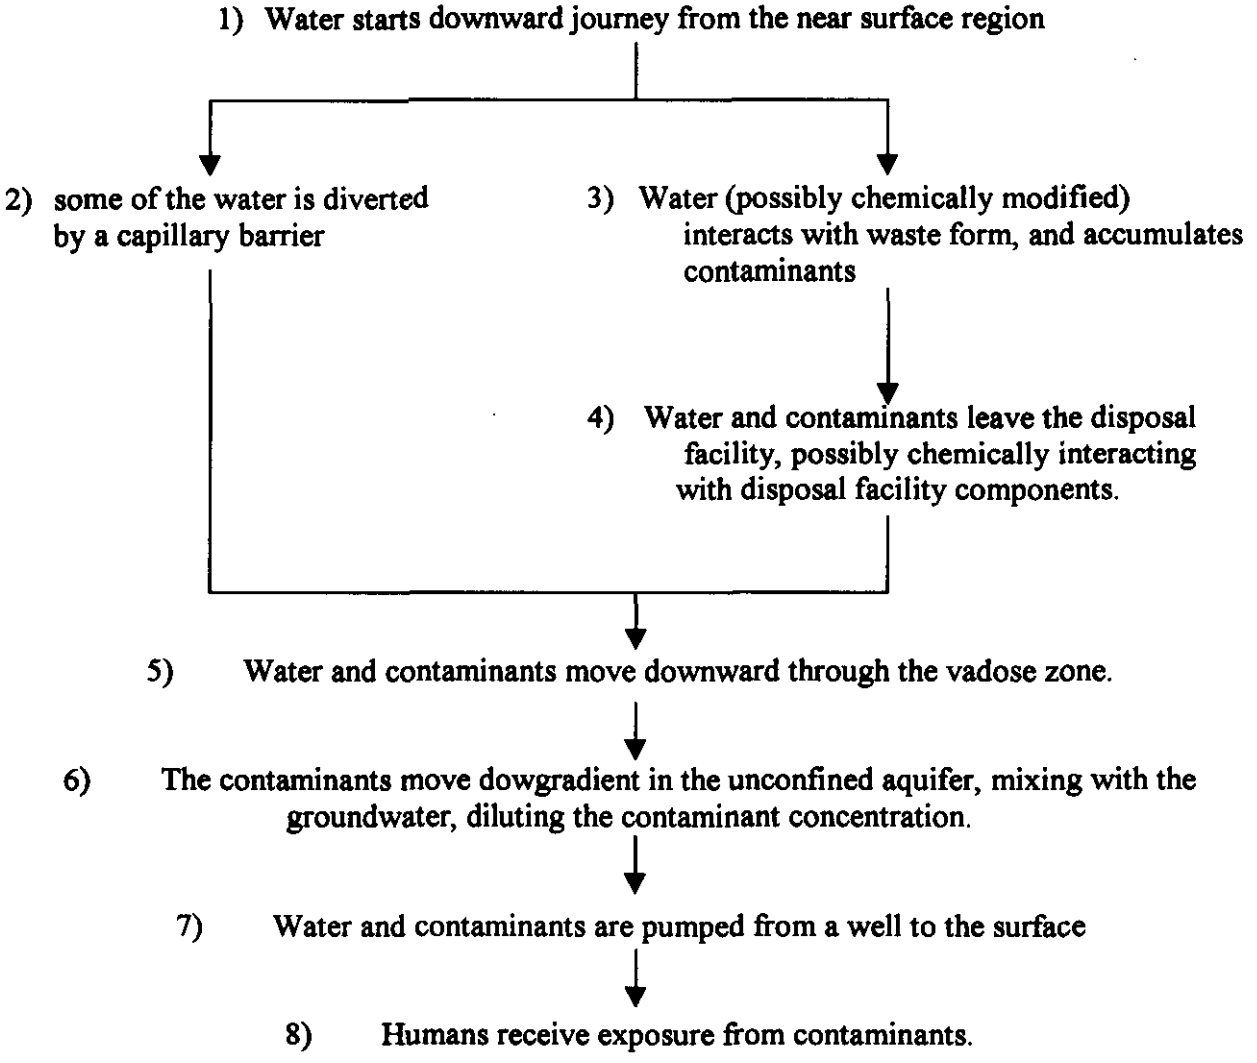
1) Precipitation (rain or snow) falls on the ground with much of the water lost to the atmosphere due to evaporation or transpiration through plant leaves. The remaining water infiltrates the soil below the surface at a very low rate.

2) The water moves downward, but some of the water is diverted by any intact sand-gravel capillary barrier.

3) The water that is not diverted away from the waste may be chemically modified by the local environment, interacts with the waste form, and accumulates contaminants.

4) The water (possibly a reduced amount because waste form dissolution and mineral formation consumes water) leaves the disposal facility carrying contaminants with it. Some contaminants may interact with the material in the disposal facility, slowing the release of contaminants to the surrounding natural environment.

5) Contaminated water moves through the undisturbed, unsaturated zone (vadose zone) below the disposal facility down to the unconfined aquifer. The contaminants may interact with soil sediments causing further retardation. Changes to the properties of the natural system are considered, but are not major.



6) The water and contaminants move and mix with the water in the unconfined aquifer until they are extracted from the aquifer and brought to the surface or until they reach the Columbia River.

7) Contaminants are extracted by being carried to the surface with groundwater being pumped through a well.

8) The contaminants result in human exposure through a variety of exposure pathways (ingestion, inhalation, dermal contact, and external radiation).

Figure 3.1 shows these eight steps (which remain unchanged from the previous ILAW PA) as a flow chart.

Figure 3.1 Sequential Steps for Groundwater Pathway

3.1 Base Case

3.1.1 General Description

The general description of the base case scenario is the one described immediately above and displayed in Figure 3.1. Explicit numerical simulations will be performed from the present to 100,000 years in the future using best-estimate values for all parameters. Such extended calculations are required because of the overlapping in time of the various contaminant plumes. The 1998 ILAW PA (Mann 1998) showed that the second most mobile radionuclides (such as uranium and its daughters) peaked at about 50,000 years, a time at which the most mobile radionuclides (technetium, selenium, and many chemicals) were still significant. Comparisons to the performance objectives will be made at 1,000 years and at 10,000 years after closure of the ILAW disposal facility (which is assumed to be in 2030).

Details for important categories of information are in the following subsections. Sections 3.2 through 3.5 contain the uncertainty, sensitivity, and reasonably bounding cases.

3.1.2 End State

The Department of Energy intends to retain the 200 Areas as long as necessary to protect human health (DOE 1996). Nonetheless, the new DOE Order on radioactive waste management (DOE 1999a) requires that the compliance point be the point of maximum exposure not nearer than 100 meters downgradient. Calculations of contaminant transport will determine the point of maximum exposure. Calculations will also be performed at the future site boundary as well as near the Columbia River. The calculations will consider the spatial overlap of the two disposal locations, but will not consider the overlap with other Hanford Site activities. The *Composite Analysis for the Low-Level Waste Disposal in the 200 Area Plateau of the Hanford Site* (Kincaid 1998 and revisions) calculates the effect of any overlap with other Hanford Site actions.

Scattered residential farms are assumed. Much of the area surrounding the Hanford Site contains irrigated farming sites. However, because of the low groundwater flow, because of the large vertical and horizontal distances from the Columbia River, and because of the difficulty to obtain water rights (Prosser 1999), it is unlikely that irrigated farming will occur and thus a dry land farming scenario is assumed. Parameters describing well construction and use will be taken from *Future Hanford Site Farming Scenarios* (Prosser 1999).

3.1.3 Engineered Facility

Immobilized low-activity waste is planned to be disposed at the two locations stated in Chapter 2. At each location, the waste will be disposed in subsurface concrete vaults that are topped by surface barriers designed to reduce water infiltration. The important parameters in modeling moisture flow, contaminant release, and contaminant transport at the disposal facility location are the elements of the disposal facility design governing moisture flow, the amount of

water entering the facility (the infiltration rate), how the water moves in the facility (hydraulic processes and properties), and how contaminants interact with the disposal structure (geochemical processes and parameters).

Only conceptual models for the disposal facilities (FDNW 1998a, FDNW 1998b) are available. The parameters to be used to describe the disposal facility in the modeling shall be taken from *Disposal Facility Parameters to be Used in the 2001 Hanford Low-Activity Tank Waste Performance Assessment* (Puigh 1999) which is based on these conceptual models.

The infiltration rate through the surface barrier will be taken from the *Recharge Data Package for the Immobilized Low-Activity Tank Waste 2001 Performance Assessment* (Fayer 1999). These estimates will be based on long-term lysimeter measurements, measurements of Cl and ^{36}Cl tracers, and detailed modeling of surface barriers. Values will be a function of space (under the surface barrier, near the barrier, and far from the barrier) and of time (intact and degraded surface barriers).

Hydraulic properties for the materials in the engineered facilities will be taken from the *Near-Field Hydrology Data Package for thee Immobilized Low-Activity Waste 2001 Performance Assessment* (Meyer 1999). The properties will be based on both existing literature and laboratory measurements including some laboratory measurements as a function of pH. Both advection and diffusion are considered. Degradation of the components of the engineered system will be accounted for by varying the hydraulic parameters as a function of time.

Chemical parameters will be taken from *Geochemical Data Package for the Hanford Low-Activity Tank Waste Performance Assessment* (Kaplan 1999). The properties will be based on, in part, laboratory measurements of geochemical reactions as a function of pH and ionic strength. Time-dependent effects will be explicitly considered in many of the performance assessment calculations.

3.1.4 Inventory

Impacts to the receptor are directly proportional to the inventory of key contaminants (e.g. ^{99}Tc). There will be a different inventory in the various ILAW packages as there is a significant variation in the waste in the various Hanford single- and double-shell tanks. ILAW package inventories will be taken from the *Immobilized Low-Activity Tank Waste Inventory Data Package* (Wootan 1999) which will be based on the best basis global and tank-by-tank inventories of the TWRS Characterization Program (Kupfer 1998) and on chemical separation efficiencies of the BNFL, INC. treatment process. The estimate will also reflect maximum concentrations required by NRC Class limits (10 CFR 61), by RCRA restrictions (10 CFR 261, 10 CFR 264, 10 CFR 269, and WAC 173-303), and by the contract between BNFL, Inc. and DOE (BNFL/DOE 1998). It is assumed that these requirements will not change with time. Inventories of hazardous materials that are part of the engineered disposal facility will be identified in *Disposal Facility Parameters to be Used in the 2001 Hanford Low-Activity Tank Waste Performance Assessment* (Puigh 1999).

3.1.5 Immobilized Low-Activity Waste

Based on the results of the previous ILAW PA (Mann 1998), the release rate from the waste form is a critical parameter. Such release rates depend on the waste form, the surrounding moisture content, the presence of key compounds (e.g. silic acid and secondary phases), as well as other environmental conditions (e.g. pH). Thus the release rate will depend on both the location of the waste form in the facility and will vary with time.

The waste form calculations will not only represent the initial release of contaminants from the glass, but also how the contaminants interact with secondary phases and with components of the engineered system. The calculations will also determine the amount of water consumed during these reactions.

Waste Form Release Data Package for the 2001 Immobilized Low-Activity Tank Waste Performance Assessment (McGrail 1999) will provide the data for calculating glass matrix dissolution, for the release of sodium from the glass matrix through ion exchange reactions, and for the creation and destruction of secondary phases. Such data are based on extensive experiments performed by both Argonne and Pacific Northwest National Laboratories following the research strategy contained in *A Strategy to Conduct an Analysis of the Long-Term Performance of Low-Activity Waste Glass in a Shallow Subsurface Disposal System at Hanford* (McGrail 1998). These experiments include the Product Consistency Test (PCT), Pressurized Unsaturated Flow (PUF) test, Single Pass Flow Through (SPFT) test, and Vapor Hydration Test (VHT).

The incoming moisture flow will come from simulations of the engineered system. Hydraulic parameters for filler material and the degraded waste form will come from the *Near-Field Hydrology Data Package for thee Immobilized Low-Activity Waste 2001 Performance Assessment* (Meyer 1999). The chemical interactions between the contaminants and the engineered materials are documented in Kaplan 1999. Impurities in the water entering the waste zone will be explicitly calculated.

3.1.6 Geotechnical Data

Transport in the vadose zone provides a significant delay in the time required before released contaminants will reach the biosphere. Transport in the groundwater further dilutes the contaminants. Although the underlying parameters in these models do not change with time as these parameters describe the properties of a stable system, vadose zone and groundwater calculations are time-dependent because the boundary conditions (recharge, groundwater inflow, and contaminant inflow) do change with time.

Inputs of moisture flow and contaminant release come from the engineered system moisture flow and from the waste form calculations. Hydraulic parameters for the vadose zone will come from the *Far-Field Hydrology Data Package for Immobilized Low-Activity Tank Waste Performance Assessment* (Khaleel 1999). The chemical interactions between the contaminants and the vadose zone soil sediments are documented in Kaplan 1999. Both the

geohydrologic and the geochemical parameters are derived from site-specific subsurface samples as well as other Hanford Site samples, corrected for upscaling from laboratory-size measurements to field-scale use. The hydraulic and geochemical data are expected to depend on the startigraphic strata. The strata will be defined in the *Geologic Data Package for 2001 Immobilized Low-Activity Tank Waste Performance Assessment* (Reidel 1999).

The contaminant flux from the vadose zone will be fed into the groundwater calculations. The Hanford Site is developing a site wide aquifer model for calculating groundwater flow and contaminant transport for impact assessments. The aquifer model and its associated database will be used for the groundwater calculations.

3.1.7 Receptor

As noted in section 3.1.2, a dry land residential farming scenario is assumed. Parameters for such a farming scenario will be taken from *Future Hanford Site Farming Scenarios* (Prosser 1999). Dosimetry parameters will follow standard Hanford Site practices (DOE 1995) and will be taken from *Data and Assumptions for Estimates of Radiation Doses for the Immobilized Low-Activity Hanford Tank Waste Performance Assessment* (Rittmann 1999).

3.2 ALARA Cases

The DOE Orders on Radioactive Waste Management (DOE 1988a and DOE 1999a) require that sensitivity calculations be performed to show that the design for the disposal action achieves impacts that are as low as reasonably achievable (ALARA). This version of the ILAW PA will analyze three areas:

- Facility design
- Inventory
- Waste Form.

The ALARA cases will also determine the effect on impacts from the uncertainty of key parameters in these three areas.

3.2.1 Facility Design

As noted in subsection 3.1.3, only conceptual designs (FDNW 1998a, FDNW 1998b) are available for the disposal facilities. Therefore, a major goal of the performance assessment is that the results of the PA will be used to optimize the disposal facility design. Sensitivity cases will be taken from *Disposal Facility Parameters to be Used in the 2001 Hanford Low-Activity Tank Waste Performance Assessment* (Puigh 1999), the *Recharge Data Package for the Immobilized Low-Activity Tank Waste 2001 Performance Assessment* (Fayer 1999), the *Near-Field Hydrology Data Package for the Immobilized Low-Activity Waste 2001 Performance Assessment* (Meyer 1999), and the *Geochemical Data Package for the Hanford Low-Activity Tank Waste Performance Assessment* (Kaplan 1999). Among the items to be investigated are

- different surface barriers
- presence of hydraulic diverters (both horizontal and vertical)
- different filler materials between the ILAW packages and between the ILAW packages and the disposal structure
- different material degradation rates
- subsidence of the ILAW packages
- different facility layouts.

3.2.2 Inventory

The uncertainty of the inventory of ILAW packages in a disposal facility arises from

- uncertainty in the inventory of each tank (and in the global inventory)
- uncertainty in the order in which the waste will be retrieved from the tanks
- uncertainty in how BNFL, Inc. will treat the waste (i.e. separate tank waste into low-activity and high-level fractions and how much waste will go into the product).

Uncertainty cases will be based on the uncertainty data presented in the *Immobilized Low-Activity Tank Waste Inventory Data Package* (Wootan 1999). The emphasis will be on contaminants (such as Tc) with the greatest impacts and on processes (such as off-site transfers and waste treatment) that have large impacts and are most susceptible to modification.

3.2.3 Waste Form

BNFL, Inc. has not yet determined the waste form that will be used during production. Uncertainty cases will be taken from *Parameters for the Calculation of Waste Form Release for the 2001 Hanford Low-Activity Tank Waste Performance Assessment* (McGrail 1999). The emphasis will be on different waste form formulations, waste loadings, and cooling rates as well as uncertainty in extrapolating laboratory measurements to long-term performance.

3.3 Uncertainty Cases

3.3.1 Geotechnical Alternatives

Our understanding of the vadose zone and the unconfined aquifer is incomplete. The uncertainty in vadose zone parameters will be taken the *Geologic Properties for the 2001 Hanford Low-Activity Tank Waste Performance Assessment* (Reidel 1999), the *Estimated Hydrologic Properties for the 2001 Hanford Low-Activity Tank Waste Performance Assessment* (Khaleel 1999), and the *Geochemical Data Package for the Hanford Low-Activity Tank Waste Performance Assessment* (Kaplan 1999). Key parameters to be investigated include hydraulic properties, diffusion parameters, dispersion parameters, chemical retardation parameters, and initial moisture conditions. Uncertainty cases in groundwater modeling will be defined in consultation with the Hanford Site Consolidated Groundwater Program.

3.3.2 Different Future End States

The future is by its nature quite uncertain. Therefore general conditions will be varied. Irrigation will be considered in various parts of the Hanford Site. In particular, irrigation over the disposal site shall be investigated. Other differences that are likely to be investigated include different well parameters.

3.3.3 Different Receptor Scenarios

Predicting future human activities is quite uncertain. Uncertainty cases will be taken from the *Future Hanford Site Farming Scenarios* (Prosser 1999) and from the *Data and Assumptions for Estimates of Radiation Doses for the Immobilized Low-Activity Hanford Tank Waste Performance Assessment* (Rittmann 1999). In particular, Prosser 1999 will provide uncertainties in well parameters, while Rittmann 1999 will provide uncertainties in dosimetry conversion factors. Rittmann 1999 will also provide alternative receptor scenarios, including Native American and industrial work scenarios.

4.0 ATMOSPHERIC RELEASES

The previous performance assessment (Mann 1998) showed that using conservative assumptions that releases to the atmosphere are many orders of magnitude (four in the case of radon releases and nine for other gases) less than performance objectives.

The release rate of gases from the waste form will be taken as the same as the dissolution rate of the glass (see subsection 3.1.5). The gases would then diffuse up through the disposal facility without taking credit for any intact-engineered barriers (such as metal containers or concrete structures). Diffusion parameters will be taken from the *Near-Field Hydrology Data Package for the Immobilized Low-Activity Waste 2001 Performance Assessment* (Meyer 1999).

5.0 INADVERTENT INTRUDER

Following the practice of the Nuclear Regulatory Commission (NRC 1998, NRC 1997), three scenarios were considered:

- A basement is excavated which extends into the waste and hence contaminants are brought to the surface
- A well is drilled through the waste, bringing contaminants to the surface,
- Contaminants that have been brought to the surface are mixed with the surrounding soil as a residential farmer works the soil.

Because the waste will be below (> 5 meters) the levels that basement excavations are dug in the Columbia Basin region, the first scenario (basement excavation) is not treated. The other two scenarios are treated.

5.1 Drilling

A likely occurrence is that a borehole will be drilled in order to obtained water either from the unconfined aquifer or, more likely, from the more voluminous confined aquifer. Because of the large gravels underlying the Hanford Site, robust drilling tools are likely to be used. Well parameters are taken from the *Future Hanford Site Farming Scenarios* (Prosser 1999). Exposure parameters are taken from the *Data and Assumptions for Estimates of Radiation Doses for the Immobilized Low-Activity Hanford Tank Waste Performance Assessment* (Rittmann 1999). No credit is taken that the driller would recognize that large blocks of glass would be brought to the surface (an unnatural occurrence). It is assumed that drilling fractures the waste form into rock-size chunks, consistent with that typically produced by ordinary drilling techniques.

5.2 Residential Farmer

After the driller leaves, with the contaminated soil still present, a residential farmer with his family occupies the land. The family is exposed to contaminants by direct irradiation from the soil, and by eating crops and animals raised on the contaminated soil. Use of contaminated groundwater is not considered as part of this scenario (because following DOE guidance for DOE O 435.1 the intruder and all-pathways scenarios are separated) as it is considered under the all pathways/groundwater scenarios. Again, credit is taken that the waste form brought to the surface will still be coarsely divided.

5.3 Uncertainty Cases

Uncertainty cases will be based on uncertainties developed in the *Future Hanford Site Farming Scenarios* (Prosser 1999) and the *Data and Assumptions for Estimates of Radiation Doses for the Immobilized Low-Activity Hanford Tank Waste Performance Assessment* (Rittmann 1999). Cases that will be included will be the volume of waste taken from the disposal facility, the type of contaminants in that volume, how intact the retrieved waste form is, and the various exposure scenarios.

6.0 PUBLIC INVOLVEMENT

It is important that Hanford stakeholders have the opportunity to affect the scenarios analyzed in the ILAW performance assessment. Public comments were requested on the original version of this document (Mann 1994) as well as revision 2 (Mann 1999b).

A summary of the initial version of the scenarios was sent to each member and alternate of the Hanford Advisory Board, to selected Hanford Site contractor employees, and to selected members of the DOE's Peer Review Panel and Performance Assessment Task Team. Their comments and corresponding responses to the previous version of this document are available for review (Murkowski 1995).

Revision 2 of this document was made available for public review following the public involvement procedures established by the Hanford Groundwater / Vadose Zone Integration Project (that is, announcements were made at biweekly meetings, the review period was noted on the published list of Integration Project activities, and the documents were available on the Integration Project's web site). Only the Oregon Office of Energy submitted comments (Blazek 1999) and these mainly dealt with waste classification, the extent of public announcement, and other general program activities. Because of the nature of the comments, no changes were made to revision 2 based on these comments. The comments from the Oregon Office of Energy as well as the responses (Taylor 1999) to them by the Department of Energy's Office of River Protection are available on request.

Comments on this version of the document should be sent to:

Frederick M. Mann
Fluor Daniel Northwest
Mail Stop H0-22
Post Office Box 1050
Richland, Washington 99352

Since calculations for the performance assessment will begin in October 1999, to be effective the comments should be sent as soon as possible.

SUMMARY

Planned performance assessments for the proposed disposal of low-activity waste (LAW) glass produced from remediation of wastes stored in underground tanks at Hanford, Washington will require calculations of radionuclide release rates from the subsurface disposal facility. These calculations will be done with the aid of computer codes. The available computer codes with suitable capabilities at the time Revision 0 of this document was prepared were ranked in terms of the feature sets implemented in the code that match a set a physical, chemical, numerical, and functional capabilities needed to assess release rates from the engineered system. The needed capabilities were identified from an analysis of the important physical and chemical processes expected to affect LAW glass corrosion and the mobility of radionuclides. This analysis was repeated in this report but updated to include additional processes that have been found to be important since Revision 0 was issued and to include additional codes that have been released. The highest ranked computer code was found to be the STORM code developed at PNNL for the U.S. Department of Energy for evaluation of arid land disposal sites.

1.0 INTRODUCTION

The Tri-Party agreement (Ecology 1996) between the State of Washington Department of Ecology, the U.S. Department of Energy (DOE), and the U.S. Environmental Protection Agency (EPA) specifies vitrification as the encapsulation technology for low-activity wastes (LAW). The DOE and its contractors are currently obligated to meet DOE Order 5820.2A on radioactive waste management. However, it is anticipated that DOE Order 435.1 will become the primary regulation governing management and disposal of radioactive waste at DOE facilities. Before the low-activity radioactive waste can be disposed of, DOE-Headquarters must issue a Disposal Authorization Statement to the Richland Operations Office. The issuance of this Disposal Authorization Statement is predicated on many analyses, including a performance assessment, which investigates the ability of the disposal system to provide long-term environmental, public health, and safety protection.

The Hanford Low-Activity Tank Waste Disposal Project currently plans to issue a performance assessment for the disposal facility in 2001. The performance assessment will be based on as much site and materials-specific data as possible to demonstrate a high likelihood that the facility will meet regulatory requirements, and therefore, support a decision to begin construction of vitrification facilities.

Performance assessments for the disposal of Hanford LAW will require calculating radiation dose to a future population as result of any release and transport of radionuclides to the unconfined aquifer located approximately 70 m below the disposal facility. The processes controlling release and transport of radionuclides to the unconfined aquifer are expected to be simulated by using computer models. However, the specific processes to be simulated by computer codes are not well defined because facility design, waste form selection, and data collection needs are currently undecided. However, three major functions will be modeled by computer codes:

1. release of contaminants from the vitrified waste form,
2. transport of those contaminants through the engineered system, and
3. transport through the vadose zone and groundwater.

This document describes the rationale and approach used to select a computer code suitable for simulating major functions 1 and 2. For reasons which are discussed in detail in the following sections, functions 1 and 2 cannot be readily decoupled. As a result, functions 1 and 2 are discussed in this report in combination as an engineered-system release model.

1.1 CODE SELECTION CRITERIA

The following general criteria (Mann 1994) were used to identify codes suitable for modeling engineered-system release:

1. The theoretical framework of the selected computer code shall be based on appropriate scientific principles (for example, conservation of mass, momentum, and energy) and well established engineering equations (for example, Darcy's law and Fick's law).

2. The selected code shall be documented in a technical report and contain descriptions of
   a) model theory, governing equations, and assumptions
   b) computational techniques and algorithms
   c) example applications.

3. The selected code shall be maintained under a software quality management program that assures that modifications and updates are traceable, auditable, and documented. Audits by the Project Hanford Management Contractor (PHMC) and other organizations may occur.

4. The selected code shall allow the use of site- and facility-specific data/standards/guidelines as appropriate. For example, the ability to use site-specific vadose zone parameters is required rather than parameters for a generic soil type.

5. Because some simulations are expected to be conducted for long-time periods (e.g., tens of thousands of years), diagnostic monitoring capability of the simulation during actual run-time or else a restart option as a minimum is required.

The following desirable features were also considered:

1. The selected code should be certified (that is, simulation results compared with field and/or laboratory data) for a system similar to that being modeled.

2. The degree of complexity of the selected code shall be consistent with the quantity and quality of data and the objectives of the computation. Screening calculations and sensitivity analyses should be used to simplify conceptual models and ultimately direct code selection.

3. Computer hardware requirements for the selected code should be consistent with available platforms and be affordable. Compatibility among computing platforms is highly desirable.

4. Proprietary codes should be used only if they provide a distinct advantage over public domain codes; and only if the author(s)/custodian(s) allow inspection and verification of the source code. If a proprietary code is used,

   a) the source code must be made available by lease or purchase to the PHMC and
   b) the executable version must be made available by lease or purchase to interested parties.

5. Consideration must be given to the ease of interfacing code input/output with other codes. The availability of pre- and post-processors should be given adequate consideration in selecting a code.

6. Familiarity with the selected code is also a consideration in light of time and resource constraints.

7. To enhance technical acceptability, the selected code should be generally known and accepted by the user community.

8. To reduce the presence of known bugs, the selected code should be a recent version, preferably the last one that has been fully tested, of a family of codes.

These code selection criteria are based on information from the LAW programs of the DOE (Case 1988) and U.S. Nuclear Regulatory Commission (Kozak 1989), as well as experience gained from submitted DOE radiological performance assessments (WSRC 1992; Kincaid 1993). A summary description of risk-assessment codes at Hanford (DOE/RL 1991) was also used.

1.2 CODE IDENTIFICATION METHODOLOGY

Although the above code selection criteria provide useful guidance for code selection, a methodology is needed to identify suitable codes for engineered-system release calculations. The methodology used in this report consists of 1) identifying model requirements, and 2) critically reviewing the capabilities of existing codes against the model requirements. In identifying model requirements, the best current information on the system geometry and materials under consideration was used to identify those physical and chemical processes that must be simulated in the selected engineered-system release model. Any computer model that met at least 50% of the requirements was included in the set of codes from which the final selection was made. Each computer code was then ranked in accordance with a point ranking system described in the Code Selection section. The intent was to make the code selection process as unbiased as possible, al-

though the authors' opinion as to the importance of a particular process certainly influenced the final ranking.

2.0 MODEL REQUIREMENTS

In this section, the model requirements are described, given the best current information on the design and materials that are under consideration for use in the engineered system.

2.1 SYSTEM DESCRIPTION

Figure 1 gives a schematic illustration of a multi-barrier, engineered-system concept for Hanford LAW. The engineered system is assumed to begin with the water chemistry conditioner (crushed glass) and end at the bottom soil/clay layer. No specific materials have been selected for any of the engineered components depicted in Figure 1, and some of these components may not be included in the final design of the disposal facility. However, Table 1 gives a list of general types of materials that have been considered. By evaluating the important physical and

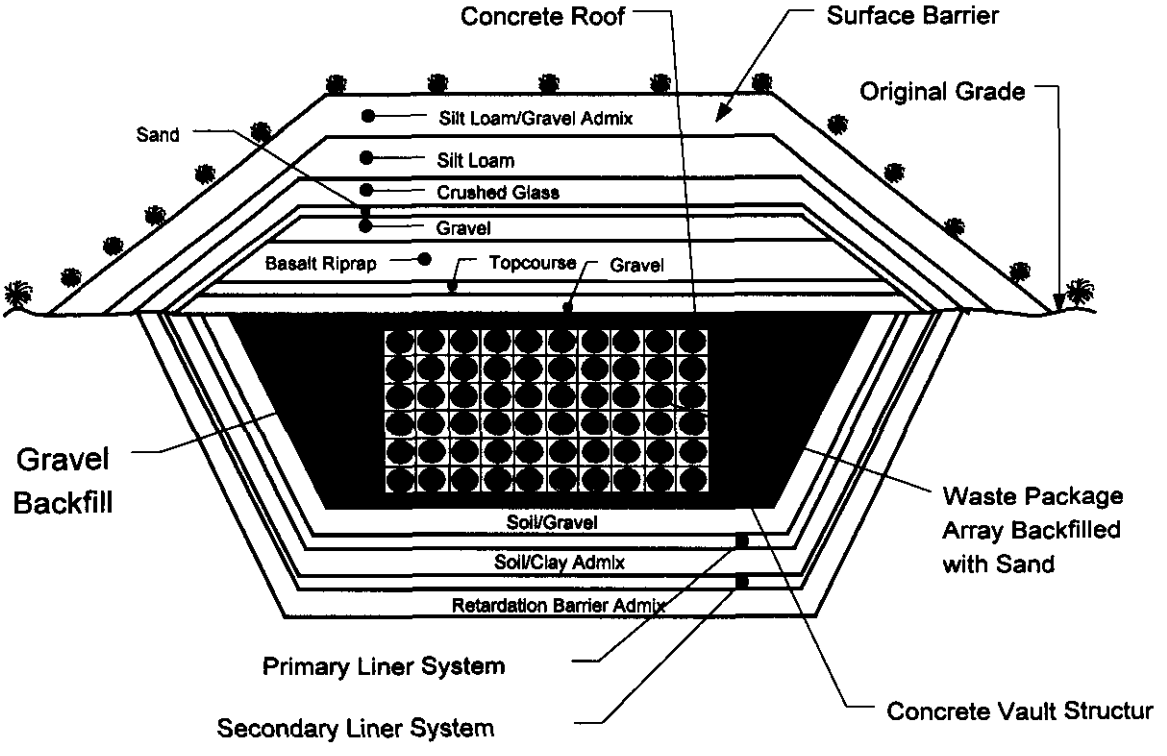

Figure 1. Engineered-System Concept for Hanford LAW

chemical properties of these materials, the important physical and chemical processes that must be modeled in the engineered system can be derived. The important physical processes are discussed in the next section followed by a discussion of the important chemical processes.

Table 1. List of Materials Under Consideration for Engineered-System Components

System Component	Materials
Water chemistry conditioner	Diatomaceous earth Amorphous silica Cristobalite Crushed glass
Vault	Portland concrete Reinforced portland concrete Sulfur polymer concrete
Backfill	Hanford soil Clay and clay-soil mixtures
Container	Carbon steel Stainless steel
Glass	Aluminosilicate Soda-lime silicate Borosilicate Phosphate
Retardation barrier	Iron metal-soil mixture Zeolites

2.2 PHYSICAL PROCESSES

Neglecting physical intrusion or a catastrophic event such as volcanism or meteor impact, radionuclide release from the engineered system can only occur by mass transport processes. Solid-state diffusion can be neglected because it is extremely slow at expected soil temperature (<25°C), and therefore, would contribute vanishingly small mass flux from the engineered system. The principal processes to be considered are therefore aqueous- and gas-phase mass transport.

2.2.1 Aqueous Phase Mass Transport

With the exception of the glass waste form and steel container, the materials being considered for the LAW engineered system are porous materials. Aqueous transport through porous materials has, traditionally, been treated with concepts derived from continuum mechanics. By averaging microscopic variations in the properties of the porous material over a representative elementary volume (REV), macroscopic properties for the REV are derived. Using the macroscopic properties of the REV and the fundamental principle of conservation of mass, the following equation can be derived:

$$\frac{\partial \theta_l c_l^i}{\partial t} = -\nabla \cdot \mathbf{q}_l^i + \theta_l \rho_l R_l^i + \dot{m}_l^i, \quad i = 1,2,...N_l \tag{1}$$

where c_l^i = aqueous concentration of component i, g/m^3

$\dot{m}_l^i$ = total mass source or sink rate of component i, g/m^3·s

N_l = number of aqueous components

$\mathbf{q}_l^i$ = total flux of component i, g/m^2·s

R_l^i = rate of production or consumption of i due to chemical reactions, g/g$_l$·s

θ_l = volumetric water content

ρ_l = fluid density, g/m^3.

If it is assumed that the phenomena of hydrodynamic dispersion in the REV can be represented by a Fickian type law, then the total flux due to advection, dispersion, and diffusion is given by

$$\mathbf{q}_l^i = \theta_l (c_l^i \mathbf{V} - \mathbf{D}_l(\theta_l) \cdot \nabla c_l^i). \tag{2}$$

where $\mathbf{D}_l$ = hydrodynamic dispersion tensor, m^2/s

$\mathbf{V}$ = fluid velocity vector, m/s.

Substituting Equation (2) into Equation (1), ones arrives at

$$\frac{\partial \theta_l c_l^i}{\partial t} = \nabla \cdot \theta_l \mathbf{D}_l(\theta_l) \cdot \nabla c_l^i - \nabla \cdot \theta_l c_l^i \mathbf{V} + \theta_l \rho_l R_l^i + \dot{m}_l^i, \quad i = 1,2,...N_l \tag{3}$$

which is commonly known as the advection-dispersion equation. The solution to Equation (3), in various forms, is the basis for almost every subsurface transport code that has been developed to date.

In principle, Equation (3) should be applicable for analyzing radionuclide release from the engineered system. However, Equation (3) may not be an adequate model for glass waste. Depending on the size of the waste glass logs and the degree of stress fracturing induced during cooling, the concept of an REV may break down. However, if the degree of fracturing is sufficiently dense, the glass may be treated as an equivalent nonfractured continuum (Berkowitz, Bear, and Braester 1988) or by a dual porosity model (Rowe and Booker 1990), and Equation (3) may be applicable. However, if the fracturing is discrete, then an alternative mathematical treatment of transport along the fractures must be developed. For the code selection, it will be assumed that the glass can be treated with an equivalent continuum model so that codes with the capability of solving a form of Equation (3) are all that is required.

2.2.2 Gas Phase Mass Transport

The radionuclides incorporated in a silicate-based glass product have a low vapor pressure under disposal system conditions; therefore, gas-phase transport can be neglected for these species. However, gas-phase transport will be an important consideration when modeling chemical processes in the engineered system and must be considered in the engineered-system code. For example, dissolved O_2 may be consumed/produced from oxidation/reduction reactions that occur with the steel container and rebar used in the concrete vaults. These oxidation/reduction reactions can have a very large effect on the solubility (and hence release) of radionuclides like ^{99}Tc.

Gas phase mass transport is treated in much the same way as the development of the aqueous phase transport Equation (3). Gas phase transport can occur through the gas phase and as a dissolved component in the aqueous phase. Assuming Darcy's law applies for the advective transport, and a Fickian type law for the dispersive transport, the gas phase conservation equation is

$$\frac{\partial \theta_g c_g^i}{\partial t} = \nabla \cdot \theta_g \mathbf{D}_g(\theta_g) \cdot \nabla c_g^i + \nabla \left[\frac{\tilde{k} k_g c_g^i}{\mu_g} (\nabla P_g + \rho_g \mathbf{g} \nabla z) \right] + \theta_g \rho_g^i R_g^i + \dot{m}_g^i, i = 1,2,...N_g \quad (4)$$

where c_g^i = concentration of gas phase component *i*, g/m^3

$\mathbf{D}_g$ = gas dispersion tensor, m^2/s

$\mathbf{g}$ = gravitational constant, m/s^2

$\tilde{k}$ = intrinsic permeability tensor, m^2

k_g = relative gas phase permeability

$\dot{m}_g^i$ = total mass source or sink rate of gas component *i*, g/m^3·s

N_g = number of gas components

P_g = total gas phase pressure, Pa

R_g^i = rate of production or consumption of *i* due to chemical reactions, g/g$_g$·s

z = elevation, m

μ_g = gas phase dynamic viscosity, Pa·s

θ_g = volumetric gas content

ρ_g = gas phase density, g/m^3.

The same caveats regarding the applicability of the REV concept discussed in Section 2.2.1 apply to the solution of Equation (4). Equation (3) for aqueous component transport and Equation (4) for gas component transport are coupled through the terms R_l^i and R_g^i, which account for interphase (gas-water) chemical reactions.

2.2.3 Fluid Flow

Water flow in the near-surface unsaturated zone is transient because of intermittent precipitation events. Transient water flow begins with the entry of water at the ground surface and subsequent infiltration downward into the disposal facility. The rate of infiltration into the facility is controlled by the rate and duration of water application at the surface, the hydraulic conductivity of engineered barriers, the vault, and surrounding soil, and the matric and gravity potential gradients. At some distance from the ground surface, transient effects will dampen out and the downward flowing water will reach a steady infiltration rate. The distance at which steady infiltration occurs is sometimes referred to as the penetration depth (Eagleson 1978; Salvucci 1993). Thus, the unsaturated zone essentially comprises two regions: an unsteady-flow region between the ground surface and penetration depth, and a steady-flow region between the penetration depth and the saturated zone water table. The steady flux in the lower unsaturated region is equal to the

annual rate of ground-water recharge, and therefore, comprises contributions not only from the most recent pulse, but from previous precipitation events as well. Given expected recharge rates for the Hanford Site, the disposal facility will be situated below the penetration depth in the region of steady flow.

Assuming, once again, that the concept of a REV applies and that Darcy's law is valid for modeling fluid flow through the engineered system, a water mass conservation equation can be derived

$$\frac{\partial \rho_l \theta_l}{\partial t} = \nabla \left[\frac{\tilde{k} k_l(\theta_l) \rho_l}{\mu_l} (\nabla P_l + \rho_l \mathbf{g} \nabla z) \right] + \theta_l \rho_l R_l + \dot{m}_l \qquad (5)$$

where k_l = relative water permeability
P_l = liquid phase pressure, Pa
R_l = rate of water consumption due to all chemical reactions, $g_w/g_l \cdot s$
$\dot{m}_l$ = total mass source or sink rate of fluid, $g/m^3 \cdot s$
μ_l = liquid phase dynamic viscosity, Pa·s.

The need to solve the fluid mass conservation Equation (5) in the engineered-system simulator is dependent on

1. assumptions regarding the effects of mass transport and chemical reactions on the properties of the engineered components, such as porosity and permeability
2. assumptions regarding the influence of chemical reactions on the water mass balance, i.e., moisture content.

If it is assumed that mass transport and chemical reactions have a negligible impact on the properties and moisture content of the engineered system, then there is no need to solve Equation (5) in the engineered-system simulator. The flow field can be calculated from any number of codes capable of simulating unsaturated flow. However, because chemical reactions are likely to play a significant role in altering the properties of the engineered-system components and in consuming/releasing water, the preferred engineered-system code would include the capability for solving the water mass conservation equation (5). Because the unsaturated hydraulic conductivity varies as a function of moisture content and particle size distribution in porous media, the ability to define different functions describing the moisture characteristic curves (e.g., van Genuchten,

1980) for each subsurface material is critical. An accurate evaluation of Equation (5) would also require a means to estimate the change in the water permeability function (k_l) as the distribution of solids change as a function of time. This could be done with an empirical function or weighted sum for the major mineral phases affecting k_l.

2.2.4 Heat Transport

The process of radioactive decay generates heat in a solid due to the energy loss associated with the interactions of the emitted charged particles or photons with the atoms in the solid and the energy loss associated with collisions from the recoiling nucleus. Because of the long half-life and small concentration of radionuclides in LAW, the increase in temperature of the engineered system over ambient conditions is expected to be small. This conjecture was checked with a simple heat transfer calculation.

The vault can be idealized as a composite, infinitely long slab as illustrated in Figure 2. By neglecting heat transfer through the side walls, a conservative estimate of the temperature rise can be obtained. The applicable steady-state heat conduction equations are obtained from Fourier's law and are

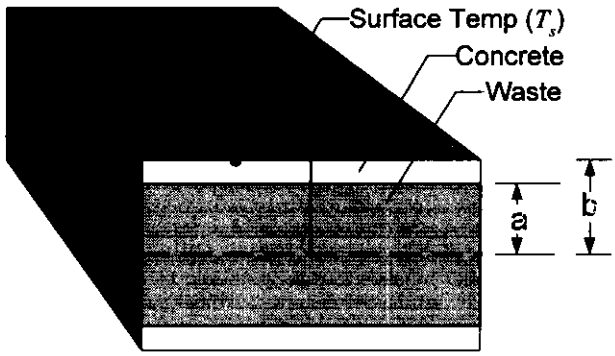

Figure 2. Schematic of Slab Geometry Used for Heat Transfer Calculation

$$\frac{d^2T_1}{dx^2} + \frac{Q}{\kappa_1} = 0, \quad 0 \le x \le a$$
$$\frac{d^2T_2}{dx^2} = 0, \quad a \le x \le b \tag{6}$$

where T_ℓ = temperature in waste ($\ell = 1$) or concrete ($\ell = 2$) regions, K
Q = volumetric heat generation rate of waste glass, W/m^3
κ_ℓ = thermal conductivity of glass ($\ell = 1$) or concrete ($\ell = 2$), W/m·K.

A solution to Equation (6) is sought subject to the following boundary conditions

$$\left.\frac{dT_1}{dx}\right|_{x=0} = 0 \tag{7}$$

$$T_1(a) = T_2(a) \tag{8}$$

$$\kappa_1 \frac{dT_1}{dx} = \kappa_2 \frac{dT_2}{dx} \tag{9}$$

$$T_2(b) = T_s \tag{10}$$

Equation (7) results from the symmetry of the problem at the vault centerline. Equations (8) and (9) specify continuity of temperature and heat flux, respectively, at the glass/concrete interface, and Equation (10) sets the temperature at the outer surface of the concrete. The solution to the equation system 6 through 10 is

$$\begin{aligned} T_1(x) &= T_s - \frac{qx^2}{2\kappa_1} + qa^2\left(\frac{1}{2\kappa_1} - \frac{1}{\kappa_2}\right) + \frac{qab}{\kappa_2}, \quad 0 \le x \le a \\ T_2(x) &= T_s - \frac{1}{\kappa_2}(qax + qab), \quad a \le x \le b \end{aligned} \tag{11}$$

The peak temperature occurs at x=0, so the maximum temperature rise expected in the vault (ΔT_{max}) is

$$\Delta T_{max} = T_1(0) - T_s = q\left[a^2\left(\frac{1}{2\kappa_1} - \frac{1}{\kappa_2}\right) + \frac{ab}{\kappa_2}\right] \tag{12}$$

Assuming an interior vault depth of 7.5 m and concrete wall thickness of 0.5 m, we have a = 3.25 m and b = 3.75m. For the glass and concrete, a thermal conductivity of 1.13 W/(m·°C) and 1.8 W/(m·°C), respectively, will be assumed. The volumetric heat generation rate, Q, can be determined from the available information (Mann et al. 1998) on the total expected radionuclide inventory. Assuming the inventory is uniformly distributed in 200,000 m^3 of glass, and conservatively assuming that the total decay energy is deposited in the solid, a decay heat generation rate of 0.045 W/m^3 was estimated. This heat generation rate is about 10 times less than was calculated in the previous version of this document. The change is due almost entirely to the factor of 4 reduction in the amount of ^{90}Sr and factor of 2 reduction in the amount of ^{137}Cs expected in the

ILAW, based on the updated inventory data in Mann et al. (1998). The maximum (center) temperature difference between the composite slab and its immediately surrounding soil is, therefore,

$$\Delta T_{max} = 0.045\left[3.25^2\left(\frac{1}{(2)(1.13)} - \frac{1}{1.8}\right) + \frac{(3.25)(3.75)}{1.8}\right] = 0.25\ °C. \quad (13)$$

This small temperature rise is within expected seasonal temperature fluctuations at the site and so is not a significant factor affecting the performance of the engineered system. Consequently, the engineered-system model need not consider temporal or spatial variations in temperature, which obviates the need for solving a heat transport equation.

2.2.5 Radioactive Decay

Although the process of radioactive decay is not an important process when considering heat transfer for a LAW site, the process is very important when modeling radionuclide release from the engineered system. Radioactive decay is a straightforward physical process that is usually included in subsurface transport codes. Much less common, however, is the capability for simulating radioactive decay chains and decay chain ingrowth. For reasons that will be discussed in Section 2.3.7, modeling radioactive decay and decay chain ingrowth in multicomponent chemical-transport codes requires careful consideration.

2.3 CHEMICAL PROCESSES

The selected engineered-system code must consider several important chemical processes coupled with the physical processes described in Section 2.2. Chemical processes control such important factors as radionuclide solubility and retardation, and corrosion rate of the LAW glass. The chemical processes to be modeled include

- aqueous complexation
- acid-base reactions
- oxidation/reduction
- dissolution/precipitation
- ion-exchange
- adsorption.

Each of these chemical processes is discussed in more detail below.

2.3.1 Aqueous Complexation

In complexation reactions, a central cation such as a radionuclide or metal ion reacts with an anion, commonly called a ligand, to form a new soluble species called a complex. In turn, these complexes can react with other ligands to form additional complexes. Complexation reactions are especially important because these reactions significantly modify the stability, and hence, mobility of actinide and transition metals. Inorganic ligands include common anions in natural waters, e.g., OH^-, Cl^-, SO_4^{2-}, CO_3^{2-}, PO_4^{3-}, etc. These ligands may also be contributed to the aqueous phase as a result of glass-water reactions. Inorganic ligands are typically present in solution in excess compared to radionuclides and metals. Important organic ligands include molecules associated with natural humic substances and synthetic organic complexing agents.

2.3.2 Acid-Base Reactions

Acid-base reactions involve the transfer of the proton (H^+) between two species. Chemical species which lose a proton are called acids and species which gain a proton are called bases. The pH of a solution is a measure of the activity of H^+ (more precisely, H_3O^+ ion) in solution; it is defined as the net negative logarithm of the H^+ activity ($pH = -\log a_{H^+}$). Acid-base reactions are involved in many aqueous complexation, precipitation, or sorption reactions. Solution pH controls aqueous speciation, solubility of compounds, sorption behavior of elements (e.g., K_d values), complex formation, and oxidation-reduction processes. For example, under oxidizing conditions in carbonate free aqueous media, the Pu^{+6} species is in the form of PuO_2^{2+} for $pH < 5$. At pH between 5 and 7, it is in the form of $PuO_2(OH)^-$, and at pH above 7 it is in the form of $PuO_2(OH)_3^-$. Corresponding measured values for the K_d of Pu range from less than 10 ml/g at low pH, to between 10 and 100 ml/g for the neutral pH range, to over 1000 ml/g at high pH. Solution pH also impacts the corrosion rate of many materials including silicate-based glass waste forms where higher pH is more corrosive to the glass.

2.3.3 Oxidation-Reduction Reactions

Oxidation-reduction (redox) reactions involve the transfer of electrons from one species to another resulting in changes in oxidation states. Redox reactions can be classified as aqueous complexation, precipitation, or adsorption reactions; these reactions can significantly alter the mobility of multiple-oxidation state radionuclides. For example, the effectiveness of adsorption mechanisms often depends on the oxidation state of the radionuclide. Important radionuclides such as ^{99}Tc, the transition metals, and the actinides uranium and plutonium have much lower solubilities in natural waters in their lower oxidation states.

The transfer of electrons in oxidation-reduction reactions is often treated in a mathematically analogous manner as the transfer of protons in acid-base reactions. For example, the activity of the hypothetical electron in solution is defined by the parameter *pe*, which equals the negative logarithm of the hypothetical electron activity. The *pe* can also be expressed in terms of the redox potential (Eh), which is related to *pe* by

$$pe = \left(\frac{F}{2.303RT}\right) Eh \qquad (14)$$

where F is the Faraday constant, R is the gas constant, and T is the absolute temperature. However, the overall redox state of real aqueous systems usually cannot be characterized by a single parameter such as Eh. The concept of a "system" *Eh* or a "system" *pe* is based on the assumption that all redox reactions in a system are in a state of thermodynamic equilibrium. This assumption is a poor one for most real systems (Jenne 1981; Hostetler 1984; Lindberg and Runnells 1984). Redox disequilibrium in natural aqueous systems is created by solar irradiation, radioactive decay, fluid mixing, slow reaction kinetics, and transfer of redox components from one phase to another. It should also be clear that *pe* is not a perfect analog to pH, because pH is defined with respect to H^+, a real aqueous species, whereas *pe* is defined with respect to a hypothetical species.

Oxidation-reduction in aqueous systems is commonly treated in terms of redox couples and their associated half-reactions. Common couples in aqueous solution include $O_{2(aq)} / H_2O_{(\ell)}$, $H_{2(aq)} / H_2O_{(\ell)}$, Fe^{2+}/Fe^{3+}, HS^-/SO_4^{2-}, SO_3^{2-} / SO_4^{2-}, $S_2O_3^{2-} / SO_4^{2-}$, NH_4^+ / NO_3^-, $N_{2(aq)} / NO_3^-$, and a host

of organic/ HCO_3^- couples. Each couple can be treated as having its own redox state. This can be expressed in a variety of ways, including a couple-specific *Eh* or *pe*.

Another way of expressing redox state that has become increasingly popular in geochemical models is the concept of a hypothetical oxygen fugacity in aqueous solution. Oxygen fugacity in an aqueous solution is hypothetical because fugacity is a property of gas species and gas species do not exist in aqueous solution. However, $O_{2(g)}$ makes a good hypothetical aqueous species, much like the hypothetical aqueous electron is used to calculate *pe*.

The concept of a hypothetical $O_{2(g)}$ aqueous species is important because it allows the modeler to express the redox state of a system in terms of a variable that does not necessarily imply redox equilibrium as does a *pe* or *Eh*. Consequently, the preferred method for treating redox reactions in the engineered-system model is with the hypothetical $O_{2(g)}$ aqueous species.

2.3.4. Dissolution-Precipitation Reactions

Dissolution-precipitation reactions are heterogeneous chemical reactions that directly remove or release radionuclides and other elements from solution. Therefore, these types of reactions play a very important role in the overall performance of the engineered system. Extensive amounts of precipitation or dissolution can also alter the pore or fracture structure of an engineered-system component and thereby indirectly alter the mass transport properties of the component.

Dissolution-precipitation of a solid phase in an aqueous solution is a dissociation-association process in which two or more soluble species are released into or removed from solution. It is subject to the common ion effect, which occurs when a solution already contains the same ions that would be released or removed when the solid dissolves or precipitates. The presence of common ions from other sources reduces the solubility of the solid relative to its solubility in pure water.

Glass corrosion is a special type of dissolution-precipitation reaction in that it is an irreversible process. Glass corrosion is the primary mechanism of releasing radionuclides from the LAW form into the adjacent environment and must be accurately described in the engineered-system

model. Fortunately, there is an extensive body of work on borosilicate glass waste forms from which a widely accepted mathematical model has been developed. Using this model, the flux of any element i released from the glass into the aqueous phase, J_i^a, is given by

$$J_i^a = \nu_i k_0 (1 - e^{\frac{A}{RT}}) \prod_j \gamma_j c_j^{-\eta_j}, \quad i = 1, 2, \ldots N \tag{15}$$

where ν_i = stoichiometric coefficient of element i in the glass
k_0 = forward rate constant, g/(m^2·s)
A = chemical affinity of the reaction, J/mol
N = number of elements
R = gas constant, J/mol/K
T = temperature, K
c_j = concentration of jth aqueous reactant species, g/m^3
γ_j = activity coefficient of jth reactant species
η_j = stoichiometric coefficient for the jth reactant species.

Equation (15) represents a constitutive relationship that relates temperature and the composition of water contacting the glass to the corrosion rate. Because these quantities are known or calculated at each node in a chemical-transport model [Equation (3)], incorporation of a glass corrosion model [Equation (15)] can be done naturally.

Mathematically, dissolution-precipitation reactions assumed to be at equilibrium could be treated via mass-action expressions or in terms of chemical potentials. A mass-action formulation results in a system of non-linear algebraic equations that must be solved, whereas a formulation in chemical potentials requires a solution to a global free energy minimization problem. Either formulation should yield equivalent results.

Because the temperature of the LAW disposal site is expected to be approximately 15°C, an assumption of chemical equilibrium for all reactions may not be appropriate, particularly for some dissolution-precipitation reactions. At 15°C, metastable phases may persist for indefinite periods of time and many of these phases may be amorphous. This is a consequence of the Ostwald Step Rule (Ostwald 1897), which states that the reaction products initially obtained are the least stable ones lying nearest to the original state in free energy and also the "simplexity princi-

ple" (Goldsmith 1953), which states that the most disordered phase should form from a random system of components. Consequently, the selected engineered-system code should have the capability for specifying kinetically constrained reaction sets.

2.3.5 Ion-Exchange

Ion-exchange reactions are a class of adsorption reactions that may be an important control on the mobility of radionuclides and other species, especially through clays and zeolites. Ion-exchange occurs when there is a free energy reduction from the substitution of an ion in the aqueous phase with an atom in the exchangeable solid. The ability of a solid to exchange ions is usually expressed by the cation exchange capacity (CEC), which is defined as the number of milliequivalents (meq) of monovalent cations per unit mass of dry solid. The equivalent of an ion is its molecular weight divided by the absolute value of its charge. Typical CEC values for soils containing organic materials range from 30 to 100 meq/100g, depending on the mineral type, pH, and composition of the contacting solution.

As was the case for the dissolution precipitation reactions, ion-exchange reactions may be treated mathematically via mass-action expressions or chemical potentials. Mass action formulations for ion-exchange reactions are similar to those for dissolution-precipitation reactions with the exception that the equilibrium constant of the latter is replaced by a selectivity coefficient. The chemical potential formulation requires a state equation that relates the change in electrostatic potential that occurs from the ion-exchange reaction.

2.3.6 Adsorption

Adsorption is the phenomenon of increase in the mass of a substance on the solid at a fluid-solid interface. The component's affinity for adsorption to the solid surface is due to 1) electrical attraction such as van der Waals attraction, or 2) chemisorption, which is a surface complexation reaction that binds the adsorbed species to the solid surface.

The main factors affecting the adsorption and desorption of species to or from the solid are the physical and chemical characteristics of the adsorbent and of the solid surface. Interactions between mineral surfaces and dissolved ions can depend strongly on solution pH and the min-

eral's zero point of charge (ZPC). If the pH of the contacting solution is above the ZPC, the mineral surface will have a net negative charge and an affinity for cations; the reverse occurs if the pH is less than the ZPC. This phenomenon is particularly important in systems containing clays and particles coated with common hydrous oxides such as those of aluminum, manganese, and iron. These materials are often dominant sorbents in geochemical systems. Clay minerals tend to have overall negative charges for all but very acidic conditions (i.e., pH<4). Metal oxides, however, may have reactive sites capable of removing anionic radionuclide species from solution for the near-neutral to slightly basic pH range.

Numerous adsorption models exist that may be used in an engineered-system code. Empirical models are the most popular type of adsorption model, usually expressed as an isotherm, that relates the quantity of an adsorbed species to its quantity in the aqueous phase at constant temperature. Equilibrium isotherms are based on the assumption that the quantities of the component on the solid and in the adjacent solution are in equilibrium. Any change in the concentration of one of the species produces an instantaneous change in the other. Common isotherms include the linear equilibrium isotherm or K_d model given by

$$F_s^i = K_d^i c_l^i, \quad i = 1,2,...N_l \tag{16}$$

where F_s^i = mass of component i per unit mass of solid

K_d^i = distribution coefficient of component i, m^3/g,

and the Langmuir isotherm

$$F_s^i = \frac{k_3 c_l^i}{1 + k_4 c_l^i}, \quad i = 1,2,...N_l \tag{17}$$

where k_3 and k_4 are constants. There are also a variety of non-equilibrium isotherms, although these have been almost never applied in transport codes.

A semi-empirical type of adsorption model that is used in several chemical-transport codes is a surface complexation model. As was the case for the chemical reactions discussed previously, the surface complexation model may be formulated in terms of mass-action expressions or by chemical potentials. Mass-action formulations require equilibrium constants for the surface

complexation reactions being considered and the chemical potential formulation requires information on the change in electrostatic potential that occurs from the adsorption reaction. This is usually done with the aid of a double or triple-layer site binding model. For the selected engineered-system code, both empirical and surface complexation adsorption model options should be available. The latter model is expected to be used in cases where particular adsorption reactions play a crucial role in the mobility and release of a radionuclide.

2.3.7 Radioactive Decay

As discussed in section 2.2.5, the process of radioactive decay is a simple physical process to include in a transport code. However, the process of decay-chain ingrowth is not so easily implemented. Decay-chain ingrowth refers to a series of parent and daughter decay reactions that can result in the accumulation of daughter radionuclide(s) because of the differences in half-life between the members of the chain. For example, consider the decay chain

$$^{243}_{95}\mathrm{Am} \xrightarrow{7.37 \times 10^{3}\ \mathrm{y}} {}^{239}_{93}\mathrm{Np} \xrightarrow{2.35\ \mathrm{d}} {}^{239}_{94}\mathrm{Pu} \xrightarrow{2.44 \times 10^{4}\ \mathrm{y}} {}^{235}_{92}\mathrm{U}. \qquad (18)$$

Because the half-life of ^{235}U is 7.1 x 10^8 y, the decay of this radionuclide is usually insignificant over the time scales of performance assessment calculations. However, the ^{243}Am parent is usually completely decayed over typical performance assessment time scales of 10^6 y. Consequently the decay of the parent results in the accumulation of ^{239}Pu and ^{235}U.

The difficulty in describing decay-chain ingrowth in coupled chemical transport codes is the fact that each radionuclide is partitioned into multiple chemical species. These species may be aqueous, precipitated, adsorbed, etc. To maintain proper mass balance, it is, therefore, necessary to explicitly write "chemical reactions" that describe the decay of each parent species. For example, the decay of the aqueous species $AmOHCO_3$ can be written as

$$^{243}_{95}\mathrm{AmOHCO_3}(aq) \rightarrow {}^{239}_{94}\mathrm{Pu}^{3+} + \mathrm{OH}^- + \mathrm{CO_3^{2-}}. \qquad (19)$$

The decay reaction (19) is written as an irreversible, kinetically constrained reaction with the rate constant given simply by the decay constant for the ^{243}Am parent. Equation (19) is only valid when the time step being taken is much larger than the 2.35d half-life of the $^{239}_{93}$Np intermediate.

Similar reactions can be written for all the radioactive species to be considered in a simulation. Obviously, for a kinetically constrained reaction like Equation (19) to be implemented, the selected engineered-system code must be capable of treating kinetically constrained reaction sets in addition to the usual equilibrium reaction sets.

3.0 COMPARISON OF EXISTING CODES

Having described in the previous section the important physical and chemical processes that are expected to significantly impact the performance of the engineered system, we now need to evaluate the capabilities of existing computer codes in meeting these requirements and develop a means to rank the computer codes. The mechanism chosen to do this is to 1) develop a list of needed capabilities and 2) assign a figure of merit score from 1 to 10 to each capability. The figure of merit score is broken into two parts:

a) importance to modeling the performance of the engineered system

b) degree of difficulty in adding the capability to an existing code.

The figure of merit score is intended as an unbiased scheme to rank computer codes with similar capabilities. For Part *a*, a score of 1 indicates that the process has little or no importance for modeling radionuclide release from the engineered system, whereas a score of 10 means that the process is critical to the model and must be included in the selected code. Part *b* of the figure of merit score is needed because it is expected that no existing code meets all of the capabilities identified in Sections 1.0 and 2.0. Consequently, the degree of difficulty in modifying or adding a particular capability to an existing code is an important consideration in the code selection process. A Part *b* score of 1 indicates that a person familiar with the process and the code could add the capability in less than a man-week, whereas a score of 10 indicates that at least a man-year of effort would be required to add the capability to the code.

To be selected for detailed ranking, the computer code must have the capability for simulating coupled chemical reactions and transport. This requirement excluded a large number of subsurface solute transport codes (such as PORFLOW) and batch equilibrium chemistry codes such as EQ3/6.

3.1 COMPUTER CODE RANKING

The needed (or desired) code capabilities were divided into four categories. These are

- Physical Processes
- Numerical Methods
- Chemical Processes
- Functionality

Each category was then broken down into specific capabilities that were assigned the two part figure of merit score discussed in the previous section. A detailed description of the important physical and chemical capabilities was provided in Section 2.0; these are reproduced in Table 2. The total possible composite score for the first two categories is 265 out of a possible 400 points, which is 66% of the score. This fact reflects an emphasis in selecting the code with the most complete physical and chemical models.

The capabilities shown in Table 2 under the Numerical Methods category reflect general issues associated with the numerical solution of the governing partial differential equations. An emphasis was placed on codes with capabilities for 2-D simulations. Wave front sharpening is an important consideration in the solution of advection-dominated transport problems and to minimize numerical dispersion. Preference was given to codes with an option to solve the reaction transport equation implicitly versus the more typical operator splitting scheme. Operator splitting schemes are conceptually easier to implement since the reaction and transport equations are solved separately. However, the method is often slow to converge and may have mass balance problems when taking large time steps with radioactive decay (Valocchi and Malmstead 1992). Finally, parallel processing features are considered important when attempting to run problems with a large number of chemical species.

The capabilities listed under the Functionality category were given only a composite figure of merit score since these capabilities do not directly impact the use of the code for performance assessment calculations. The functionality categories considered important were the availability of a graphical user interface, a separate version of the code compiled for parallel computing, familiarity in the waste management community with code (name recognition), public availability

of the code, and finally whether the code is under active software quality assurance configuration management.

Each part *a* and *b* figure of merit score was added together to arrive at a composite figure of merit score. Codes having a specific capability were assigned the composite figure of merit score for that capability. Codes not having the capability were assigned a composite figure of merit score of zero for that capability. Figure of merit scores for each code were then tabulated to arrive at a total figure of merit score for the computer code. Table 2 gives a detailed listing of the figure of merit score for each computer code considered. The references used to compile the information on the capabilities of each code are given in Section 5.1 following the formal reference list.

Table 2. List of Engineered-System Code Capabilities and Figure of Merit Scores. References for each code are given at the end of the References section.

4.0 CONCLUSIONS AND RECOMMENDATIONS

The results from the composite figure of merit scores for the computer codes are listed in Table 2. The results show that the STORM code is the most suitable model for the purposes of conducting performance assessment calculations for the Hanford LAW engineered system. However, two codes that have been released since Revision 0 of this document was prepared rank just behind STORM. The second highest ranked code is FEHM. This code has been developed by George A. Zyvoloski and colleagues at Los Alamos National Laboratory to assist in the understanding of flow fields and mass transport in the saturated and unsaturated zones below the proposed Yucca Mountain nuclear waste repository in Nevada. Although FEHM's figure of merit score is quite good (328 compared with 336 for STORM), currently, FEHM is limited to a total of 10 interacting species, which is simply inadequate to model radionuclide release from the expected LAW glass formulations that contain 8 or more major components, excluding the radionuclides of interest. Also, FEHM is based on the operator splitting method of coupling water flow and reactive transport, which limits the size of time steps that can be achieved. The third highest ranked code is MULTIFLO, which has been developed by Peter C. Lichtner at the Center for Nuclear Waste Regulatory Analyses for application to a repository-scale model of the redistribution of moisture, heat and various chemical constituents at Yucca Mountain. Currently MULTIFLO does not simulate radioactive decay or other kinetic aqueous reactions. Discussions with Dr. Lichtner have also indicated difficulties in taking large time steps with the operator-splitting numerical method used in MULTIFLO.

The STORM code meets all of the general code selection criteria specified in Section 1.1 and nearly all of the desirable features. Desirable feature #1, "The selected code should be certified (that is, simulation results compared with field and/or laboratory data) for a system similar to that being modeled," has not been performed. However, experiments are underway that will be used to confirm the STORM code. Confirmation efforts to date only include verification of the numerical algorithms in STORM. Desirable feature #2, "The degree of complexity of the selected code shall be consistent with the quantity and quality of data and the objectives of the computation," is only partially met. The complexity of the STORM code is consistent with the objectives

of the computation to calculate radionuclide release from the engineered system but specific thermodynamic and kinetic data required to run the code have not been measured for the proposed LAW engineered-system components. However, experimental programs are in progress so that these data will be available for use in STORM calculations.

STORM was developed by coupling STOMP, a nonisothermal multiphase flow simulator (White and Oostrom, 1996), with AREST-CT version 1.1, a reactive transport and porous medium alteration simulator (Chen et al. 1995; Chen et al. 1997). The general approach was to couple the two codes by making major modifications to AREST-CT subroutines while modifying STOMP routines as little as possible. The AREST-CT code had been developed for the DOE specifically for the analysis of radionuclide releases from waste packages being designed for high-level waste disposal at the proposed Yucca Mountain repository in the state of Nevada. The characteristics of this site, i.e., unsaturated zone, glass waste forms, etc., has led to the incorporation of process models that are directly applicable to assessing the performance of currently anticipated engineered-system designs for the LAW site at Hanford. Hence, the relatively high ranking of the STORM code is to be expected. The fact that this code is also supported for use on a separate DOE program is an additional benefit in lowering the overall cost of code development and maintenance to the DOE.

It is important to note that in 1995, when the AREST-CT code was selected in Revision 0 of this document, reactive transport codes were considered fairly exotic computational tools and were few in number. Since then, development of reactive transport codes with increasingly sophisticated capabilities is being done at several universities, national laboratories, and research institutes both in the U.S. and abroad. The more widespread recognition and application of these powerful codes in solving waste disposal problems lends support for the approach we recommended in 1995 and again in this document in using the STORM reactive transport code for ILAW disposal system performance assessment.

Summary

The U.S. Department of Energy must approve a performance assessment (PA) to support the design, construction, approval, and closure of disposal facilities for immobilized low-activity waste (ILAW) currently stored in underground tanks at Hanford, Washington. A critical component of the PA is to provide quantitative estimates of radionuclide release rates from the engineered portion of the disposal facilities. Computer simulations are essential for this purpose because impacts on groundwater resources must be projected to periods of 10,000 years and longer. The computer code selected for simulating the radionuclide release rates is the Subsurface Transport Over Reactive Multiphases (STORM) simulator.

The STORM simulator solves coupled conservation equations for component mass and energy that describe subsurface flow over aqueous and gas phases through variably saturated geologic media. The resulting flow fields are used to sequentially solve conservation equations for reactive aqueous phase transport through variably saturated geologic media. These conservation equations for component mass, energy, and solute mass are partial differential equations that mathematically describe flow and transport through porous media.

The STORM simulator solves the governing-conservation equations and constitutive functions using numerical techniques for nonlinear systems. The partial differential equations governing thermal and fluid flow processes are solved by the integral volume finite difference method. These governing equations are solved simultaneously using Newton-Raphson iteration. The partial differential equations governing reactive solute transport are solved using either an operator split technique where geochemical reactions and solute transport are solved separately, or a fully coupled technique where these equations are solved simultaneously.

The STORM simulator is written in the FORTRAN 77 language, following American National Standards Institute (ANSI) standards. The simulator utilizes a variable source code configuration that allows tailoring of the execution memory and speed to the specific problem by editing text parameter files and recompiling the code. Execution of the STORM simulator is controlled through a text input file. This input file uses a structured format of associated groups of input data. Input data files and results are also presented for model verification and example simulations. Appendix A to this report presents examples of the STORM Version 2 input data format for each of the groups.

Acronyms and Abbreviations

ANSI	American National Standards Institute
AREST-CT	TBS
DOE	Department of Energy
Ecology	Washington State Department of Ecology
Eh	electrode potential in volts
GMRES	Generalized Minimal Residual Method (accelerator)
IC	Incomplete Cholesky (preconditioner)
L	length
ILAW	immobilized low activity waste
LAW	low activity waste
M	mass
N/A	not applicable
NSPCG	nonsymmetric preconditioned conjugate gradient
ODE	ordinary differential equation
PA	performance assessment
PDE	partial differential equation
PNNL	Pacific Northwest National Laboratory
PUF	Pressurized Unsaturated Flow (experiments)
SI	Systeme Internationale
STDIO	standard input/output device
STOMP	Subsurface Transport Over Multiple Phases
STORM	Subsurface Transport Over Reactive Multiphases
STORM1	STORM mode with unsaturated flow
STORM2	STORM mode with two-phase flow
STORM3	STORM mode with two-phase flow and heat transfer
T	time
TVD	Total Variation Diminishing (transport scheme)
VOC	volatile organic carbon

1.0 Introduction

The Hanford Site, in southeastern Washington State, has been used extensively to produce nuclear materials for the U.S. strategic defense arsenal by the Department of Energy (DOE) and its predecessors, the U.S. Atomic Energy Commission and the U.S. Energy Research and Development Administration. A large inventory of radioactive and mixed waste has accumulated in 177 buried single- and double shell tanks. Liquid waste recovered from the tanks will be pretreated to separate the low-activity fraction from the high-level and transuranic wastes (Ecology 1996). Vitrification is the leading option for immobilization of these wastes, expected to produce approximately 550,000 metric tons of Low Activity Waste (LAW) glass. This total tonnage, based on nominal Na_2O oxide loading of 20 percent by weight, is destined for disposal in a near-surface facility.

Before disposal of the immobilized waste can proceed, the DOE must approve a performance assessment, a document that describes the impacts, if any, of the disposal facility on public health and environmental resources. Results from a recent performance assessment are in a study published 2 years ago (Mann et al. 1998). A major conclusion from this study is that release rates of radionuclides from the glass waste form by reaction with water determines the impacts of the disposal action more than any other independent parameters. Consequently, a sound scientific basis for determining the long-term release rates of radionuclides from these glasses must be developed before this disposal action is accepted by regulatory agencies, stakeholders, and the public.

The rate of glass corrosion depends on temperature and the chemical composition of the water contacting it. Because glass dissolution itself changes the pH and solution composition, water percolating through a disposal system has neither a constant nor a uniform composition. Consequently, the glass corrosion rate in the disposal system also varies as a function of time and space. Over the last several years, DOE has supported the development of a numerical simulator at the Pacific Northwest National Laboratory (PNNL). This simulator can compute time and spatial variations in the chemical environment of unsaturated disposal systems in response to the corrosion of waste forms as well as other physical and chemical processes (McGrail and Bacon 1998). This report describes the latest accomplishments in the development of this computational tool, Subsurface Transport Over Reactive Multiphases (STORM), Version 2, a general, coupled non-isothermal multiphase flow and reactive transport simulator. It was developed by coupling STOMP, a non-isothermal multiphase flow simulator (White and Oostrom 1996), with AREST-CT Version 1.1, a reactive transport and porous medium alteration simulator (Chen et al. 1995; Chen et al. 1997). The general approach was coupling the two codes by making major modifications to AREST-CT subroutines, and modifying STOMP routines as little as possible.

The underlying mathematics in STORM is contained in a set of coupled, nonlinear, partial differential equations. They describe the rate of change of the solute concentrations of pore water in a variably saturated, non-isothermal porous medium, and the alteration of waste forms, packaging materials, backfill, and host rocks. The detailed mathematics is discussed elsewhere (Chen et al. 1996; White and Oostrom 1996). The following topics are included.

- kinetic dissolution of waste forms
- kinetic dissolution of host rocks
- kinetic precipitation and dissolution of secondary phases
- aqueous equilibrium speciation
- gas-aqueous equilibria
- redox reactions
- two-phase flow (water and air)
- dynamic hydraulic properties

Other physical and chemical features of the code are:

- 1-D (vertical Z-axis) or 2-D (X-Z Plane) solution domains
- general interface to take user specified chemistry and hydraulic properties
- non-isothermal multiphase flow and chemistry
- ionic strength correction according to modified B-dot equation
- spatially varying distribution of minerals in solid phase
- effective reaction surface varies with dissolution and precipitation of solids

The primary output of STORM, as a function of time and space, consists of the following:

- concentrations of aqueous species
- concentrations of gaseous species
- release flux of aqueous species and chemical components
- pH and Eh changes
- radii, surface areas, and volume fractions of solids
- dissolution/precipitation rates of solids
- production/consumption rates of aqueous species, including water
- temperature
- porosity and permeability changes
- aqueous phase saturations, velocities
- gas phase saturations, velocities

2.0 Governing Equations

2.1 Multiphase Flow and Heat Transfer

In broad terms, the STORM simulator solves coupled conservation equations for component mass and energy that describe subsurface flow over multiple phases through variably saturated geologic media. The resulting flow fields are used to sequentially solve conservation equations for reactive aqueous phase transport through variably saturated geologic media. These conservation equations for component mass, energy, and solute mass are partial differential equations. They mathematically describe flow and transport through porous media and are collectively entitled the governing equations. The STORM simulator has capabilities for modeling subsurface flow over two distinct phases: aqueous and gas. The aqueous phase primarily comprises liquid water with small quantities of dissolved air. The gas phase comprises variable amounts of air and water vapor.

It is possible to compile three modes of STORM: STORM1 (unsaturated flow), STORM2 (2-phase flow), and STORM3 (2-phase flow and heat transfer). STORM1 provides the fastest execution time if neither gas-phase flow or heat transfer is a major consideration.

2.1.1 Water Mass Conservation Equation

The water mass conservation equation, shown in Equation (2.1), equates the time rate of change of water mass within a control volume with the flux of water mass crossing the control volume surface. In the STORM simulator, water exists in the diffusive pore space as liquid water in the aqueous phase and as water vapor in the gas phase. Phase partitioning of water mass is computed assuming equilibrium conditions, implying the time scale for establishing thermodynamic equilibrium is significantly shorter than for component transport. Water transport occurs by advection through the aqueous and gas phases and also by diffusion-dispersion through the gas phase. Following the low solubility assumption for dissolved air in the aqueous phase, air diffusion-dispersion through the aqueous phase is neglected. Flow of fluid phases is computed from Darcy's law. Transport of phase components is computed from Fick's law.

$$\frac{\partial}{\partial t}\left[\sum_{\gamma=\ell,g}\left(\phi_D\,\omega_\gamma^w\,\rho_\gamma\,s_\gamma\right)\right]=-\sum_{\gamma=\ell,g}\left(\nabla\mathbf{F}_\gamma^w+\nabla\mathbf{J}_\gamma^w\right)+\dot{m}^w \tag{2.1}$$

where

$$\mathbf{F}_\gamma^w=-\frac{\omega_\gamma^w\,\rho_\gamma\,k_{r\gamma}\,\mathbf{k}}{\mu_\gamma}\left(\nabla P_\gamma+\rho_\gamma\,g\,\mathbf{z}_g\right)\ for\ \gamma=\ell,g \tag{2.2}$$

$$\mathbf{J}_\gamma^w = -\tau_\gamma \phi_D \rho_\gamma s_\gamma \frac{M^w}{M_\gamma} D_\gamma^w \nabla \chi_\gamma^w \quad for\ \gamma = \ell, g \tag{2.3}$$

where ϕ_D = diffusive porosity

ω_γ^j = mole fraction of component j in phase γ

ρ_γ = phase density for phase γ, kg m^{-3}

s_γ = phase saturation for phase γ

$\mathbf{F}_\gamma^j$ = advective flux of component j in phase γ, kg m^{-2} s^{-1}

$\dot{m}^w$ = **mass source rate of component j, kg m^3 s^{-1}**

$\mathbf{J}_\gamma^j$ = **diffusive-dispersive flux of component j for phase γ, kg m^{-2} s^{-1}**

$\mathbf{k}$ = intrinsic permeability tensor, m^2

$k_{r\gamma}$ = fluid relative permeability of phase γ

P_γ = pressure of phase γ, Pa

$\mathbf{z}_g$ = unit gravitational direction vector

g = acceleration of gravity, m s^{-2}

μ_γ = kinematic viscosity of phase γ, Pa s

τ_γ = phase tortuosity for phase γ

M_γ = molecular weight of phase γ, kg mol^{-1}

D_γ^j = diffusion coefficient of component j for phase γ, m^2 s^{-1}

χ_γ^j = mole fraction of component j in phase γ

a = air component

w = water component

g = gas phase

ℓ = **aqueous phase**

t = **time, s**

2.1.2 Air Mass Conservation Equation

In a similar manner to the water mass conservation equation, the air mass conservation equation, shown in Equation (2.4), equates the time rate of change of the air mass within a control volume with the flux of air mass crossing the control volume surface. In the STORM simulator, air exists in the diffusive pore space as a component of the gas phase and is dissolved in the aqueous phase. Phase partitioning of air mass is computed assuming equilibrium conditions: this assumption implies the time scale for thermodynamic equilibrium in geologic media is significantly shorter than that for component transport. Air transport occurs by advection and diffusion dispersion through the aqueous and gas phases. Flow of fluid phases is computed from Darcy's law. Transport of phase components is computed from Fick's law.

$$\frac{\partial}{\partial t}\left[\sum_{\gamma=\ell,g}\left(\phi_D\,\omega_\gamma^a\,\rho_\gamma\,s_\gamma\right)\right]=-\sum_{\gamma=\ell,g}\left(\nabla\mathbf{F}_\gamma^a+\nabla\mathbf{J}_\gamma^a\right)+\dot{m}^a \tag{2.4}$$

where

$$\mathbf{F}_\gamma^a=-\frac{\omega_\gamma^a\,\rho_\gamma\,k_{r\gamma}\,\mathbf{k}}{\mu_\gamma}\left(\nabla P_\gamma+\rho_\gamma\,g\,\mathbf{z}_g\right)\ for\ \gamma=\ell,g \tag{2.5}$$

$$\mathbf{J}_\gamma^a=-\tau_\gamma\,\phi_D\,\rho_\gamma\,s_\gamma\,\frac{M^a}{M_\gamma}\,D_\gamma^a\,\nabla\,\chi_\gamma^a\ for\ \gamma=\ell,g \tag{2.6}$$

2.1.3 Energy Conservation Equation

The energy conservation equation, shown in Equation (2.7), equates the time rate of change of energy within a control volume with the flux of energy crossing the control volume surface. In the STORM simulator, thermal energy is partitioned, according to thermal equilibrium conditions, among the fluid and solid phases. The thermal capacitance of unconnected pore space, represented by the difference between the total and diffusive porosity, is computed as it is filled with liquid water. Heat transfer occurs by advection of phase mass, diffusion of component mass, and thermal diffusion through the fluid and solid phases. Heat transfer by hydraulic dispersion of flowing fluid phases is neglected. Enhanced vapor transport is incorporated through enhancement factors for component diffusion through the gas phase. Energy associated with component mass sources is included as internal heat generation sources. Reference states for enthalpy and internal energy are component dependent. Latent heat transport is considered through vapor transport using the gas phase and equilibrium thermodynamics.

$$\begin{aligned}&\frac{\partial}{\partial t}\left[\sum_{\gamma=\ell,g}\left(\phi_D\,\rho_\gamma\,s_\gamma\,u_\gamma\right)+\left(1-\phi_T\right)\rho_s\,u_s+\left(\phi_T-\phi_D\right)\rho_\ell\,u_\ell\right]=\\&-\sum_{\gamma=\ell,g}\left(\nabla\left(\rho_\gamma\,h_\gamma\,\mathbf{q}_\gamma\right)+\sum_{j=w,a}\left(\nabla\,h^j\,\mathbf{J}_\gamma^j\right)\right)+\nabla\left(\mathbf{k}_e\,\nabla\,T\right)+\sum_{j=w,a}\left(h^j\,\dot{m}^j\right)+\dot{Q}\end{aligned} \tag{2.7}$$

where the Darcy velocity is given by

$$\mathbf{q}_\gamma=-\frac{k_{r\gamma}\,\mathbf{k}}{\mu_\gamma}\left(\nabla P_\gamma+\rho_\gamma\,g\,\mathbf{z}_g\right)\ for\ \gamma=\ell,g \tag{2.8}$$

and the diffusive flux by

$$\mathbf{J}_\gamma^j = -\tau_\gamma \phi_D \rho_\gamma s_\gamma \frac{M^j}{M_\gamma} D_\gamma^j \nabla \chi_\gamma^j \quad \text{for } \gamma = \ell, g \text{ and } j = w, a \tag{2.9}$$

where ϕ_T = total porosity
h_j = enthalpy of component j, J kg^{-1}
h_γ = enthalpy of phase γ, J kg^{-1}
$\mathbf{k}_e$ = equivalent thermal conductivity tensor, W m^{-1} K^{-1}
T = temperature, K
$\dot{Q}$ = thermal energy source, W
μ_γ = kinematic viscosity of phase γ, Pa s
μ_γ = internal energy of phase γ, J kg^{-1}

2.2 Solute Transport

2.2.1 Solute Mass Conservation Equation

The solute mass conservation equation, shown in Equation (2.10), equates the time rate for change of solute mass within a control volume with the flux of solute mass crossing the control volume surface. The solute mass conservation equation is solved when an *Operator Split* solution scheme is used. In the STORM simulator, solute mass is partitioned among the fluid and solid phases assuming thermodynamic and geochemical equilibrium conditions. This assumption implies the time scales for thermodynamic and geochemical equilibrium are short compared against those for solute transport. For geologic media, this assumption is generally appropriate. Solute transport occurs by advection and diffusion-dispersion through the aqueous phase and gas phase. Radioactive chain decay of solutes is computed using first-order decay kinetics. Solute mass conservation equations are solved sequentially with progeny solutes preceding parent solutes. Progeny solute production rates are computed from parent decay rates and chain decay fractions with

$$\frac{\partial C}{\partial t} = -\sum_{\gamma=l,g} \left(\nabla \left[C_\gamma q_\gamma \right] \right) + \dot{m}^C - \dot{R}^C C + \sum_{\gamma=l,g} \left(\nabla \left[\left(\tau_\gamma s_\gamma \phi_D D_\gamma^C + s_\gamma \phi_D \mathbf{D}_{hy} \right) \nabla C_\gamma \right] \right) \tag{2.10}$$

where C = mass of solute per unit volume of porous media, m^{-3}
C_γ = mass of solute per unit volume of either liquid or gas, m^{-3}
D_γ^C = solute diffusion coefficient for phase γ, $m^2\ s^{-1}$
$\mathbf{D}_{h\gamma}$ = hydraulic dispersion tensor for phase γ, $m^2\ s^{-1}$
$\dot{m}_C$ = solute source rate, s^{-1}
R^C = solute decay rate constant, s^{-1}

2.2.2 Aqueous Species Mass Conservation Equation

The aqueous species mass conservation equation is written as follows

$$\frac{\partial \phi_D \rho_\ell s_\ell C_i^\ell}{\partial t} = -\nabla \cdot F_i^\ell + S_i^r \tag{2.11}$$

where C_i^ℓ is the concentration of species i in the aqueous phase (denoted by ℓ) in mol kg^{-1}, F_i^ℓ is the solute flux of species i in the aqueous phase, S_i^r is the source/sink term of species i due to chemical reactions in mol $m^{-3}\ s^{-1}$. The aqueous species mass conservation equation is solved when a *Fully Coupled* solution scheme is used.

If it is assumed that the phenomenon of hydrodynamic dispersion can be represented by a Fickian type law, then the total solute flux due to advection, dispersion, and diffusion is given by

$$\mathbf{F}_i^S = \phi_D \rho_\ell s_\ell \left(C_i \mathbf{V}_\ell - \mathbf{D}(s_\ell) \cdot \nabla C_i \right) \tag{2.12}$$

where $\mathbf{D}$ is the hydrodynamic dispersion tensor of species i in the aqueous phase, $m^2\ s^{-1}$.

The flow fields resulting from the air, water, and energy conservation equations are coupled with the solute mass conservation equations via transient changes in water saturation and average linear pore water velocity. This velocity is related to the Darcy velocity by

$$\mathbf{V}_\ell = \frac{\mathbf{q}_\ell}{\phi_D s_\ell} \ . \tag{2.13}$$

2.2.3 Coupled Aqueous and Gaseous Species Mass Conservation Equation

The mass conservation law for a particular species can be written as the sum of transport in the gas and aqueous phases:

$$\frac{\partial}{\partial t}\rho_l \phi_D \left(s_g C_i^g + s_l C_i^l\right) = -\nabla \bullet F_i^S + S_i^r \tag{2.14}$$

where F_i^S is the total flux of species i in both the gas and aqueous phases.

The total flux due to advection, dispersion, and diffusion in both the aqueous and gas phases is given by

$$F_i^S = \phi_D s_g \left(\mathbf{V}_g C_i^g - \mathbf{D}_i^g \cdot \nabla C_i^g\right) + \phi_D s_l \left(\mathbf{V}_l C_i^l - \mathbf{D}_i^l \cdot \nabla C_i^l\right) \tag{2.15}$$

where V_g is the pore-gas velocity and $\mathbf{D}_i^g$ is the hydrodynamic dispersion tensor for species i in the gas phase. The coupled aqueous and gaseous species mass conservation equation is solved when a *Fully Coupled* solution scheme is used.

Assuming equilibrium between the gaseous phase and aqueous phase, the concentration of the dissolved gas component in the aqueous phase can be expressed as a linear function of the concentration (or mole fraction or partial pressure) of that component in the gaseous phase through Henry's constant

$$C_i^l = K_H p_i^g = K_H^{'} C_i^g \tag{2.16}$$

where C_i^l = aqueous phase concentration of the dissolved gas component
p_g = partial pressure of the component in the gas phase
C_i^g = gas phase concentration of the component
K_H = Henry's law constants expressed as a function of partial pressure
$K_H^{'}$ = Henry's law constants expressed as a function of mole fraction

Substituting (2.15) and (2.16) into (2.14) gives the mass conservation law in terms of the aqueous phase concentration of each species.

$$\frac{\partial}{\partial t}\left[\phi_D \rho_\ell \left(s_g K_H'^{-1} + s_\ell\right) C_i^\ell\right] = S_i^r + \nabla \cdot \left[-\phi_D \rho_\ell \left(s_g \mathbf{V}_g K_H'^{-1} + s_\ell \mathbf{V}_\ell\right) C_i^\ell + \phi_D \rho_\ell \left(s_g \mathbf{D}_i^g K_H'^{-1} + s_\ell \mathbf{D}_i^\ell\right) \cdot \nabla C_i^\ell\right] \quad (2.17)$$

A series of transformations are applied to Equation (2.17) to eliminate terms associated with equilibrium chemical reactions. Each aqueous species is defined as a reactive species, a non-reactive species, or an equilibrium species. Because of the transformations applied, equilibrium species must be transported at the same rate as the linearly related reactive species. A different Henry's Law constant and dispersion coefficient is allowed only for each reactive aqueous species that is in equilibrium with a gas species.

2.3 Geochemical Reactions

A chemical reaction generally can be written as

$$\nu_{mj} B_m + \sum_{i=1}^{N_s} \nu_{ij} A_i = 0 \quad (2.18)$$

where B_m = solid m
A_i = aqueous species i
ν_{ij} = stoichiometric coefficient of aqueous species i in reaction j (negative for reactants, positive for products)
ν_{mj} = stoichiometric coefficient of solid m in reaction j (negative for dissolution, positive for precipitation, zero for pure aqueous reaction)

If the rate of the reaction in unit bulk volume is shown as W_j (in general a nonlinear function of the aqueous species concentrations), the rate of aqueous species i in that reaction is $\nu_{ij} W_j$. (This nonlinear function is defined in Section 1.3.2.) The source/sink term due to reactions in Equation (2.14) is then

$$S_i^r = \sum_{j=1}^{N_r} \nu_{ij} W_j \quad (2.19)$$

where N_r is the number of reactions.

2.3.1 Equilibrium and Kinetic Reactions

Geochemical models usually assume some reactions to be in equilibrium. This assumption is often justified for some reactions, especially those involving only aqueous species. However, solid dissolution/precipitation reactions can be quite slow and should be treated as kinetic. Furthermore, the equilibrium approach cannot capture some metastable solid phases, such as amorphous solids, that in many cases are intermediate products of reaction. For this reason, STORM has been designed to treat both equilibrium and kinetic reactions separately. To this end, the source/sink term is split, due to chemical reactions, into equilibrium and kinetic parts.

$$S_i^r = \sum_{j=1}^{N_e} \nu_{ij} W_j^e + \sum_{j=1}^{N_k} \nu_{ij} W_j^k \tag{2.20}$$

where W_j^e = the rate of equilibrium reaction j (mol m^{-3} s^{-1})

W_j^k = the rate of kinetic reaction j (mol m^{-3} s^{-1})

N_e = the number of equilibrium reactions

N_k = the number of kinetic reactions

$N_r = N_e + N_k$.

Equilibrium reactions are by no means zero-rate reactions. In fact, equilibrium reactions have high reaction rates and reach equilibrium quickly when transport, other reactions, or changes in physical-chemical conditions disturb it. Specifically, if the rate of a reaction is much greater than the characteristic time of the problem being solved, it should be classified as equilibrium; otherwise it should be classified as kinetic.

2.3.2 Rate Law of Kinetic Reactions

For any kinetic reaction, assuming its rate law is of the mass-action type, two equivalent ways can define the reaction rate: one is to use the forward rate and backward rate; the other is to use the forward rate and the equilibrium constant. In STORM, the latter approach is used. Thus,

$$W_j = A_{m(j)} k_j \left[\prod_{\nu_{ij}<0} (\gamma_i c_i)^{\frac{|\nu_{ij}|}{f_j}} - \prod_{\nu_{ij}>0} (\gamma_i c_i)^{\frac{\nu_{ij}}{f_j}} \Big/ \left(K_j^{eq}\right)^{1/f_j} \right] \tag{2.21}$$

where $A_{m(j)}$ = a factor that for aqueous reactions equals 1, and for surface-limited reactions it equals the effective reaction area in unit bulk volume
k_j = the rate constant of reaction j
K_j^{eq} = the equilibrium constant of reaction j
γ_i = the activity coefficient of species i
f_j = the factor of the reaction order
W_j = generally a nonlinear function of concentrations of aqueous species

Several formulas, such as the Davies equation (Davies 1962), the B-dot equation (Helgeson 1969), and Pitzer's model (Pitzer 1973), can be used to calculate activity coefficients. The B-dot equation, with modifications for neutral species (Wolery 1992), is computationally economic and stable for problems of moderately high salinity. Although Pitzer's model can handle high ionic strength, the lack of constants for all but a few aqueous species limits its applicability. Thus, the B-dot equation is used to calculate activity coefficients in STORM.

2.3.3 Solid Reactions

In the subsurface, chemical reactions change not only the concentration of solutes but also the properties of the porous media. Changes in the volume fraction and surface area of solids, porosity and permeability result in changes in the fluid flow field, solute transport, and chemical reactions. Interactions may take place through several paths and in some cases be very strong. Ignoring the interactions will not only decrease the accuracy of the simulations but in many cases, also will yield even qualitatively incorrect predictions. To fully account for the interactions between the fluid phases and the porous media, it is necessary to consider dynamic changes in the properties of porous media as a result of mass redistribution from chemical reactions. The first step is to introduce variables that describe porous media texture.

STORM uses two primary variables to describe a mineral: the volume fraction V_m and one or more sizes of variables (depending on the shape of the mineral grains). The volume fractions of minerals and the porosity of the porous medium obey the relation

$$\sum_{m=1}^{N_m} V_m + \phi_T = 1 \tag{2.22}$$

From the volume fraction and size variables, the number density n_m (number of grains of mineral m in unit bulk volume of porous media) is derived and the specific surface area A_m (surface area of mineral m in unit bulk volume of porous media) is determined when the shape of the grains is specified. For spherical grains, the size variable is the radius R_m, so that

$$n_m = \frac{3V_m}{4\pi R_m^3} \tag{2.23}$$

and

$$A_m = 4\pi R_m^2 n_m \tag{2.24}$$

By assuming that a dissolution/precipitation reaction is a surface-limited kinetic reaction, observing the rate law of Equation (2.21), the change rate of the volume fraction is

$$\frac{\partial V_m}{\partial t} = 4\pi R_m^2 n_m \frac{\partial R_m}{\partial t} \tag{2.25}$$

For general cases of more than one dissolution/precipitation reaction occurring for one mineral, the rate of change of the mineral radius is

$$\frac{\partial R_m}{\partial t} = \sum_{j=1}^{N_k} \frac{k_j}{\rho_m} \left[\prod_{\nu_{ij}<0} (\gamma_i c_i)^{\frac{|\nu_{ij}|}{f_j}} - \prod_{\nu_{ij}>0} (\gamma_i c_i)^{\frac{\nu_{ij}}{f_j}} \Big/ \left(K_j^{eq}\right)^{1/f_j} \right] \tag{2.26}$$

where ρ_m is the molar density of mineral m (mol m^{-3}), and the summation is over all kinetic reactions pertaining to mineral m.

Substituting Equation (2.24) into Equation (2.21) gives

$$W_j^k = 4\pi R_{m(j)}^2 n_{m(j)} k_j \left[\prod_{\nu_{ij}<0} (\gamma_i c_i)^{\frac{|\nu_{ij}|}{f_j}} - \prod_{\nu_{ij}>0} (\gamma_i c_i)^{\frac{\nu_{ij}}{f_j}} \Big/ \left(K_j^{eq}\right)^{1/f_j} \right] \tag{2.27}$$

that serves as a bridge between the aqueous phase and solid phases so that the whole system is mass-conservative.

2.4 Coupling Between Fluid Flow and Geochemical Reactions

2.4.1 Porosity Changes Coupled with Multiphase Flow

Porosity changes due to mineral dissolution and precipitation could have a significant effect on the flow regime surrounding the disposal facility. Therefore, porosity changes, calculated by the STORM texture solver, are coupled with the multiphase flow solver. Dissolution and precipitation reactions can change the volume fractions of solids as a function of time, thus changing the porosity as described in

Section 2.3.3. Furthermore, intrinsic permeability varies as a function of porosity. Two options for modeling this relationship are available in STORM. One option is the Fair and Hatch (1933) formula, developed from dimensional considerations and verified experimentally,

$$k = \frac{1}{\beta}\left[\frac{(1-\phi_T)^2}{\phi_T^3}\left(\frac{\alpha}{100}\sum_{(m)}\frac{P_m}{d_m}\right)^2\right]^{-1} \tag{2.28}$$

where k = intrinsic permeability in cm^2
β = packing factor, found experimentally to be about 5
α = sand shape factor, varying from 6.0 for spherical grains to 7.7 for angular ones
P_m = percentage of sand held between adjacent sieves
d_m = geometric mean diameter of adjacent sieves

The second option is the Kozeny-Carmen equation that was obtained from a theoretical derivation of Darcy's law and includes numerical coefficients that must be determined empirically,

$$k = C_0 \frac{\phi_T^3}{(1-\phi_T)^2 M_S^2}, \tag{2.29}$$

where M_S = specific surface area of the porous matrix (defined per unit volume of solid)
C_o = coefficient for which Carman (1937) suggested the value of 1/5

This modification was tested on a 3-node problem to ensure that water mass was being conserved as porosity varied during glass dissolution.

2.4.2 Water Consumption in Chemical Reactions Coupled with Multiphase Flow

Consumption of water varied during dissolution of waste glass, such as the following hydrolysis reaction for LD6-5412 glass:

$$\begin{aligned} &Glass + 0.5OH^- + 0.45H_2O = 0.0202K^+ + 0.4208Na^+ 0.046Ca^{2+} + \\ &0.154Al(OH)_{3(aq)} + 0.094BO_2^- + 0.2712HSiO_3^- + 0.3348H_2SiO_4^{2-} + \\ &2.2795x10^{-8}SeO_3^{2-} + 1.6172x10^{-6}TcO_4^{2-} + 3.8318x10^{-8}IO_3^- + \\ &2.7213x10^{-5}U(OH)_{4(aq)} + 1.9265x10^{-9}Pu(OH)_5^- + 2.7251x10^{-9}NpO_2(OH)_{(aq)} \end{aligned} \tag{2.30}$$

The consumption/production of water during precipitation of hydrated minerals may be large enough to affect unsaturated flow in the region of the waste repository. The STORM code couples unsaturated

flow with water production/consumption by chemical reactions through the mass source rate of water in Equation (2.1).

$$\dot{m}^w = \sum_{j=1}^{N_r} \nu_{wj} W_j / \Omega \tag{2.31}$$

where N_r is the total number of reactions, ν_{wj} is the stoichiometric coefficient of water in reaction j, W_j is the rate of reaction per unit bulk volume, given by Equation (2.21), and Ω is the number of moles of solvent water comprising a mass of 1 kg (Ω=55.51). The water source/sink term due to reactions is added to any other water source/sinks specified in the STORM input file.

2.4.3 Gas Consumption in Chemical Reactions Coupled with Multiphase Flow

Consumption of gaseous species, particularly oxygen, may occur at large enough rates to affect the flow of air in the vadose zone. The STORM code couples unsaturated flow with gas production/consumption by chemical reactions through the mass source rate of air in Equation (2.4).

$$\dot{m}^a = \sum_{j=1}^{N_r} \nu_{gj} W_j M_j \tag{2.32}$$

where N_r is the total number of reactions, ν_{gj} is the stoichiometric coefficient of the gaseous species in reaction j, W_j is the rate of reaction per unit bulk volume, and M_j is the molecular weight of the gaseous species. The gas source/sink term due to reactions is added to any other gas source/sinks specified in the STORM input file.

3.0 Numerical Solution Methods

3.1 Introduction

The STORM simulator solves the governing-conservation equations and constitutive functions using numerical techniques for nonlinear systems. This section documents the transformation of the governing-conservation equations from partial-differential form to algebraic form, algebraic expression of boundary conditions, linearization of the conservation equations and constitutive functions, and solution of linear systems.

The governing-conservation equations for water, air, and energy conservation are discretized to algebraic form following the integrated-finite-difference method of (Patankar 1980). This transformation requires the physical domain to be spatially discretized into an orthogonal computational domain comprised of non-overlapping volumes (nodes). Each volume can contain a maximum of two neighboring nodes for each dimensional direction. Intrinsic properties are assumed to be uniform over the volume domain and are defined for a node point at the geometric center of the volume. Flux quantities are defined at the geometric center of the surfaces between node volumes and along a direction parallel to the surface normal. Fluxes across node surfaces between neighboring inactive nodes or adjacent to the domain boundary are controlled through boundary conditions. Solution of the governing-conservation equations in time requires discretization of the time domain. The method of Patankar (1980) is implicit using backward Euler time differencing. The expressions that result from discretizing the governing equations are nonlinear algebraic equations.

The STORM simulator uses a Cartesian grid system. Coordinate directions for Cartesian systems follow the right-hand rule from the x to y to z directions. Positive and negative directions along the x, y, and z coordinates are referred to as East, West, North, South, Top, and Bottom, respectively. The gravitational vector can be aligned arbitrarily with respect to the Cartesian directions.

The system of algebraic equations that include the discretized governing-conservation equations and the constitutive functions are nonlinear. Non-linearities in the soil-moisture retention functions, relative permeability functions, and physical properties near phase transitions are the primary contributors. Conversion of the algebraic equations from nonlinear to linear form follows the iterative Newton-Raphson (Kreyszig 1979) technique for multiple variables. Typically, the technique yields quadratic convergence of the residuals, given sufficiently close estimates of the primary unknowns. Each iteration loop requires the solution of a system of linear equations in terms of the equation residuals. Because only orthogonal grid systems are considered, the system of linear equations has a block-banded structure.

The governing-conservation equations are discretized following the integrated finite difference of Patankar (1980) that is locally and globally conserving. Mass conservation equations for water and air components are nearly identical in form and, therefore, result in similar algebraic forms. The

conservation equation for energy differs from the mass conservation equations having diffusive-dispersive and advective components. Discretization of combined diffusive and advective transport requires donor-cell weighting of the transport components, yielding different algebraic forms than those for the mass conservation equations. The conservation equation for solute transport is similar in form to the energy conservation equation, but its discretization uses a different donor-cell weighting scheme, resulting in a separate algebraic form.

3.2 Water and Air Mass Conservation Equation

The water and air mass conservation equations, shown in Equations **(2.1)** and **(2.4)**, are discretized by assuming a piecewise profile to express the variation in primary variables between node points and integrating over the node volume. The accumulation terms (that is, left-hand-side terms) are integrated over the node volume according to Equation (3.1), where the specific terms for the water and air conservation equations appear as shown in Equations (3.2) and (3.3), respectively. Intrinsic properties for the node volume are represented by properties at the node centroid. Source terms are similarly integrated over the node volume according to Equation (3.4).

$$\frac{\partial}{\partial t}\left[\int_{\bar{V}} \overline{M}^{j} d\bar{V}\right] = \frac{\partial}{\partial t}\left[\overline{M}^{j}\bar{V}\right] \quad \text{for } j = w,a \tag{3.1}$$

$$\frac{\partial}{\partial t}\left[\overline{M}^{w}\bar{V}\right] = \frac{\partial}{\partial t}\left[\bar{V}\sum_{\gamma=l,g}\left(\phi_D \omega_\gamma^w \rho_\gamma s_\gamma\right)\right] \tag{3.2}$$

$$\frac{\partial}{\partial t}\left[\overline{M}^{a}\bar{V}\right] = \frac{\partial}{\partial t}\left[\bar{V}\sum_{\gamma=l,g}\left(\phi_D \omega_\gamma^a \rho_\gamma s_\gamma\right)\right] \tag{3.3}$$

$$\int_{\bar{V}} \dot{m}^{j} d\bar{V} = \dot{m}^{j}\bar{V} \quad \text{for } j = w,a \tag{3.4}$$

Flux terms are evaluated on the node surfaces and for the mass conservation equations comprise advective and diffusive components. Integration of the flux terms over the node volume proceeds by first converting the volumetric integral of flux over a control volume to a surface integral through Green's theorem (Kreyszig 1979) according to Equation (3.5). Discretizing the control volume surfaces into node surfaces and defining flux directions parallel to the surface normal allows the surface integrals to be converted to summations over all node surfaces, according to Equation (3.6). This transformation strictly requires an orthogonal grid system for the flux directions to be aligned with the surface normals.

Nonorthogonal systems will yield mass balance errors. Darcy fluxes are discretized, in the six coordinated directions, using upwind interfacial averaging for the component mass fraction, phase density, and relative permeability and harmonic averaging for the intrinsic permeability and phase viscosity according to Equation (3.6). These default interfacial averaging schemes can be altered by user input. Diffusive fluxes are discretized, in the six coordinate directions, using harmonic averaging for the combination of terms that comprise an effective diffusion coefficient. The user can also alter the default interfacial averaging scheme for each parameter. Geometric variables for a Cartesian coordinate system are shown in Figure 3.1 for the X-Z coordinate plane and in Figure 3.2 for the Y-Z coordinate plane.

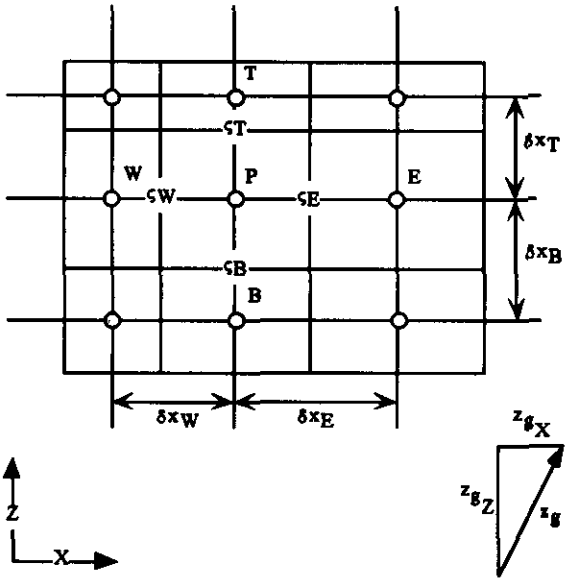

Figure 3.1. X-Z Coordinate Plane for Cartesian Systems

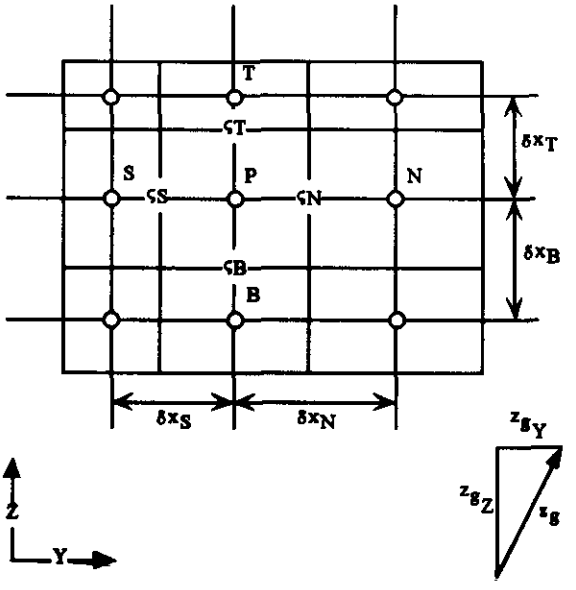

Figure 3.2. Y-Z Coordinate Plane for Cartesian Systems

$$\int_{\bar{V}}\left[\sum_{\gamma=l,g}\left(\nabla\mathbf{F}_\gamma^j+\nabla\mathbf{J}_\gamma^j\right)d\bar{V}\right]=\int_{\Gamma}\left[\sum_{\gamma=l,g}\left(\mathbf{F}_\gamma^j+\mathbf{J}_\gamma^j\right)\cdot\mathbf{n}d\Gamma\right]\ \text{for}\ j=w,a \tag{3.5}$$

where $\int_{\bar{V}}[\ ]d\bar{V}$ = volume integral

$\int_{\Gamma}[\ ]d\Gamma$ = surface integral

$\sum_{\gamma=l,g}$ = summation over aqueous and gas phases

$\sum_{j=w,a}$ = summation over water and air components

where

$$\mathbf{F}_\gamma^j=\frac{\omega_\gamma^j\rho_\gamma k_{r\gamma}\mathbf{k}}{\mu_\gamma}\left(\nabla P_\gamma+\rho_\gamma g\mathbf{z}_g\right)\ \text{for}\ \gamma=l,g\ \text{and}\ j=w,a$$

$$\mathbf{J}_\gamma^j=-\tau_\gamma\phi_D\rho_\gamma s_\gamma\frac{M^j}{M_\gamma}D_\gamma^j\nabla\chi_\gamma^j\ \text{for}\ \gamma=l,g\ \text{and}\ j=w,a$$

$$\int_{\Gamma}\left[\sum_{\gamma=l,g}\left(\mathbf{F}_\gamma^j+\mathbf{J}_\gamma^j\right)\cdot\mathbf{n}d\Gamma\right]=\sum_{\varsigma=\mathrm{W,E,S,N,T,B}}\left[\sum_{\gamma=\mathrm{l,g}}\left(\mathrm{F}_{\gamma\varsigma}^{\mathrm{j}}+J_{\gamma\varsigma}^{\mathrm{j}}\right)\right]\mathrm{A}_\varsigma\ \ \text{for}\ j=w,a \tag{3.6}$$

where A_ς is the area of surface ς, and where,

$$F_{\gamma\varsigma}^j=-\frac{\left\langle\omega_\gamma^j\rho_\gamma k_{r\gamma}\right\rangle_\varsigma^{uw}\left\langle\mathbf{k}\right\rangle_\varsigma^h}{\left\langle\mu_\gamma\right\rangle_\varsigma^h}\left[\frac{P_{\gamma\varsigma+}-P_{\gamma\varsigma-}}{\delta x_\varsigma}+\left\langle\rho_\gamma g\right\rangle_\varsigma^a z_{g\varsigma}\right]\ \text{for}\ \gamma=l,g;j=w,a;\ \text{and}\ \varsigma=E,W,S,N,B,T$$

$$J_{\gamma\varsigma}^j=-\left\langle\tau_\gamma\phi_D\rho_\gamma s_\gamma\frac{M^j}{M_\gamma}D_\gamma^j\right\rangle_\varsigma^h\frac{\chi_{\gamma\varsigma+}^j-\chi_{\gamma\varsigma-}^j}{\delta x_\varsigma}\ \ \text{for}\ \gamma=l,g;j=w,a;\ \text{and}\ \varsigma=E,W,S,N,B,T$$

and where $\langle\ \rangle_{\varsigma}^{h}$ represents harmonic interfacial averaging at surface ς, $\langle\ \rangle_{\varsigma}^{uw}$ represents upwind or donor cell interfacial averaging at surface ς, $\langle\ \rangle_{\varsigma}^{a}$ represents harmonic interfacial averaging at surface ς, and $\sum_{\varsigma=W,E,S,N,T,B}$ is the summation over all node surfaces (West, East, South, North, Top, Bottom).

The mass conservation equations are discretized in time using a fully implicit scheme according to Equation (3.7), where the time levels are indicated with superscripts. The primary unknowns for the mass conservation equations are intrinsic properties at node volume centroids (node grid point) for time level $t+\delta t$.

1621b-8.doc

(3.7)

Converting Equation (3.7) to residual form, where $\bar{R}^{j}$ is the residual for the mass conservation equation of component j, yields the expression shown in Equation (3.8).

$$\left\{\bar{R}^{j}\right\}^{t+\delta t} = \bar{V}\left[\frac{\left\{\bar{M}^{j}\right\}^{t+\delta t} - \left\{\bar{M}^{j}\right\}^{t}}{\delta t}\right] - \bar{V}\left\{\dot{m}^{j}\right\}^{t+\frac{\delta t}{2}} + \sum_{\varsigma=W,E,S,N,T,B}\left[\sum_{\gamma=l,g}\left(\left\{F_{\gamma\varsigma}^{j}\right\}^{t+\delta t} + \left\{J_{\gamma\varsigma}^{j}\right\}^{t+\delta t}\right)\right]A_{\varsigma} \quad \text{for } j = w,a \tag{3.8}$$

3.3 Energy Conservation Equation

The energy conservation equation, shown in Equation **(2.7)**, is discretized by assuming a piecewise profile to express the variation in primary variables between node points and integrating over the node volume. The thermal capacitance terms (that is, left-hand-side terms) and energy source terms are integrated over the node volume according to Equations (3.9) and (3.10), respectively.

$$\frac{\partial}{\partial t}\left[\int_{\bar{V}} \bar{E}\,d\bar{V}\right] = \frac{\partial}{\partial t}\left[\bar{E}\bar{V}\right] \tag{3.9}$$

where

$$\bar{E} = \sum_{\gamma=l,g} \left(\phi_D \, \rho_\gamma \, s_\gamma \, u_\gamma\right) + \left(1-\phi_T\right) \rho_s \, u_s + \left(\phi_T - \phi_D\right) \rho_l \, u_l$$

$$\int_{\bar{V}} \left[\sum_{j=w,a} \left(h^j \dot{m}^j\right) + \dot{Q} \right] d\bar{V} = \left[\sum_{j=w,a} \left(h^j \dot{m}^j\right) + \dot{Q} \right] \bar{V} \tag{3.10}$$

Thermal energy is transferred through advection and diffusion. Spatial discretization of the advective and diffusive thermal flux proceeds by first converting the volumetric integral of flux over a control volume to a surface integral using Green's theorem (Kreyszig 1979), according to Equation (3.11). Surface integrals are approximated by discretizing the control volume surfaces into node surfaces and summing the contributions to heat flux over the node surfaces, according to Equation (3.12).

$$\begin{aligned} &\int_{\bar{V}} \left[-\sum_{\gamma=l,g} \left(\nabla \rho_\gamma h_\gamma \mathbf{q}_\gamma + \sum_{j=w,a} \left(\nabla h^j \mathbf{J}_\gamma^j\right) + \nabla\left(\mathbf{k}_e \nabla T\right) \right) \right] d\bar{V} \\ &= \int_{\Gamma} \left[-\sum_{\gamma=l,g} \left(\rho_\gamma h_\gamma \mathbf{q}_\gamma + \sum_{j=w,a} \left(h^j \mathbf{J}_\gamma^j\right) + \left(\mathbf{k}_e \nabla T\right) \right) \right] \mathbf{n} d\Gamma \end{aligned} \tag{3.11}$$

where

$$\mathbf{q}_\gamma = -\frac{k_{r\gamma}\mathbf{k}}{\mu_\gamma}\left(\nabla P_\gamma + \rho_\gamma g \mathbf{z}_g\right) \quad \text{for } \gamma = l,g$$

$$\mathbf{J}_\gamma^j = -\tau_\gamma \phi_D \rho_\gamma s_\gamma \frac{M^j}{M_\gamma} D_\gamma^j \nabla \chi_\gamma^j \quad \text{for } \gamma = l,g \text{ and } j = w,a$$

$$\begin{aligned} &\int_{\Gamma} \left[-\sum_{\gamma=l,g} \left(\rho_\gamma h_\gamma \mathbf{q}_\gamma + \sum_{j=w,a} \left(h^j \mathbf{J}_\gamma^j\right) + \left(\mathbf{k}_e \nabla T\right) \right) \right] \mathbf{n} d\Gamma \\ &= \sum_{\varsigma=W,E,S,N,B,T} \left[-\sum_{\gamma=l,g} \left(\left(\rho_\gamma h_\gamma \mathbf{q}_\gamma\right)_\varsigma + \sum_{j=w,a} \left(h^j \mathbf{J}_\gamma^j\right)_\varsigma + \left(\mathbf{k}_e \nabla T\right)_\varsigma \right) \right] A_\varsigma \end{aligned} \tag{3.12}$$

where

$$q^j_{\gamma\varsigma} = -\frac{\left\langle k_{r\gamma}\right\rangle^{uw}_{\varsigma}\left\langle \mathbf{k}\right\rangle^{h}_{\varsigma}}{\left\langle \mu_\gamma \right\rangle^{h}_{\varsigma}}\left[\frac{P_{\gamma\varsigma+}-P_{\gamma\varsigma-}}{\delta x_\varsigma}+\left\langle \rho_\gamma g\right\rangle^{a}_{\varsigma} z_{g\varsigma}\right] \text{ for } \gamma = l,g; j = w,a; \text{ and } \varsigma = E,W,S,N,B,T$$

$$J^j_{\gamma\varsigma} = -\left\langle \tau_\gamma \phi_D \rho_\gamma s_\gamma \frac{M^j}{M_\gamma} D^j_\gamma \right\rangle^{h}_{\varsigma}\frac{\chi^j_{\gamma\varsigma+}-\chi^j_{\gamma\varsigma-}}{\delta x_\varsigma} \text{ for } \gamma = l,g; j = w,a; \text{ and } \varsigma = E,W,S,N,B,T$$

The diffusive term of Equation (3.12) is computed using a user-defined interfacial average for the effective thermal conductivity, where the default form is harmonic averaging, according to Equation (3.13). The advective components of Equation (3.12) are computed using upwind (donor cell) averaging, according to Equations (3.14) and (3.15).

$$\left(\mathbf{k}_e \nabla T\right)_\varsigma = \left\langle \mathbf{k}_e\right\rangle^{h}_{\varsigma}\frac{T_{\varsigma+}-T_{\varsigma-}}{\delta x_\varsigma} \text{ for } \varsigma = E,W,S,N,B,T \tag{3.13}$$

$$\left(\rho_\gamma h_\gamma \mathbf{q}_\gamma\right)_\varsigma = \left(\rho_\gamma h_\gamma\right)_{\varsigma-}\max\left[q_{\gamma\varsigma-},0\right]-\left(\rho_\gamma h_\gamma\right)_{\varsigma+}\max\left[-q_{\gamma\varsigma+},0\right] \quad \text{for } \gamma = l,g \text{ and } \varsigma = E,W,S,N,B,T \tag{3.14}$$

$$\left(h^j \mathbf{J}^j_\gamma\right)_\varsigma = \left(h^j\right)_{\varsigma-}\max\left[J^j_{\gamma-},0\right]-\left(h^j\right)_{\varsigma+}\max\left[-J^j_{\gamma+},0\right] \quad \text{for } \gamma = l,g \text{ and } \varsigma = E,W,S,N,B,T \tag{3.15}$$

As with the mass conservation equations, the energy conservation equations are discretized in time using a fully implicit scheme, according to Equation (3.16), where the time levels are indicated with superscripts. The primary unknowns for the energy equation are the temperatures at the node centroids (node grid points) for time level t + δt. In residual form, Equation (3.16) appears as shown in Equation (3.17).

$$\bar{V}\left[\frac{\{\bar{E}\}^{t+\delta t}-\{\bar{E}\}^{t}}{\delta t}\right] = \bar{V}\left\{\sum_{j=w,a}\left(h^j \dot{m}^j\right)+\dot{Q}\right\}^{t+\frac{\delta t}{2}} = \sum_{\varsigma=W,E,S,N,B,T}\left[\left\{\left(\mathbf{k}_e\nabla T\right)_\varsigma\right\}^{t+\delta t}\right]A_\varsigma - \sum_{\varsigma=W,E,S,N,B,T}\left[\sum_{\gamma=l,g}\left(\left\{\left(\rho_\gamma h_\gamma \mathbf{q}_\gamma\right)_\varsigma\right\}^{t+\delta t}-\sum_{j=w,a}\left\{\left(h^j \mathbf{J}^j_\gamma\right)_\varsigma\right\}^{t+\delta t}\right)\right]A_\varsigma \tag{3.16}$$

$$\{R_e\}^{t+\delta t} = \bar{V}\left[\frac{\{E\}^{t+\delta t} - \{E\}^{t}}{\delta t}\right] - \bar{V}\left\{\sum_{j=w,a}\left(h^j \dot{m}^j\right) + \dot{Q}\right\}^{t+\frac{\delta t}{2}}$$
$$- \sum_{\varsigma=W,E,S,N,B,T}\left[\left\{\left(\mathbf{k}_e \nabla T\right)_\varsigma\right\}^{t+\delta t}\right] A_\varsigma \qquad (3.17)$$
$$+ \sum_{\varsigma=W,E,S,N,B,T}\left[\sum_{\gamma=l,g}\left(\left\{\left(\rho_\gamma h_\gamma \mathbf{q}_\gamma\right)_\varsigma\right\}^{t+\delta t} - \sum_{j=w,a}\left\{\left(h^j \mathbf{J}_\gamma^j\right)_\varsigma\right\}^{t+\delta t}\right)\right] A_\varsigma$$

3.4 Solute Conservation Equation

The solute mass conservation equation, shown in Equation **(2.10)** is discretized by assuming a piecewise profile for the solute concentration between node points and integrating over the node volume. The advection and diffusion-dispersion transport terms of the solute mass conservation equation are combined following the power-law scheme of Patankar (1980). Integration of the accumulation, source, and decay terms for solute mass over the node volume proceeds according to Equation (3.18).

$$\int_{\bar{V}}\left(\frac{\partial C}{\partial t} - \dot{m}^C - \dot{R}^C C\right) d\bar{V} = \frac{\partial C}{\partial t}\bar{V} - \dot{m}^C \bar{V} - \dot{R}^C C \bar{V} \qquad (3.18)$$

Solute transport fluxes are computed between node points and comprise advective and diffusive-dispersive components. Integration of the flux terms proceeds by converting volumetric integrals to surface integrals following Green's theorem (Kreyszig 1979), according to Equation (3.19). Surface integrals are approximated by discretizing the control volume surfaces into node surfaces and summing the contributions to solute transport over the node surfaces, according to Equation (3.20). The diffusive-dispersive term of Equation (3.20) is computed using a user-defined interfacial average where the default scheme is harmonic averaging, according to Equation (3.21).

$$\int_{\bar{V}}\left[-\sum_{\gamma=l,g}\left(\nabla\left[C_\gamma q_\gamma\right]\right) + \sum_{\gamma=l,g}\left(\nabla\left[\left(\tau_\gamma\, s_\gamma \phi_D D_\gamma^C + s_\gamma \phi_D \mathbf{D}_{h\gamma}\right)\nabla C_\gamma\right]\right)\right] d\bar{V}$$
$$= \int_{\Gamma}\left[-\sum_{\gamma=l,g}\left(C_\gamma q_\gamma\right) + \sum_{\gamma=l,g}\left(\left(\tau_\gamma\, s_\gamma \phi_D D_\gamma^C + s_\gamma \phi_D \mathbf{D}_{h\gamma}\right)\nabla C_\gamma\right)\right] \cdot \mathbf{n} d\Gamma \qquad (3.19)$$

where

$$\mathbf{q}_\gamma = -\frac{k_{r\gamma}\,\mathbf{k}}{\mu_\gamma}\left(\nabla P_\gamma + \rho_\gamma\, g\, \mathbf{z}_g\right) \text{ for } \gamma = l, g$$

$$\begin{aligned}&\int_\Gamma \left[-\sum_{\gamma=l,g}\left(C_\gamma q_\gamma\right) + \sum_{\gamma=l,g}\left(\left(\tau_\gamma\, s_\gamma \phi_D D_\gamma^C + s_\gamma \phi_D \mathbf{D}_{h\gamma}\right)\nabla C_\gamma\right)\right]\cdot \mathbf{n}\, d\Gamma \\ &= \sum_{\varsigma=W,E,S,N,B,T}\left[-\sum_{\gamma=l,g}\left(C_\gamma q_\gamma\right)_\varsigma + \sum_{\gamma=l,g}\left(\left(\tau_\gamma\, s_\gamma \phi_D D_\gamma^C + s_\gamma \phi_D \mathbf{D}_{h\gamma}\right)\nabla C_\gamma\right)_\varsigma\right] A_\varsigma\end{aligned} \tag{3.20}$$

where

$$q_{\gamma\varsigma}^j = -\frac{\left\langle k_{r\gamma}\right\rangle_\varsigma^{uw}\left\langle \mathbf{k}\right\rangle_\varsigma^h}{\left\langle \mu_\gamma\right\rangle_\varsigma^h}\left[\frac{P_{\gamma\varsigma+} - P_{\gamma\varsigma-}}{\delta x_\varsigma} + \left\langle \rho_\gamma g\right\rangle_\varsigma^a z_{g\varsigma}\right] \text{ for } \gamma = l,g;\ j = w,a;\ \text{and } \varsigma = E,W,S,N,B,T$$

$$\left(\left(\tau_\gamma\, s_\gamma \phi_D D_\gamma^C + s_\gamma \phi_D \mathbf{D}_{h\gamma}\right)\nabla C_\gamma\right)_\varsigma = \left\langle \tau_\gamma\, s_\gamma \phi_D D_\gamma^C + s_\gamma \phi_D \mathbf{D}_{h\gamma}\right\rangle_\varsigma^h \frac{C_{\gamma\varsigma+} - C_{\gamma\varsigma-}}{\delta x_\varsigma} \tag{3.21}$$

$$\text{for } \gamma = l,g \text{ and } \varsigma = E,W,S,N,B,T$$

Solution of the solute transport equation depends on the local Peclet number that represents the ratio of advective transport to diffusive-dispersive transport, according to Equation (3.22)

$$Pe_{\gamma_\varsigma} = \frac{q_{\gamma\varsigma}\delta x_\varsigma}{\left\langle \tau_\gamma\, s_\gamma \phi_D D_\gamma^C + s_\gamma \phi_D \mathbf{D}_{h\gamma}\right\rangle_\varsigma^h} \tag{3.22}$$

The power law scheme is based on the solute concentration profile for steady conditions with no sources or decay. For a Peclet number of zero, diffusion-dispersion transport dominates and a linear profile of solute concentration occurs between two spatial points. For a Peclet number of one, advection and diffusion-dispersion equally contribute to solute transport. The solute concentration profile will be skewed towards an upstream solute concentration. For large Peclet numbers, advection transport dominates and the upstream solute concentration defines the solute concentration profile between two spatial points. The power-law scheme closely approximates the exact solution for steady conditions without excessive computational expense. Solute flux from combined advective and diffusive-dispersive transport can be expressed using the power-law scheme according to Equation (3.23).

$$G^C_{\gamma_\varsigma} = -C_{\gamma_{\varsigma^+}}\left[\max\left(-q_{\gamma_\varsigma},0\right)+\left(D^C_{\gamma_e}\right)_\varsigma \max\left(\left(1-\left(\frac{0.1\left|q_{\gamma_\varsigma}\right|}{\left(D^C_{\gamma_e}\right)_\varsigma}\right)\right)^5,0\right)\right]$$

$$+C_{\gamma_{\varsigma^-}}\left[\max\left(q_{\gamma_\varsigma},0\right)+\left(D^C_{\gamma_e}\right)_\varsigma \max\left(\left(1-\left(\frac{0.1\left|q_{\gamma_\varsigma}\right|}{\left(D^C_{\gamma_e}\right)_\varsigma}\right)\right)^5,0\right)\right] \qquad (3.23)$$

for $\gamma = l,g$ and $\varsigma = W,E,S,N,B,T$

where

$$\left(D^C_{\gamma_e}\right)_\varsigma = \frac{\left\langle \tau_\gamma\, s_\gamma \phi_D D^C_\gamma + s_\gamma \phi_D \mathbf{D}_{h\gamma} \right\rangle^h_\varsigma}{\delta x_\varsigma}$$

The discretized solute concentration equation can be written in two compact forms. The first form uses the expressions of solute flux according to Equation (3.24). The second form uses a linear system format with coefficients for the solute concentrations according to Equation (3.25).

$$\sum_{\gamma=l,g}\left(G^C_{\gamma_W} - G^C_{\gamma_E} + G^C_{\gamma_S} - G^C_{\gamma_N} + G^C_{\gamma_B} - G^C_{\gamma_T}\right) = \frac{\partial C}{\partial t}\bar{V} - \dot{m}^C\bar{V} - \dot{R}^C C\bar{V} \qquad (3.24)$$

$$a_P C_P - \sum_{\varsigma=W,E,S,N,B,T} a_\varsigma C_\varsigma = \frac{\partial C}{\partial t}\bar{V} - \dot{m}^C\bar{V} - \dot{R}^C C\bar{V} \qquad (3.25)$$

where

$$a_\varsigma = \sum_{\gamma=l,g} a_{\gamma_\varsigma}$$

$$a_{\gamma_P} = \sum_{\varsigma=W,E,S,N,B,T} a_{\gamma_\varsigma} + \sum_{\varsigma=E,N,T} q_{\gamma_\varsigma} - \sum_{\varsigma=W,S,B} q_{\gamma_\varsigma}$$

$$a_{\gamma_\varsigma} = \max\left(q_{\gamma_\varsigma}, 0\right) + \left(D^C_{\gamma_e}\right)_\varsigma \max\left(\left(1 - \left(\frac{0.1\left|q_{\gamma_\varsigma}\right|}{\left(D^C_{\gamma_e}\right)_\varsigma}\right)\right)^5, 0\right) \text{ for } \gamma = l,g \text{ and } \varsigma = W,S,B$$

$$a_{\gamma_\varsigma} = \max\left(-q_{\gamma_\varsigma}, 0\right) + \left(D^C_{\gamma_e}\right)_\varsigma \max\left(\left(1 - \left(\frac{0.1\left|q_{\gamma_\varsigma}\right|}{\left(D^C_{\gamma_e}\right)_\varsigma}\right)\right)^5, 0\right) \text{ for } \gamma = l,g \text{ and } \varsigma = E,N,T\,.$$

The solute mass conservation equation is discretized in time using a fully implicit scheme, according to Equation (3.26), in linear system format, where time levels are indicated with superscripts.

$$\sum_{\varsigma=P,w,E,S,N,B,T} a_\varsigma \left\{C_\varsigma\right\}^{t+\delta t} = \frac{\left\{C_P\right\}^t}{\delta t}\bar{V} - \dot{m}^C\bar{V} \tag{3.26}$$

where

$$a_\varsigma = \sum_{\gamma=l,g} a_{\gamma_\varsigma}$$

$$a_{\gamma_P} = \sum_{\varsigma=W,E,S,N,B,T} a_{\gamma_\varsigma} + \sum_{\varsigma=E,N,T} V_{\gamma_\varsigma} - \sum_{\varsigma=W,S,B} V_{\gamma_\varsigma} + \frac{\bar{V}}{\delta t} + \dot{R}^C\bar{V}$$

$$a_{\gamma_\varsigma} = \max\left(q_{\gamma_\varsigma}, 0\right) + \left(D^C_{\gamma_e}\right)_\varsigma \max\left(\left(1 - \left(\frac{0.1\left|q_{\gamma_\varsigma}\right|}{\left(D^C_{\gamma_e}\right)_\varsigma}\right)\right)^5, 0\right) \text{ for } \gamma = l,g \text{ and } \varsigma = W,S,B$$

$$a_{\gamma_\varsigma} = \max\left(-q_{\gamma_\varsigma}, 0\right) + \left(D^C_{\gamma_e}\right)_\varsigma \max\left(\left(1 - \left(\frac{0.1\left|q_{\gamma_\varsigma}\right|}{\left(D^C_{\gamma_e}\right)_\varsigma}\right)\right)^5, 0\right) \text{ for } \gamma = l,g \text{ and } \varsigma = E,N,T\,.$$

3.4.1 Newton-Raphson Linearization

The discretized governing equations for component mass conservation and energy conservation, Equations (3.8) and (3.17), form a nonlinear set of algebraic equations. Nonlinear equation sets arise from the dependence of secondary variables on the primary unknowns. Cross dependencies of secondary

variables in one governing equation with the primary variable unknown in other governing equations requires this system of nonlinear equations be solved simultaneously. A primary assumption associated with the solute mass conservation equation is that solute concentrations are infinitely dilute. This assumption implies that fluid properties are independent of solute concentrations, which allows the solute conservation equations to be solved separately from the coupled flow and energy transport solutions. The discretized governing equations for solute mass conservation, Equation (3.26), form a linear set of algebraic equations that are solved directly following the solution of the coupled flow and energy transport system. The nonlinear situations in the coupled flow and energy transport system of equations are resolved through the application of the iterative Newton-Raphson technique.

The Newton-Raphson linearization technique is an iterative method for solving nonlinear algebraic equations of the form shown in Equation (3.27), where $f(x)$ is differentiable in x. The linearization concept approximates $f(x)$ with suitable tangents. Each iteration yields a new estimate of x as the intersection of the tangent to the function $f(x)$ at the previous estimate of x and the abscissa axis, according to Equation (3.28) in mathematical form. In this formulation, $f(x)$ is considered the equation residual. For convergent systems, the residual decreases quadratically with iteration. In multiple variable systems, as with the coupled flow and energy transport system, the scalar function, $f(x)$, is replaced with a vector function $\mathbf{R}(\mathbf{x})$, according to Equation (3.29). The vector function, $\mathbf{R}(\mathbf{x})$, represents the system of nonlinear algebraic equations produced from discretizing the conservation equations for component mass and energy, Equations (3.8) and (3.17). The vector of unknowns, $\mathbf{x}$, represents the set of primary variables for the system that are determined by the operational mode and phase conditions. Equation (3.29) can be rewritten in terms of increments to the primary variables, according to Equation (3.30). The partial derivatives shown in Equation (3.30) form the Jacobian matrix.

$$f(x)=0 \tag{3.27}$$

$$x^{n+1}=x^{n}-\frac{f(x)}{f'(x)} \tag{3.28}$$

$$x^{n+1}=x^{n}-\frac{\mathbf{R}(\mathbf{x})}{\mathbf{R}'(\mathbf{x})} \tag{3.29}$$

$$\frac{\partial \mathbf{R}(\mathbf{x})}{\partial \mathbf{x}}\Delta\mathbf{x}=-\mathbf{R}(\mathbf{x}) \tag{3.30}$$

To simplify these discussions, a one-dimensional system involving the solution of the water mass, air mass, and energy conservation equations is considered. The system of linear equations that result from

applying the Newton-Raphson linearization technique to this system of nonlinear algebraic equations is shown in Equation (3.31) for a computational domain with n nodes. In Equation (3.31), each Jacobian matrix element represents a block matrix of order three, according to Equation (3.32). Each unknown vector element represents a vector of increments to the primary variables of order three, according to Equation (3.33). Each solution vector element represents a vector of equation residuals of order three, according to Equation (3.34).

$$\begin{vmatrix} \frac{\partial \mathbf{R}_1}{\partial \mathbf{x}_1} & \frac{\partial \mathbf{R}_1}{\partial \mathbf{x}_2} & 0 & 0 & \cdot & 0 & 0 & 0 \\ \frac{\partial \mathbf{R}_1}{\partial \mathbf{x}_1} & \frac{\partial \mathbf{R}_2}{\partial \mathbf{x}_2} & \frac{\partial \mathbf{R}_2}{\partial \mathbf{x}_3} & 0 & \cdot & 0 & 0 & 0 \\ 0 & \frac{\partial \mathbf{R}_3}{\partial \mathbf{x}_2} & \frac{\partial \mathbf{R}_3}{\partial \mathbf{x}_3} & \frac{\partial \mathbf{R}_3}{\partial \mathbf{x}_4} & \cdot & 0 & 0 & 0 \\ 0 & 0 & \frac{\partial \mathbf{R}_4}{\partial \mathbf{x}_3} & \frac{\partial \mathbf{R}_4}{\partial \mathbf{x}_4} & \cdot & 0 & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & 0 & 0 & \cdot & \frac{\partial \mathbf{R}_{n-2}}{\partial \mathbf{x}_{n-2}} & \frac{\partial \mathbf{R}_{n-2}}{\partial \mathbf{x}_{n-1}} & 0 \\ 0 & 0 & 0 & 0 & \cdot & \frac{\partial \mathbf{R}_{n-1}}{\partial \mathbf{x}_{n-2}} & \frac{\partial \mathbf{R}_{n-1}}{\partial \mathbf{x}_{n-1}} & \frac{\partial \mathbf{R}_{n-1}}{\partial \mathbf{x}_n} \\ 0 & 0 & 0 & 0 & \cdot & 0 & \frac{\partial \mathbf{R}_n}{\partial \mathbf{x}_{n-1}} & \frac{\partial \mathbf{R}_n}{\partial \mathbf{x}_n} \end{vmatrix} \begin{vmatrix} \mathbf{x}_1 \\ \mathbf{x}_2 \\ \mathbf{x}_3 \\ \mathbf{x}_4 \\ \cdot \\ \mathbf{x}_{n-2} \\ \mathbf{x}_{n-1} \\ \mathbf{x}_n \end{vmatrix} = \begin{vmatrix} -\mathbf{R}_1 \\ -\mathbf{R}_2 \\ -\mathbf{R}_3 \\ -\mathbf{R}_4 \\ \cdot \\ -\mathbf{R}_{n-2} \\ -\mathbf{R}_{n-1} \\ -\mathbf{R}_n \end{vmatrix} \tag{3.31}$$

$$\frac{\partial \mathbf{R}_k}{\partial \mathbf{x}_l} = \begin{vmatrix} \frac{\partial R_k^w}{\partial PV_l^w} & \frac{\partial R_k^w}{\partial PV_l^a} & \frac{\partial R_k^w}{\partial PV_l^e} \\ \frac{\partial R_k^a}{\partial PV_l^w} & \frac{\partial R_k^a}{\partial PV_l^a} & \frac{\partial R_k^a}{\partial PV_l^e} \\ \frac{\partial R_k^e}{\partial PV_l^w} & \frac{\partial R_k^e}{\partial PV_l^a} & \frac{\partial R_k^e}{\partial PV_l^e} \end{vmatrix} \tag{3.32}$$

$$-\mathbf{x}_l = \begin{vmatrix} \Delta PV_l^w \\ \Delta PV_l^a \\ \Delta PV_l^e \end{vmatrix} \tag{3.33}$$

$$-\mathbf{R}_k = \begin{vmatrix} -R_k^w \\ -R_k^a \\ -R_k^e \end{vmatrix} \tag{3.34}$$

For a 2-dimensional system involving the solution of the water mass, air mass, and energy conservation equations, the Jacobian matrix contains two extra bands of block matrixes: one below and one above the diagonal band. These extra bands are located one half-band width from the main diagonal band, where the half-band width equaled the lesser of the number of nodes per row or column for a 2-dimensional grid. A 3-dimensional grid contains four extra bands of block matrixes, two below and two above the diagonal band. The furthest bands are located one half-band width from the main diagonal band, where the half-band width equaled the least number of nodes in a plane. For example, a 3-dimensional Cartesian grid with 20 nodes in the X coordinate direction, 30 nodes in the Y coordinate direction, and 40 nodes in the Z coordinate direction, has a half-band width of 600.

The Newton-Raphson scheme has two major computational components. The first component involves computing the Jacobian matrix and solution vector elements; the second component involves solving the resulting linear system of equations. During each iteration, both components are required. The Jacobian matrix elements are essentially partial derivatives of the equation residuals with respect to the primary variables. These partial derivatives are computed numerically as exemplified in Equation (3.35)

$$\frac{\partial R_k^j}{\partial PV_l^i} \cong \frac{R_k^j \left|^{PV_l^i + \Delta PV_l^i} - R_k^j \right|^{PV_l^i}}{\Delta PV_l^i}. \tag{3.35}$$

For robustness and directness in coding, numerical evaluation of these partial derivatives was chosen over analytical evaluation. The numerical evaluation scheme requires that the equation residuals be evaluated with the most current values of the primary variables and with each primary variable slightly incremented. Increments to the primary variables are critical parameters for implementing the Newton-Raphson linearization scheme using numerical derivatives. Excessively large increments can lead to non-convergent solutions because the tangents to the residual equations are computed incorrectly. In contrast, excessively small increments can result in changes in the equation residuals that are below the precision limit.

Each Newton-Raphson iteration procedure begins with the start of a new time step or after a convergence failure and reduction in time step. Each iteration begins by executing logic algorithms that determine the primary variable set from phase conditions and fix the primary variable increments. The next step is to calculate all secondary variables with the current primary variables and with each primary variable incremented. Following this, all flux variables are evaluated with the current primary variable and associated secondary variables and then repeated with the incremented primary and associated secondary variables. With the secondary variables and fluxes evaluated, the residuals to the governing

equations are computed using current and incremented values of the primary, secondary, and flux variables. The current and incremented equations residuals are then used to compute the partial derivatives that comprise the Jacobian matrix and the solution vector.

The resulting system of linear equations is then solved with either a direct or iterative linear system solver, with the unknowns as increments to the primary variables. Converged solutions are recognized by comparing the maximum normalized increment to the primary variables against a convergence criterion (that is, a user-specified limit). A Newton-Raphson iteration ends by updating the primary variables with the latest computed primary increments. If the largest normalized primary variable increment exceeds the convergence limit, another iteration is executed. If the solution is convergent, the solute transport equations are solved or a new time step is initiated. In the case of a non-convergent solution, the time step is reduced, the primary variables are reset to the most recent converged values, and the time step is reinitiated.

3.4.2 Linear System Solvers

The system of linear equations that results from the discretization of the governing partial differential equations over a particular computational domain always has a banded structure, where the number of off diagonal bands equals the dimensions of the computational domain. Elements within the Jacobian coefficient are actually submatrixes, where the submatrix order equals the number of solved coupled governing equations. For example, the solution of only the water conservation equation produces single element submatrixes, whereas the simultaneous solution of the three mass conservation equations with the energy equation yields four-by-four submatrixes. These structured Jacobian coefficient matrixes arise from the element sequencing scheme incorporated into the STORM simulator and the limitations on the computational domain structures. The matrix sequencing or numbering algorithms are designed to minimize the largest half-band width for a given computational domain and solution option combination. The sequencing algorithms are designed for orthogonal grid systems that are six-surfaced in three dimensions or four-sided in two dimensions.

Two linear equation solvers are available within the STORM simulator, a direct-banded matrix algorithm and an iterative conjugate gradient algorithm. The banded matrix algorithm is generally more appropriate for small to moderately sized Jacobian matrixes (order less than 35,000); whereas, the conjugate gradient algorithm appears more appropriate for larger order Jacobian matrixes. In general, the banded matrix algorithm requires more memory than the conjugate gradient algorithm that uses an efficient sparse matrix storage scheme. The banded matrix algorithm is computationally more efficient on small to moderately sized problems; however, for larger problems the conjugate gradient algorithm is the better performer. Both linear equation solution algorithms were obtained from publicly available software packages.

The banded matrix solution algorithm was extracted from the LINPACK subroutines (Dongarra et al. 1979) for general nonsymmetric band matrixes. The algorithm operates on band matrixes by decomposing the matrix into an upper triangular and lower triangular matrix. The matrix product of the lower triangular matrix times the upper triangular matrix equals the original band matrix (that is, $\mathbf{A} = \mathbf{L} \cdot \mathbf{U}$, where $\mathbf{A}$ is the band matrix, $\mathbf{L}$ is the lower triangular matrix and $\mathbf{U}$ is the upper triangular

matrix). The system of linear equations, $\mathbf{A}\cdot\mathbf{x} = \mathbf{b}$, is solved with the preceding decomposition or factorization by solving successively $\mathbf{L}(\mathbf{U}\cdot\mathbf{x}) = \mathbf{b}$. This factorization procedure produces nonzero elements outside the bands of the original band matrix. If m_l equals the half-band width of the Jacobian coefficient matrix (the STORM simulator produces band matrixes with equal lower and upper bandwidths), the two triangular factors have bandwidths of m_l and $2m_l$. Storage must be provided for the extra m_l diagonals. This requirement is illustrated for a 1-dimensional problem of five nodes and two solved mass conservation equations. The Jacobian coefficient matrix for this problem appears as shown in Equation (3.36). The band storage requires $3m_l + 1 = 10$ rows of storage arranged as shown in Equation (3.37). The * indicates elements that are never referenced but for which storage space must be provided. The + indicates elements that may be occupied during the factorization process. The original Jacobian coefficient matrix is referred to as **A** and its storage counterpart as **a**. The columns of **A** are stored in the columns of **a**, and the diagonals of **A** are stored in the rows of **a**, so the principal diagonal is stored in row $2m_l + 1$ of **a**.

$$\mathbf{A} = \begin{vmatrix} x_{1,1} & x_{1,2} & x_{1,3} & x_{1,4} & 0 & 0 & 0 & 0 & 0 & 0 \\ x_{2,1} & x_{2,2} & x_{2,3} & x_{2,4} & 0 & 0 & 0 & 0 & 0 & 0 \\ x_{3,1} & x_{3,2} & x_{3,3} & x_{3,4} & x_{3,5} & x_{3,6} & 0 & 0 & 0 & 0 \\ x_{4,1} & x_{4,2} & x_{4,3} & x_{4,4} & x_{4,5} & x_{4,6} & 0 & 0 & 0 & 0 \\ 0 & 0 & x_{5,3} & x_{5,4} & x_{5,5} & x_{5,6} & x_{5,7} & x_{5,8} & 0 & 0 \\ 0 & 0 & x_{6,3} & x_{6,4} & x_{6,5} & x_{6,6} & x_{6,7} & x_{6,8} & 0 & 0 \\ 0 & 0 & 0 & 0 & x_{7,5} & x_{7,6} & x_{7,7} & x_{7,8} & x_{7,9} & x_{7,10} \\ 0 & 0 & 0 & 0 & x_{8,5} & x_{8,6} & x_{8,7} & x_{8,8} & x_{8,9} & x_{8,10} \\ 0 & 0 & 0 & 0 & 0 & 0 & x_{9,7} & x_{9,8} & x_{9,9} & x_{9,10} \\ 0 & 0 & 0 & 0 & 0 & 0 & x_{10,7} & x_{10,8} & x_{10,9} & x_{10,10} \end{vmatrix} \tag{3.36}$$

$$\mathbf{a} = \begin{vmatrix} * & * & * & * & * & * & + & + & + & + \\ * & * & * & * & * & + & + & + & + & + \\ * & * & * & * & + & + & + & + & + & + \\ * & * & \bullet & x_{1,4} & 0 & x_{3,6} & 0 & x_{5,8} & 0 & x_{7,10} \\ * & * & x_{1,3} & x_{2,4} & x_{3,5} & x_{4,6} & x_{5,7} & x_{6,8} & x_{7,9} & x_{8,10} \\ * & x_{1,2} & x_{2,3} & x_{3,4} & x_{4,5} & x_{5,6} & x_{6,7} & x_{7,8} & x_{8,9} & x_{9,10} \\ x_{1,1} & x_{2,2} & x_{3,3} & x_{4,4} & x_{5,5} & x_{6,6} & x_{7,7} & x_{8,8} & x_{9,9} & x_{10,10} \\ x_{2,1} & x_{3,2} & x_{4,3} & x_{5,4} & x_{6,5} & x_{7,6} & x_{8,7} & x_{9,8} & x_{10,9} & * \\ x_{3,1} & x_{4,2} & x_{5,3} & x_{6,4} & x_{7,5} & x_{8,6} & x_{9,7} & x_{10,8} & * & * \\ x_{4,1} & 0 & x_{6,3} & 0 & x_{8,5} & 0 & x_{10,7} & * & * & * \end{vmatrix} \tag{3.37}$$

The conjugate gradient solution algorithm was extracted from a package of subroutines intended for solving large sparse linear systems by iterative methods (Oppe et al. 1988). This package of subroutines

is referred to as Nonsymmetric Preconditioned Conjugate Gradient (NSPCG) and has various acceleration techniques and preconditioners available for solving large sparse linear systems. The algorithms available from the NSPCG package are the Incomplete Cholesky (IC) preconditioner and the Generalized Minimal Residual Method (GMRES) accelerator. Preconditioners compute a splitting matrix Q so the preconditioned system of linear equations, $\mathbf{Q^{-1}Ax = Q^{-1}b}$, is better conditioned than the original system, $\mathbf{A \cdot x = b}$. The splitting matrix for the IC preconditioner is an incomplete LU decomposition of the Jacobian matrix A. The form of the splitting matrix is $\mathbf{Q = (D - S)D^{-1}(D - T)}$, where D is a diagonal matrix containing the factorization pivots, S is a lower triangular matrix, and T is an upper triangular matrix. It is necessary to store both S and T because the Jacobian coefficient matrix A is nonsymmetrical.

The NSPCG package allows several modes of storage for the Jacobian coefficient matrix. The storage mode selected for the STORM simulator represents the Jacobian coefficient matrix with two rectangular arrays, one real and one integer. Both arrays are dimensioned n by m, where n equals the number of unknowns and m equals seven times the number of solved coupled governing equations. Each row in the real coefficient matrix **C** contains the nonzero values of the corresponding row in the Jacobian coefficient matrix A; the corresponding row in the integer coefficient matrix J contains the column indexes. The Jacobian matrix, shown in Equation (3.36), is expressed as the real and integer matrixes shown in Equations (3.38) and (3.39), respectively. Although this storage format requires two coefficient matrixes, the storage requirements for large sparse systems (such as those for large multidimensional problems) are greatly reduced over those for the banded matrix solution scheme.

$$\mathbf{C} = \begin{vmatrix} x_{1,1} & x_{1,2} & x_{1,3} & x_{1,4} & 0 & 0 \\ x_{2,1} & x_{2,2} & x_{2,3} & x_{2,4} & 0 & 0 \\ x_{3,1} & x_{3,2} & x_{3,3} & x_{3,4} & x_{3,5} & x_{3,6} \\ x_{4,1} & x_{4,2} & x_{4,3} & x_{4,4} & x_{4,5} & x_{4,6} \\ x_{5,1} & x_{5,2} & x_{5,3} & x_{5,4} & x_{5,5} & x_{5,6} \\ x_{6,1} & x_{6,2} & x_{6,3} & x_{6,4} & x_{6,5} & x_{6,6} \\ x_{7,1} & x_{7,2} & x_{7,3} & x_{7,4} & x_{7,5} & x_{7,6} \\ x_{8,1} & x_{8,2} & x_{8,3} & x_{8,4} & x_{8,5} & x_{8,6} \\ x_{9,1} & x_{9,2} & x_{9,3} & x_{9,4} & 0 & 0 \\ x_{10,1} & x_{10,2} & x_{10,3} & x_{10,4} & 0 & 0 \end{vmatrix} \tag{3.38}$$

$$\mathbf{J} = \begin{vmatrix} 1 & 2 & 3 & 4 & 0 & 0 \\ 1 & 2 & 3 & 4 & 0 & 0 \\ 1 & 2 & 3 & 4 & 5 & 6 \\ 1 & 2 & 3 & 4 & 5 & 6 \\ 3 & 4 & 5 & 6 & 7 & 8 \\ 3 & 4 & 5 & 6 & 7 & 8 \\ 5 & 6 & 7 & 8 & 9 & 10 \\ 5 & 6 & 7 & 8 & 9 & 10 \\ 7 & 8 & 9 & 10 & 0 & 0 \\ 7 & 8 & 9 & 10 & 0 & 0 \end{vmatrix} \tag{3.39}$$

3.5 Geochemical Reactions

Combining Equation **(2.17)** and Equation **(2.20)** yields the solute mass conservation equation including geochemical reactions

$$\begin{gathered} \frac{\partial}{\partial t}\left[\phi_D \rho_l \left(s_g K_H'^{-1} + s_l\right) C_i^l\right] = \\ \nabla \bullet \left[-\phi_D \rho_l \left(s_g \mathbf{V}_g K_H'^{-1} + s_l \mathbf{V}_l\right) C_i^l + \phi_D \rho_l \left(s_g \mathbf{D}_i^g K_H'^{-1} + s_l \mathbf{D}_i^l\right) \cdot \nabla C_i^l\right] \\ + \sum_{j=1}^{N_e} \nu_{ij} W_j^e + \sum_{j=1}^{N_k} \nu_{ij} W_j^k \end{gathered} \tag{3.40}$$

In matrix form, Equation (3.40) can be written as

$$\frac{\partial}{\partial t}\left[\phi_D \rho_t \left(s_g K_H'^{-1} + s_t\right) \dot{\mathbf{C}}\right] = \dot{\mathbf{L}}(\dot{\mathbf{C}}) + \mathbf{N}\dot{\mathbf{W}} \tag{3.41}$$

where

$$\dot{\mathbf{L}}(\dot{\mathbf{C}}) = \left[L_1(C_1), \ldots, L_{N_s}(C_{N_s})\right]^T$$

$$L_t(C_i) = \nabla \bullet \left[-\phi_D \rho_t \left(s_g \mathbf{V}_g K_H'^{-1} + s_t \mathbf{V}_t\right) C_i^t + \phi_D \rho_t \left(s_g \mathbf{D}_i^g K_H'^{-1} + s_t \mathbf{D}_i^t\right) \cdot \nabla C_i^t\right]$$

$$\dot{\mathbf{W}} = \left(W_1^e, \ldots W_{N_e}^e, W_1^k, \ldots W_{N_k}^k\right)^T$$

$$\mathbf{N} = \begin{bmatrix} \nu_{11} & \cdot\cdot & \cdot\cdot & \nu_{1,N_r} \\ \cdot & \cdot\cdot & \cdot\cdot & \cdot \\ \cdot & \cdot\cdot & \cdot\cdot & \cdot \\ \cdot & \cdot\cdot & \cdot\cdot & \cdot \\ \nu_{N_s,1} & \cdot\cdot & \cdot\cdot & \nu_{N_s,N_r} \end{bmatrix}$$

where N_s is the number of species, N_e is the number of equilibrium reactions, and N_k is the number of kinetic reactions.

3.5.1 Linear Transformation of the Reaction-Transport Equation

Ortoleva et al. (1987) pointed out that a subsurface system usually contains reactions of different time scales, and, therefore, "straightforward numerical solution of the solute equations is impractical." To remedy the stiffness of Equation (3.41), a modification is needed to the equation that separates reactions with different time scales. As discussed in Section **2.3.1**, geochemical models usually assume some reactions with a short time scale are equilibrium reactions, while assuming others are kinetic reactions. In most cases, separating reactions with different time scales is separating equilibrium reactions from kinetic reactions.

One approach to performing such separations is based on a canonical representation of reactions (Kirkner and Reeves 1988; Lichtner 1985; Reed 1982; Sevougian et al. 1993; Steefel and Lasaga 1994; Yeh and Tripathi 1991). That approach arbitrarily assigns one subset of species as the primary species (or base species) and the others as the secondary species. Reactions are written in canonical form, that is, each reaction involves only one secondary species, but requires several primary species (Lichtner 1985). Consequently, the rate of production/destruction of primary species, due to reversible reactions, is expressed as the weighted summary of secondary species with the number of moles of primary species in the secondary species as the weight. Adding the mass conservation equation of secondary species with that of the primary species leads to a mass conservation equation that does not contain a source/sink term of reversible reactions. It not only separates equilibrium reactions from kinetic ones, but it also reduces the number of nonlinear partial differential equations (PDE) from N_s to $N_s - N_e$.

From the perspective of linear algebra, the canonical representation approach is equivalent to a linear transformation on aqueous species. The original variables-species concentrations are transformed to total concentrations of chemical components, a linear combination of relevant species. This generalization has led toward a more general approach to separating equilibrium from kinetic reactions.

3.5.2 Q-R Decomposition

Look at the reaction matrix $\mathbf{N}$. Assume its columns are linearly independent (that is, the reactions are linearly independent) with the dimension of $N_s \times N_r$. The reactions are arranged so the first N_e

columns represent equilibrium reactions and the rest are kinetic reactions. The independent assumption guarantees $N_r \le N_s$. Matrix algebra states that $\mathbf{N}$ can be decomposed to

$$\mathbf{N}_{N_s \times N_r} = \mathbf{Q}_{N_s \times N_r} \cdot \begin{bmatrix} \mathbf{R}_{N_s \times N_r} \\ 0_{N_r \times (N_s - N_r)} \end{bmatrix} \tag{3.42}$$

(Golub and Van Loan 1983) where $\mathbf{Q}$ is an orthogonal matrix:

$$\mathbf{Q}^T = \mathbf{Q}^{-1} \tag{3.43}$$

and $\mathbf{R}$ is an upper-triangular matrix:

$$\mathbf{R}_{N_R \times N_R} = \begin{bmatrix} r_{11} & \cdot & \cdots & \cdot & \cdot \\ 0 & r_{22} & \cdots & \cdot & \cdot \\ 0 & \cdot & \cdots & \cdot & \cdot \\ \cdot & \cdot & \cdots & \cdot & \cdot \\ 0 & 0 & \cdots & 0 & r_{N_R, N_R} \end{bmatrix} \tag{3.44}$$

Multiplying Equation (3.41) by $\mathbf{Q}^T$ gives

$$\frac{\partial}{\partial t}\left[\phi_D \rho_t \left(s_g K_H'^{-1} + s_t\right)\mathbf{Q}^T \dot{\mathbf{C}}\right] = \mathbf{Q}^T \dot{\mathbf{L}}(\dot{\mathbf{C}}) + \mathbf{R}\dot{\mathbf{W}} \tag{3.45}$$

Denote

$$\mathbf{Q}^T \dot{\mathbf{C}} = \dot{\vec{x}} = \left(\chi_1, \cdots, \chi_{N_e}, \chi_{N_e+1}, \cdots, \chi_{N_e+N_k}, \chi_{N_e+N_k+1}, \cdots, \chi_{N_s}\right)^T \tag{3.46}$$

and recognize that each χ_i is a linear combination of (C_i). Following the notes from the canonical representation approach (Lichtner 1985), χ_i is called the general component. However, χ_i does not bear the straightforward physical meaning as the chemical components do.

Also denote

$$\mathbf{R}\vec{\mathbf{W}} = \vec{\beta} = \left(\beta_1,\ldots,\beta_{N_e},\beta_{N_e+1},\ldots,\beta_{N_e+N_k}\right)^T \tag{3.47}$$

and

$$\vec{\mathbf{L}}(\vec{\chi}) = \mathbf{Q}^T\vec{\mathbf{L}}(\vec{\mathbf{C}}). \tag{3.48}$$

Note the last N_k components of $\vec{\beta}$ contain only the source terms of kinetic reactions.

Now Equation (3.45) can be written in three groups with different source terms. Group I, $\left(\chi_1,\ldots,\chi_{N_e}\right)^T$, contains source terms of equilibrium and kinetic reactions:

$$\frac{\partial}{\partial t}\left[\phi_D\rho_1\left(s_g K_H'^{-1}+s_1\right)\chi_l\right] = L(\chi_l)+\beta_l,\ \ l=1,\mathrm{K}\ ,N_e \tag{3.49}$$

Group II, kinetic reactive general components, $\left(\chi_{N_e+1},\ldots,\chi_{N_e+N_k}\right)^T$, contains the source terms only of the kinetic reactions:

$$\frac{\partial}{\partial t}\left[\phi_D\rho_1\left(s_g K_H'^{-1}+s_1\right)\chi_l\right] = L(\chi_l)+\beta_l,\ \ l=N_e+1,\mathrm{K}\ ,N_r \tag{3.50}$$

where $N_r = N_e + N_k$ is the total number of reactions. Group III, non-reactive general components, $\left(\chi_{N_e+N_k+1},\ldots,\chi_{N_s}\right)^T$, does not contain the source terms of either type of reactions:

$$\frac{\partial}{\partial t}\left[\phi_D\rho_1\left(s_g K_H'^{-1}+s_1\right)\chi_l\right] = L(\chi_l),\ \ l=N_{r+1},\mathrm{K}\ ,N_s \tag{3.51}$$

Because Equation (3.49) contains source terms of equilibrium reactions, it is still difficult to directly solve Equations (3.49) through (3.51) together. However, because of the equilibrium assumption made for the N_e reactions Equation (3.49) is disregarded and replaced with the N_e equilibrium conditions

$$\prod_{i=1}^{N_s}(\gamma_i C_i)^{\nu_{ij}} = K_j^{eq},\ \ j=1,\ldots,N_e \tag{3.52}$$

Equations (3.50) through (3.52) are the working equations. They contain N_s unknowns and N_s equations; thus, this system of equations is closed.

Note the working equations contain only N_k nonlinear PDE plus N_e algebra equations and $N_s - N_r$ linear PDE. Compared with the canonical representation approach that yields $N_s - N_e$ nonlinear PDE, this approach yields $N_s - N_e - N_k$ fewer nonlinear PDE. At the extreme case where $N_s = N_e + N_k$, those two approaches yield the same number of nonlinear PDE. Reducing the number of nonlinear PDE can save computing time. The real saving depends on the ratio of N_s and N_r. Observations indicate a speed-up factor of 1.5-3.

Unlike the canonical representation approach, the Q-R decomposition approach does not bear the concepts of primary species and secondary species. Thus, it does not impose the constraint of the canonical form on reactions. Eliminating this constraint frees the user from the trivial, but time-consuming, work of writing every reaction in canonical forms. The user has more time to consider whether or not the chemical model is physically relevant.

3.5.3 Finite Difference Discretization

Equations (3.50) and (3.51) are discretized using the control-volume finite difference method on a rectangular 2-D domain (Strikwerda 1989). For notational convenience in the discretization procedure, the subscript i is no longer used to denote different equations. Rather, as by convention, the subscript is used to denote grid point, and superscript denotes different time slices. Equation (3.50) can be discretized to

$$\frac{\left\{\phi_D \rho_t \left(s_g K_H^{t-1} + s_t\right)\chi\right\}_{i,j}^{t+\delta t} - \left\{\phi_D \rho_t \left(s_g K_H^{t-1} + s_t\right)\chi\right\}_{i,j}^{t}}{\Delta t}$$

$$= \lambda \left[\frac{\left\{\phi_D \rho_t \left(s_g \mathbf{V}_g K_H^{t-1} + s_t \mathbf{V}_t\right)\chi\right\}_{i,j}^{t+\delta t} - \left\{\phi_D \rho_t \left(s_g \mathbf{V}_g K_H^{t-1} + s_t \mathbf{V}_t\right)\chi\right\}_{i-1,j}^{t+\delta t}}{x_{i,j} - x_{i-1,j}} \right]$$

$$+ \lambda \left[\frac{\left\{\phi_D \rho_t \left(s_g \mathbf{V}_g K_H^{t-1} + s_t \mathbf{V}_t\right)\chi\right\}_{i,j}^{t+\delta t} - \left\{\phi_D \rho_t \left(s_g \mathbf{V}_g K_H^{t-1} + s_t \mathbf{V}_t\right)\chi\right\}_{i,j-1}^{t+\delta t}}{y_{i,j} - y_{i,j-1}} \right]$$

$$+ (1-\lambda) \left[\frac{\left\{\phi_D \rho_t \left(s_g \mathbf{V}_g K_H^{t-1} + s_t \mathbf{V}_t\right)\chi\right\}_{i,j}^{t} - \left\{\phi_D \rho_t \left(s_g \mathbf{V}_g K_H^{t-1} + s_t \mathbf{V}_t\right)\chi\right\}_{i-1,j}^{t}}{x_{i,j} - x_{i-1,j}} \right]$$

$$+ (1-\lambda) \left[\frac{\left\{\phi_D \rho_t \left(s_g \mathbf{V}_g K_H^{t-1} + s_t \mathbf{V}_t\right)\chi\right\}_{i,j}^{t} - \left\{\phi_D \rho_t \left(s_g \mathbf{V}_g K_H^{t-1} + s_t \mathbf{V}_t\right)\chi\right\}_{i,j-1}^{t}}{y_{i,j} - y_{i,j-1}} \right]$$

$$+ \lambda \left[\frac{\dfrac{\{\chi\}_{i+1,j}^{t+\delta t} - \{\chi\}_{i,j}^{t+\delta t}}{x_{i+1,j} - x_{i,j}} \left\{\phi_D \rho_t \left(s_g \mathbf{D}_i^g K_H^{t-1} + s_t \mathbf{D}_i^t\right)\right\}_{i+\frac{1}{2},j} - \dfrac{\{\chi\}_{i-1,j}^{t+\delta t} - \{\chi\}_{i,j}^{t+\delta t}}{x_{i-1,j} - x_{i,j}} \left\{\phi_D \rho_t \left(s_g \mathbf{D}_i^g K_H^{t-1} + s_t \mathbf{D}_i^t\right)\right\}_{i-\frac{1}{2},j}}{\left(x_{i+1,j} - x_{i-1,j}\right)/2} \right]$$

$$+ (1-\lambda) \left[\frac{\dfrac{\{\chi\}_{i+1,j}^{t} - \{\chi\}_{i,j}^{t}}{x_{i+1,j} - x_{i,j}} \left\{\phi_D \rho_t \left(s_g \mathbf{D}_i^g K_H^{t-1} + s_t \mathbf{D}_i^t\right)\right\}_{i+\frac{1}{2},j} - \dfrac{\{\chi\}_{i-1,j}^{t} - \{\chi\}_{i,j}^{t}}{x_{i-1,j} - x_{i,j}} \left\{\phi_D \rho_t \left(s_g \mathbf{D}_i^g K_H^{t-1} + s_t \mathbf{D}_i^t\right)\right\}_{i-\frac{1}{2},j}}{\left(x_{i+1,j} - x_{i-1,j}\right)/2} \right]$$

$$+ \lambda \left[\frac{\dfrac{\{\chi\}_{i,j+1}^{t+\delta t} - \{\chi\}_{i,j}^{t+\delta t}}{y_{i,j+1} - y_{i,j}} \left\{\phi_D \rho_t \left(s_g \mathbf{D}_i^g K_H^{t-1} + s_t \mathbf{D}_i^t\right)\right\}_{i,j+\frac{1}{2}} - \dfrac{\{\chi\}_{i,j-1}^{t+\delta t} - \{\chi\}_{i,j}^{t+\delta t}}{y_{i,j-1} - y_{i,j}} \left\{\phi_D \rho_t \left(s_g \mathbf{D}_i^g K_H^{t-1} + s_t \mathbf{D}_i^t\right)\right\}_{i,j-\frac{1}{2}}}{\left(y_{i,j+1} - y_{i,j-1}\right)/2} \right]$$

$$+(1-\lambda)\left[\frac{\frac{\{\chi\}^{t}_{i,j+1}-\{\chi\}^{t}_{i,j}}{y_{i,j+1}-y_{i,j}}\left\{\phi_D\rho_i\left(s_g\mathbf{D}^g_i K^{j-1}_H+s_i\mathbf{D}^i_i\right)\right\}_{i,j+\frac{1}{2}}-\frac{\{\chi\}^{t}_{i,j-1}-\{\chi\}^{t}_{i,j}}{y_{i,j-1}-y_{i,j}}\left\{\phi_D\rho_i\left(s_g\mathbf{D}^g_i K^{j-1}_H+s_i\mathbf{D}^i_i\right)\right\}_{i,j-\frac{1}{2}}}{\left(y_{i,j+1}-y_{i,j-1}\right)/2}\right]$$

$$+\beta_l \qquad (3.53)$$

where λ is a time-weighting parameter: when λ =1, it is a fully implicit scheme, λ = 0.5 is the Crank-Nicolson scheme; λ = 0, is an explicit scheme. An upwinding scheme is used; thus,

$$i' = \begin{cases} i+1, \text{ when } \mathbf{V}_{ix} > 0 \\ i \quad , \text{ when } \mathbf{V}_{ix} < 0 \end{cases}, \text{ and } j' = \begin{cases} j+1, \text{ when } \mathbf{V}_{iy} > 0 \\ j \quad , \text{ when } \mathbf{V}_{iy} < 0 \end{cases}$$

Equation (3.51) can be discretized in the same manner. The only difference is that Equation (3.51) does not contain the β term.

The main argument against upwinding is the associated numerical diffusion that smears reaction fronts. However, upwinding has the advantage of being less prone to numerical oscillation. As noted by (Yeh et al. 1993), "one scheme resolving the problems of numerical oscillation tends to yield excessive numerical spreading, whereas the other scheme resolving the problems of numerical spreading tends to create severe numerical oscillation."

3.5.4 Fully Coupled Algorithm

Equation (3.53) is a nonlinear equation that can be solved by Newton-Raphson iteration that first converts Equation (3.53) to a linear equation (Press et al. 1986)

$$\mathbf{A}\vec{\delta}^{k} = \mathbf{b} \qquad (3.54)$$

where $\mathbf{A}$ is the global Jacobian matrix, $\vec{\delta}^{k}$ is a correction on the previous solution $\vec{\chi}^{k}$, and $\mathbf{b}$ is the constant term. After solving Equation (3.54), corrections are made on $\vec{\chi}^{k}$:

$$\vec{\chi}^{k+1} = \vec{\chi}^{k} - \vec{\delta}^{k} \qquad (3.55)$$

The new solution $\vec{\chi}^{k+1}$ gives new values of $\mathbf{A}$ and $\mathbf{b}$ that in turn yield $\vec{\chi}^{k+2}$... and the iteration is continued until the solution meets convergence criteria.

The preceding algorithm solves the transport and reaction parts in one step. Such an algorithm is referred to as Fully Coupled, although other researchers have given it different names, such as one-step (Mangold and Tsang 1991), DAE (Yeh and Tripathi 1989), and global implicit (Steefel and Lasaga 1994).

As stated by Yeh and Tripathi (1989), the difficulty of implementing a *Fully Coupled* algorithm is in the huge size of the global Jacobian matrix **A**. In their 2-dimensional example with 60 x 50 grids and 30 species, the global Jacobian matrix **A** has 90,000 x 90,000 = 8,100,000,000 entries. Assuming each entry uses 32 bits (double precision), the matrix requires 2025 MB of memory. It is impractical to store such a large matrix in most computers, and even matrix compression techniques cannot help much. However, the difficulty of storing **A** does not necessarily mean it is impractical to solve the equation. Many numerical algorithms used to solve Equation (3.54), for example, iteration schemes (Golub and Van Loan 1983), do not need to generate and store the global Jacobian matrix **A** in one piece.

Generally, in iteration algorithms, **A** is divided into many submatrixes, so that during the iteration procedure, only one of these submatrixes is needed. A natural way is to divide **A** into submatrixes with each submatrix containing the information of one node. The size of the submatrixes is $N_s \times N_s$. During the iteration, it is necessary only to solve a much smaller linear equation:

$$\mathbf{A}_{i,i}\vec{\delta}_i = \mathbf{b}_i - \sum_{i \neq j} \mathbf{A}_{i,j}\vec{\delta}_j \tag{3.56}$$

where $\mathbf{A}_{i,i}$ is the i th submatrix in diagonal, while $\mathbf{A}_{i,j}$ is an off-diagonal submatrix.

This way of dividing **A** allows the solution of the problem on the entire domain, node by node. Two classical ways are known to iterate the node-by-node scheme: one is the Jacobi iteration; the other is the Gauss-Seidel iteration (Press et al. 1986). The difference between the Jacobi and the Gauss-Seidel iterations is the latter utilizes the latest updated results of iteration, but the former does not. That difference gives the Gauss-Seidel iteration a factor of two in speed over the Jacobi iteration (Press et al. 1986). Therefore, Gauss-Seidel iteration is always preferred, and the Jacobi iteration is of little value in practice.

Equation (3.56) involves a fully coupled solute transport and geochemical reactions, solved on a node-by-node basis using Gauss-Seidel iteration. This algorithm is hereafter referred to as the *Fully Coupled* algorithm. The size of the Jacobian matrix involved in the *Fully Coupled* algorithm is only $N_s \times N_s$. Even a system with 100 species can be handled easily by most computers. Moreover, the size of the matrix is independent of the number of nodes and, thus, independent of the dimensions of problems. The algorithm is applicable to 1-, 2-, or 3-dimensional domains. Although the *Fully Coupled* algorithm bears the inherent disadvantage of slow convergence from Gauss-Seidel, it does not require large memory that otherwise prevents the problem from solution. Experience shows that combined with a flexible time-step control scheme, the algorithm can solve various practical problems.

3.5.5 Operator Split Algorithm

As an alternative to the *Fully Coupled* algorithm, an *Operator Split* algorithm to solve the reaction-transport equations is available in STORM. As its name suggests, the *Operator Split* algorithm splits the reaction-transport PDE into two parts. One is the transport part that is a linear PDE; the other is the chemical reaction part that is a nonlinear ordinary differential equation (ODE). The algorithm then solves them separately and sequentially (Mangold and Tsang 1991). It has been proved the *Operator Split* algorithm has an inherent mass conservation error (Valocchi and Malmstead 1992). Although a remediation scheme has been proposed by these authors to address that problem, the scheme works only when the boundary condition is homogenous (Barry et al. 1996). Otherwise, it can introduce an even larger error. Another remedial method is to iterate the two steps until they converge (Yeh and Tripathi 1991). This latter approach is implemented in STORM.

In the *Operator Split* algorithm, by splitting the transport part from the reaction part, the solute transport mass conservation equation is decoupled and, thus, can be solved separately. In STORM, when using the *Operator Split* algorithm, the solute transport mass conservation equation is solved as described in Section 3.4. The advantage is that each discretized PDE is a linear equation where the dimension of the coefficient matrix, $\mathbf{b}$, is equal to the number of nodes squared. Therefore, $\mathbf{b}$ is $(N_z)^2$ times smaller than the global matrix $\mathbf{A}$. For the preceding example, it is 9,000,000. Combined with matrix compression techniques, the matrix can be stored in workstations with moderate memory. Because $\mathbf{b}$ can be generated and stored at once, more sophisticated techniques of solving linear equations (such as conjugate gradient or preconditioning conjugate gradient methods) can be used to accelerate convergence.

The second step of *Operator Split* algorithm is to solve the nonlinear ODE at each node to obtain reaction rates for each species. This step is similar to the *Fully Coupled* algorithm. However, unlike the *Fully Coupled* algorithm where the latest updated results of neighboring nodes are used, the *Operator Split* algorithm cannot use them because the latest updated results of neighboring nodes cannot propagate to the current node until the next iteration between the first step and the second step. The solution of the geochemical reaction rates, while using the *Operator Split* algorithm, then effectively uses Jacobi iteration. Therefore, as described in Section 3.5.4, its convergence speed is only half that of the *Fully Coupled* algorithm.

Although the *Operator Split* algorithm is slower than the *Fully Coupled* algorithm, it is well known that contaminant transport simulators based on single-point upstream-weighting for solution of the conservation equations (Section 3.5.3) suffer from a grid size dependent artificial diffusion that smears otherwise sharp fronts. To enable STORM to better manage advection-dominated problems, such as simulating the Pressurized Unsaturated Flow (PUF) experiments, a Total Variation Diminishing (TVD) transport scheme has been implemented in conjunction with the *Operator Split* algorithm.

A flux-limited third-order scheme is applied to the advective-diffusion equations in STORM, following a method that is shown to exhibit close agreement with analytical solutions (Gupta et al. 1991). The difference scheme for the conservation equation is illustrated for 1-dimensional, strictly advective flow with constant grid size. This arrangement results in a strictly hyperbolic conservation equation

$$\frac{\partial c}{\partial t} + u\frac{\partial c}{\partial x} = 0 \tag{3.57}$$

where c is the concentration of the aqueous species, t is time, x is distance, and u is the velocity (taken to be a positive constant). Integrating over mesh cell i and time step interval $[n,n+1]$ yields

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} = \frac{u\bar{c}_{i+1/2} - u\bar{c}_{i-1/2}}{\Delta x} = 0 \tag{3.58}$$

where $u\bar{c}_{i+1/2}$ represents the time averaged flux through the right edge of the ith mesh cell. The principal problem in the formulation of difference schemes lies in the evaluation of these time-averaged fluxes. The finite-difference approximation may be generalized as

$$\bar{c}_{i+1/2} = c_i^n + \tfrac{1}{2}(1-\lambda)F_i\Delta x \tag{3.59}$$

where λ is the Courant number and F_i is the concentration gradient of the upwind cell. For $F_i = 0$, Equation (3.59) reduces to single-point upstream weighting, the technique used in the *Fully Coupled* algorithm that is only first-order accurate and consequently highly diffusive. A third-order scheme provides higher accuracy (Gupta et al. 1991)

$$F_i = \frac{2-\lambda}{3}\frac{c_{i+1}^n - c_i^n}{\Delta x} + \frac{1+\lambda}{3}\frac{c_i^n - c_{i-1}^n}{\Delta x} \tag{3.60}$$

Although higher-order schemes give better resolution for discontinuities, they exhibit spurious oscillations around these points. The underlying principle of constructing a TVD scheme is to combine lower and higher order fluxes and impose limiting functions on the higher-order flux to prevent formation of local extrema (Harten 1983). The higher order flux is viewed as consisting of the first-order flux, plus a corrective term. Rewrite Equation (3.59) in the following terms

$$\bar{c}_{i+1/2} = c_i^n + \phi(r)\frac{c_{i+1}^n - c_i^n}{2}(1-\lambda) \tag{3.61}$$

where $\phi(r)$ is the flux-limiting function and r is a measure of the smoothness of the data. One possible choice for r is the ratio of consecutive gradients (Sweby 1984). For $u > 0$,

$$r = \frac{c_i^n - c_{i-1}^n}{c_{i+1}^n - c_i^n} \ . \tag{3.62}$$

The third-order scheme can now be obtained by defining $\phi(r)$ appropriately

$$\phi(r) = \frac{2-\lambda}{3} + \frac{1+\lambda}{3} r \tag{3.63}$$

In order to prevent non-physical oscillations, the limiting function $\phi(r)$ must be chosen so that limited anti-diffusive flux is maximized in amplitude subject to the constraint of the resulting scheme being TVD that requires the following equation (Sweby 1984)

$$0 \le \frac{\phi(r)}{r}, \ \phi(r) \le 2 \ . \tag{3.64}$$

Equation (3.64) results in the following TVD limiting function for the third-order scheme

$$\phi(r) = \mathrm{MAX}\left[0, \mathrm{MIN}\left(2, 2r, \phi(r)\right)\right] \tag{3.65}$$

For multidimensional flow problems, the difference scheme given by Equation (3.61) can be applied similarly in the y and z directions.

3.6 Boundary Conditions

The discretization methods described previously for the mass, energy, and solute mass conservation equations strictly applied to interior nodes (that is, nodes surrounded by neighboring nodes). For nodes adjacent to a domain boundary or an inactive node, the discretized forms of the governing equations are modified according to the user specified boundary conditions. Zero flux boundary conditions are applied whenever no boundary condition is specified for a boundary surface. Boundary conditions that can be specified for a boundary surface are varied, depending on the operational mode, and other associated boundary conditions.

A total of eight boundary conditions are appropriate for flow boundaries and are applicable to the conservation equations for water and air: Dirichlet, Neumann, zero flux, initial condition, saturated, unit gradient, hydraulic gradient, and free gradient. The Dirichlet boundary condition specifies the value of intrinsic properties on the boundary surfaces (for example, aqueous pressure and gas pressure). The Neumann boundary condition specifies a surface flux on the boundary surface (for example, aqueous Darcy velocity and gas Darcy velocity). The zero flux boundary condition specifies an impermeable boundary for flow or transport and serves as the default condition for undeclared boundary surfaces (for example, zero fluid flow). The initial condition boundary condition uses the initial conditions in the nodes adjacent to a boundary surface to fix the intrinsic properties on the boundary surface. The saturated boundary condition is appropriate for fluid flow boundaries for 2-phase systems and establishes zero

capillary pressure conditions on the boundary surface. The unit gradient boundary condition is appropriate for fluid flow boundaries and establishes a fluid pressure on the boundary surface equal to the fluid pressure at the adjacent node, modified by the hydraulic gradient for the fluid. The free gradient boundary condition is appropriate for fluid flow boundaries for 2-phase systems and establishes a fluid pressure on the boundary surface by extrapolating the local pressure gradient within the computational domain to the boundary surface. The hydraulic gradient boundary condition is appropriate for fluid flow boundaries and establishes a series of boundary pressures according to the local hydraulic gradient for the fluid.

The five boundary conditions appropriate for transport boundaries and applicable to the conservation equations for energy and solute mass follow: Dirichlet, zero flux, initial condition, outflow, and inflow. The Dirichlet boundary condition specifies the value of intrinsic properties on the boundary surfaces (for example, temperature or solute concentration). The zero flux boundary condition specifies an impermeable boundary for flow or transport and serves as the default condition for undeclared boundary surfaces (e.g., zero heat flux, or zero solute flux). The initial condition boundary condition uses the initial conditions in the nodes adjacent to a boundary surface to fix the intrinsic properties on the boundary surface. The outflow boundary condition considers transport out of the computational domain by advection only, so no diffusive transport occurs. This boundary condition will not transport energy or solute mass into the domain. The inflow boundary condition considers transport into the computational domain only by advection and no diffusive transport occurs. This boundary condition will not transport energy or solute mass out of the domain.

In general, boundary conditions for simulations that involve the solution of multiple governing equations can be combined in a variety of ways, with one major restriction. Specification of a Neumann boundary condition for the energy equation on a boundary surface (other than the zero flux condition) requires that flow equation boundary conditions for that boundary surface be specified as zero flux. Nonzero fluid flow and heat transport can be achieved for boundary nodes through a combination of flow boundary conditions, a zero flux energy boundary, and energy sources for the boundary nodes. Regardless of the boundary condition or combination of boundary conditions a sufficient number of independent intensive variables must be declared to specify the thermodynamic and hydrologic state on the boundary surface. Definitions for geometric parameters for nodes with boundary surfaces on the west side are shown in Figure 3.3 for the X-Z Cartesian coordinate plane and in Figure 3.4 for the X-Y Cartesian coordinate plane.

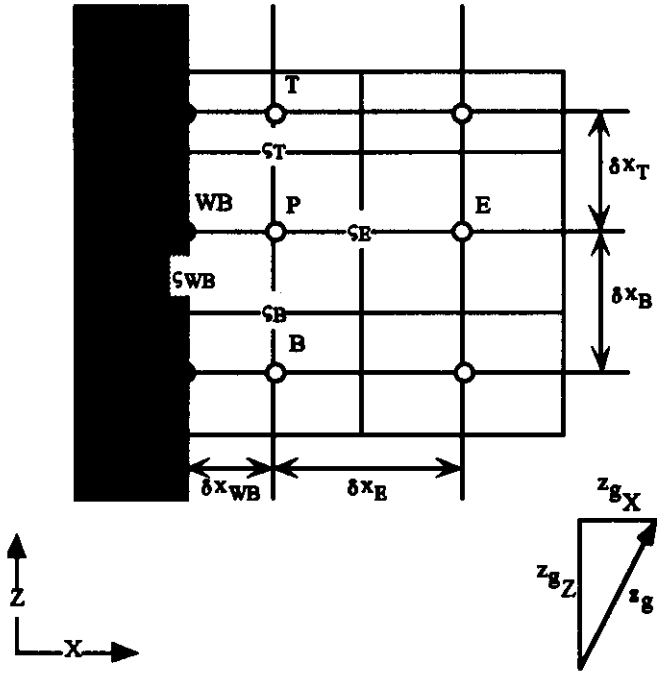

Figure 3.3. X-Z Cartesian Coordinate Plane for West Boundary

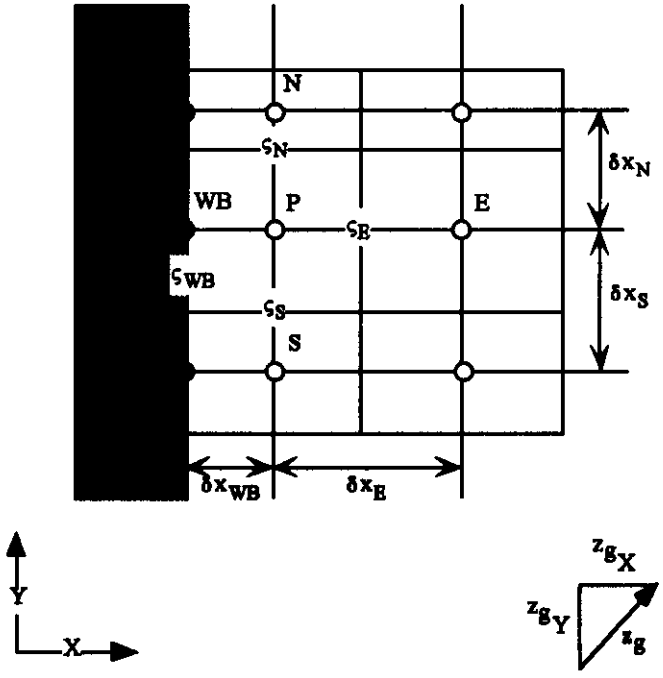

Figure 3.4. X-Y Cartesian Coordinate Plane for West Boundary

3.6.1 Dirichlet Boundary Condition

The Dirichlet boundary condition is equivalent to specifying the value for the primary unknown on the boundary surface. Assigned values of primary variables are used to compute secondary variables for the boundary surface. Average properties for transport between a boundary surface and the adjacent node are computed with user-specified averaging schemes between the values of the properties on the boundary surface and adjacent node. For example, the discretized forms for Darcy mass flux and diffusive mass flux rates of water, Equation (3.6), are modified for a Dirichlet aqueous phase boundary condition on a west boundary surface, according to Equations (3.66) and (3.67), respectively. For the solute mass conservation equation, a Dirichlet boundary condition on the west surface produces a modification to the discretized conservation equation, Equation (3.26), according to Equation (3.68).

$$F_l^{w}{}_{WB} = -\frac{\left\langle \omega_l^{w} \rho_l k_{rl} \right\rangle_{WB}^{uw} \langle \mathbf{k} \rangle_{WB}^{h}}{\langle \mu_l \rangle_{WB}^{h}} \left(\frac{(P_{lP} - P_{lWB})}{\delta x_{WB}} + \langle \rho_l g \rangle_{WB}^{a} z_{gWB} \right) \tag{3.66}$$

$$J_l^{w}{}_{WB} = -\left\langle \tau_l n_D \rho_l s_l \frac{M^{w}}{M_l} \mathbf{D}_l^{w} \right\rangle_{WB}^{h} \frac{\left(\chi_l^{w}{}_{P} - \chi_l^{w}{}_{WB}\right)}{\delta x_{WB}} \tag{3.67}$$

$$a_P C_P - \sum_{\zeta = E,S,N,B,T} a_\zeta C_\zeta = \frac{\partial C}{\partial t}\overline{V} - m^C \overline{V} - R^C C \overline{V} + a_{WB} C_{WB} \tag{3.68}$$

3.6.2 Neumann Boundary Condition

The Neumann boundary condition is equivalent to specifying the flux on a boundary surface. Fluxes that may be specified are aqueous volumetric, gas volumetric, energy, and solute mass. For example, the discretized form for Darcy mass flux of water, Equation (3.6), is modified for a Neumann boundary condition on a west boundary surface, according to Equation (3.69). Sufficient information is needed to fix the thermodynamic and hydrologic state on the boundary surface. Calculation of phase pressures from phase volumetric flow rates requires an iterative solution because averaged values of properties (for example, relative permeability) are nonlinear functions of the phase pressure on the boundary. To avoid an iterative solution of the phase pressure on the boundary phase, pressures are computed assuming a unit relative permeability, according to Equation (3.70) for a west boundary surface.

$$F_l^{w}{}_{WB} = \left\langle \omega_l^{w} \rho_l \right\rangle_{WB}^{uw} V_{lWB} \tag{3.69}$$

$$P_{lWB} = \delta x_{WB} \left(\frac{V_l^w{}_{WB} \langle \mu_l \rangle_{WB}^h}{\langle \mathbf{k} \rangle_{WB}^h} + \langle \rho_l g \rangle_{WB}^a z_{gWB} \right) + P_{lP} \tag{3.70}$$

3.6.3 Zero Flux Boundary Condition

The zero flux boundary condition is the default boundary condition and is equivalent to specifying zero flow or transport across the boundary surface. Complex boundary conditions that involve multiple specifications on a single boundary surface, require that sufficient information be specified to fix the thermodynamic and hydrologic state on the boundary surface. For example, a recognized boundary condition combination for a water-air system (that is, the Two-Phase Volatile operational mode) is a Dirichlet aqueous boundary and zero flux gas boundary. Isothermal water-air systems require two independent intensive variables to fix the thermodynamic and hydrologic state of the system. For this boundary system, the Dirichlet aqueous boundary assigns a value to the aqueous pressure. The gas pressure can be specified by user input or be computed using zero flux boundary conditions and solving Equation (3.6) for the gas pressure, according to Equation (3.71) for a west boundary surface.

$$P_{gWB} = \delta x_{WB} \langle \rho_g g \rangle_{WB}^a z_{gWB} + P_{gP} \tag{3.71}$$

3.6.4 Initial Condition Boundary Condition

The initial condition boundary condition is identical in application to the Dirichlet boundary condition, with the following exception: the primary variable is fixed to the initial value at the adjacent node. No user input is required for this type of boundary condition because boundary values are obtained through the initial condition specifications. Initial boundary pressures are computed once at the start of a simulation.

3.6.5 Saturated Boundary Condition

The saturated boundary condition is recognized for water-air systems and performs as do dynamic Dirichlet boundary conditions, where zero capillary pressure is maintained on the boundary surface. The saturated boundary condition fixes the aqueous pressure equal to the gas pressure on a boundary surface, regardless of the boundary condition for the gas pressure. For a single-phase system, the gas pressure is fixed through the initial conditions and the aqueous pressure is maintained on a saturated boundary equal to this gas pressure. For a 2-phase system, the gas pressure on a boundary surface is user-specified according to the gas-phase boundary conditions. The saturated boundary condition for the aqueous phase fixes the aqueous pressure at the boundary surface equal to the gas pressure. Saturated boundary pressures are computed with each Newton-Raphson iteration.

3.6.6 Unit Gradient Boundary Condition

The unit gradient boundary condition is recognized for aqueous-phase and gas-phase boundary conditions and maintains a unit gradient in the phase hydraulic head. A unit gradient in the phase hydraulic head is equivalent to setting the normalized Darcy velocity equal to minus one, according to Equation (3.72) for a west boundary surface. Phase pressure on the boundary surface is computed by solving Equation (3.72) for the boundary pressure, according to Equation (3.73), for a west boundary surface. Unit gradient boundary pressures are computed with each Newton-Raphson iteration.

$$\frac{V_{\gamma WB}\left\langle \mu_{\gamma}\right\rangle_{WB}^{h}}{\left\langle k_{r\gamma}\right\rangle_{WB}^{uw}\left\langle \mathbf{k}\right\rangle_{WB}^{h}} = -1 = -\left(\frac{\left(P_{\gamma P} - P_{\gamma WB}\right)}{\delta x_{WB}} + \left\langle \rho_{\gamma} g\right\rangle_{WB}^{a} z_{gWB} \right) \text{ for } \gamma = l, g \tag{3.72}$$

$$P_{\gamma WB} = P_{\gamma P} + \delta x_{WB}\left(\left\langle \rho_{\gamma} g\right\rangle_{WB}^{a} z_{gWB} \right) \text{ for } \gamma = l, g \tag{3.73}$$

3.6.7 Free Gradient Boundary Condition

The free gradient boundary condition is recognized for aqueous-phase and gas-phase boundary conditions. This boundary condition is essentially a dynamic Dirichlet-type boundary, where the pressure on the boundary surface is set to maintain the pressure gradient in the interior nodes adjacent to the boundary surface. This boundary type requires, as a minimum, two active nodes adjacent to the boundary surface. The gradient in phase pressure is linearly extrapolated from the interior nodes to the boundary surface to determine the boundary pressure. Free gradient boundary pressures are computed with each Newton-Raphson iteration.

3.6.8 Outflow Boundary Condition

The outflow boundary condition is recognized for transport boundaries (for example, energy transport, solute transport). This boundary condition allows transported quantities to be moved across a boundary surface by advection only. Inward transport by diffusion or transport across the boundary surface is prohibited. Energy flux across an outflow boundary surface on a west boundary is computed according to Equation (3.74). Solute flux across an outflow boundary surface on a west boundary is computed according to Equation (3.75).

$$Q_{\gamma WB} = -\left(\rho_{\gamma} h_{\gamma}\right)_{P} \max\left[-V_{\gamma WB}, 0\right] \text{ for } \gamma = l, g \tag{3.74}$$

$$G^{C}_{\gamma\, WB} = -C_{\gamma P} \max\left[-V_{\gamma WB}, 0\right] \text{ for } \gamma = l, g \tag{3.75}$$

3.6.9 Inflow Boundary Condition

The inflow boundary condition is recognized for transport boundaries (for example, energy transport and solute transport). This boundary condition allows transported quantities to be inwardly transported across a boundary surface by advection only. Transport by diffusion or transport outward across the boundary surface is prohibited. Energy flux across an inflow boundary surface on a west boundary is computed according to Equation (3.76). Solute flux across an inflow boundary surface on a west boundary is computed according to Equation (3.77).

$$Q_{\gamma WB} = \left(\rho_\gamma h_\gamma\right)_p \max\left[V_{\gamma WB}, 0\right] \text{ for } \gamma = l, g \tag{3.76}$$

$$G^C_{\gamma\ WB} = C_{\gamma P} \max\left[V_{\gamma WB}, 0\right] \text{ for } \gamma = l, g \tag{3.77}$$

4.0 Input File

4.1 Introduction

The STORM simulator is controlled through a text file that must be named *input* for proper execution. This input file has a structured format composed of cards that contain associated groups of input data. Depending on the operational mode, input cards might be required, either optional or unused. Required cards must be present in an input file. Optional cards are not strictly required to execute the simulator, but may be required to execute a particular simulation. Unused cards are treated as additional text that is not recognized by the simulator, but does not hinder a proper execution. Cards may appear in any order within the input file. However, the data structure within a card is critical and must follow the formatting directives shown in Appendix A. Data structures within cards vary with the operational mode, which requires the user to follow a series of logic type statements to construct a readable input file. The STORM simulator contains logic to capture and report input errors. These capabilities are primarily limited to indicating syntax or formatting type errors and generally do not reveal such errors as those associated with ill-posed problems, atypical parameters, or inappropriate grid structures, for example. Because of its text format, STORM input files are generated with text editors, word processors, spread sheet programs, or graphical interfaces and are portable between computing environments. The input is case insensitive and allows considerable flexibility in specifying the simulation directives; however, close attention to the formatting instructions in this section will be necessary to prepare an executable input file.

4.2 Input File Structure

A STORM input file is composed of cards, some of which are required and others that are optional or unused. The number of required cards depends on the operational mode. If an attempt is made to execute the STORM simulator on an input file with an incomplete set of required cards, an error message will be generated and the code execution will stop. Optional cards are used to specify the STORM capabilities that may be required to execute a particular problem or generate desired output data. These cards are considered optional, because the capabilities accessed through these cards are not necessarily required to execute the code. Execution of the STORM simulator on input files with an incomplete set of optional cards yields messages that note the missing optional cards and allow the execution to continue. A summary of the required and optional cards that compose a STORM input file for each operational mode is shown in Table 4.1.

Each card is delimited on the first line with a card header that must contain a tilde symbol (for example, ~ Simulation Title Card) as the character in the first column of the line. Cards may be arranged in any order within an input file; however, the input format within a card is generally structured. If a card type is repeated within an input file, the STORM simulator reads only the first card. Blank lines or additional comment lines can be included in the input file outside of the card structures.

Table 4.1. Required and Optional Input Cards

Operational Mode	Card Name	Card Status
All	Initial Conditions	Optional
	Boundary Conditions	Optional
	Source	Optional
	Output Control	Optional
	Surface Flux	Optional
Water	Simulation Title	Required
	Solution Control	Required
	Grid	Required
	Rock/Soil Zonation	Required

	Rock/Soil Zonation	Required
	Mechanical Properties	Required
	Hydraulic Properties	Required
	Thermal Properties	Required
	Saturation Function	Required
	Aqueous Relative Permeability Function	Required

4.3 Formatting and Notation

Each input card has formatting specifications that must be followed to create an input file readable by the STORM simulator. The format structure of certain cards varies with the operational mode or other input options, and the user must strictly follow the formatting instructions for the particular operational mode of interest. As expected, the complexity of the input increases with the operational mode. Guides

for formatting input cards and card lines are presented in Appendix A. The formatting guides shown in this appendix were written in a compact format using special notations. Definitions of the formatting notations used in Appendix A are given in Table 4.2.

Input files are organized into three hierarchical structures, cards, lines, and data. Cards are delimited by a tilde (~) in the first column of the card title. Lines are delimited by hard returns and commas delimit data. The STORM simulator recognizes three different types of data, integers, real data, and character strings. Integers are used primarily to indicate indexes or integral numbers. Integer data must be entered without decimal points or exponential notation. Real data are used to indicate dimensional parameters and can contain decimal points or exponential notation. Character string data are primarily used to indicate names, options, and units, and are limited to 64 characters, unless otherwise noted. Card lines comprise a series of input data items delimited by commas. A comma at the end of the card line is required to close the last data item. The format structure for each line in a card is shown in Appendix A using a format guide (for example, **Format:** *Integer*^{a}, *Real*^{b}, *Char*^{c},). Data types in the format statements are indicated as *Integer*, *Real* and *Char* (that is, integer, real, and character string) with lowercase letter superscripts. The lettered superscripts are used to correlate the data item with its position in the input line. The total length of a single input line cannot exceed 132 characters. Additional text may appear after the closing comma of an input line. Many input variables contain default values (indicated with underlining in Appendix A). Using a *null* entry accesses a default value. The *null* entry requires the closing comma for the input data item to immediately follow the previous closing comma or that only blank spaces fill the space between the closing commas. To start a line with a *null* entry, the closing comma can occur in column 1 or after a number of blank spaces. Example input cards are shown in Appendix A after the formatting instructions for each card. A considerable portion of the input file formatting and creation work is eliminated by developing input files from previously generated files or through an input generator.

4.4 Units

The STORM simulator offers considerable flexibility in specifying units. The user can declare units for both input or output data. Unspecified units are assumed to be in standard Systeme Internationale (SI) units for the data item. The STORM simulator operates internally almost exclusively in SI units, with pressures expressed in gauge, relative to 1 atmosphere. Unless specifically stated, all input and output pressures are expressed in absolute values. Unit variables are read by the STORM simulator as character strings, translated into primary unit form, and compared against the standard unit form for each data item. During the translation to primary unit form, a conversion factor to SI units is generated. A unit character string comprises a combination of the recognized units delimited by spaces or a single divisor symbol (that is, /). Only one divisor may appear in a unit character string. Spaces should not be used to separate the units immediately prior to or following the divisor symbol. The unit strings prior to the divisor symbol are considered part of the numerator and, conversely, the unit strings following the divisor symbol are considered part of the denominator. Units recognized by the STORM simulator are listed in Table 4.3.

Table 4.2. Input Format Notation Guide

Notation	Description
{ Option }	Enclosing braces indicate character string options. Options are chosen by entering word(s) within the braces, exactly as shown. Only one option should be chosen for each data entry.
[Optional]	Enclosing brackets indicate optional characters or words. These characters can be entered to include the input file to improve its readability.
{{ Fractured }}	Indicates the word fractured is within the rock/soil type name, thus indicating a dual porosity model.
< Data Types >	Indicates repeated formatting.
Char[a]	Character string data type, referenced by superscript a
Integer[a]	Integer data type (no character data or decimal points) reference by superscript a.
Real[a]	Real data type (decimal points and exponential notation are acceptable), reference by superscript a.
#	A pound symbol in the first column indicates a comment line that is ignored during execution. Comment lines may be placed inside or outside card structures. All lines outside of the card structures are ignored during execution.
~ Card Name	A tilde symbol in the first column indicates the start of a new card.
,	Data entries are comma delimited. Commas shown in the line format structures must be entered as shown, including a closing comma at the end of each line. Characters following the last comma of a data line are ignored during execution.
Units[a] (m)	Indicates the SI unit for the input data item referenced by superscript a.
Format:	Indicates line formatting instructions and the beginning of a new input line. Each format statement requires a new input line.
Endcard:	Indicates end of a card.
For: Integer Instructions **Endfor**: Integer	Indicates instruction looping.
If: Name: Card = { Opt_1 } Instructions1 **Elseif**: Name: Card = { Opt_2 } Instructions2 **Elseif**: Instructions3 **Endif**:	Indicates decision logic.

Table 4.2. Input Format Notation Guide (contd)

Notation	Description
IfDef: Opt_1 Instructions1 **ElseifDef**: Opt_2 Instructions2 **ElseDef**: Instructions3 **EndifDef**:	Indicates C preprocessor options and logic.
Note:	Indicates formatting information.

The units listed under the subtitle *Miscellaneous Units* are primarily descriptive units that may be included in a unit character string to increase its readability. The *hc* unit, however, is uniquely reserved for specifying rock/soil hydraulic conductivity that is normally expressed in velocity units. Without the *hc* unit, the input for rock/soil permeability is interpreted as an intrinsic permeability value. The STORM simulator does not apply hydraulic conductivity values directly, but instead first converts hydraulic conductivity values into intrinsic permeability values using the density and viscosity of water at 20°C. Therefore, when rock/soil permeability values are read as hydraulic conductivity, the associated unit character string should include the *hc* unit (for example, hc cm/hr).

As an example, the standard units for thermal conductivity are W/K m; however, a user may prefer to specify thermal conductivity in the standard English units of Btu in/hr ft^2 F. In this case, the user enters the character string Btu in/hr ft^2 F for the unit data item. Note the carat (^) symbol is used to indicate an exponential. During simulator execution, the string of English units for thermal conductivity is translated into the primary unit form, m/s^3 kg K, and compared against the standard unit form. If the primary unit form does not agree with the standard unit form, an error message is generated by the STORM simulator and the program execution stops. Otherwise, if the comparison is successful, the input data for thermal conductivity, that precedes its unit string, is converted to SI units.

4.5 Card Descriptions

Formatting instructions for the input cards are provided in Appendix A. This section provides a brief synopsis of each input card with emphasis on its purpose and application. Italicized words refer to specific files, cards, options, and data entries shown in the card formats in Appendix A.

4.5.1 Simulation Title Card

This card primarily provides a means to document a simulation. Information recorded in this card is rewritten on the *output* file that then serves as a permanent record of the simulation. The user is encouraged to use descriptive titles and to briefly record the specifics and purpose of the simulation in the *Simulation Notes* section of the card. This record becomes especially valuable, when the user is making repeated simulations with small modifications to the input parameters. The changes required in either the *Simulation Title* or *Simulation Notes* will be invaluable when reviewing archived output files.

4.5.2 Solution Control Card

This card controls many general operational aspects of a simulation. Simulations are executed in one of three *Execution Modes*: *Normal*, *Restart*, or *Initial Conditions*. In the *Normal* mode, the simulation executes from initial conditions specified with the *Initial Conditions* Card, and no *restart* file is required. The *Restart* mode requires a *restart* file generated from a previous execution. Unless specified with an *Overwrite* indicator, initial conditions specified on the *Initial Conditions* Card are ignored. Restart files are generated during each plot file write sequence, and have name extensions that correspond to the generating time step (for example, the file *restart*.28 is generated after time step 28). Restart files contain principal field variables and time information. The *Initial Conditions* mode only executes through the initial checks on the input; no time steps are executed. The *No Flow* option (*Water/Transport* mode only) is used for transporting solutes through a steady-state flow field. For these simulations, the flow field is computed once during the initial time step and then remains unaltered. The *Dynamic Domain* option (*Water* mode only) conserves computations by temporarily removing nodes from the computational domain where changes in the flow field are insignificant. The active computational domain is updated every time step.

The *Operation Mode* option determines the governing equations that are solved by the simulator. Because execution performance is indirectly proportional to the number of solved governing equations, the user selects an *Operation Mode* most appropriate for the problem of interest. For example, if the physical system to be modeled does not contain thermal or gas pressure gradients, the most appropriate operational mode is the Water operational mode, where only the water mass conservation equation is solved. Executing the described physical system under the *Water-Air* operational mode yields nearly identical results; however, the execution time is significantly increased. Considerable attention is given to the selection of an appropriate operational mode for the physical system of interest. In terms of efficient and representative simulations, it is equally important not to eliminate critical physical phenomena through an erroneous assumption, as it is not to solve superfluous governing equations. Each operational mode allows the solution of solute transport equations, indicated by including the keyword Transport in the operational mode (for example, *Water-Air* and *Solute Transport*). Solute transport is solved using the Patankar method, unless the keyword TVD appears, indicating the TVD method.

Execution periods refer to a period of simulation time. The STORM simulator allows the user to specify single or multiple execution periods. For each execution period, the user can control the initial time step, maximum time step, time step acceleration factor, maximum number of Newton-Raphson iterations and convergence criterion. Recommended value for the *Time Step Acceleration Factor* is 1.25, the *Maximum Number of Newton-Raphson Iterations* is 8, and the *Convergence Criterion* is 1.e-06. Simulations involving complex phase transitions often require more Newton-Raphson iterations to reach convergence because of the design of the phase transition algorithms. For these types of simulations a value of 16 is recommended for the *Maximum Number of Newton-Raphson Iterations*. Except under special circumstances, it is not advisable to change the value for the *Convergence Criterion* from its recommended value. This value has proven through numerous applications to achieve a preferred balance between accuracy and execution speed.

Field variables, including physical, thermodynamic, and hydrologic properties, are defined in the finite-difference formulation at the node centers. Conversely, flux variables are defined at node

interfaces. Computation of flux variables requires knowledge of field variables at node interfaces. Such values are evaluated by averaging the field values for the two nodes adjoining an interfacial surface. Interfacial averaging schemes may be declared individually for each field variable through the *Interfacial Averaging Variables* input. The default interfacial averaging schemes for the STORM simulator are shown in Table 4.4.

Table 4.4. Default Interfacial Averaging Options

Field Variable	Interfacial Averaging
Aqueous density	Upwind
Aqueous relative permeability	Upwind
Aqueous viscosity	Harmonic
Dissolved air diffusion	Harmonic
Gas density	Upwind
Gas relative permeability	Upwind
Gas viscosity	Harmonic
Hydraulic dispersion	Harmonic
Intrinsic permeability	Harmonic
Solute diffusion	Harmonic
Thermal conductivity	Harmonic
Water vapor diffusion	Harmonic

For simulations of physical systems involving heat transfer, note that convergence problems may arise if the density properties are not averaged with upwind weighting. Likewise, infiltration problems typically demonstrate strong dependencies on the relative permeability of the infiltrating fluid.

4.5.3 Grid Card

The finite-difference formulation of the STORM simulator is based on orthogonal grid systems. Currently, two orthogonal grid systems are recognized, the Cartesian and cylindrical coordinate systems. The Cartesian coordinate system is a "right-handed" system with the longitudinal axis (z–direction) aligned with the negative gravitational vector. Cartesian coordinate systems can be defined that are tilted with respect to the gravitational vector. The cylindrical coordinate system has the longitudinal axis (z-direction) aligned with the negative gravitational vector and the radial (r–direction), and azimuthal (Q-direction) axes constrained to a horizontal plane. For the Cartesian coordinate system, the terms West, South, and Bottom refer to the negative x-, y-, and z-directions, respectively, and the terms East, North, and Top refer to the positive x-, y-, and z-directions, respectively. For the cylindrical coordinate system, the terms West, South, and Bottom refer to the negative r-, Q-, and z-directions, respectively, and the terms East, North, and Top refer to the positive r-, Q-, and z-directions, respectively. Negative dimensional values are not recognized and axes are defined as positive toward increasing node numbers. The grid dimensions that are specified on the Grid Card refer to node surfaces; therefore, for grids with non-uniform spacing, one plus the number of nodes entries are required for each grid direction. Node volumes are defined by their bounding surfaces. Cylindrical coordinates systems are restricted to

azimuthal axes that are less than 360 degrees. Refer to the STOMP Theory Manual (White and Oostrom 1996) for graphical descriptions of the Cartesian and cylindrical coordinate systems.

4.5.4 Rock/Soil Zonation Card

This card allows the user to partition the computational domain into rock/soil types. All active nodes within the computational domain must have an associated rock/soil type. Rock/soil types are defined with a unique name that must contain no more than 64 characters. Because most physical systems of interest contain formations or zones of rocks or soils, the computational domain also contains zones of nodes with similar hydrogeologic properties. With this card, the user defines the distribution of rock/soil zones. In subsequent input cards, hydrogeologic properties are defined with respect to the defined rock/soil types. This approach avoids having to specify hydrogeologic properties uniquely for every node. Generally, this approach is preferred. For simulations using statistically generated rock or soil formations, which require unique hydrogeologic properties for each node, no advantage is gained with this approach. The rock/soil types are extended to the boundary surfaces for nodes adjacent to boundary surfaces. Therefore, field variables for boundary surfaces are computed using the rock/soil type property descriptions from the node adjacent. Hydrogeologic properties for rock/soil types are specified through the *Mechanical Properties* Card, *Hydraulic Properties* Card, *Thermal Properties* Card, *Saturation Function* Card, *Aqueous Relative Permeability Function* Card, *Gas Relative Permeability Function* Card, and *Solute/Porous Media Interaction* Card. A rock/soil type may be repeatedly applied to a node with the last definition being applied. For example, to simplify the zonation of a problem with a dominant rock/soil type and isolated pockets or bands of another rock/soil type, the user initially declares the dominant rock/soil type as covering the entire problem domain. With subsequent lines, the user can overwrite the original rock/soil type for selected nodes with another rock/soil type. This layering approach is recommended and often avoids undeclared rock/soil types.

4.5.5 Mechanical Properties Card

This card allows the user to assign values to the particle density, porosity, specific storativity, compressibility, and tortuosity function for each defined rock/soil type. Every rock/soil type defined on the *Rock/Soil Zonation* Card must be referenced. *Particle Density* represents the rock grain density. This value can be defaulted to 2650 kg/m^3 by using a *null* entry for both the particle density and its associated unit. *Total Porosity* refers to total connected and unconnected pore volumes. *Diffusive Porosity* refers only to the connected pore volume. As with Particle Density, the Specific Storativity can be defaulted by using a *null* entry for both the *Specific Storativity* and its associated *Units*. Default specific storativity is computed from the *Diffusive Porosity* and with a default value of $1.x10^{-7}$1/Pa for the compressibility. Tortuosity functions are required for simulations that involve solute transport or diffusion of components through phases (for example, water vapor diffusing through the gas phase). Tortuosities can be computed as either constants that require input values, or as functions of the phase saturation and diffusive porosity through the Millington and Quirk function. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a description of the Millington and Quirk tortuosity function.

4.5.6 Hydraulic Properties Card

This card allows the user to assign values to the intrinsic permeability for each defined rock/soil type. Every rock/soil type defined on the *Rock/Soil Zonation* Card must be referenced. *Intrinsic Permeability* can be declared directly or through entering the *Hydraulic Conductivity* at reference conditions, where reference conditions refer to atmospheric pressure and 20°C. By default, the STORM simulator reads the permeability values on this card as intrinsic permeabilities, unless the character string *hc* is included in the associated units. Default units of *m^2* are applied to *null* entries for the units associated with permeability values. With the STORM simulator, a primary assumption is that principal components of the intrinsic permeability tensor are aligned with the principal coordinate directions. For cylindrical coordinate systems the radial, azimuthal, and vertical permeabilities correspond with the x-, y-, and z-direction values, respectively. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a description of the conversion of hydraulic conductivity to intrinsic permeability at reference conditions.

4.5.7 Thermal Properties Card

This card allows the user to assign values to the thermal conductivity and specific heat for each defined rock/soil type. Every rock/soil type defined on the *Rock/Soil Zonation* Card must be referenced. This card is required only for simulations involving the solution of the energy conservation equation. Declaration of the thermal conductivity, depends on the operational mode and function option. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a description of thermal conductivity functions. The *Constant* option fixes the thermal conductivity to a constant value, independent of temperature or saturation. The *Parallel* option requires the thermal conductivity of the soil grains and models thermal conductivity with an equivalent parallel path model dependent on porosity, phase saturations, and temperature. The *Linear and Somerton* options scale the thermal conductivity between the unsaturated and saturated values depending on phase saturation. A primary assumption with the STORM simulator is that principal components of the thermal conductivity tensor are aligned with the principal coordinate directions. For cylindrical coordinate systems, the radial, azimuthal, and vertical permeabilities correspond with the x-, y-, and z-direction values, respectively.

4.5.8 Saturation Function Card

This card allows the user to declare and define a saturation-capillary pressure function for each defined rock/soil type. Every rock/soil type defined on the *Rock/Soil Zonation* Card must be referenced. Saturation function types and the required input items are primarily dependent on the operational mode. Although functional forms for the saturation-capillary pressure functions are preferred, tabular input is acceptable. By default, tabular data is interpolated using linear interpolation. Values beyond the table limits will be assigned either the table minimum or maximum values, as appropriate. For the van Genuchten function, the *m Parameter* can be defaulted (with a *null* entry) or assigned a value. Default values will depend on which porosity distribution model (Mualem or Burdine) is chosen from the relative permeability function cards for the liquid phases. Hysteretic functions are those for which the drainage and imbibition scanning paths differ and that include capabilities for entrapment of fluids of lower wettabilities. Non-hysteretic functions require fewer input items than their hysteretic counterparts and use a single scanning path for drainage and imbibition events. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a complete description of saturation-capillary pressure functions.

4.5.9 Aqueous Relative Permeability Function Card

This card allows the user to declare and define a relative permeability-saturation function for the aqueous phase for each defined rock/soil type. Every rock/soil type defined on the *Rock/Soil Zonation* Card must be referenced. Aqueous relative permeability function types and the required input items are dependent on the operational mode. The Mualem and Burdine relative permeability functions are also dependent on the saturation function type and are strictly applicable to the van Genuchten and Brooks and Corey functions. For these functions, either the van Genuchten *m Parameter* or the Brooks and Corey λ *Parameter* can be defaulted to the values entered or defaulted with the saturation function. Although functional forms for the relative permeability-saturation functions are preferred, tabular input is acceptable. By default, tabular data is interpolated using linear interpolation. Values beyond the table limits are assigned appropriately either the table minimum or maximum values. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a complete description of aqueous relative permeability-saturation functions.

4.5.10 Gas Relative Permeability Function Card

This card is used to declare and define a relative permeability-saturation function for the gas phase for each defined rock/soil type. Every rock/soil type defined on the *Rock/Soil Zonation* Card must be referenced. This card is required only for simulations involving flow or transport through the gas phase. Gas relative permeability function types and the required input items are dependent on the operational mode. The Mualem and Burdine relative permeability functions are also dependent on the saturation function type and are strictly applicable to the van Genuchten and Brooks and Corey functions. For these functions, either the van Genuchten *m Parameter* or the Brooks and Corey λ *Parameter* can be defaulted to the values entered or defaulted with the saturation function. Functional forms for the relative permeability-saturation functions are preferred; however, tabular input is acceptable. By default, tabular data are interpolated using linear interpolation; cubic spline interpolation is optional. Values beyond the table limits are assigned either the table minimum or maximum values, as appropriate. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a complete description of gas relative permeability-saturation functions.

4.5.11 Solute/Fluid Interaction Card

This card allows the user to define solutes, solute-fluid interactions, and solute radioactive decay paths. It is required only for simulations involving solute transport. The STORM simulator is capable of simulating any number of solutes with the assumption that solute concentrations remain dilute. (Solute concentrations do not vary the physical properties of the transporting fluid phases.) Solutes can decay radioactively to produce other solutes. For the loose coupling between parent solutes and progeny solutes to function properly, parent solutes must be defined on this card prior the definition of their progeny. The STORM simulator actually solves the transport equation for each solute sequentially and in reverse order from the definition list on this card. Solutes are defined by a unique solute name that must contain no more than 64 characters. *Chain Decay Fraction* relates a parent decay member with a progeny and refers to the fraction of the decaying parent that produces a particular progeny. *Chain Decay Fraction* inputs are fractional values from 0.0 through 1.0, inclusively. Solute-fluid interaction parameters, such as

molecular diffusion coefficients and interphase partition coefficients, depend on the operational mode. Molecular diffusion coefficients refer to the diffusion of the solute through the transporting fluid phase outside of the porous media. Corrections for transport through porous media are handled within the STORM simulator. The interphase partition coefficients define the equilibrium distribution of solute between the active liquid phases. Partition coefficients that define the equilibrium adsorption of solute onto the solid phase are determined on the *Solute/Porous Media Interaction* Card. It is important for the user to carefully note the definitions and requested units for each interphase partition coefficient. The *Aqueous-Gas Partition Coefficient* is the ratio of the solute mass in the aqueous phase per unit mass of aqueous phase to the solute mass in the gas phase per unit volume of gas phase. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a more detailed description of the interphase partition coefficients, solute diffusion coefficients, radioactive decay rate equations, and radioactive chain decay fractions.

4.5.12 Solute/Porous Media Interaction Card

This card allows the user to define solid-aqueous phase partition coefficients and porous media dependent hydraulic dispersivities. It is required only for simulations involving transport of solutes. This card differs from the *Solute/Fluid Interaction* Card because the input parameters declared are dependent on the solute and rock/soil type. For every solute defined on the *Solute/Fluid Interaction* Card, every rock/soil type defined on the *Rock/Soil Zonation* Card must be referenced. The *Solid-Aqueous Partition Coefficient* defines the interphase equilibrium of a solute adsorbed on the solid and dissolved in the aqueous phase. This definition refers to the concentration of solute adsorbed on the solid phase per unit mass of solid phase with the concentration of solute dissolved in the aqueous phase per unit mass aqueous phase. The longitudinal and transverse hydraulic dispersivities are properties only of the rock/soil type. *Longitudinal Dispersivity* is defined with respect to dispersion along the flow path and is assumed independent of the flow direction with respect to the porous media structure. Likewise, *Transverse Dispersivity* is defined with respect to dispersion transverse to the flow path, independent of the flow direction. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a more complete description of the solid-aqueous interphase partitioning and hydraulic dispersion of transported solutes.

4.5.13 Initial Conditions Card

This card allows the user to assign starting values to primary and secondary field variables by initializing primary variables. However, the current version of the STORM simulator does not allow the user to initialize flux or surface variables. Such initializations are useful for solving transport problems with steady flow fields. Transport problem simulations with the STORM simulator require the solution of the flow fields. The variables that may be initialized are dependent on the operational mode. For all operational modes, default values for the initial conditions are specified within STORM as shown in Table 4.5.

For the *Water*, *Water-Air*, and *Water-Air-Energy* operational modes, STORM allows the user to specify the initial aqueous saturation by assigning initial conditions for any two of the following three variables: gas pressure, aqueous pressure, and aqueous saturation. The unassigned variable is computed from the other two through the declared saturation-capillary pressure functions. Initial conditions are

Table 4.5. Initial Condition Default Values

Initial Field Variable	Symbol	Default Value
Temperature (C)	T	20.
Pressure of phase j (Pa)	P_j	101325.
Saturation of phase j	s_j	0.
Mole fraction of component i in phase j	χ_j	0.
Solute concentration in phase j	Sj	0.

declared repeatedly for a node with the application of last definition. Initial conditions for solutes are expressed in terms of solute per unit volume where the volume can refer to the total node volume (*Volumetric*), the aqueous-phase volume (*Aqueous Volumetric*), or the gas-phase volume (*Gas Volumetric*). Solute units are undefined and expressed as the user chooses (for example, Ci, pCi, gm, kg, mol, or kgmol). Although units for expressing solute quantity vary among solutes, units must be consistent for a single solute among all input data entries.

The gradient utilities of the initial condition card are invaluable and are used to advantage whenever possible. Gradients to the initial conditions allow the user to specify that initial value of a field variable varies along one or more directions in the physical domain. The initial condition variable assigned to an initial condition domain applies to the node with the lowest x-, y-, and z-direction indexes. If nonzero gradient values are specified, the initial condition values vary according to the gradients specified for each physical direction. Default values for the initial condition gradients are zero, indicating no variation. Gradient values are applicable only over the initial condition domain of the state. An exemplary application of the initial condition gradient utility occurs for problems that start with hydrostatic conditions. For these problems, the pressure at the lowest z-direction node positions is entered with a *Z-Dir. Gradient* that equaled minus the fluid density times the acceleration of gravity. For water at 20°C, a z–direction gradient of -9793.5192 1/m yields constant head conditions, that is the equivalent to hydrostatic conditions. This approach is used to locate the position of a water table under no-recharge equilibrium conditions, given the rock/soil saturation function properties and a single pressure using an *Initial Condition* execution mode simulation.

4.5.14 Boundary Conditions Card

This optional card allows the user to control the simulation by defining time varying boundary conditions. Boundary conditions may be applied to any boundary surface or surface dividing active and inactive nodes. By default, all undeclared boundary surfaces have zero flux boundary conditions for flow and transport. Boundary conditions can be applied only to surfaces of active nodes. To apply a boundary condition to a boundary surface, the surface is referenced by the adjacent active node location and a direction with respect that node. To apply a boundary condition to a surface dividing an active and inactive node, the surface is referenced by the active node and the direction to the inactive node with respect to the active node. Boundary conditions vary within periods. The user is not allowed to assign multiple boundary conditions to a boundary surface during the same time period, but multiple boundary conditions do so over different time periods. The STORM simulator controls time steps to agree with time transitions in boundary conditions.

Application of boundary conditions requires an appropriate conceptualization of the physical problem and translation of that conceptualization into boundary condition form. The variety of boundary condition types available in the STORM simulator allow the user the flexibility to solve most subsurface flow and transport problems. In addition, the boundary condition card reader within the STORM simulator performs limited error checking on the boundary condition inputs. However, an error-free boundary condition card does not guarantee the user has not created either an ill-posed problem or an execution that successfully converges. For example, a mistake frequently made by STORM users is to specify infiltration rates at the top of a column with positive fluxes. Although this input is perfectly acceptable to the STORM boundary condition input reader, the specified condition actually withdraws flux from the top of the column because the z-axis and z-direction flux are positive in the upward direction.

The *Boundary Surface Direction* is specified with respect to the active node adjacent to a boundary surface. For the Cartesian coordinate system, the terms West, South, and Bottom refer to the negative x-, y-, and z-directions, respectively, and the terms East, North, and Top refer to the positive x-, y-, and z-directions, respectively. For the cylindrical coordinate system the terms West, South, and Bottom refer to the negative r-, Q-, and z-directions, respectively, and the terms East, North, and Top refer to the positive r-, Q-, and z-directions, respectively.

Boundary condition inputs depend on the operational mode, with the required inputs becoming more complex with increasing number of solved equations. Generally, the number of boundary types that must be declared for each boundary equals the number of solved governing flow and transport equations. The *Dirichlet* boundary type is used to specify a field value (for example, pressure, temperature, or solute concentration) at the boundary surface. The *Neumann* boundary type allows the user to specify a flux (for example, liquid phase flux, heat flux, or solute flux) at the boundary surface. The *Zero Flux* boundary type is used to impose no flow or transport conditions across the boundary. The *Saturated* boundary type is available only for 2-phase conditions and imposes total-liquid saturation conditions (for example, water table) at the boundary surface. The *Unit Gradient* boundary type imposes hydrostatic conditions across the boundary surface for the specified phase. The *Free Gradient* boundary type is available only for the *Water* operational mode and models a free drainage surface with respect to the aqueous phase. The *Hydraulic Gradient* boundary type is applied only to a column or plane of vertical surfaces. With this boundary type, the user specifies a fluid phase pressure at the lowest surfaces of a column or row. The simulator then computes fluid phase pressure for the remaining boundary surfaces assuming hydrostatic conditions for the fluid phase. The *Initial Conditions* boundary type fixes the boundary field variables (for example, pressure, temperature, or solute concentration) to the initial values of the field variables at the node adjacent to the boundary surface. This boundary type is invariant with time. *Outflow* boundary types are applicable only to solute and energy boundary conditions. This boundary type considers only advectively transported solute or energy to exit the computational domain. Diffusion transport across the boundary surface is neglected. The solute concentration boundary types (for example, *Volumetric Concentration*, *Aqueous Conc.*, or *Gas Conc.*) are equivalent to *Dirichlet* boundary types for solute transport. These boundary types differ by their definitions of solute concentration.

Time variations of the boundary conditions are controlled through declaring multiple boundary times. All *Boundary Time* inputs are referenced against the *Initial Time* specified on the *Solution Control* card or obtained from a restart file. A boundary condition declared with a single *Boundary Time* implies the

boundary condition is time invariant; the specified *Boundary Time* represents the start time for the boundary condition. Prior to the start time, the boundary surface type is assumed to be *Zero Flux*. The specified boundary condition remains in effect from the start time until the execution completion. If a boundary condition is declared with multiple *Boundary Times*, the first time listed equals the start time; the last time listed equals the stop time, and the intermediate times are transition points. For simulation times outside of the start and stop time limits, *Zero Flux* boundary conditions apply. For simulation times between two *Boundary Times*, linear interpolation of the boundary conditions is applied. Step boundary condition changes are simulated by defining duplicate *Boundary Times*; the first time indicates the completion of the previous boundary condition and the second time indicates the start of the new boundary condition. At the completion of the step boundary condition, another set of duplicate *Boundary Time* declarations is used. Step boundary conditions are convenient methods for introducing slugs of fluids, heat, or solute in conjunction with the *Neumann* boundary type.

4.5.15 Source Card

This card allows the user to control sources or sinks of mass, energy, and solutes by defining the timing-varying sources. By definition, sinks are negative sources, and sources refer to an influx of mass, energy, or solute into a node. Sources can be specified for interior or boundary nodes and are functionally analogous to *Neumann* type boundary conditions. Sources applied to inactive nodes are not recognized. Sources are time varying; however, unlike boundary conditions, application of multiple sources to a node are allowed during the same time period. The STORM simulator controls time steps to agree with time transitions in sources. Source inputs depend on the operational mode, with the required inputs becoming more complex with an increasing number of solved equations. Sinks withdraw mass, energy, or solutes from a node. The physical properties for the fluids withdrawn through sinks equal those of the node. Sources inject mass, energy, or solutes into a node. The physical properties for fluids injected through sources are computed from the specified input parameters.

Sources of type *Aqueous Volumetric* and *Aqueous Mass* inject aqueous fluid. For non-isothermal problems, the injected fluid also transports an amount of heat into the node, based on the enthalpy of the entering aqueous fluid. Sources of types *Gas Volumetric/Mass Fraction*, *Gas Volumetric/Relative Humidity*, *Gas Mass/Mass Fraction*, and *Gas Mass/Relative Humidity* are similar to the two aqueous sources, in that mass and heat injected into the node include contributions from water vapor and air. The source type suffix *Mass Fraction* indicates that water vapor and air concentrations in the gas phase are specified through inputs of mass fractions for these quantities. Similarly, the source type suffix *Relative Humidity* indicates that water vapor and air vapor concentrations in the gas phase are specified through inputs of relative humidities for the water. Energy sources are specified as either type *Power* or *Power Density*, where *Power* type sources inject energy per unit time and *Power Density* type sources inject energy per unit time per node volume. *Solute* sources inject solute mass in the assumed units for solute (for example, Ci, pCi, gm, kg, mol, or kgmol).

Time variations of sources are controlled through declaring multiple source times. All *Source Time* inputs are referenced against the *Initial Time* specified on the *Solution Control* card or are obtained from a restart file. A source declared with a single *Source Time* implies the source is time invariant; the specified *Source Time* represents the start time for the source. Prior to the start time, the source is zero and from the start time to execution completion, the source is as specified. If a source is declared with

multiple *Source Times*, the first time listed equals the start time, the last time listed equals the stop time, and the intermediate times are transition points. For simulation times outside of the start and stop time limits, zero source conditions apply. For simulation times between two *Source Times*, linear interpolation of the sources is applied. Step source changes are simulated by defining duplicate *Source Times*; the first time indicates the completion of the previous source and the second time indicates the start of the new source. At the completion of the step source another set of duplicate *Source Time* declarations is used. Step sources are convenient methods for introduction slugs of fluids, heat, or solute into an interior node.

4.5.16 Output Control Card

This card allows the user to control output written to the *output* file, *plot* file, and *screen* (that is, STDIO). The *output* file contains an interpreted and reformatted version of the *input* and simulation results for selected variables at selected *reference nodes* over the simulation period. The *plot* file contains values of geometric parameters and selected variables for the entire computational domain (both active and inactive nodes) at selected simulation times. A *plot* file always is generated at the conclusion of an execution. The output to the STDIO primarily comprises variable results of the reference node versus the simulation time or time step. The user is advised to request *screen* output, because well-chosen output may be invaluable in tracking the simulation progress and identifying possible input errors. If a suite of repetitive simulations is in progress, then *screen* output can be reduced to minimum values. As with other input cards, output options are dependent on the operational mode. With respect to this card, output options primarily refer to computed field and flux variables.

Reference node output is generated by selecting reference nodes and output variables. The user may request any number of reference nodes. However, reference node output was primarily designed for tracking the time evolution of selected variables at key nodes of interest. Reference nodes are defined with three indexes that indicate the x-, y-, and z-direction coordinates of the node. Node numbering in the STORM simulator increments in the order i, j, and k, where the indexes refer to the x-, y-, and z-directions, respectively, for Cartesian coordinate systems and r-, q-, and z-directions, respectively, for cylindrical coordinate systems. *Reference Node Screen Output Frequency* and *Reference Node Output File Frequency* are parameters that indicate how often, with respect to time step, reference node output is written to STDIO and the *output* file. A frequency value of 1 indicates reference node output occurs every time step, whereas a frequency value of 10 indicates reference node output occurs every 10 time steps. The user controls the output time and length units and the number of significant digits reported to the various output media. Unless declared through the *Output Time Units* or *Output Length Units* input items, values for time and lengths recorded to the output media are expressed in units of seconds and meters, respectively. These inputs allow the user to customize time- and length-scale units to those most appropriate for the solved problem. The *Screen Significant Digits*, *Output File Significant Digits*, and *Plot File Significant Digits* input items allow the user to customize the number of significant digits that appear in field and flux variable results written to the STDIO, *output* file, and *plot* file. Default values for the number of significant digits is 5; the minimum number of significant digits is 4. Field and flux variables output for the reference nodes are selected from the list shown in Appendix A for each operational mode. The same list of variables for each operational is available for output to the *plot* files. Output units for all variables that have units can be specified immediately following the variable name. Variables without units require a *null* entry for the variable units. The *null* entries for variables with units yield default output units that are expressed in SI units.

Plot files are written by default at the conclusion of an execution and at each requested *Plot File Output Time*. Plot files contain geometrical data and selected field and flux variable results for every node in the computational domain. These files represent a snapshot of the simulation at a certain point in time. Requests for *Plot File Output Times* can be specified with user defined units. A *restart* file is generated with every *plot* file. Both restart and plot files are suffixed with an file name extension of a dot followed by an integer (for example, plot.567, restart.32). The extension integer corresponds with the time step for which the file was written. Both *plot* and *restart* files are written at the conclusion of a time step. Field and flux variables recorded to *plot* files are selected from the list shown for each operational mode in Appendix A (refer to the reference node variable options). Output units for all variables with units are specified in the input item immediately following the variable name. Variables without units require a *null* entry for the variable units. *Null* entries for variables with units yield default output units that are expressed in SI.

4.5.17 Surface Flux Card

This card allows the user to define surfaces to track fluxes of fluid mass, fluid volume, heat, or solutes. A surface defined with this card can be composed of rectangular areas of coplanar surfaces on exterior boundaries or between interior nodes. Output from the surface flux integration routines are written to the *surface* file and contain flux rate and integral data for each defined surface at every time step. The types of fluxes that can be tracked depend on the operational mode. Declaration of surfaces is similar to defining boundary condition surfaces. Surfaces are defined by referencing a group of coplanar nodes and a surface direction with respect to the nodes. For the Cartesian coordinate system, the terms West, South, and Bottom refer to the negative x-, y-, and z-directions, respectively; the terms East, North, and Top refer to the positive x-, y-, and z-directions, respectively. For the cylindrical coordinate system the terms West, South, and Bottom refer to the negative r-, Q-, and z-directions, respectively, and the terms East, North, and Top refer to the positive r-, Q-, and z-directions, respectively. For example, a surface to track the flux rate and integral of a particular solute entering the water table is defined for a simulation with saturated conditions along the bottom boundary surface by referencing the node group along the bottom of the computational grid and defining the *Surface Flux Orientation* as *Bottom*. One surface flux rate and integral value is computed for each defined surface and represents the summation of surface flux contributions from the individual surfaces in the coplanar group of surfaces.

4.5.18 Reactive Transport Control Card

This card lists several parameters that control the execution of the reactive transport subroutines. The first line requires specification of the reactive transport *Execution Mode*. Currently, only one *Execution Mode* is available for the reactive transport subroutines: Normal. In the *Normal* mode, the simulation executes from initial conditions specified with the *Reaction IC Card.*

The second line requires the user to select the reactive transport *Solution Mode*. Two solution modes are available: *Fully Coupled mode*, in which the transport equations and the chemical reactions are solved simultaneously, and *Operator Split* mode, in which advective-diffusive transport equations and the chemical reactions are solved sequentially.

The third line lists eight integer values that must be set to either zero or one (Table 4.6).

Table 4.6. Description of Reactive Transport Execution Control Switches

Description Of Variable	0	1
Aitken extrapolation scheme	off	on
Column scan switch for 2-D problems	off	on
Non-reacting solver switch	off	on
Effective reaction area	off	on
Texture solver coupled with transport solver	off	on
Porosity updated with precipitation/dissolution	off	on
Lower boundary condition for all species	No flux	C = 0
Water consumption in chemical reactions coupled with water flow	off	on
Gas consumption in chemical reactions coupled with gas flow	off	on

The "Aitken extrapolation scheme" accelerates the convergence of the Newton-Raphson iteration scheme related to the reactive transport solver. The "Column scan switch for 2-D problems" enables the Gauss-Seidel iterative solver to scan in the horizontal, as well as the vertical direction when solving 2-dimensional problems. The "non-reacting solver switch" allows the user to solve problems with pure transport (no reactions) in the *Fully Coupled* solution mode. The "Effective reaction area" switch allows recalculation of the effective reaction surface area for each mineral at each node, as the minerals precipitate or dissolve. The "Texture solver coupled with transport solver" switch allows the recalculation of the mineral volume and radius as minerals precipitate and dissolve in slow reactions. The "Porosity updated with precipitation/dissolution" switch allows changes in porosity to be passed back to the water or gas flow subroutines. The "Lower boundary condition for all species" switch allows either a no flux or a specified concentration of zero at the lower boundary for all aqueous species. The "Water consumption in chemical reactions coupled with water flow" switch allows the net water consumption rate, due to all chemical reactions, to be coupled with the water flow subroutines. The "Gas consumption in chemical reactions coupled with water flow" switch allows the net gas consumption rate, due to all chemical reactions, to be coupled with the gas flow subroutines.

The fourth line lists seven real variables that control the convergence of the reactive transport solver.

The Courant number is defined as $Cr = V\Delta t/\Delta l$, where Δt is the initial time step, Δl is the minimum horizontal and vertical grid spacing, and V is the average linear pore water velocity. The time stepping parameter is used to select the time-stepping scheme for reactive transport: a value of 0.0 gives an explicit scheme, 0.5 gives a Crank-Nicholson scheme, and 1.0 provides a fully implicit scheme. A fully implicit scheme is likely to be the most stable. The other six input variables allow the user to specify the maximum error allowed in the solution of various reactive transport subroutines.

4.5.19 Aqueous Species Card

This card lists the aqueous species to be considered in the simulation. Examples of aqueous species include ions, such as HCO_3^- and dissolved gases, such as O_2(aq). Required input includes the overall

Table 4.7. Reactive Transport Convergence Control Variables

Description Of Variable	Range Of Appropriate Values
Initial time step Courant number	1 to 1.e-6
Time stepping parameter	0.0 to 1.0
Error in non-reacting species	1.e-2 to 1.e-7
Error in equation point solver	1.e-2 to 1.e-7
Error in transport point solver	1.e-2 to 1.e-7
Error in texture solver	1.e-2 to 1.e-7

charge of the aqueous species and the hard core diameter. Values of these input parameters for many aqueous species are found in the EQ3/6 database file data0.com.R2, for example. Also required is a list of the elements contained in each species.

4.5.20 Gas Species Card

This card lists gas phase species to be considered in the simulation. Examples of gas phase species include $CO_2(g)$ and $O_2(g)$. These species must be related by Henry's Law Constant to an aqueous species, specified in the Aqueous Species Card. Required input includes the diffusion coefficient of the gas phase species and the Henry's Law equilibrium coefficient. The Henry's Law equilibrium coefficient may be specified as a constant or as a polynomial function of temperature, with a user-specified number of terms. Additionally, a list of the elements contained in each gaseous species is required.

4.5.21 Components Card

This card lists the components that consist of the groups aqueous species related by a single element. Components provide a way to keep track of the total mass of a given element in solution. For instance, the component Al(total) can consist of two aqueous species: $Al(OH)_3(aq)$ and $Al(OH)_4^-$.

4.5.22 Solid Species Card

This card lists and describes all solid species in the simulation. Examples of solid species include silicate or carbonate minerals, metals or soil organic matter. Solid species are defined by specifying the mass density of the solid species and the mole fraction (stoichiometric coefficient) and name of each element in the solid species.

4.5.23 Fast Reactions Card

This card lists and describes all aqueous fast (equilibrium) reactions considered in the simulation. Fast reactions are defined by specifying the number of moles of each aqueous species participating in the reaction. The equilibrium coefficient must also be specified, either as a constant or as a polynomial function of temperature with a user-specified number of terms.

4.5.24 Kinetic Aqueous Reactions Card

This card lists and describes all kinetic reactions involving only aqueous species. An example of kinetic aqueous reactions is the biodegradation of dissolved organic carbon.

4.5.25 Slow Reactions Card

This card lists all kinetic reactions involving at least one solid species. Each reaction may involve one or two solid species. Examples of slow reactions include mineral dissolution or precipitation, metal corrosion, or biodegradation of soil organic matter. Slow reactions are defined by specifying the number of moles of each aqueous and solid species participating in the reaction. The equilibrium coefficient must also be specified, either as a constant or as a polynomial function of temperature, with a user-specified number of terms. Various parameters related to the rate law must also be defined. Three different types of rate law may be specified.

4.5.26 Fluid Decay Card

The option to simulate the radioactive decay of aqueous species is not currently implemented.

4.5.27 Solid Decay Card

The option to consider the radioactive decay of solid species is not currently implemented.

4.5.28 Lithology Card

This card specifies the relative fraction of each solid species found in each of the porous materials initially defined in the *Rock/Soil Zonation* Card Card, described in Section 4.5.4.

4.5.29 Reaction BC Card

This card lists the boundary conditions, specified at the upper boundary, for all aqueous and gas species. This simplification was originally introduced into the code because the upper boundary is usually the location of the inlet of a 1-dimensional column. In the future, the ability will be added to define specified concentration (Dirichlet) or specified flux (Neumann) conditions along any boundary segment of the domain.

4.5.30 Reaction IC Card

Currently, the only option is to set the initial aqueous species concentrations equal to those specified at the upper boundary.

5.0 Parameter Files

5.1 Introduction

This section describes the format and contents of the parameters file and the parameters.astct file, that are required to compile and execute the STORM simulator. Parameters are used by the FORTRAN programming language and compilers to allocate memory for storage of variables. The FORTRAN language is unable to allocate memory dynamically; therefore, all memory storage requirements must be defined at compilation time. No execution errors occur if the memory allocated is greater that required by the simulation, unless the memory requirements exceed the computer capabilities. Unless necessary, the user avoids executing simulations that require the use of virtual memory. The time required to swap data between the virtual memory storage device and the active memory typically yields poor execution speeds. The STORM simulator requires definitions of two types of parameters (declared and computed), prior to compilation. The user is responsible for properly assigning all of the declared parameters. Declared parameters are assigned by modifying the parameters file supplied with the STORM simulator using a text editor (word processor) or by creating a new parameters file. The equations for the computed parameters must be included in each parameters file following the declared parameters. The parameter definitions given in this manual represent minimum acceptable values. All declared parameters, except for switch type parameters, must have minimum values of one. Undersized parameters will generally yield execution errors that may or may not be detected by the system. Oversized parameters are permissible, but can result in excessive memory allocation.

5.2 Parameters File

5.2.1 Solution/Simulation Parameters

The "LNOTES" parameter equals the number of lines in the *Simulation Notes* field and should equal the variable *Number of Simulation Note Lines* on the *Simulation Title* card. The "LEPD" parameter equals the number of execution periods and should equal the variable *Number of Execution Periods* on the *Solution Control* card. A simulation with seven lines of simulation notes and four execution periods would have a solution/simulation parameter set that appeared as

PARAMETER(LNOTES=7, LEPD=4)

5.2.2 Computational Domain Parameters

The "LFX," "LFY," and "LFZ" parameters equal the number of nodes in the x-, y-, and z-directions, respectively, for Cartesian coordinate systems or the number of nodes in the r-, -, and z-directions, respectively, for cylindrical coordinate systems. These parameters equal the variables *X-Dir. Nodes*, *Y-Dir. Nodes*, and *Z-Dir. Nodes* on the *Grid* card. The parameter "LAN" equals the number of active nodes and should equal the total number of nodes minus the number of inactive nodes. The parameter

"LAD" equals the number of active dimensions, where active dimensions are coordinate directions with more than one node. The number of active dimensions is a number between one and three, inclusive. The parameter "LMNP" equals the minimum plane size and should equal the minimum of the following three products: "LFX*LFY," "LFY*LFZ," and "LFZ*LFX." A simulation with 2 active dimensions, having 22, 1, and 103 nodes in the x-, y-, and z- directions, respectively, and 51 inactive nodes has a computational domain parameter set that appeared as

PARAMETER(LFX=22, LFY=1, LFZ=103)
PARAMETER(LAN=2215, LAD=2, LMNP=22)

5.2.3 Operation Mode Switch Parameters

The parameters "LT," "LL," "LG," "LN," and "LC" are switches for the energy, water mass, air mass, VOC mass, and solute conservation equations. For these switch-type parameters, a value of one indicates the equation is solved and a value of zero indicates the equation is unsolved. The parameter "LFC" is a switch for freezing conditions. The parameter "LS" is a switch for coupled solute transport. A value of zero indicates nonfreezing conditions, whereas a value of one indicates freezing conditions. The switch combinations set with these parameters agrees with the operational mode. A simulation using the *Water-Air/Transport* operational mode has a operational mode parameter set that appeared as

PARAMETER(LT=0, LL=1, LG=1, LN=0, LC=1, LFC=0, LS=0)

5.2.4 Linear System Solver Switch Parameters

The parameters "LBD" and "LCG" are switches for the banded and conjugate gradient linear system solvers. For these switch type parameters, a value of one indicates the solver is active and value of zero indicates the solver is inactive. Only one solver can be active for a simulation, either the banded matrix or the conjugate gradient solver. These parameters switches, similar to a toggle, are the only means the user has for declaring a linear equation solution scheme. A simulation that used the banded matrix linear system solver has a linear system solver parameter set that appeared as

PARAMETER(LBD=1, LCG=0)

5.2.5 Boundary Condition Parameters

The parameters "LBC" and "LBTM" equal the number of boundary surfaces and maximum number of boundary condition times. A *Boundary Condition Domain* as declared on the *Boundary Conditions* card may contain more than one boundary surface. The parameter "LBC" indicates the total number of boundary surfaces, not the number of boundary condition domains. Although they may refer to the same computational domain surface, boundary surfaces declared in one boundary condition domain differ from those declared in another. The maximum number of boundary condition times equals the maximum number of times declared for all boundary condition domains. A simulation with three boundary condition domains, the first with 6 boundary surfaces and 13 boundary condition times, the second with

2 boundary condition surfaces and 26 boundary condition times, and the third with 34 boundary condition surfaces and 2 boundary condition times has a boundary parameter set that appeared as

PARAMETER(LBC=42, LBTM=26)

5.2.6 Source Parameters

The parameters "LSR" and "LSTM" equal the number of sources and maximum number of source times. Unlike the boundary condition parameters, a single source may contain more than one node, but is only counted as one with respect to the parameter "LSR." The maximum number of source times equals the maximum number of times declared for all sources. A simulation with 3 source domains, the first with 6 nodes and 13 source times, the second with 2 sources and 26 source times, and the third with 34 sources and 2 source times would have a source parameter set that appears as

PARAMETER(LSR=3, LSTM=26)

5.2.7 Rock Type and Solute Transport Parameters

The parameters "LRC" and "LSOLU" equal the number of rock types and number of transported solutes. The number of rock types equals the number of rock/soil types listed on the *Rock/Soil Zonation* card. Because one rock/soil type can define the rock/soil type for more than one rock/soil zonation domain, the number of rock/soil types does not equal the *Number of Rock/Soil Zonation Domains* declared on the *Rock/Soil Zonation* card. Each rock/soil type has a unique name. The number of solutes should equal the number of solutes defined on the *Solute/Fluid Interactions* card. Each solute must have a unique name. A simulation with 14 rock/soil zonation domains, 3 rock/soil types, 7 solutes for the *Water-Air/Transport* operational mode has a rock types and solutes parameter set that appeared as

PARAMETER(LRC=3, LSOLU=7)

5.2.8 Output Parameters

The parameters "LREF," "LPTM," and "LSF" equal the number of reference nodes, number of *plot* file output times, and the number of flux surfaces, respectively. The number of reference nodes equals the *Number of Reference Nodes* input on the *Output Control* card. The number of *plot* file output times equals the *Number of Plot File Times* input on the *Output Control* card. The *plot* file that is generated, by default at the conclusion of an execution is not counted as a *plot* file time. The number of flux surfaces should equal the *Number of Surface Flux Inputs* input on the *Surface Flux* card. A simulation with 4 reference nodes, 6 plot file output times (other than the *plot* file generated at the conclusion of the execution), and 23 flux surfaces would have an output parameter set that appeared as

PARAMETER(LREF=4, LPTM=6, LSF=23)

5.2.9 k-S-P Function Parameters

The parameters "LTBL" and "LPATH" equal the total number of table entries and the number of scanning paths for hysteretic saturation functions, respectively. The number of table entries equals the sum of *Number of Table Entries* on the *Saturation Function*, *Aqueous Relative Permeability Function*, and *Gas Relative Permeability Function* cards. The number of scanning paths equals the *Number of Scanning Paths* input for hysteretic saturation functions on the *Saturation Function* card. The recommended number of scanning paths for a hysteretic saturation function is seven. For non-hysteretic saturation functions, the number of scanning paths should equal one. A *Water* operational mode simulation with 2 rock/soil types, 34 tabular entries for the saturation function for the first rock/soil type, a declared non-hysteretic saturation function for the second rock/soil type, 27 tabular entries for the aqueous relative permeability for the first rock/soil type, and 31 tabular entries for the aqueous relative permeability for the second rock/soil type has a *k-S-P* function parameter set that appears as

PARAMETER(LTBL=92, LPATH=7)

5.2.10 Computed Parameters

Computed parameters are arithmetic combinations of the declared parameters and must follow the declared parameters in the parameters file. Computed parameters related to the conjugate gradient linear system solver are declared within the source code. Definitions of the computed parameters in the parameters file are given in Table 5.1. The computed parameter set for all simulations appears as

```
PARAMETER(LUK=LT+LL+LG+LN+LS, LPH=LL+LG+LN)
PARAMETER(LHBW=LUK*LMNP+LUK-1)
PARAMETER(LCOL=LBD*LAN*LUK + LCG*(2*LAD+1))
PARAMETER(LROW=LBD*(3*LHBW+1) + LCG*LAN*LUK)
PARAMETER(LSCG=LBD + LCG*LAN*LUK)
PARAMETER(LSBD=LBD*LAN*LUK + LCG)
PARAMETER(LSOL=LAN*LUK)
PARAMETER(LSV=LUK+2, LSFV=2*LUK+1)
PARAMETER(LFD=LFX*LFY*LFZ)
PARAMETER(LSX=(LFX+1)*LFY*LFZ)
PARAMETER(LSY=LFX*(LFY+1)*LFZ)
PARAMETER(LSZ=LFX*LFY*(LFZ+1))
PARAMETER(LFDT=LFD**LT,LFDL=LFD**LL,LFDG=LFD**LG,LFDN=LFD**LN)
PARAMETER(LFDC=LFD**LC, LFDI=LFD**LFC, LFDS=LFD**LS)
PARAMETER(LSXT=LSX**LT,LSXL=LSX**LL,LSXG=LSX**LG,LSXN=LSX**LN)
PARAMETER(LSXC=LSX**LC, LSXS=LSX**LS)
PARAMETER(LSYT=LSY**LT,LSYL=LSY**LL,LSYG=LSY**LG,LSYN=LSY**LN)
PARAMETER(LSYC=LSY**LC, LSYS=LSY**LS)
PARAMETER(LSZT=LSZ**LT,LSZL=LSZ**LL,LSZG=LSZ**LG,LSZN=LSZ**LN)
PARAMETER(LSZC=LSZ**LC, LSZS=LSZ**LS)
PARAMETER(LRCT=LRC**LT,LRCL=LRC**LL,LRCG=LRC**LG,LRCN=LRC**LN)
```

```
PARAMETER(LRCC=LRC**LC, LRCI=LRC**LFC, LRCS=LRC**LS)
PARAMETER(LBCT=LBC**LT,LBCL=LBC**LL,LBCG=LBC**LG,LBCN=LBC**LN)
PARAMETER(LBCC=LBC**LC, LBCI=LBC**LFC, LBCS=LBC**LS)
PARAMETER(LBCU=LUK+LPH, LBCV=LBCU+LSOLU, LOUPV=100+11*(LSOLU))
```

5.3 parameters.astct File

5.3.1 Specified Parameters

The parameter *maxxd* specifies the maximum number of points in the vertical (Z) direction, and is always set equal to the value of LFZ+1. The parameter *maxyd* specifies the maximum number of points in the horizontal (X) direction, and is always set equal to the value of LFX+1. The parameter *maxaqs* specifies the maximum number of aqueous species. The parameter *maxsld* specifies the maximum number of solid species. The parameter *maxfrxn* specifies the maximum number of fast reactions. The parameter *maxsrxn* specifies the maximum number of slow reactions. The parameter *maxfdec* specifies the maximum number of fluid decays. The parameter *maxsdec* specifies the maximum number of solid decays. The parameter *maxkrxn* specifies the maximum number of kinetic aqueous reactions. The parameter *maxlith* specifies the maximum number of lithologic units, and is always set equal to the value of LRC. The parameter *maxelem* specifies the maximum number of elements in one species. The parameter *maxgas* specifies the maximum number of gaseous species. An example of the specified parameters in a parameters.astct file is

```
parameter(maxxd=822,maxyd=26)
parameter(maxaqs=40,maxsld=20)
parameter(maxfrxn=20,maxsrxn=20)
parameter(maxfdec=1,maxsdec=1)
parameter(maxkrxn=1)
parameter(maxlith=6)
parameter(maxelem=14)
parameter(maxgas=3)
```

5.3.2 Computed Parameters

The parameter *maxrxn* specifies the maximum total number of reactions. The last line in the parameters.astct file is, therefore,

```
parameter(maxrxn=maxfrxn+maxkrxn+maxsrxn+maxfdec+maxsdec)
```

Table 5.1. Computed Parameter Definitions

Parameter	Definition
LUK	Number of solved coupled equations
LPH	Number of phases
LHBW	Block banded matrix half-band width
LCOL	Number of columns in the Jacobian matrix
LROW	Number of rows in the Jacobian matrix
LSCG	Number of unknowns for the conjugate gradient solver
LSBD	Number of unknowns for the banded matrix solver
LSOL	Number of unknowns
LSV	Number of field variable indexes
LSFV	Number of flux variable indexes
LFD	Number of nodes
LSX	Number of surfaces in the x- or r-directions
LSY	Number of surfaces in the y- or ÿ-directions
LSZ	Number of surfaces in the z-direction
LFDT	Number of energy field variables
LFDL	Number of aqueous field variables
LFDG	Number of gas field variables
LFDC	Number of solute transport equation field variables
LFDI	Number of solute transport equation field variables
LSXT	Number of energy flux variables in the x-direction
LSXL	Number of aqueous flux variables in the x-direction
LSXG	Number of gas flux variables in the x-direction
LSXC	Number of solute flux variables in the x-direction
LSYT	Number of energy flux variables in the y-direction
LSYL	Number of aqueous flux variables in the y-direction
LSYG	Number of gas flux variables in the y-direction
LSYC	Number of solute equation surfaces in the y-direction
LSZT	Number of energy flux variables in the z-direction
LSZL	Number of aqueous flux variables in the z-direction
LSZG	Number of gas flux variables in the z-direction
LSZC	Number of solute equation surfaces in the z-direction
LRCT	Number of energy variable rock/soil types
LRCL	Number of aqueous variable rock/soil types
LRCG	Number of gas variable rock/soil types
LRCC	Number of solute variable rock/soil types
LBCT	Number of energy boundary condition variables
LBCL	Number of aqueous boundary condition variables

Table 5.1. Computed Parameter Definitions (contd)

Parameter	Definition
LBCG	Number of gas boundary condition variables
LBCC	Number of solute boundary condition variables
LBCU	Number of coupled boundary condition variables
LBCV	Number of total boundary condition variables
LOUPV	Number of output variables

6.0 Compilation and Execution

6.1 Introduction

The STORM simulator was designed primarily for execution on computers with UNIX(1) operating systems. An assembled source code, however, can be compiled and executed on any computer with an ANSI FORTRAN compiler, if the computer has sufficient memory. Although a general correspondence is present in computer design between memory size and execution speed, sufficient memory to compile and execute does not guarantee the machine has sufficient execution speeds to complete a simulation within a reasonable time period. The STORM simulator should be thought of as a collection of source code libraries. The libraries that become part of the executable code are dependent on the operational mode. Each operational mode requires a particular group of library source codes. The normal procedure for building an executable version for a particular operational mode involves compiling the required group of library source codes, using the declared and computed parameters in the parameters and parameters.astc files to define memory requirements, and linking the compiled object files to create an executable. An alternate option is to assemble or concatenate all of the source code libraries required for a particular operational mode into a single file and, subsequently, compile the assembled source code. Either procedure can be performed manually or automatically. The *make* utility (Talbott 1988) that generates a sequence of commands for execution by the UNIX shell, can be used to automatically compile and link the required source code libraries for a particular operational mode. A *makefile*, which contains a *make* utility instruction set is designed to generate an executable or assembly source code for the STORM simulator.

6.2 Compilation

Executing the make command compiles and links all of the source and object coding required for an operational mode into a single executable file. Operational mode options are specified on the command line by specifying the name of the executable. As an example, the following UNIX shell command string on a computer that supports the *make* utility generates an optimized executable of the *Water-Air-Energy* operational mode

make storm3

where a file named "storm3" is generated. Table 6.1 shows the correspondence between the name of the executable and operational modes.

(1) UNIX is a registered trademark of AT&T Information Systems.

Table 6.1. Glossary of Operational Mode Indexes

Index	Operational Mode
storm1	*Water/Reactive Transport*
storm2	*Water-Air/Reactive Transport*
storm3	*Water-Air-Energy/Reactive Transport*

Assembly options are entered on a line within the file named *Makefile*, and assigned to a variable named FFLAGS. For example, the following line compiles the code on a SUN workstation with the options to generate a fast executable with the extended source code line length (132 characters) turned on.

FFLAGS = -fast -e

The assembly process has certain requirements with respect to source files, the commons file, the parameters file, and the *make* description file. Storing all of the source files (those files that have *.f* or *.c* extensions) and the commons file in a single directory is recommended. A path name to this directory can be defaulted into the make description file.

Executing make produces object files, with *.o* extensions for every required FORTRAN source file. These object files appear in the current directory but are not necessary for code execution and can be discarded. Any modifications to the parameters file would require that the code be recompiled and linked. Executing make following a modification to the parameter file automatically regenerates the object and executable files. Because of the updating features in make, any recompilation using a different assembly option requires the user to remove all of the object files from the current directory.

6.3 Execution

Executing the STORM simulator is straightforward and only requires that an input file named *input* resides in the current directory. For restart simulations, a restart file named *restart* must also reside in the current directory. Because restart files are created with an extension that corresponds with the generating time step, the user must rename the appropriate restart file to restart. For a UNIX operating system, execution is started by typing in the path to and the name of the executable file. Execution is indicated by printing a STORM title banner and program disclaimer to the standard input/output device (for example, a monitor).

6.3.1 Error Messages

Two types of error messages can be generated during a STORM execution. The first type is a system-generated message that typically indicates a memory error, FORTRAN error, or other system error identified by the system. The second type of error messages is that generated by the STORM code that typically refer to input, parameter, or convergence failure type messages. STORM-generated messages are divided into three categories, according to severity. The most severe are the ERROR messages that abort the program execution. Undersized parameters are typical of errors that yield

ERROR messages because execution of the simulator with undersized parameters may yield gross errors, or even worse, subtle errors that can pass undetected in the results. Next on the severity level are the WARNING messages that generally indicates to the user that a problem with the input file probably exists. The least severe are NOTE messages that are used to record events such as the absence of an optional input card.

When an execution is terminated with a STORM-generated ERROR message two types of information appear on the standard input/output device. The first piece of information is an error message with or without related data that indicates the nature of the error. To a limited degree, the STORM simulator also traps input formatting errors. Unfortunately, the resulting input error message that results may not always agree with the actual location of the identified input error. This situation arises because the original error may have skipped detection. For example, a missing input item on an input line is not identified until STORM identifies an incorrect data type or the end of the line was reached. The user will expect to find input errors slightly before the location indicated by the generating error message. The second type of information, which is generated with an ERROR message, is a calling sequence. The calling sequence is a slash delineated list of routine names that were called prior to the identified error. The calling sequence for an input error on the *Aqueous Relative Permeability* card for the *Water* operational mode appears as

/STORM1/RDINPT1/RDRPL/WRMSG

where the called routine names are delineated with a forward slash. For this example, the main routine STORM1 called the subroutine RDINPT1 to read the input file for the *Water* operational mode. It in turn, called RDRPL, the global routine, to read the *Aqueous Relative Permeability* card that identified an error and called WRMSG to write an error message to the standard input/output device.

This page intentionally left blank.

7.0 Output Files

7.1 Introduction

The STORM simulator can generate, depending on the requested output and saturation function type, two data files for restarting a simulation and three simulation result files. Every execution produces an *output* file. If the simulation concludes without a fatal error, a *restart* and *plot* file are also generated. *Restart* and *plot* files names include an extension that corresponds to the time step at which the file was written. For example, a restart file named *restart.39* was written at the conclusion of the 39th time step. Simulations involving hysteretic saturation functions also produce a *hyster* file that contains saturation history records. *Hyster* file names also include an extension that corresponds to the time step at which the file was written. A *surface* file is only generated when a *Surface Flux* card is included in an input file. All output files generated by the STORM simulator are ASCII text files.

7.2 Output File

An *output* file is generated with every execution. If a file named *output* already exists in the current directory, the file is erased and overwritten. The user is responsible for renaming previous *output* files prior to executing the STORM simulator. An *output* file begins with a welcome statement, a disclaimer, and a banner that appear similar to

Welcome to ...

STORM
Subsurface Transport Over Reactive Multiphases

This file was produced by STORM, a numerical simulator
developed by the Pacific Northwest National Laboratory
with support from the U.S. Department of Energy.

Results from this version of STORM should not be used
for license related applications. Distribution of the
STORM source code is strictly prohibited.

For inquiries or assistance: Call (509) 372-6132

--- OUTPUT ---

Following this banner is an input record that documents the simulation input. An input record is included on the *output* file to document the simulation in the event the *input* file is destroyed or becomes separated from the *output* file. The input record is formatted differently that an *input* file, but contains all of the information listed on an input file. Optional cards that are not included in the *input* file are noted in the input record. If an input error is identified by the STORM simulator, an error message appears in the input record at the point the error was noted. Input cards are read by the STORM simulator in a specific order and appear in that order in the input record. Because input cards can be organized randomly on the *input* file, the card order on the input record may not match that on the *input* file.

7.3 Refnod File

The *refnod* (reference node) output file is a table of simulation data and selected reference node variables that are printed according the frequency requested on the *Output Control* card with the input item *Reference Node Output File Frequency*. Every 10 print records a table column header is printed to delineate the columns. Each print record shows simulation data and reference node variable data for each reference node requested. Simulation data comprises the time step, the reference node number, the simulation time, the simulation time step, and the number of Newton-Raphson iterations required to reach convergence. Reference node variable data comprise values of the variables specified on the *Output Control* card through the *Reference Node Variable* inputs. Reference nodes are indexed by node number. The corresponding x-, y-, and z-direction indexes are shown for each reference node on the line preceding the column headers. For example, a simulation with reference node 272 at x-, y-, and z-direction indexes of 2, 3, and 6, respectively, has a reference node header line that appeared as

Reference Node(s) (2, 3, 6: 272)

Column headers for reference node variables are delineated with an abbreviated title and associated units. Units are enclosed in brackets below the variable abbreviation. A portion of a reference node output record for a horizontal heat pipe problem, involving 50 nodes for time steps 70 through 73, appears as

Reference Node(s) (1, 1, 1: 1) (50, 1, 1: 50)

Step	Node	Time [day]	Timestep [day]	Itr	T [c]	SL	PL [pa]
70	1	2.837E+01	1.793E+00	8	7.1893E+01	9.9893E-01	1.0133E+05
70	50	2.837E+01	1.793E+00	8	1.3564E+02	2.0992E-02	-1.9896E+08
71	1	3.061E+01	2.242E+00	9	7.1895E+01	9.9903E-01	1.0133E+05
71	50	3.061E+01	2.242E+00	9	1.4039E+02	1.9265E-02	-2.2722E+08
72	1	3.341E+01	2.802E+00	9	7.1878E+01	9.9933E-01	1.0133E+05
72	50	3.341E+01	2.802E+00	9	1.4598E+02	1.7489E-02	-2.6050E+08
73	1	3.692E+01	3.503E+00	8	7.1869E+01	9.9951E-01	1.0133E+05
73	50	3.692E+01	3.503E+00	8	1.5225E+02	1.5759E-02	-2.9758E+08

The reference nodes are nodes 1 and 50; the reference node variable data includes the temperature, reported in degrees Celsius, the aqueous saturation, and the aqueous pressure, reported in Pascal (absolute).

7.4 Plot File

A *plot* file is generated by default at the conclusion of every execution and, additionally when requested on the *Output Control* card with the *Plot File Output Times* input items. If a file named *plot.xx* (where *xx* refers to the time step extension) already exists in the current directory, the file is erased and overwritten. The user is responsible for renaming previous *plot.xx* files prior to executing the STORM simulator. A *plot* file begins with a welcome statement, a disclaimer, and a banner that appear similar to

Welcome to ...

--- PLOT ---

Following this header are data on the current time step, simulation time, and number of nodes in three coordinate directions. The remaining portion of a *plot* file comprises arrays of geometric and variable data. These data are arranged in groups, each with a title line that indicates the type of data that follows. Data groups are arranged in rows with 10 data items per row. Each group of data contains a field or surface variable listed sequentially for every node or surface in the computational domain. The first four groups of data appear in every plot file and contain the x- or r-direction node positions, y- or θ-direction node positions, z-direction node positions, and node volumes for every node in the computational domain. The remaining groups of data correspond to the requested *Plot File Variables*. Field variable data groups list the value of the field variable at the node centroid. Surface variables or fluxes are written twice to the plot file. The first flux variable data group lists the value of the flux variable at the node centroid, whereas the second group lists the value at the node surfaces. Node centroid values for flux variables are simple arithmetic averages of the two node surface values.

Two post-processing programs are available, d_plot1d and d_plot2d. The program d_plot1d parses output data from a 1-dimensional simulation into columnar format. The program d_plot2d parses data from a 2-dimensional simulation into Spyglass Transform format.

7.5 Surface File

A *surface* file is generated during an execution if surfaces are defined on the *Surface Flux* card If a file named *surface* already exists in the current directory, the file is erased and overwritten. The user is responsible for renaming previous *surface* files prior to executing the STORM simulator. A *surface* file begins with a welcome statement, a disclaimer, and a banner that appear similar to

Welcome to ...

--- SURFACE ---

Following the header, are columns of surface flux rate and integral data. Surface flux information is written to the *surface* file at the conclusion of every time step. The first column of data in the *surface* file is the time step in units that are specified with the *Output Time Units* variable on the *Output Control* card. Each surface flux output is written in two columns: the first column is the surface flux rate at the current time step and the column is the integral of the surface flux rate from the beginning of the current simulation. Surface flux integral data are not carried over on restart simulations. Each column in the *surface* file is titled with an abbreviated header and associated units shown in brackets under the column title. Definitions of the header abbreviations for the *surface* file are given in Table 7.1. Each header title is followed with an integer enclosed in parentheses. The integer refers to the surface flux number, as defined on the *Surface Flux* card (that is, the surface flux definition order).

7.6 Restart File

A *restart* file is generated by default at the conclusion of every execution and also when requested on the *Output Control* card with the *Plot File Output Times* input items. If a file named *restart.xx* (where *xx* refers to the time step extension) already exists in the current directory, the file is erased and overwritten.

Table 7.1. Surface Flux Column Title Abbreviations

Abbreviation	Definition
UGM	Gas mass flux rate (x-direction)
UGMS	Gas mass flux integral (x-direction)
ULM	Aqueous mass flux rate (x-direction)
ULMS	Aqueous mass flux integral (x-direction)
UGV	Gas volumetric flux rate (x-direction)
UGVS	Gas volumetric flux integral (x-direction)
ULV	Aqueous volumetric flux rate (x-direction)
ULVS	Aqueous volumetric flux integral (x-direction)
UQV	Energy flux rate (x-direction)
UQVS	Energy flux integral (x-direction)
VGM	Gas mass flux rate (y-direction)

--- RESTART ---

All data values in *restart* files are in SI units with pressures expressed in gauge. The first data line of a *restart* file contains the following timing and simulation information: time, time step, maximum time step, time step acceleration factor, convergence criterion, maximum number of Newton-Raphson iterations, number of time steps, and number of nodes. The remaining lines are node data lines that contain the following field variable data for the current time step for every node (one line per node): temperature, aqueous pressure, gas pressure, water vapor pressure, aqueous saturation, and gas saturation. If the simulation includes solute transport, the node data lines also contain solute volumetric concentrations for each solute. Moreover, if the simulation includes freezing water conditions, the node data lines also contain the frozen water pressure and frozen water saturation. All node data lines are terminated with an integer value for the phase condition. Refer to the STOMP Theory Manual (White and Oostrom 1996) for a discussion of phase conditions.

8.0 Model Verification

8.1 Aqueous Phase Advection and Diffusion

For the case of 1-dimensional, steady state diffusion and advection of a single aqueous species, with constant production from a single reaction with depth, Equations **(2.17)** through **(2.27)**simplify to

$$W = -\left(\theta_a \mathbf{D}^a\right)\frac{\partial^2 C^a}{\partial z^2} + \left(\theta_a \mathbf{V}_a\right)\frac{\partial C^a}{\partial z} \tag{8.1}$$

Assuming production occurs over a finite depth $0<z<L$, with a specified concentration (C_0^a) at the top boundary ($z = 0$) and no diffusive flux at the lower boundary (z = L), the aqueous phase concentration of that gas species is given by

$$C_z^a = \frac{\mathbf{D}\left(e^{\frac{L\mathbf{v}}{\mathbf{D}}} - e^{\frac{(L-z)\mathbf{v}}{\mathbf{D}}}\right)W + \mathbf{v}\left(C_0^a\mathbf{v} - Wz\right)}{\mathbf{v}^2} \tag{8.2}$$

where $\mathbf{V} = \theta_a \mathbf{V}_a$ and $\mathbf{D} = \theta_a \mathbf{D}^a$. A STORM simulation of Halite dissolution was run that corresponds to this analytical solution. Both the *Fully Coupled* and the *Operator Split* solution modes were used. Output from STORM was compared to the analytical solution. The model parameters are listed in Table 8.1; the results are shown in Figure 8.1. Results for STORM run in the *Fully Coupled* solution mode and the analytical solution agree well. Results for STORM run in the *Operator Split* mode agree, if the time step is constrained to a maximum value of 0.5 hour.

Table 8.1. Simulation Parameters for Gas Phase Diffusion

Parameter	Value
Temperature, C	25
C_0^a, mol kg^{-1}	1.0×10^{-7}
D^a, m^2 s^{-1}	5.0×10^{-4}
V_a, m s^{-1}	1.6×10^{-8}
θ_a	5.2×10^{-2}
W, mol m^{-3} s^{-1}	1.2×10^{-9}

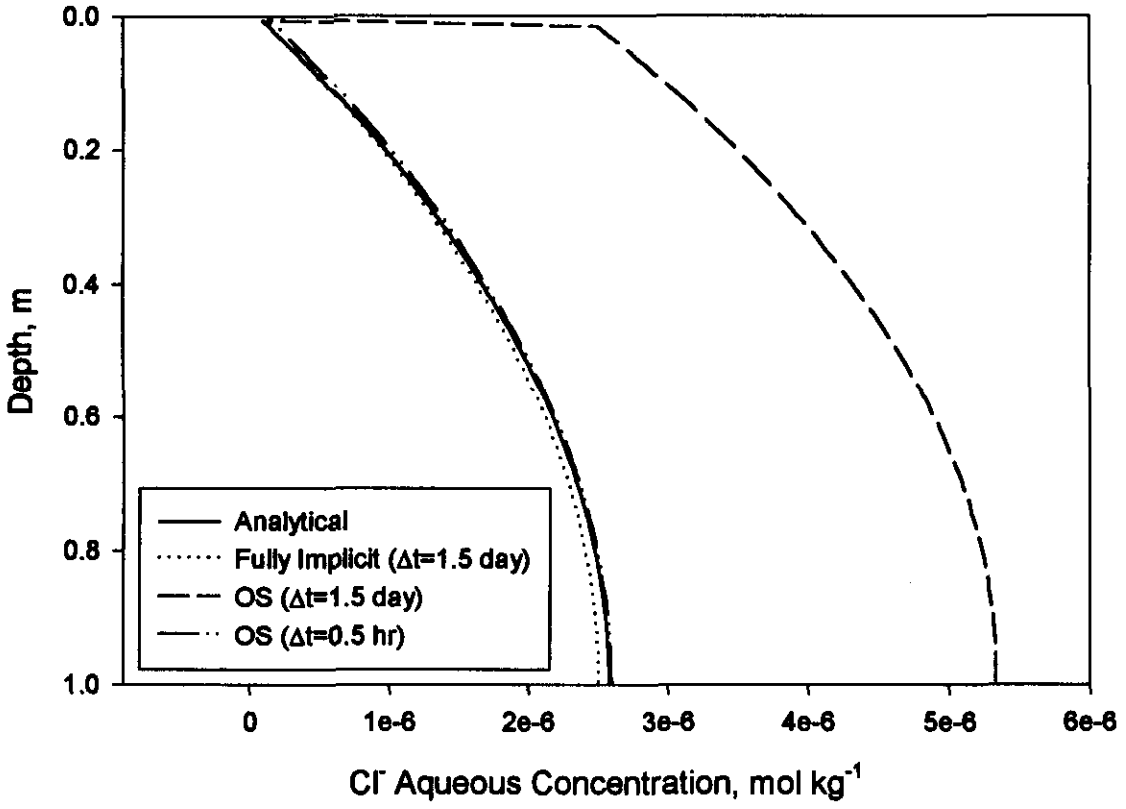

Figure 8.1. Comparison of STORM Results Using Either *Fully Coupled* or *Operator Split* Solution Modes to Analytical Solution for Constant Source, Advection, and Diffusion

8.2 Gas Phase Advection and Diffusion

For the case of 1-dimensional, steady state diffusion of a single gas species, with constant production from a single reaction with depth, Equation **(2.17)** simplifies to

$$W = -\left(\theta_g \mathbf{D}^g K_H'^{-1} + \theta_a \mathbf{D}^a\right)\frac{\partial^2 C^a}{\partial z^2} \tag{8.3}$$

Assuming production occurs over a finite depth $0<z<L$, with a specified concentration (C_0^a) at the top boundary ($z = 0$) and no diffusive flux at the lower boundary (z = L), the aqueous phase concentration of that gas species is given by

$$C_z^a = C_0^a + \frac{W}{\left(\theta_g \mathbf{D}^g K_H'^{-1} + \theta_a \mathbf{D}^a\right)}\left(zL - \frac{z^2}{2}\right) \tag{8.4}$$

and the gas phase concentration may be determined using Equation **(2.16)**. A STORM simulation was run that corresponds to this analytical solution. The model parameters are listed in Table 8.2.

Results for simulations with two different CO_2(g) production rates are shown in Figure 8.2 (open and closed diamond symbols). Results for STORM and the analytical solution agree quite well. Concentrations of CO_2(g) shown are reasonable values found in vadose zones where organic matter is being decomposed by aerobic bacteria.

Table 8.2. Simulation Parameters for Gas Phase Diffusion

Parameter	Value
Temperature, C	15
C_0^a, atm	3×10^{-4}
K_H'	1.088
D^g, $m^2\ s^{-1}$	1.6×10^{-6}
D^a, $m^2\ s^{-1}$	5×10^{-9}
θ_g	0.24
θ_a	0.0266
W, mol $m^{-3}\ s^{-1}$	4.65×10^{-9} or 9.60×10^{-9}

For the case of 1-dimensional, steady state diffusion and advection of a single gas species, with constant production from a single reaction with depth, Equation **(2.17)** simplifies to

$$W = -\left(\theta_g \mathbf{D}^g K_H'^{-1} + \theta_a \mathbf{D}^a\right)\frac{\partial^2 C^a}{\partial z^2} + \left(\theta_g \mathbf{V}_g K_H'^{-1} + \theta_a \mathbf{V}_a\right)\frac{\partial C^a}{\partial z} \tag{8.5}$$

Assuming production occurs over a finite depth $0<z<L$, with a specified concentration (C_0^a) at the top boundary ($z = 0$) and no diffusive flux at the lower boundary (z = L), the aqueous phase concentration of that gas species is given by

$$C_z^a = \frac{\mathbf{D}\left(e^{\frac{Lv}{\mathbf{D}}} - e^{\frac{(L-z)v}{\mathbf{D}}}\right)W + \mathbf{v}\left(C_0^a\mathbf{v} - Wz\right)}{\mathbf{v}^2} \tag{8.6}$$

where $\mathbf{V} = \theta_g \mathbf{V}_g K_H'^{-1} + \theta_a \mathbf{V}_a$ and $\mathbf{D} = \theta_g \mathbf{D}^g K_H'^{-1} + \theta_a \mathbf{D}^a$. The gas phase concentration may be determined using Equation **(2.16)**. A STORM simulation was run that corresponds to this analytical solution. The model parameters are listed in Table 8.2. The results are shown in green in Figure 8.2. Results for STORM and the analytical solution again agree quite well. The upward gas velocity of $2.3\text{x}10^{-7}$ m s^{-1} increases the CO_2(g) concentrations found at any given depth, as compared to a similar test case without gas advection (Figure 8.2, square symbols).

8.3 Gas Phase Mass Balance

A simple simulation runs where oxygen is consumed in one kinetic reaction. Hand calculations are used to verify that oxygen consumption rate is passed correctly to the flow routines and that overall gas mass balance is preserved. A 10-year simulation with a constant sink term for O_2(g) is used to test whether gas consumption rates are passed correctly from the transport subroutines to the flow subroutines, and whether the total air mass is conserved.

The O_2(g) consumption rate was specified as a constant $-4.04\text{x}10^{-9}$ mol m^{-3} s^{-1}. In the STORM subroutine D_WATERSINK that calculates the water and air consumption rates passed to the flow routines, the total mass consumption rate of air in units of kg s^{-1} is calculated using

$$R_{\text{Air}} = R_{O_2} M_{O_2} V_{\text{node}} \tag{8.7}$$

where R_{O_2} is the O_2(g) consumption rate in mol m^{-3} s^{-1}, M_{O_2} is the molecular weight of oxygen in kg mol^{-1}, and V_{node} is the node volume in m^3. Using Equation (8.7), and assuming a molecular weight of $3.2\text{x}10^{-2}$ kg mol^{-1} for O_2(g) and a node volume of $1\text{x}10^{-6}$ m^3, the calculated R_{Air} should be

$$R_{\text{Air}} = \left(-4.04\times10^{-9}\text{mol m}^{-3}\text{s}^{-1}\right)\left(3.2\times10^{-2}\text{kg s}^{-1}\right)\left(1\times10^{-6}\text{m}^3\right) = 1.29\times10^{-16}\text{kg s}^{-1}. \tag{8.8}$$

As shown in Table 8.3, this value agrees with that calculated by the transport subroutine D_WATERSINK.

Table 8.3. STORM Input/Output Variables for Test Case 3

Variable	Where Calculated	Initial	10 Years
Total Air Mass, kg	Flow subroutine	2.9366E-07	2.5289E-07
Air Mass Source Integral, kg	Flow subroutine	0.0000E+00	-4.0761E-08
Air Rate, kg s^{-1}	Transport subroutine	-1.2917E-16	-1.2915E-16
O_2(g) Rate, mol m^{-3} s^{-1}	Transport subroutine	-4.0368E-09	-4.0362E-09

Over a period of 10 years, or 3.156×10^8 s, the total mass of air consumed is equal to $(-1.2916 \times 10^{-16}$ kg $s^{-1})(3.156 \times 10^8$ s) = -4.076×10^{-7} kg. This figure is equal to the Air Mass Source Integral calculated by the flow subroutines, indicating the Air Mass Source Rate is being passed correctly from the transport subroutines to the flow subroutines. The difference of the Total Air Mass between the beginning and the end of the simulation is equal to 2.5289×10^{-7} kg – 2.9366×10^{-7} kg = -4.077×10^{-7} kg, indicating that total air mass is being conserved. The small error in these calculations is due to the small decrease in R_{O_2} over the course of the simulation. As the solid (organic matter) decay reaction responsible for the consumption of O_2(g) proceeds, the surface area of organic matter decreases slightly, thus lowering R_{O_2}.

8.4 Quartz Dissolution

The chemical reaction solver of STORM is verified by comparing STORM results to EQ3/6. In STORM, advective and diffusive transport were made negligible by assuming a very low hydraulic conductivity for the porous media and very small aqueous diffusion coefficients for aqueous species. As an example of a simple kinetic reaction path, quartz sand reacts at 100°C with deionized water according to the reaction

$$\text{Quartz} \; f \quad SiO_2(aq) \tag{8.9}$$

Quartz dissolves according to the pH-independent rate law (Rimstidt and Barnes 1980)

$$r_{qtz} = A_s k \left(1 - \frac{Q}{K}\right) \tag{8.10}$$

where r_{qtz} is the dissolution rate (mol s^{-1}), A_s is the surface area of the mineral (500 m^2), k is the reaction rate constant (2×10^{-11} mol m^{-2} s^{-1}), K is the equilibrium coefficient ($10^{-3.9993}$ at 100°C), and Q is the activity product, in this case equal to the concentration of SiO_2(aq).

After 8 days, 1 kg of water is saturated with SiO_2(aq) (Figure 8.3). The results from EQ3/6 and STORM are nearly identical.

8.5 Calcite Precipitation

As an example of a slightly more complicated kinetic reaction path, calcite precipitates from supersaturated solution at 25°C according to the reaction

$$Calcite + H^+ \leftrightarrow Ca^{2+} + HCO_3^- \tag{8.11}$$

Calcite dissolves according to the rate law (Reddy et al. 1981)

$$r_{calcite} = A_s k\left(1 - \frac{Q}{K}\right) \tag{8.12}$$

where $r_{calcite}$ is the dissolution rate (mol s^{-1}), A_s is the surface area of the mineral (0.24168 m^2), k is the reaction rate constant ($7x10^{-7}$ mol m^{-2} s^{-1}), K is the equilibrium coefficient ($10^{1.8487}$ at 25°C), and Q is the ion-activity product, in this case equal to

$$Q = \frac{[Ca^{2+}][HCO_3^-]}{[H^+]} \tag{8.13}$$

Several other species participate in equilibrium reactions (Table 8.4) and are included in the simulations. The CO_2(g) partial pressure is fixed at a partial pressure of $10^{-1.5421}$ bars. The initial total Ca concentration is $1.2732x10^{-2}$ mol kg^{-1} and the initial pH is 7.5815.

Precipitation of calcite in 1 kg of water proceeds rapidly, and virtually ceases after the solution has reached saturation (0.12 days). Results from EQ3/6 and STORM are nearly identical (Figure 8.4).

Table 8.4. Aqueous Species, Equilibrium Reactions, and Equilibrium Constants Related to Calcite Dissolution

Reaction	Log K At 25°C
$OH^- + H^+ \leftrightarrow H_2O$	13.9951
$CO_2(aq) + H_2O \leftrightarrow H^+ + HCO_3^-$	-6.3447
$CO_2(g) \leftrightarrow CO_2(aq)$	-1.4689
$CaHCO_3^+ \leftrightarrow Ca^{2+} + HCO_3^-$	-1.0467
$CaCO_3(aq) + H^+ \leftrightarrow Ca^{2+} + HCO_3^-$	7.0017
$CO_3^{2-} + H^+ \leftrightarrow HCO_3^-$	10.3288
$CaOH^+ + H^+ \leftrightarrow Ca^{2+} + H_2O$	12.8500

9.0 Example Simulations

Three simulations are presented to demonstrate unique features of STORM. The first simulation presents a 2-dimensional, waste-form-alone-design simulation of steady-state unsaturated flow and transient reactive transport of aqueous species released as the glass waste dissolves. In the first simulation, glass dissolves according to a rate law dependent on aqueous phase silica concentration and pH. The approach is new in that a full set of recent experimentally derived rate parameters for LD-5412 glass is used. The second simulation demonstrates how exchange of hydrogen for sodium in the glass enhances the rate of glass dissolution. This simulation approach is also new in that mass balance is preserved by tracking the masses of altered and unaltered glass separately. The third simulation demonstrates how gas phase diffusion of CO_2 may increase the dissolution rate of the glass. Transient gas phase transport is a new feature added to the code this fiscal year.

9.1 Base Case

The disposal facility is modeled as a 2-dimensional domain where the waste form, a borosilicate waste glass (LD6-5412), is surrounded by backfill soil above several layers of Hanford sediments and the water table (Figure 9.1). Laboratory-measured hydraulic properties are used for each porous material (Rockhold et al. 1993); the glass waste is assumed to have hydraulic properties equivalent to that of a gravel (Fayer et al. 1997). These properties are used to calculate the water saturation distribution below a surface barrier designed to allow a water flux of no more than 0.5 mm yr^{-1}. The coarse glass acts as a hydraulic barrier, causing water to pond on top of the waste form and flow around the sides (Figure 9.2).

Included in the reactive transport portion of the simulation were 22 aqueous species, 1 gaseous species, 9 minerals, 11 equilibrium reactions, and 9 kinetic reactions (Table 9.1).

The corrosion of silicate glasses in water is represented by a special type of irreversible dissolution reaction. A conventional transition state kinetic rate equation (Aagaard and Helgeson 1982) is used to develop a constitutive relationship to compute the flux of any element i released from the glass into the aqueous phase. Currently, H^+ is the only aqueous species shown to directly influence the dissolution rate, that gives

$$J_i^a = \upsilon_i k e^{-\frac{E_a}{RT}} a_{H^+}^{-\eta} \left[1 - \left(\frac{Q}{K} \right)^{\sigma} \right], i = 1,2,\ldots,N \qquad (9.1)$$

where J_i^a is the flux of element i (mol m^{-2} s^{-1}), υ_i is the stoichiometric coefficient of element i in the glass, k is the intrinsic rate constant (mol m^{-2} s^{-1}), E_a is the activation energy (J mol^{-1}), R is the gas constant (J mol^{-1} K^{-1}), T is the temperature (K), a_{H^+} is the hydrogen ion activity, η is the order of the hydrogen ion activity dependence, Q is the ion-activity product of the rate controlling phase, K is the

Table 9.1. List of Reactions

(Note: 1-11 are equilibrium reactions, 12-21 are kinetic reactions)	
1.	$H_2O = H^+ + OH^-$
2.	$CO_2(g) = CO_2(aq)$
3.	$CO_2(aq) + H_2O = H^+ + HCO_3^-$
4.	$HCO_3^- = H^+ + CO_3^{2-}$
5.	$Al(OH)_4^- + H^+ = Al(OH)_3 + H_2O$
6.	$H_2SiO_4^{2-} + 2H^+ = SiO_2(aq) + 2H_2O$
7.	$H_2SiO_3^- + H^+ = SiO_2(aq) + 2H_2O$
8.	$BO_2^- + H^+ + H_2O = B(OH)_3(aq)$
9.	$CaCO_3(aq) + H^+ = Ca^{2+} + HCO_3^-$
10.	$CaHCO_3^+ = Ca^{2+} + HCO_3^-$
11.	$CaOH^+ + H^+ = Ca^{2+} + H_2O$
12.	$Glass + 0.5OH^- + 0.45H_2O = 0.0202K^+ + 0.4208Na^+ 0.046Ca^{2+} + 0.094BO_2^- + 0.154Al(OH)_3(aq) + 0.2712HSiO_3^- + 0.3348H_2SiO_4^{2-} + 1.6172x10^{-6}TcO_4^{2-}$
13.	$Quartz + OH^- = HSiO_3^-$
14.	$Calcite = Ca^{2+} + CO_3^{2-}$
15.	$Albite(high) + 2OH^- = Na^+ + Al(OH)_3(aq) + 3HSiO_3^-$
16.	$K-feldspar + 2OH^- = K^+ + Al(OH)_3(aq) + 3HSiO_3^-$
17.	$Illite + 2.4OH^- = 0.6K^+ + 0.25Mg^{2+} + 2.3Al(OH)_3(aq) + HSiO_3^-$
18.	$Analcime + 0.96H^+ = 0.96Na^+ + 0.96Al(OH)_3(aq) + 2.04SiO_2(aq) + 5.04H_2O$
19.	$Chalcedony = SiO_2(aq)$
20.	$NaAlSi_2O_6 \cdot 6H_2O + OH^- = Na^+ + Al(OH)_3(aq) + 2HSiO_3^- + 4H_2O$

equilibrium constant of the rate controlling phase, and σ is the net reaction order. Assigning K to a simple SiO_2 polymorph, such as chalcedony, yields the best agreement with experimental data for LD6-5412 glass (McGrail et al. 1997). Consequently, K, the equilibrium constant for chalcedony, is assigned for the simulations discussed here. Experiments utilizing a single-pass flow-through apparatus for measuring glass dissolution rates at various pH and temperatures yield values for the parameters in Equation **(2.16)**, as shown in Table 9.2.

Table 9.2. Glass Dissolution Rate Parameters

Parameter	Value
$\tilde{k}$	$10^{2.05}$ g m^{-2} s^{-1}
η	0.40
E_a	74.8 kJ mol^{-1}
σ	1

The subsurface is assumed open to the atmosphere, and the subsurface gas phase concentrations are not limited by diffusion, so that $CO_2(g)$ concentrations are a constant 0.035 percent by volume. The diffusion coefficient for all species in pure water is assumed to be $5x10^{-9}$ m^2 s^{-1}. As time advances, the pH rises to a maximum value of 8.1 because dissolution of the glass releases alkali metals (Na, K) (Figure 9.3). The largest glass dissolution rates ($6.3x10^{-11}$ mol s^{-1}) appear at the interface between the vault and the surrounding soil because the steep concentration gradient into the soil lowers the concentration of Si near the interface (Figure 9.4). Concentrations of ^{99}Tc are smooth because under the oxidizing conditions in the disposal facility, ^{99}Tc is highly soluble as a pertechnitate ($^{99}TcO_4^-$) anion and so is subject to aqueous phase diffusion (Figure 9.5). A maximum $^{99}TcO_4^-$ concentration of $1.9x10^{-9}$ mol kg^{-1} is observed at the bottom of the waste form. Concentrations of ^{99}Tc are presented because this species provides the dominant contribution to the drinking water dose (Mann et al. 1998).

9.2 Ion Exchange

Experimental results (McGrail et al. 1997) suggest the exchange of sodium for hydrogen in the glass waste form

$$\text{GlassL } 0.4208\text{Na} + 0.4208\text{H}^+ = \text{GlassL } 0.4208\text{H} + 0.4208\text{Na}^+ \qquad (9.2)$$

is important at the low temperatures expected in the waste form. When this reaction is included, the maximum pH in the waste form increases by one pH unit to a value of 9.1 (Figure 9.6). As would be predicted by Equation **(2.15)**, the higher pH causes the glass dissolution rate to increase to a maximum value of $7.4x10^{-11}$ mol s^{-1} at the edges of the waste form (Figure 9.7). The increase in glass dissolution results in the maximum Tc concentration (Figure 9.8) also increasing to a value of $3.0x10^{-9}$ mol kg^{-1}. The increases in pH and Tc concentrations are significantly less than those predicted in previous analyses (Mann et al. 1998), due to the buffering capacity provided by assuming a fixed partial pressure of $CO_2(g)$.

9.3 Gas Diffusion

In the previous two simulations, the assumption is that partial pressure of CO_2 in the gas phase was constant, implying the diffusion rate of $CO_2(g)$ through the vadose zone

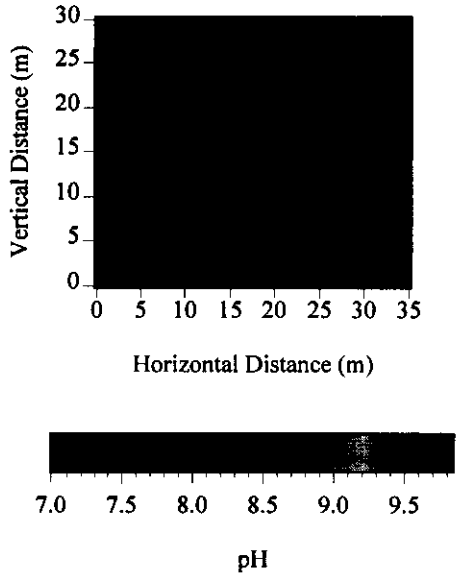

Figure 9.3. pH After 20,000 Years, No Ion Exchange, Fixed P_{CO_2}

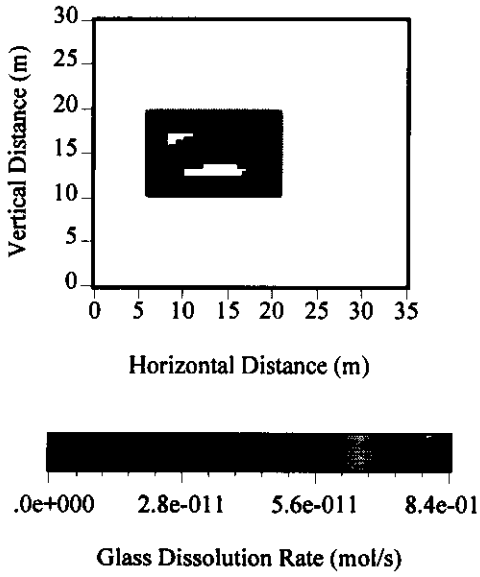

Figure 9.4. Glass Dissolution Rate After 20,000 Years, No Ion Exchange, Fixed P_{CO_2}

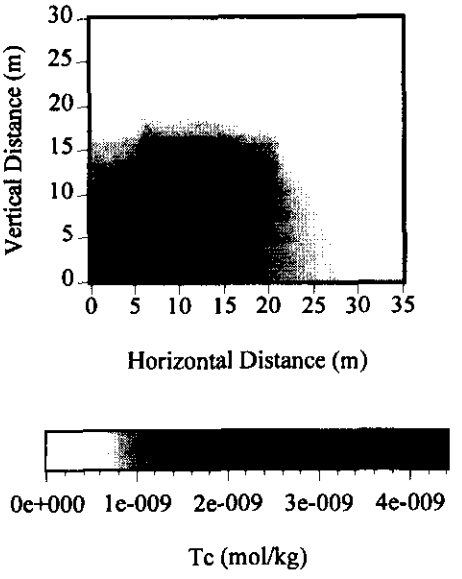

Figure 9.5. Tc Concentration After 20,000 Years, No Ion Exchange, Fixed P_{CO_2}

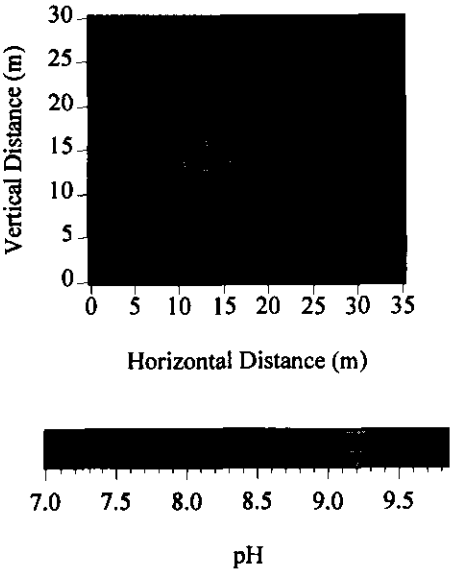

Figure 9.6. pH After 20,000 Years, with Ion Exchange, Fixed P_{CO_2}

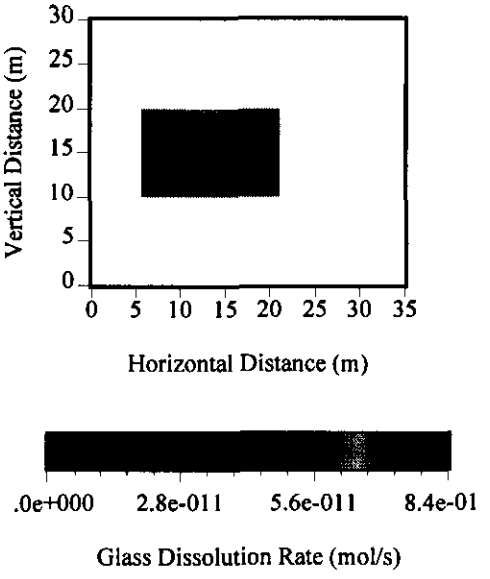

Figure 9.7. Glass Dissolution Rate After 20,000 Years, with Ion Exchange, Fixed P_{CO_2}

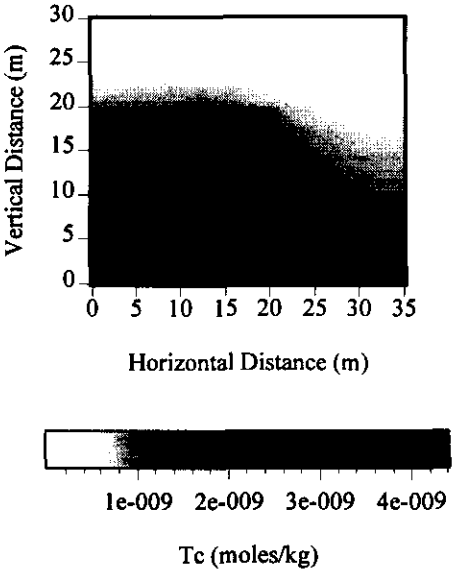

Figure 9.8. Tc Concentration After 20,000 Years, with Ion Exchange, Fixed P_{CO_2}

is fast relative to the rate of consumption of $CO_2(aq)$ in aqueous complexation and dissolution-precipitation reactions. This assumption is relaxed by assuming a diffusion coefficient for $CO_2(g)$ of $1.6x10^{-6}$ m^2 s^{-1} and allowing STORM to transport $CO_2(g)$ throughout the spatial domain. The results (Figure 9.9) show that $CO_2(g)$ concentrations in the center of the vault decrease to a partial pressure nearly an order of magnitude below atmospheric pressure. This reduces the concentration of carbonic acid produced from dissolution of $CO_2(g)$ into the pore water, thus causing the pH to increase to a maximum value of 9.8 (Figure 9.10). Again, the increase in pH causes the glass dissolution rate (Figure 9.11), both on the edges and at the center of the waste form, and the aqueous Tc concentrations (Figure 9.12) to increase accordingly.

9.4 Conclusions

These three simulations demonstrate the long-term performance of the low-activity waste glasses can be successfully simulated with the STORM code under realistic field conditions of 2-phase flow of water and air. The results show that ion exchange and gas phase diffusion can have a significant effect on radionuclide release rates from the glass waste form. Assuming equilibrium with atmospheric $CO_2(g)$ throughout the spatial domain does not appear to be appropriate and can lead to non-conservative radionuclide release rates from the disposal system.

1. Summary of Recommendations ..... E 5

I. INTRODUCTION

The Tank Waste Remediation System (TWRS) is responsible for the safe storage, retrieval, and disposal of waste currently being held in 177 underground tanks at the Hanford Site. In order to successfully carry out its mission, TWRS must perform environmental analyses describing the consequences of immobilized low-activity tank waste contaminants leaving disposal facilities.

Because of the large size of the facilities and the great depth of the dry zone (known as the vadose zone) underneath the facilities, sophisticated computer codes are needed to model the transport of the contaminants. Code selection criteria were established (Mann 1998) based on the information from the low-level waste programs of the U.S. Department of Energy [DOE] (Case 1988) and of the U.S. Nuclear Regulatory Commission (Kozak 1989a) as well as experience gained in the DOE Complex [Mann 1995, WSRC 1992] in applying these criteria.

This document analyzes each of the requirements and desirable features of the three codes that were submitted for consideration, PORFLOW (ACRi 1998, Runchal 1998a), STOMP (White 1996, Nichols 1997, White 1997, Freshley 1998), and VAM3D-CG (HG (1994), Puigh 1998). This version of the recommendation includes information received after April 30, 1998, from Runchal (1998b,c) and from Connelley (1998). This document follows the format of the code selection criteria document and judges how well each of these codes meet the criteria.

- Chapter II - Mandatory Administrative Criteria: those criteria dealing with how the code is created, maintained, and used;

- Chapter III - Mandatory Technical Criteria: the technical features which the code must have; and

- Chapter IV - Desirable Features: those feature which the code should have, but the absence of which will not disqualify a code.

The proposals from each of the code proponents was reviewed and evaluated against the criteria. The results of the review are organized by the code selection criteria (Mann 1998). Also attached are results from an independent review conducted by Bechtel, San Francisco, for the Groundwater/Vadose Zone Integration Project.

The TWRS Decision Management Procedure (LMHC 1998) was followed.

II. SUMMARY AND ANALYSIS

The code selection review process recommends that ILAW proceed with the use of VAM3D-CG as the basis for vadose zone modeling efforts leading to completion of the 2001 performance assessment. This recommendation evolves from the findings described in this document. While each code presented an impressive set of features for vadose zone modeling, each code represented a unique mix of features important to the ILAW disposal program.

In summary the key features that became discriminating factors for the recommendation included:

- Acceptance by the regulatory and technical community.
- The ability to utilize the investment in staff knowledge and working relationships.

A very knowledgeable and capable staff at PNNL supports the STOMP code. The staff supporting the geotechnical data collection for the performance assessment is closely tied to staff proposing use of the STOMP code. However, the ILAW program would be taking on a significant avoidable risk by using a code that has not been formally accepted by WDOE or EPA for use in an application like the TWRS Immobilized Low-Activity Waste Disposal effort. The proposal for the STOMP code indicated a path forward for resolving this issue but the ILAW Disposal Program would be taking on additional unnecessary risk.

The PORFLOW code is well accepted by both the technical and regulatory community. In fact, PORFLOW has been used by the ILAW Performance Assessment for vadose zone calculations. However, the previous modeler is not available due to illness. Analytical and Computational Research, Inc. has indicated a willingness to establish a local capability and work with the program on modeler assignment and training. However, the need to develop new working relationships and develop understandings of the project technical and programmatic issues was a risk the project would be taking on.

The VAM3D-CG code has been accepted by the regulatory community for applications similar to ILAW disposal. Fluor Daniel Northwest, Inc. and GeoHydraulic staff are knowledgeable and available to begin working on the performance assessment. There is a concern that the current version of the code does not adequately handle radioactive decay, however, this appears to be a risk that could be quantified (approximately $10,000) and controllable by the ILAW program.

Each proposal was reviewed independently and evaluated against the specific criteria established in Mann 1998. The proposals were largely reviewed as written with some credit given based upon the experience and judgment of the reviewer. Criteria for the Mandatory Administrative features and Mandatory Technical features were evaluated on a met/not met basis. The Desirable Features were presented on a percentage basis. For two of the reviewers this percentage was based upon judgment, for the third reviewer the value represents the percentage of desirable feature attributes met by the code. Input from three independent reviewers was combined as shown in Table 1. The review data collection, analysis and final recommendation was performed by the ILAW Program Office.

Table 1.

SUMMARY OF RECOMMENDATIONS

IV-J	Version	75% 75% 100%	90% 75% 100%	100% 90% 100%

The recommendation for the code was made after assuring that a code could meet all of the mandatory criteria then establishing a preferred code from comparison of the desirable features. All three codes were able to meet all of the Mandatory Administrative Criteria. The Mandatory Technical Criteria provided some discrimination between codes with one code failing to meet all of the Mandatory Technical Criteria. Discrimination between the codes became more apparent in the Desirable Features and the presentation of the proposals from each of the potential code suppliers.

Evaluation of the Mandatory Technical Criteria lead to the following:

1. PORFLOW was judged to meet all of the Mandatory Technical Criteria.

2. STOMP was judged unable to meet the Mandatory Technical Criteria for output. The specific technical criteria identified a need to provide mass balance and mass balance errors at each time step. The proposal states "The current released version of the STOMP simulator does not provide mass balance information after time step . . ." In addition, one reviewer judged that STOMP was unable to meet criteria for III-F Geochemical Models. A basis for this judgment was not provided by the reviewer and, therefore, was not a factor in the recommendation. STOMP was judged not to meet criteria III-G Time-Dependent Hydraulic and Geochemical Values by one reviewer. No basis for this judgment was provided by the reviewer, however, the STOMP submittal states "The current released version of the STOMP simulator can only accommodate time-dependent hydraulic and geochemical values through modification of rock/soil properties through the restart function."

3. VAM3D-CG was judged to meet all of the mandatory Technical Criteria.

The Desirable Features were evaluated on a comparative basis:

1. PORFLOW was distinguished by its ability provide Additional Contaminant Transport Capabilities and Decay Products. The factor that significantly affected the scoring for Ease of Use and User Support is lack of experienced PORFLOW users onsite that are also familiar with the ILAW disposal effort and the ILAW Performance Assessment in particular.

2. STOMP was distinguished by its ability to provide Decay Products and the absence of a fully proprietary Code. The factor that significantly affected scoring for Reputation among User Community was absence of regulatory acceptance and wide commercial use of the code.

3. VAM3D-CG was distinguished by its Certification-Verification-Benchmarking and Reputation among the User Community. VAM3D-CG scored poorly for its handling of decay products. The proposal indicated that this deficiency in VAM3D-CG could be remedied through several different methods for approximately $10,000.
Based upon the factors noted, VAM3D-CG is recommended for use leading to completion of the 2001 ILAW Performance Assessment.

III. MANDATORY ADMINISTRATIVE CRITERIA

These criteria deal with how the code is created, maintained, and used.

A. Technical Documentation

1. **Requirements.** The proponent of the code shall submit the documentation that describes
   - model theory, governing equations, and assumptions,
   - computational techniques and algorithms,
   - code verification,
   - user input, and
   - example applications

   The items listed above to the cognizant engineer along with a notation describing the location of each required item.

   It is recognized that the current version of the code may not have all the documentation at the time of code selection. If this is the case, the proponent shall supply documentation for the latest version of the code for which documentation exists along with a schedule of the expected availability of documentation for the current code version.

   General note: Verification documentation deals mainly with benchmarking tests (analytical and other codes) rather than code verification in computer science.

2. **PORFLOW.** Met/Met. Proposal (1998a) states that two documents exist, but do not reference them. However, ACRi 1998 does describe governing equations (Chapter 2), numerical basis (Chapter 4), and user input (Chapters 5, 6, and 7). Validation manual on web site could not be downloaded. Verification and benchmarking manual that was to be sent has not been received. Revised proposal (Runchal 1998b) references the documents, which were sent by E-mail.

   The online manual describes Version 3.5, while Version 4.0 is being proposed. There is no indication when documentation for Version 4.0 would be available. The revised proposal sent the Version 4.0 manual, which is substantially the same as the Version 3.5.

   An electronic copy of the Manual containing all the above items was sent as an attachment. In addition, a verification and benchmarking manual was mailed. (unable to open)

3. **STOMP.** Met/Met. Model theory, governing equations and assumptions, and computational techniques and algorithms are described in White 1996. User input is described in White (1997). Code verification and example applications are presented in Nichols (1997). Documents are cited by proponents, which is adequate since each document deals with specified component.

   Code is "continuously being upgraded and modified" (proponents' submittal for this requirement). Updated documentation is available on web site (which was checked) and will be incorporated in revisions.

   Pg. 2, A. The STOMP simulator is documented through three published guide manuals: application, theory, and users. Technical documentation descriptions of the code's governing equations, constitutive relations (secondary equations), primary assumptions, and numerical solutions techniques are provided in the STOMP Theory Guide (White and Oostrom 1996).

4. **VAM3D-CG.** Met/Met. Model theory, computational techniques and algorithms, code verification, user input, and example applications are given in HG (1994). The proponents described the location for each item. The version being proposed (3.1) is the one for which documentation was submitted.

   Technical documentation is included in Appendix A (Documentation and User's Guide):

   - Model theory, governing equations and assumptions: pg. 2-1 through 2-26
   - Computational techniques and algorithms: pg. 3-1 through 3-30
   - Code verification: pg. 4-1 through 4-67
   - User input: pg. 8-1 through 8-49
   - Example applications: pg. 4-1 through 4-67

B. Code Availability

1. **Requirements.** The proponent of the code shall document the availability of the executable version of the code and list those computers (and operating systems) on which it will run.

   Satisfactory computer hardware are Intel-compatible processors using the Windows or NT operating system or Sun/SGI/HP computers using the UNIX operating system. Large parallel systems (having more than four processors) will not be considered.

2. **PORFLOW.** Met/Met. Claim installations on UNIX and Intel PCS under Windows.

   PORFLOW Simulation Tool is available for practically any computer and operating systems; the installations have included:

1. Intel x-86 and Pentium processors
2. IBM RISC
3. Sun
4. HP
5. SGI
6-9. Others

Among the current installations are those on:

1. Windows 95
2. Windows NT
4. UNIX (including variations from IBM, HP, SUM, SGI, DEC)

3. **STOMP.** Met/Met. Code has been compiled on a number of UNIX computers without warning messages. However, code proponents do not state on which the code has been shown to run. A subsequent E-mail indicates that the code runs on various UNIX machines and INTEL PCS.

   Pg. 3, B, The U.S. Department of Energy has granted copyright for the software to Battelle Memorial Institute (Battelle), with the stipulation that the simulator be made available to Federal and State agencies through the Energy and Science Technology Software Center or alternate route without royalties to Battelle. . . . The code has previously been compiled on NIX base operating systems around the world and currently compiles free of warning messages.

4. **VAM3D-CG.** Met/Met. Code is available on SGI UNIX and Intel PC computers.

   The executable version of VAM3D-CG Version 3.1 is available for use by on site on the Silicon Graphics, Inc. workstation operating under the UNIX system. Appendices B & C provide the verification and benchmarking information for VAM3D-CG installed on the SGI workstation.

   VAM3D-CG version is also available for use by FDNW on an INTEL PC operating under Windows NT4.0. The code has been verified and benchmarked for the INTEL platform for use in the 200 Areas low-level solid waste performance assessment maintenance activities.

C. Configuration Control

1. **Requirement.** The proponent of the code must submit the software quality management program plan for the code.

2. **PORFLOW.** Met/Met. Original proposal (Runchal 1998a) stated that code is designed to meet "ASME Software QA criteria," but no reference given. Revised proposal (Runchal 1998b) provides a QA procedure which is acceptable.

3. **STOMP.** Met/Met. Submitted acceptable configuration management plan based on IEEE standards.

   Pg. 4, C. The STOMP Configuration Management Plan is a version of the IEEE Std. 828-1990, "Software Configuration management Plans." . . . In brief, version control for the STOMP simulator was initiated on June 19, 1997, using the Revision Control System (RCS) utility on the "muse" cluster of IBM RISC 6000s at the PNNL. RCS is a conventional UNIX utility, which is designed to keep track of multiple file revisions.

4. **VAM3D-CG.** Met/Met. Plans are consistent with Fluor Daniel Hanford requirements, to which Lockheed Martin Hanford Corporation is a subcontractor.

   Configuration control for VAM3D-CG Version 3.1 is maintained per . . . FDNW practice 134.200.0960, "Control of Engineering Software," . . . and assures that the control is consistent with Fluor Daniel Hanford "Configuration Management Plan," HNF-MP-013, Rev. 0, and "Quality Assurance Plan," HNF-MP-014, Rev.1.

D. Input Flexibility

1. **Requirements.** The proponent of the code must show that the code can accept input that is site- and facility-specific.

2. **PORFLOW.** Met/Met. Proposal not responsive. However, online manual (ACRi 1998) indicates that input is site- and facility-specific (MATE card in Chapter 7 of ACRi 1998).

   "PORFLOW provides the most comprehensive set of input options and flexibility of any such code currently available. Among these are:

   1. Over 20 options for soil-moisture and conductivity's

   2. Built-in functions (space, time, or phase variable) for:

      - Boundary conditions
      - Initial conditions
      - Field conditions
      - Sources
      - Properties (fluid density, fluid viscosity, storativity, diffusivity, specific heat).

3. **STOMP.** Met/Met. Input manual (White 1996) indicates that all parameters can be submitted. An example is cited where each grid cell had different parameter set. Pg. 4, D, A primary assumption associated with this numerical scheme is that all physical properties within each grid cell are represented by their values at the cell centroid. In respect, each grid cell is identified with a rock/soil type, which relates geohydrologic properties to the grid cell. Table 1, pg. 5 lists the User Defined Rock/Soil properties.

3. **VAM3D-CG.** Met/Met. Input manual (Section 8 Input Data Preparation of HG 1944) indicates that all parameters can be submitted. Examples are provided where site- and facility-specific data are used.

4. VAM3D-CG does not use any generic data as input for either the site or the facility. The code can use Hanford site-specific data and vadose zone parameters.

E. Real-Time Monitoring/Restart Capabilities

1. **Requirements.** The proponent of the code shall document the real-time diagnostic and restart capability of the code. The monitoring activity can be satisfied by time stamps written to a file.

2. **PORFLOW.** Met. See ACRi 1998, particularly Section 6.4.

PORFLOW provides extensive real-time monitoring and restart capabilities. Among its monitoring capabilities are:

1. Step number and time
2. Any of the phase variables
3. The change in any variable
4. The residual of any of the equations
5. The flux balance for any of the equations.

Any combination of any of these can be monitored at any given time or with any given equency.

PORFLOW provides two types of files, which can be used, for restarting.

3. **STOMP.** Met/Met. Real-time monitoring performed by writing a user-chosen subset of cells to special files (documented in Section 7.2 of White 1977). Restart files are created in every run and can be generated at user selected times (documented in Section 7.5 of White 1997). Restart runs are denoted on Solution Control Card (Appendix A.2).

Pg. 6, E, For real-time monitoring the user can specify particular grid cells within the computational domain as reference nodes. Reference node output is written to

standard output (e.g., typically the screen) and an output file called "output." Every STOMP simulation concludes with the creation of a restart file . . . For example, the restart file entitled "restart.342" would have been created at the conclusion of time step number 342.

4. **VAM3D-CG.** Met/Met. Capabilities involve use of special history files (Section 8.4 Special History Files). Restart capabilities are stated in Section 6.5, "Restart Procedures."

   The real-time monitoring capability is controlled via input data preparation and is described in pg. 8-44 and 8-45 (Appendix A). A restart option is provided in the code for continuation of solution to time-dependent problems.

IV. MANDATORY TECHNICAL CRITERIA

These criteria are the technical features, which the code must have. In general, the theoretical framework of the code shall be based on appropriate scientific principles (e.g., conservation of mass, momentum, and energy) and well established engineering equations (e.g., Darcy's law, lick's law).

A. Moisture Flow

1. **Requirements.** The proponent of the code shall document that the code can perform two- and three-dimensional modeling of unsaturated, constant density moisture flow in an isothermal setting, both under steady state and transient conditions. The code proponent shall supply the authors, titles, and document identifiers of some published papers or reports that document use of the code to model moisture flow.

2. **PORFLOW.** Met/Met. See online manual, particularly Chapter 1. A partial list of publication reports was sent with proposal, including Hanford Site applications. PORFLOW has been used widely to perform simulation under conditions of:

   - 2D & 3D Geometry
   - Steady and transient flow
   - Unsaturated and saturated flow
   - Constant and varying density
   - Isothermal and non-isothermal conditions.
   - A partial list of publications is included (por_pub.doc).

3. **STOMP.** Met/Met. The code can model moisture flow (see White 1996). Two/three dimensional is determined by grid card (A3 of White 1997). All calculations are transient, thus making steady-state calculations a special case.

   Examples are provided.

   Pg. 7, A, . . . the STOMP simulator operates on Cartesian and vertically oriented cylindrical grid domains of either one, two, or three dimensions. The STOMP simulator has robust capabilities for modeling multiple-, pseudo multiple- and single-phase fluid flow through subsurface environments. All STOMP simulations are technically transient where the time step is controlled by user specified limitations or by the nonlineartities of the particular problem. Steady-state solutions are obtained by simulating from an initial condition through a transient solution until steady conditions are achieved.

   References Las Cruces Trench Site - Rockhold, Yucca Mountain - Eslinger, Edwards AFB - White and Gilmore, SX-109 - Ward, water through vadose zone of low-level radioactive waste disposal sites - Meyer.

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation) and from examples of HG (1994) (Example Verification and Application Problems). Hanford Site applications show capability.

   VAM3D-CG is capable of simulating two- and three-dimensional unsaturated flow of water of a constant density in an isothermal setting under both steady state and transient flow-field conditions, particularly under conditions expected at the Hanford Site. . . . The ability to model moisture flow under both steady state and transient flowfield conditions at the Hanford Site is documented in 200E Burial Grounds PA (Wood, et al. 1996), 200W Burial Grounds PA (Wood, et al. 1995b), ERDF PA (Wood, et al. 1995a) and TWRS EIS (DOE 1996).

B. Contaminant Transport

1. **Requirements.** The proponent of the code shall document that the code can simulate contaminant transport in two- and three-dimensions as a function of hydrologic conditions established by the moisture flow subsystem and by advection, hydrodynamic dispersion, molecular diffusion, or adsorption. The code proponent shall supply the authors, titles, and document numbers of some published papers or reports that document use of the code to model contaminant transport.

2. **PORFLOW.** Met/Met. See online manual, particularly Chapter 1. A partial list of publication reports was sent with proposal, including Hanford Site applications. "PORFLOW provides for a very comprehensive set of options for transport of contaminants." List provided.

3. **STOMP.** Met/Met. The code can model contaminant transport (see White 1996). Two/three dimensional is determined by grid card (A3 of White 1997).

   Two-dimensional examples are provided.

   - Per the STOMP Application, Theory, and User's Guides, the STOMP simulator solves the governing equation for solute transport over multiple phases. Solutes are assumed to be transported via advection, hydrodynamic dispersion, and molecular diffusion.

   - Las Cruces Trench Site, those of strontium transport at the 100-N Area, Hanford Site, and the investigations of soluted-transport solution scheme are three pertinent examples of STOP generate solution to two dimensional solute transport problems.

   (Note 3D not discussed).

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation) and from examples of HG (1994) (Example Verification and Application Problems). Hanford Site applications show capability.

   VAM3D-CG is capable of simulating two-/three-dimensional contaminant transport (including advection, hydrodynamic dispersion, molecular diffusion, decay, and adsorption). The ability to model contaminant transport at the Hanford Site is documented in 200E Burial Grounds PA (Wood, et al. 1996), 200W Burial Grounds PA (Wood, et. al 1995b), ERDF PA (Wood, et al. 1995a) and TWRS EIS (DOE 1996).

C. Boundary Conditions

1. **Requirements.** The proponent of the code shall document the code's ability to simulate moisture flow for an infiltration rate which varies with time. The proponent shall also document that the code is capable of simulating homogeneous and non-homogeneous Dirichlet and Neumann boundary conditions. It shall be possible to configure the boundary conditions to simulate either upward or downward migration and fate of contaminants.

2. **PORFLOW.** Met/Met. See discussion of BOUN card in Chapter 7 of ACRi 1998.

   Dirichlet type, Neumann, Mixed Radiation, Open boundary, and switching between the Dirilicht & Neumann.

   Boundary conditions can vary as arbitrary functions of time, space phase variables, user defined variables. Boundary conditions can be imposed in any manner and combination, such as:

   - element by element
   - material type
   - block elements
   - whole boundary directed by direction cosines.

3. **STOMP.** Met/Met. Boundary conditions are defined on Boundary Conditions card (Section A.20 of White 1997).

   Pg 8, C. 1) All surfaces on the exterior boundaries of the computational domain require boundary conditions; 4) Boundary conditions variables can be defined as time dependent or constant . . . Beyond these basic rules, the user is free to specify boundary conditions as needed.

   . . . if a user created a one-dimensional simulation and attempted to declare inward flow boundaries (Neumann-type boundary conditions) on both ends of the domain,

STOMP would attempt to find an aqueous pressure solution to the problem. . . . The 'Initial Condition' type boundary condition is a special form of the Dirichlet boundary condition, where the value of the boundary surface variable is set equal to the initial value of the field variable at the node adjacent to the boundary surface.

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation) and from examples of HG (1994) (Example Verification and Application Problems). Hanford Site applications show capability.

   A time-dependent boundary condition is handled via Group 17 input data (pg. 8-2, 8-32, 8-33, Appendix A), "Transient flux boundary condition." Other boundary conditions including Dirichlet and Neumann, boundary conditions, are handled via Groups 15 and 16 (pg. 8-2, 8-29, through 8-31; Appendix A) input data.

D. Source Term

1. **Requirements.** The proponent of the code shall document the code can accept a specified time-dependent release rate from one or more volume sources and from disconnected surface sources and then simulate the release until the inventory is depleted.

2. **PORFLOW.** Met/Met. The original proposal (Runchal 1998a) was not responsive. The capabilities are probably contained in SOUR card (Chapter 7 of ACRi 1998), but proposal provides only generalities. The revised proposal (Runchal 1998b) confirmed that the SOUR card does contain information.

   "The SOURce command with TABLe and TIME modifier meets the requirements as stated. In fact, any functional relationship can be specified by the SOURce command or in combination with ALLOCate, SET, and SOURce commands."

3. **STOMP.** Met/Met. Source terms conditions are defined on Source Conditions card (Section A.21 of White 1997). Disconnected surface sources must be modeled at the boundary between active and inactive cells. User inputs explicit time history.

   "As documented in the STOMP User's Guide, source can be specified as time dependent with unique start and stop times. Unlike boundary conditions, multiple sources can be specified for a single grid cell and most source types offer two specification options, volume dependent, and independent."

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation) and from examples of HG (1994) (Example Verification and Application Problems). User inputs explicit source history.

   VAM3D-CG is capable of simulating specified time-dependent release rates from one or more volume sources and from disconnected surface sources. Such

capability is handled via Group 18I input data input data and prescribing variables NDCSRC (number of sources to be considered) and TLDCS contaminant release time duration (pg. 8-33; Appendix A).

E. Hydrologic Properties

1. **Requirements.** The proponent of the code shall document that the code has the capability to use the van Genutchen - Mualem relationships to represent moisture retention and unsaturated conductivity functions in the simulation of moisture movement and that the code has the ability to have different values in each user chosen zone.

2. **PORFLOW.** Met/Met. The original proposal (Runchal 1998a) indicates that PORFLOW has van Genutchen/Mualem relationships and past Hanford Site applications have used this feature. Chapter 3.3 and 3.5 of ACRi 1998 indicate that van Genuchten and Mualem relationships, respectively, are supported by the code. However, the proposal does not indicate where in the manual nor is it obvious which input card contains information. The revised proposed (Runchal 1998b) Providees that the option is available with the MULTphase command using the VAN and MUALem modifiers.

   "The MULTiphase command with VAN and MUALem modifiers meets the requirements as stated."

3. **STOMP.** Met/Met. Van-Genutchen/Mualem representations can be specified by proper choices on Saturation Function Card (Section 1.9 of White 1997) and on Aqueous Relative Permeability Card (Section A.10). Each grid could have a different property.

   Hydrologic properties are specified for rock/soil types, which in turn are specified across domains of grid cells. Table 3 identifies Saturation-Capillary Pressure (s-P) function options. Table 4 identifies Aqueous Relative permeability-Saturation (k-s) function options.

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation). Hanford Site applications show capability.

   VAM3D-CG can use either table lookup or van Genuchten-Mualem relationships to represent moisture retention and unsaturated hydraulic conductivity functions. VAM3D-CG has the capability to assign van Genuchten-Mualem parameters by different material types.

F. Geochemical Model

1. **Requirements.** The proponent of the code shall document that the code can simulate geochemical retardation using the linear sorption isotherm model where K_d only depends on the contaminant and the spatial position.

2. **PORFLOW.** Met/Met. The original proposal (Runchal 1998a) indicates that PORFLOW can use the linear sorption isotherm model and past Hanford Site applications have used this feature. However, the proposal does not indicate where in the manual nor is it obvious which input card contains information. The revised proposal (Runchal 1998b) states that ability is present using TRANsport, PROPerty, DISTribution, and RETArdation commands.

   "The linear sorption isotherm model is invoked by an appropriate selection of TRANsport (constant kd or Rd for each material type), PROPerty (to interpret input as kd or Rd), ISTribution (kd as a function), RETArdation (Rd as function) commands. In addition, non-linear isotherm can be specified by a combination of DISTribution, RETArdation, and REACtion commands."

3. **STOMP.** Met/Met. Kd values can be specified on Solute/Porous Media Interaction Card (Section A.18 of White 1997) for each rock type.
   As referenced in the STOMP User's and Theory Guide, the STOMP simulator transports solutes as a function of the solute and rock/soil type according to a linear adsorption isotherm model. . . . additionally allow solute transport via the Freundlich and Langmuir adsorption models.

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation). Hanford Site applications show capability. Note RPROG(I,2) specifies Kd.

   "VAM3D-CG can simulate geochemical retardation using the linear sorption isotherm or Kd model where the value of Kd depends on the contaminant and on the spatial location. Such a capability is handled via Group 11 input data and prescribing data for PROP(J,4) for each contaminant species being modeled (pg. 8-18; Appendix A). VAM3D-CG has the capability to assign Kds by material types."

G. Time-Dependent Hydraulic and Geochemical Values

1. **Requirements.** The proponent of the code shall document the ability of the code to simulate changes in hydrogeologic and geochemical properties which are an explicit function of time.

2. **PORFLOW.** Met/Met. The original proposal (Runchal 1998a) indicates that PORFLOW can use time-dependent variables. Past Hanford Site applications have used the restart feature instead. However, proposal does not indicate place in manual nor is it obvious which input card contains information. The revised proposal (Runchal 1998b) states that ability is present using STORativity, DISTribution, RETArdation, and VISCOsity commands.

   See assessment above. "In addition, RESTart feature and MATEreal type designation can be used to assign step-wise changes in properties with time."

3. **STOMP.** Met/Met. Uses restart capability.

"The current released version of the STOMP simulator can only accommodate time-dependent hydraulic and geochemical values through modification of rock/soil properties through the restart function. . . . requires the user to use the restart function . . . Drastic changes in rock/soil properties could result in convergence problems upon restart . . ."

"An alternative would be to modify the simulator to accept time-dependent input for the rock/soil properties. . . . This modification would eliminate the need to halt and restart the simulation as all the rock/soil property transitions could be specified within the input file. A modification of this nature would require approximately one to two man-weeks to implement . . ."

4. **VAM3D-CG.** Met/Met. Uses restart capability.

"VAM3D-CG can simulate time-dependence of hydraulic and geochemical parameters for the engineered facility. Such a capability is accomplished by controlling Group 6 "Temporal discretization data" (pg. 8-12; Appendix A) and invoking the restart option."

H. Layering

1. **Requirements.** The proponent of the code shall document that the code can readily simulate:

   - geologic or engineered layering (including structures),
   - heterogenous features, and
   - anisotropic conditions that would affect moisture flow or contaminant transport.

   The layering shall not be restricted to a horizontal representation.

2. **PORFLOW.** Met/Met. No reference was given in the original proposal (Runchal 1998a) to check that capabilities presence. The revised proposal (Runchal 1998b) documents such capabilities.

   Each material type is assigned with a MATEreal command. Each type may be arbitrarily located and may be contiguous or non-contiguous in any geometric shapes. Multiple commands with the same material type may be used to handle spatial non-uniformity.

   Properties can be assigned to each material type in a heterogenoeus manner.

   For each material type anisotropic properties can be assigned with HYDRaulic, THERmal, and TRANsport commands.

Additional complexity can also be accommodated with STOR, DIST, RETA, and VISC commands.

3. **STOMP.** Met/Met. Uses orthogonal grid systems to define geometry. Nonuniform spacing allowed (Section 4.5.3 of White 1997). Heterogeneous features can be specified as each cell can have different properties. Anisotropic moisture conditions specified by hydraulic properties card (Section A.7 of White 1997).

   All geologic features and engineered structures below the ground surface can be incorporated into a geohydrologic conceptual model for the STOMP simulator with the restriction that the shape of such structures are approximated by grid cells defined by the computational grid.

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation). Savannah River Site application shows layering capability.

   VAM3D-CG uses curvilinear grid and transition elements to represent inclined geologic formations and complex geometries such as the engineered system. Unlike finite-difference and integrated finite difference models (e.g., PORFLO), use of finite-element discretization and curvilinear grids in VAM3D-CG avoids "stair-stepping" to represent inclined boundaries.

   The use of curvilinear grid and transition elements is invoked via Group 3 ICURVL input parameter and Group curvilinear mesh data.

   The heterogeneities in geologic formations are modeled in VAM3D-CG via variable NMAT. The anisotropic behavior in saturated media flow and transport properties is modeled in VAM3D-CG via Group 9 input data for the principal components of saturated hydrualic conductivity tensor and Group 11 transport parameters.

I. Output

1. **Requirements.** The proponent of the code shall document that the code can provide moisture content throughout model domain and contaminant concentration and flux at user chosen points, internal surfaces, and/or along boundary segments; all as functions of time as well as be able to calculate flow lines for user chosen source points. The code shall be able to report mass balance and mass balance errors at each time step.

2. **PORFLOW.** Met/Met. No reference was given in the original proposal (Runchal 1998a) to check that capabilities presence. No indication in proposal mass balance is outputted, but past Hanford applications indicate that this is done. The revised proposal (Runchal 1998b) does document capabilities.

3. **STOMP.** Potentially not met/Not. Most output options allowed (see exceptions below). Mass balance errors are a user-specified value (however, where value is specified could not be found). Flowlines would have to be calculated using external software, but is discouraged.

   Two principal output mechanisms for the simulator are reference nodes and plot files. Reference nodes allow the user to specify that a collection of variables are printed or displayed for a number of grid cells after an interval of converged time step.

   The current released version of the STOMP simulator does not provide mass balance information after each time step and does not provide flow-line calculations from selected points.

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation). Output at user chosen points, internal surfaces, and/or along boundary segments is handled by VAM3D-CG. TECPLOT (document not supplied) creates flowlines as demonstrated in Hanford Site application. Mass balance input defined in Section 8.

   VAM3D-CG outputs on moisture contents through model domain, contaminant concentrations, and fluxes at user-chosen points (specified nodes), internal surfaces and/or along boundary segments, all as functions of time, are controlled via Group 5 input variables . . . .

   Via TECPLOT, the code is able to draw flow lines for user chosen source points. TECPLOT is a commercial graphical package . . . VAM3D-CG is able to report mass balance errors at each time step for both flow and transport; the option is invoked by setting IMBAL=1 on Group 5 input data.

J. Interface Between Moisture Flow and Contaminant Transport

1. **Requirements.** The proponent of the code shall document that the code is able to perform a moisture flow simulation only, a steady-state contaminant transport simulation based on a previously run moisture flow calculation, and a combined moisture flow/contaminant transport simulation performs. The proponent shall also document that redundant information is not needed for a combined moisture flow/contaminant transport simulation.

2. **PORFLOW.** Met/Met. The original proposal (Runchal 1998a) indicates that requirement met and past Hanford Site applications also indicate that requirement is met. The revised proposal (Runchal 1998b) documents use of SOLVE, SAVE, and RESTART commands.

3. **STOMP.** Met/Met. Solution Control Card (Section A.2 of White 1997).
As referenced in the STOMP User's Guide, the STOMP simulator has options for executing a flow only simulation, a transport only simulation, or a combined flow and transport simulation. . . . Sequencing the solute transport equation solutions allow for first order chemical reactions and radioactive chain decay, but does not allow for complex chemical systems to be resolved. . . .Converting between the three different simulation types only requires single word modification to the input file; no duplication of input file variables is required.

4. **VAM3D-CG.** Met/Met. From Section 8 of HG (1994) (Input Data Preparation).
VAM3D-CG can perform a moisture flow simulation only, a steady-state contaminant transport simulation based on a previously run moisture flow simulation and a combined moisture flow/contaminant transport simulation. Note that for a combined VAM3D-CG moisture flow/contaminant transport simulation, only one set of input file is required; no redundant input files is required.

V. DESIRABLE FEATURES

These items are features which the code should have, but the absence of which will not disqualify a code. However, code selection will depend on the applicability of these desired features. Notably poor performance on a desired feature (such as excessive cost) can be reason for code disqualification. The following sections are listed in order of priority.

A. Ease of Use

1. **Criteria.** The proponent of the code shall document the pre- and post-processing modules that aid user's use of the code and the user's understanding of the output of the code. In particular, the capability to graphically display the numerical grid discretization along with zone identifiers, the contaminant, and moisture fluxes across selected boundaries and/or regions in the modeling domain and contours, spatial cross sections, and time histories of contaminant concentrations is highly desired. The pre- and post-processing systems can be commercial or public domain products not developed by those responsible for the vadose zone code.

   (General note: responses poorly documented ease of use.)

2. **PORFLOW.** 40%/60%. A GUI (undescribed and undocumented) is available for Windows 95 and NT operating systems and is under development for UNIX. A post-processor is available, but is not described or documented. Because of output format, third party software can be used. The validation documentation could not be downloaded from the website. Because of illness, there is no experienced user of PORFLOW in the Hanford Site community and the proposal was submitted by the code developer. Based on proposal's lack of responsiveness, the difficulty of interface with nonlocal users and lack of providing helpful information, ranking is downrated.

   PORFLOW provides on-line manual for problem setup and an acrSHELL work environment. The acr PLOT post processor provides for XY, Vector, Contour, Raster, 3D Surface, and Profile plots. In addition, PORFLOW provides an open file format which has been integrated with powerful post-processing packages such as TECPLOT, SURFER, PLOT3D, etc.

   The code developer has indicated a willingness to establish a local office and provide a senior knowledgeable staff should PORFLOW be chosen.

3. **STOMP.** 50%/60%. Input format is flexible and is checked by code. A graphical interface is available for Macintosh (which is not hardware under consideration). A link between GIS and input is under development. Several undocumented post-processing utilities are available. However, calculation of flowlines (a mandatory requirement) is difficult and is discouraged. Property changes require restarting

the run rather than a smooth transition during a run. Downrated because of lack of specificity and comparison to other codes.

The simulator contains a considerable amount of error check utilities and will provide the user with information about the type of error that was discovered.

This utility (GEOSTOMP) will provide an interface between geologic data contained in GIS or Earth vision, geohydrologic descriptions of the rock/soil types . . . .

Several undocumented post process utilities have been written for the STOMP simulator, that are primarily used to convert output in the "output" and "plot" files to formats required for plotting or visualizing.

PNNL has a local staff knowledgeable of the program, however, code is the least developed of the alternatives.

4. **VAM3D-CG.** 50%/70%. Undocumented pre- and post-processors are available. The use of curvilinear coordinates is a significant feature given that structural components and geologic layers will not be parallel to surface or to each other. However, property changes require restarting the run rather than a smooth transition during a run. Downrated because of lack of specificity and comparison to other codes.

   RETC is a code that provides best fit curve to measured data on soil hydraulic properties . . . . VAMGEN is a customized pre-processor which generates a geometry of the numerical grid discretization along with zone identifiers. VAM2TEC is a post-processor that reads the output files . . . and formats the data for use with the graphical package TECPLOT to display . . . .In addition, at HGL, VAM3D-CG is fully integrated with ARGUS MESH MAKER . . . to generate finite-element mesh with GIS interface.

   Some local staff is available through FDNW and teaming with Hydro Geologic, Inc.

B. Certification/Verification/Benchmarking

1. **Criteria.** The proponent of the code shall supply documentation of such testing. The experimental data need not be from the Hanford Site, but should reflect similar environmental conditions (dryness, geochemistry). The proponent shall also supply any information concerning verification/benchmarking simulations against other codes which are relevant for Hanford Site vadose zone-like conditions.

2. **PORFLOW.** 80%/80%. Validation document could not be downloaded from web site. Alternate website could not be contacted. The proposal states a large number of users of the code, but provides no references to documents providing

certification, verification, and benchmarking data in this section. List of publications does provide some (including Hanford Site) references. Because of its use in 98 ILAW PA, PORFLOW is known to have a well documented testing base. Downrated because of poorness of response. Even revised proposal (Runchal 1998c) does not provide references.

3. **STOMP.** 100%/80%. The proposal referenced and supplied good documentation on benchmarking. Documents are cited for Hanford Site-relevant conditions including the relevant simulation of the Sisson-Lu experiment.

   Although the verification process has been formally documented in the STOMP Application Guide, the simulator continues to be compared against analytic solutions, numerical solutions, and experimental data.

   With respect to benchmarking against field experiments at the Hanford Site, the simulator was applied against the injection experiment of Sisson and Lu. There is implied benchmarking against Las Cruces Trench Site.

4. **VAM3D-CG.** 100%/100%. The proposal referenced and supplied good document action on benchmarking. Documents are cited for Hanford Site-relevant conditions including the relevant simulation of the Sisson-Lu experiment.

   Detailed information on VAM3D-CG certification, verification, and benchmarking for the Hanford Site is provided in Appendices B and C. Additional testing of VAM3D-CG using data from a field experiment (Sisson and Lu 1984) in 200 East Area is described by Lu and Khaleel (1993). Additional benchmarking and testing identified . . . .

C. Reputation Among User Community

1. **Criteria.** The proponent of the code shall document examples of use of the code beyond the developing organization. The proponent shall document whether the code has been accepted by the U.S. Environmental Protection Agency (EPA) and the Washington State Department of Ecology (Ecology) for environmental analyses for the Hanford Site. If the code has not been accepted, then the proponent shall indicate plans for achieving such acceptance. The code proponent shall supply the authors, title, and document identifiers of some of the reports which have used the code to model moisture flow and contaminant transport in the Hanford Site vadose zone. The proponent shall indicate for each report cited the type of external review that was conducted. Such external reviews shall be provided if requested.

2. **PORFLOW.** 60%/100%. The proposal notes that PORFLOW has been used by a wide variety of users. Although unstated by the proposal, but of significant importance, is the use of PORFLOW in the 98 ILAW PA (Mann 1998) as well as performance assessments at other DOE sites. The proposal makes no acknowledgment of acceptance of the code by the EPA or Ecology for use at the

Hanford Site, although a earlier version has been accepted for Hanford Site use by the two agencies. The proposal does not "indicate for each report cited the type of external review that was conducted." Even though PORFLOW has an extremely high reputation among the user community, the proposal was downrated because of lack of responsiveness.

The proposal included a long list of users and references including the U.S. Nuclear Regulatory Commission (NRC) and numerous DOE contractors.

3. **STOMP.** 25/50%. As noted by the proposal, because of the newness of the code, STOMP has not yet developed a large user reputation. However, it was used by the Hanford Site Environmental Remediation Contractor (although not for 200E Area analyses) and by a member of the NRC staff. Significant concerns are that the output files contain the disclaimer "Results from this version of STOMP should not be used for license related applications." The analyses to be performed, if not "license related applications," are at the same level as they will be reviewed as part of a regulatory decision making process by the DOE, the NRC, and Ecology. The proposal notes discussion has been held with EPA concerning the use of STOMP on Hanford Site analyses, but makes no indication whether conversations have been held with Ecology (the lead agency for most of our activities). Downrated because of lack of acceptance in user community, "license-related" remark, and because of lack of discussions with Ecology.

   The simulator has gained recognition among the Hanford Site community through the application by M. Connelley at CH2M Hill Incorporated.

   Extensive academic usage: Oklahoma Christian University has used the simulator as part of the curriculum for an engineering design class. Ed Hill at the University of North Carolina used the simulator to investigate the behavior of DNAPL pools during enhanced remediation by surfactant and co-solvent flushing.

   Stomp has yet to be formally accepted by EPA or Ecology.

4. **VAM3D-CG.** 95%/90%. The proposal notes that EPA and Ecology have accepted VAM for Hanford Site uses in 1990; however, this was for earlier version of code. The proposal notes that code has been used in Hanford Site performance assessments approved by DOE. The proposal also notes approval of analyses by NRC using code. Proposal slightly downrated because of much earlier version approved by EPA and Ecology not recent version, but this probably reflects more on agencies than on code.

   Under TPA milestone M-29-01 "Description of Codes and Models to be Used in Risk Assessment," a committee was established in 1990 comprised of personnel from RL, contractors, and regulators. The committee recommended that VAM2D, a predecessor of VAM3D-CG, be selected as one of the vadose zone codes at Hanford. A series of peer-reviewed articles (Huyakorn, et al. 1986, 1985, 1984;

McCord, et al. 1991) on VAM3D-CG and its predecessors have appeared in Water Resource Research, a journal that is ranked number one in impact factor in the water resource category by the ISI Journal Citation Reports.

Use by other DOE, U.S. Department of Defense (DOD), Superfund, Resource Conservation and Recovery Act of 1976 (RCRA), and commercial sites.

NRC funding of HG to develop VAM3D-CG.

D. Additional Contaminant Transport Capabilities

1. **Criteria.** The proponent of the code shall document whether the code has the ability to modify the K_d value and/or the diffusion parameter based on moisture content and whether the code can model sorption-enhanced dispersivity. The code proponent may submit additional capabilities that may be advantageous to TWRS.

2. **PORFLOW.** 80%/80%. The proposal claims that criteria are satisfied, but does not provide references to the user's manual and it is not obvious where in user's manual such capabilities are described. Note has been made of proposed added capabilities. The revised proposal (Runchal 1998c) repeats the claims, but does not provide significantly more information.

   In response to Mandatory Criteria G above: Time-Dependent Hydraulic and Geochemical Values; distribution and retardation co-efficients are stated to be arbitrary functions of time, space, phase variables, and user defined variables.

3. **STOMP.** 60%/60%. The proposal claims that the first two criteria are satisfied, but does not provide references to the user's manual. A modification of code to allow sorption-enhanced dispersion and to allow a single run of time dependent Kd would be easy.

   "The simulator also offers two models for the effective diffusion co-efficient as a function of aqueous saturation. The conventional model reduces the molecular diffusion co-efficient by the tortuosity and aqueous saturation . . . The current released version of the STOMP simulator does not address sorption-enhanced dispersivity."

4. **VAM3D-CG.** 75%/80%. The code handles moisture-dependent diffusion co-efficients and sorption-enhanced dispersivities and provides references to their collection in the user's manual. It does not handle moisture-dependent Kds but the capacity can be added. Note has been made of proposed added capabilities.

   VAM3D-CG does not accept Kd as a function of saturation, however, in computing the retardation factor, the variability in saturation is included. The code can be modified to account for variation in Kd due to saturation.

Additional capabilities that may be advantageous:

- molecular diffusion co-efficient
- sorption-enhanced dispersivity
- upstream weighting and uncertainty analysis
- flow and transport predictions with quantified uncertainty.

E. Additional Moisture Flow Capabilities

1. **Criteria.** The proponent of the code shall document the functional representations available in the code to represent hydraulic conductivity and moisture retention as well as the ability to treat saturation-dependent anistropy. The proponent shall document how the code treats moisture hysteresis. The code proponent may submit additional capabilities that may be advantageous to TWRS.

2. **PORFLOW.** 35%/70%. The proposal states a number of representations are available in the code, but does not point to reference in user's manual. No mention is made of hysteresis. Moisture-dependent anistrophy is available in an earlier version and could be easily added to current version. The revised proposal (Runchal 1998c) again makes claims, but does not add significantly more information.

   Options include Van Genuchten with Mualem and Burdine, Brooks and Corey with Mualem and Burdine, Exponential Characteristic, 4th Order Polynomial Characteristic, Logarithmic Characteristic, Power (and Inverse) Law Characteristic, Arbitrary Tabulated Values.

   In PORFLOW the user flexibility is further increased by the fact that the characteristic for saturation characteristic can be different than that for relative conductivity.

3. **STOMP.** 100%/70%. Criteria are in code and adequately presented in proposal. Added capabilities were noted.

   "Constitutive functions for relative permeability, saturation, and capillary pressure currently recognized by the STOMP simulator are shown in Tables 3 and 4. The hysteretic k-s-p model applied in the STOMP simulator for the Water Operational Mode follows the theory of Kaluarachchi and Parker . . ."

4. **VAM3D-CG.** 100%/70%. Criteria are in code and adequately presented in proposal. Added capabilities were noted.

   VAM3D-CG can use Brooks-Carey relationships for representing soil moisture characteristics data. Saturation-dependent anistropy option is invoked by . . . . This is a significant field-scale phenomenon for the dry, heterogenous sediments such as those expected beneath the ILAW disposal facility. VAM3D-CG can include soil moisture retention data for both main drainage and main wetting curves and can model hysteresis phenomena in flow calculations. Additional

VAM3D-CG capabilities of interest include mass lumping and Newton-Raphson technique and upstream weighting.

F. Decay Products

1. **Criteria.** The proponent of the code shall document those features of the code which allow different contaminant transport properties to be assigned automatically to progeny by the code based on position in the radioactive decay chain.

2. **PORFLOW.** 90%/100%. Proposal claims ability. Documented in ACRi 1998 using DECA line. Downrated because location not provided. The revised proposal (Runchal 1998c) again makes claim, but does not provide information.

3. **STOMP.** 90%/100%. Proposal claims ability, although how implemented could not be found in user's manual in a quick search. Proposal provides method of solution, a bonus.

   "As referenced in the STOMP User's Guide, the simulator can address multiple solutes with radioactive decay and complex decay chains."

4. **VAM3D-CG.** 40%/50%. Capability not available in submitted version, but could be added based on capability of alternate version.

   To model decay chain, VAM3D-CG uses RESTART option. VAM2D and VAM3DF model the chanted decay transport with much more ease. Benchmarking and certification of VAM3DF decay chain option $10K.

G. User Support

1. **Criteria.** The proponent of the code shall document available user support (including applicable costs). The code proponent shall also document relevant instances of user support.

2. **PORFLOW.** 50%/75%. Schedule of 1998 charges supplied. Proposal does not contain relevant instances of user support. Analytic and Computational Research, Inc. is a well established and well thought of company. However, based on responsiveness of proposal, user support may not be adequate.

   Telephone conversation indicates that ACRi would set up office in the Tri-Cities, if necessary, to support ILAW. The issue is dedicated knowledgeable staff tied to ILAW and it's needs. There would be several months learning for ACRi and devotion of project staff to support learning estimate $20 – $30K.

3. **STOMP.** 80%/75%. Applicable costs not supplied. However, proposal does provide instance of Hanford Site support. Major concern is that the code is still considered by developers as a scientific tool rather than as a tool used for license-type applications.

   "For private clients, government agencies, and government contractors, the policy has been to provide user support through a cost recovery basis. Because the original development team continues to apply and modify the simulator, the laboratory can offer full user support for STOMP, including application consulting, code modifications, and output interpretation. An example of user support for the stomp simulator being extended to a Hanford Site contractor is the investigative project of 90-Sr migration by M. Connelley at CH2M Hill."

4. **VAM3D-CG.** 90%/90%. Applicable costs not supplied. However, proposal does contain instances of Hanford Site support. More significantly, proposal contains teaming letter with commercial firm which developed VAM. A phone call from Connelley (1998) indicated that as of July 1, 1998, HydroGeologic, Inc. has opened a Northwest Office in Richland. However, rating was not changed.

   Five knowledgeable VAM3D-CG users are with Fluor Daniel Northwest, Inc. (FDNW) and its consultants. In addition to the code developer, a total of 25 VAM3D-CG modelers are with HydroGeologic, Inc. A teaming arrangement has been worked out with the code developer for ILAW modeling support.

H. Speed of Execution

1. **Criteria.** The proponent of the code shall provide evidence of the relative speed of the code.

   General Note: No comparison figures were provided.

2. **PORFLOW.** Not rated because of lack of information. However, code does provide a number of solvers. Past experience indicates that execution speed of PORFLOW is not a basis for elimination. The revised proposal (Runchal 1998c) is silent.

   To handle a variety of applications, it provides for a number of efficient matrix solvers. In addition, an interface is provided so that any external matrix solver can be used without any code modification.

   Typical execution time for a vadose flow problem on an Intel Pentium II 400MHz system is on the order of 0.02 millisecond per element per step per equation. This means that a flow and transport problem with 10,000 elements and 1,000 time steps can be completed in less than seven minutes.

3. **STOMP.** Not rated because of lack of information. However, according to the proposal, the predecessor to STOMP was slower than other codes because of use of multiple-phase calculations. As this application will be mainly single-phase application, STOMP is expected to be slower than other codes, but not to a significant extent.

   "The current release version of the STOMP simulator has not been subjected to a formal comparison for execution speed against comparable software. (The predecessor MSTS) - MSTS was executed against the multi-phase and single-phase codes for two isothermal, unsaturated flow problems. With respect to execution speed, MSTS was comparable to the other multi-phase simulators, but slower than the dedicated single-phase simulators. The STOMP simulator currently offers a variety of options to decrease execution time ..."

4. **VAM3D-CG.** Not rated because of lack of information. Past experience indicates that execution speed of VAM3D-CG is not a basis for elimination.

   A comparison of PORFLO and VAM3D-CG run times for a PA production run shows the processing times for the two codes are comparable and runs can be completed overnight.

I. Non-Proprietary Codes

1. **Criteria.** The proponent of the code shall document whether the code is proprietary. If the code is proprietary, then the code proponent must document that the source code will be made available by lease or purchase to the U.S. Department of Energy, Richland Operations Office (RL) and its contractors (including LMHC and its agents. The proponent shall also supply the licensing cost (and any other mandatory fees for the use of the code).

2. **PORFLOW.** 50%/50%. PORFLOW is a proprietary code. The source code is available by lease. License cost was provided. Downrated because code is proprietary.

   "We have reason to believe that PORFLOW can handle all current and future needs of the Hanford Site with minimal, if any, additional development costs." Any cost savings of a public domain code will be more than offset by the future development costs."

3. **STOMP.** 75%/75%. STOMP is a mixture of proprietary code and code developed under DOE support. The source code is available and there is no license cost. The parts that are proprietary will probably not be used by TWRS. Downrated because the code is not fully in public domain.

   Battelle maintains copyright on all versions, revisions, and operational modes of STOMP simulator as granted by the DOE with stipulation that Versions 1.x of the STOMP simulator be made available to Federal and State agencies. RL and its

contractors under Battelle's copyright stipulations will be provided a royalty-free copy of the STOMP software source coding for use on the TWRS environmental analysis program.

4. **VAM3D-CG.** 50%/50%. VAM3D is a proprietary code. The source code is at FDNW and is available from the code developer for inspection by other parties. License costs have already been paid by FDNW. Downrated because code is proprietary.

   Although proprietary, VAM3D-CG, Version 3.1, including the source code, is already available for FDNW use. The required licensing fees have been paid and no other mandatory fees are required. If needed, the source code for VAM3D-CG can be made available, via HGL, to a third party without additional fees for inspection and verification.

J. Version

1. **Criteria.** The proponent of the code shall document the history of code versions and shall indicate where the particular version submitted falls in this history.

2. **PORFLOW.** 75%/75%. PORFLOW, Version 4.0 is the latest version in a long line. However, no mention of the previous history is given in the proposal.

   PORFLOW, Version 4.0 is fully tested. The release of each version of PORFLOW is tested against a suite of 42 test problems. A beta version was released in mid-1997. The current version was released in December 1997. As such, it has already been in use by our clients for a few months.

3. **STOMP.** 90%/75%. The current version in Version 1, Revision 1. The proposal does not give indication of sub-versions (e.g., revision is 12). Information is obtainable from configuration management file.

   "The current release version of the simulator is Version 1, with various revision numbers depending on the particular library file. . . . currently carries the revision number 12 . . . . The RCS revision log which documents the modifications made to this file is shown in Figure 1."

4. **VAM3D-CG.** 100%/90%. History of versions provided.

   A timeline for different versions of VAM3D-CG is provided below:

   1988 - VAM2D
   1991 - VAM2D v 5.0
   1993 - VAM3D v 2.4b
   1994 - VAM3D v 3.1
   1995 - VAM3DF

1.0 INTRODUCTION

VAM3DF (typically called VAM) is a vadose zone/groundwater modeling code. The code and supporting documentation are provided by HydroGeoLogic (HGL). Earlier versions of VAM have been in use at the Hanford Site since the 1980's. Fluor Federal Services (FFS) has acquired this new version to support the 2001 ILAW PA. Prior to using this new version for production calculations, it is necessary to demonstrate that the code is adequately verified and validated. This report serves to document the verification and validation of VAM3DF.

VAM3DF has been verified and validated by HGL (Huyakorn and Panday 1999, and Appendix A). Earlier versions of VAM (e.g., VAM3DCG) have been verified and validated (Lu and Langford 1995 and Puigh, 1998) for use at Hanford. The new version, VAM3DF (Huyakorn and Panday 1999), is substantially the same as version VAM3DCG but with the addition of some significant new features. This new version provides an integration technique called 'data fusion' (which will not be used in the ILAW analyses), and provides for decay chain nuclide analysis. In addition, a variable anisotropy feature has been added. In order to qualify VAM3DF for use, it is necessary to complete an installation test of the code and show that the test cases produce the same results as published by HGL (which has validated the code). In addition, VAM3DF will be tested with Hanford specific cases, which were run on version VAM3DCG, to show that any differences in the calculational results (between this version and the previous) are within acceptable limits.

2.0 FFS NT COMPUTER SYSTEM

2.1 Hardware

VAM3DF will be run on the FFS Advanced Computing Center (ACC). This system is composed of a network of Intergraph PC type computers. Each computer is based on an Intel Pentium II Xeon processor. The individual computers have some variations (such as clock speed and amount of RAM) but are generally similar. The minimum configuration is a 400 MHz cpu, 256 MB RAM, and 9.1 GB hard disk (partitioned into smaller drives).

The installation and detailed testing were conducted on one specific computer, id# NW30032274 (currently located in 1200 Jadwin, Room 448).

2.2 Operating System

All of the computers (that will be used for running VAM) in the ACC are running the Microsoft Windows NT operating system, version 4.0, service pack 3.0 or higher.

3.0 VAM INSTALLATION

VAM3DF was provided by HGL as an NT executable and a dynamic link library (dll) file. Installation of the VAM3DF code only required placing the two files in the desired directory on the host machine.

4.0 VERIFICATION TESTING

Verification testing is intended to assure that the code is calculating results correctly. This can be done by running test cases and demonstrating that the code produces essentially the same results with the new installation as it did with the previous installation. Verification can also be accomplished by comparing results to hand calculations or other data sources. Both of these methods were employed in verifying VAM3DF.

4.1 Test Cases

A suite of cases has been identified for testing the VAM installation. This suite consists of three cases provided by HGL, two cases from a previous Hanford modeling effort (using VAM3DCG), and a variation of one of the Hanford cases to test the new decay chain feature. In addition, three cases were constructed to demonstrate new features (decay chain with variable Kd, and variable anisotropy) that are not amenable to formal validation. These cases were not compared to previous calculations but the results were reviewed qualitatively and will serve as comparisons for new code versions that may be installed in the future. A copy of each of the input files is included in Appendix B. The cases are described below:

1) 2-D Transient Unsaturated Flow in a Rectangular Slab

2) 2-D Transient Solute Transport in a Rectangular Slab

3) 2-D Concurrent Flow and Transport in a Rectangular Slab

4) Vadose and Groundwater Flow Beneath a Solid Waste Trench

5) Solute Transport Beneath a Solid Waste Trench

6) Solute Transport Beneath a Solid Waste Trench with Uranium Decay

7) Solute Transport Beneath a Solid Waste Trench with Decay and Variable Kd.

8) Isotropic Vadose Flow.

9) Anisotropic Vadose Flow.

Case 2 uses the results from case 1 as an input, and case 3 is equivalent to the combination of case 1 and case 2. Cases 5, 6, and 7 use the results of case 4. Case 8 is used as a comparison for case 9.

4.2 Verification Test Results

All of the cases were run on the ACC. For the first five cases, the output files from the benchmark runs were copied to the ACC and the equivalent files from each case were compared. For the sixth case, the results were compared to hand calculations.

4.2.1 HGL Test Cases

The three installation test cases (cases 1-3) were compared to the HGL output files using a 'diff' utility. This comparison indicated that the output files were identical.

4.2.2 Hanford Benchmark Cases

The two Hanford cases (cases 4-5) produced very similar but not identical results when run with VAM3DF and compared to VAM3DCG calculations. This is expected due to the changes in the modeling methods employed in VAM3DCG. The flow runs were compared by using a visualization program (Tecplot) to view the flow field. The overall fields were compared visually and a selection of specific points were compared numerically. The results of the VAM3DF calculation were vertical velocity values of 0.0500 cm/yr throughout the vadose zone (this is equal to the recharge rate and is therefore the 'correct' solution). The results of the VAM3DCG calculation were vertical velocity values of 0.0499 cm/yr. This difference of less than 1% is considered acceptable. The transport cases were evaluated using the mass reaching the 100 m well (one of the primary results of the modeling effort). This value was plotted against time for both cases and found to be nearly identical, with a time offset and magnitude change of less than 2 %. This level of agreement is considered acceptable.

4.2.3 Decay Chain

The Hanford transport benchmark case (case 5) was also set up as a decay chain problem (case 6), using an abbreviated uranium decay chain and a Kd of 100 L/mg for all species (the Kd was set to a large value to facilitate the verification effort). The mass percentage in each daughter nuclide was calculated by summing the nodal results produced by the code. As a check, the expected values were calculated using the Bateman equations (Lapp and Andrews 1972) shown below. The results of these calculations are shown in Table 4.1. As can be seen, the differences are small (<1% for the worst case).

$$A_1(t)=A_1(0)e^{-\lambda_1 t}$$

$$A_2(t)=A_1(0)*(\lambda_2/(\lambda_2-\lambda_1))*(e^{-\lambda_1 t} - e^{-\lambda_2 t})$$

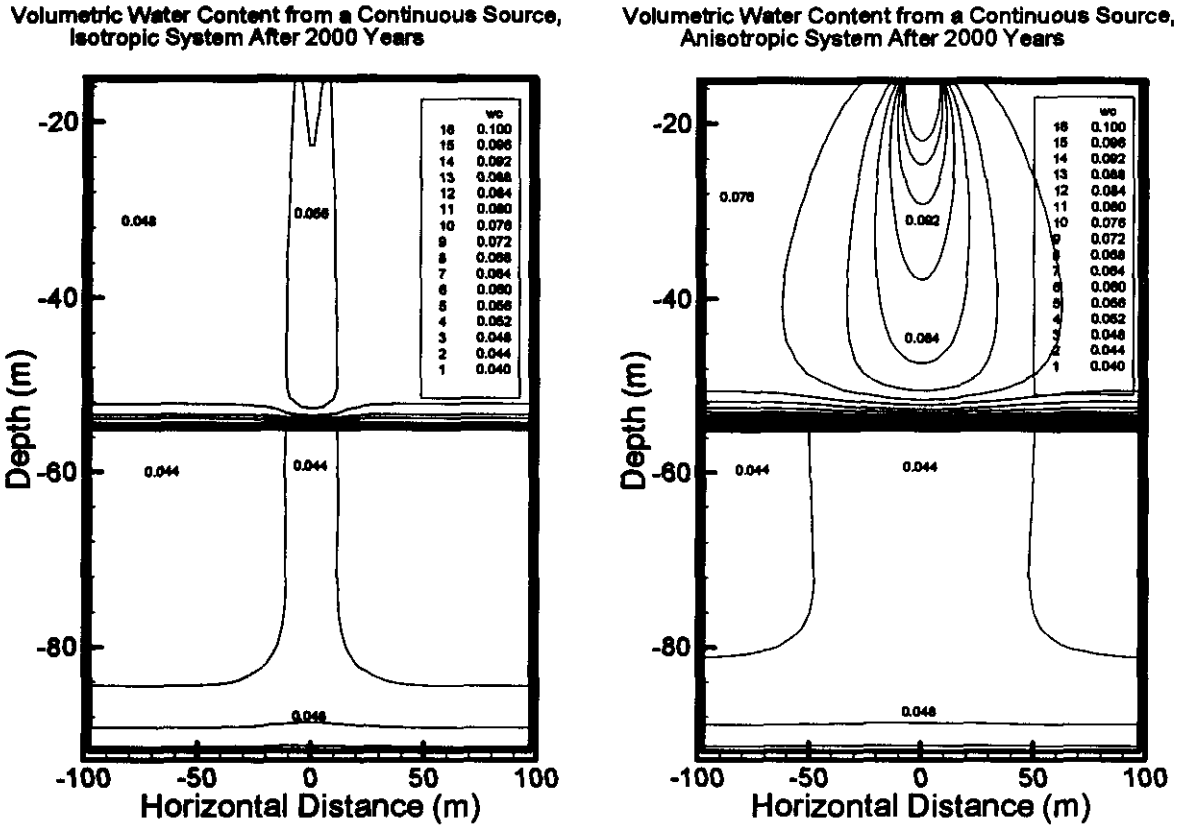
$$A3(t)= A_1(0)*(\lambda_1\lambda_2)*(a*e^{-\lambda_1 t} + b*e^{-\lambda_2 t} + c*e^{-\lambda_3 t})$$
$$a=(1/((\lambda_2-\lambda_1)*(\lambda_3-\lambda_1))$$
$$b=(1/((\lambda_1-\lambda_2)*(\lambda_3-\lambda_2))$$
$$c=(1/((\lambda_1-\lambda_3)*(\lambda_2-\lambda_3))$$

$$A4(t)= A_1(0)*(\lambda_1\lambda_2\lambda_3)*(a*e^{-\lambda_1 t} + b*e^{-\lambda_2 t} + c*e^{-\lambda_3 t} + d*e^{-\lambda_4 t})$$
$$a=(1/((\lambda_2-\lambda_1)*(\lambda_3-\lambda_1)*(\lambda_4-\lambda_1))$$

$b=(1/((\lambda_1-\lambda_2)*(\lambda_3-\lambda_2)*(\lambda_4-\lambda_2))$
$c=(1/((\lambda_1-\lambda_3)*(\lambda_2-\lambda_3)*(\lambda_4-\lambda_3))$
$d=(1/((\lambda_1-\lambda_4)*(\lambda_2-\lambda_4)*(\lambda_3-\lambda_4))$

Table 4.1

Nuclide Id	Initial Activity (Ci)	Decay Constant (yr^{-1})	Activity at t=100,000 yr (Bateman Eqns.)	Activity at t=100,000 yr (VAM3DF Calculations)
U235	1	1.55e-10	9.9998E-01	9.9998E-01
Th230	0	9.19e-6	1.0144E-05	1.0143E-05
Bi210	0	2.31e-7	5.3272E-06	5.3407E-06
Pb206	0	0.0	4.4102E-08	4.4361E-08



4.2.4 Decay Chain with Variable Kd

The decay chain case (case 6) was also run with variable Kd's (case 7) to test the effect of this option. It is not practical to check the results of this calculation with a hand calculation but the results can be evaluated qualitatively to ascertain that the results are reasonable. In this case the four isotopes modeled in the decay chain case described in section 4.2.3 were each given a different Kd. The relative formation and transport of each of the different isotopes were then compared and found to be consistant with their relative decay coefficients and Kd values.

4.2.5 Variable Anisotropy

Two numerical simulations were run, one using an anisotropy option (case 9) within VAM3DF and the other for an isotropic case (case 8). There are three anisotropy options included in version 2.0 of the VAM3DF code (Huyakorn and Panday 1999). The anisotropy simulation presented here uses the third option based on the work of Polmann (1990). The results of the simulations are shown in Figure 4.1. This figure shows that the moisture distribution in the upper sand layer is much higher for the anisotropic case than for the isotropic case. In the lower gravel there is more spread in the anisotropic case but the water content ranges are much closer for both isotropic and anisotropic systems. This suggests that the upper sand absorbs much of the water and dominates the system. These results are qualitatively what would be expected for the inclusion of an anisotropic condition.

Figure 4.1. Simulated Water Contents For The Isotropic And The Variably Anisotropic Conditions

5.0 CONFIGURATION MANAGEMENT

All files associated with the installation and testing of VAM3DF on the ACC were placed on the hard disk of cpu NW30032274. A directory was created, e:\data\vam\vam3df\benchmark, for storing all of the files.

The executable file is named vam3df100.exe, and is identified as VAM3DF version 1.00, FFS installation version 1.00. The executable file and the library file, tecutil.dll is stored on cpu fdnweng02, in subdirectory \\applications\vam\bin.

7.0 CONCLUSION

VAM3DF has been verified for use on the ACC. The code was installed, and the test cases were run and produced identical results to the previous (HGL) installation. Test cases using Hanford site models were run and compared to the same models run with the previous version of Vam (VAM3DCG). These cases produced results that had differences in the results that were within acceptable limits. This gives confidence that cases run with the old version of Vam are still valid.

CHECKLIST FOR TECHNICAL PEER REVIEW

Document Reviewed:	HNF-5769 Rev. 0
Title:	Verification and Validation for VAM3DF, Version 1.00 (FFS version 1.00)
Author:	Scott H. Finfrock
Date:	January 24, 2000
Scope of Review:	Full Document

Yes	No*	NA	
[ ]	[ ]	[X]**	Previous reviews complete and cover analysis, up to scope of this review, with no gaps.
[X]	[ ]	[ ]	Problem completely defined.
[ ]	[ ]	[X]	Accident scenarios developed in a clear and logical manner.
[X]	[ ]	[ ]	Necessary assumptions explicitly stated and supported.
[X]	[ ]	[ ]	Computer codes and data files documented.
[ ]	[ ]	[X]	Data used in calculations explicitly stated in document.
[X]	[ ]	[ ]	Data checked for consistency with original source information as applicable.
[ ]	[ ]	[X]	Mathematical derivations checked including dimensional consistency of results.
[X]	[ ]	[ ]	Models appropriate and used within range of validity or use outside range of established validity justified.
[ ]	[ ]	[X]	Hand calculations checked for errors. Spreadsheet results should be treated exactly the same as hand calculations.
[X]	[ ]	[ ]	Software input correct and consistent with document reviewed.
[ ]	[ ]	[X]	Software output consistent with input and with results reported in document reviewed.
[X]	[ ]	[ ]	Limits/criteria/guidelines applied to analysis results are appropriate and referenced. Limits/criteria/guidelines checked against references.
[ ]	[ ]	[X]	Safety margins consistent with good engineering practices.
[X]	[ ]	[ ]	Conclusions consistent with analytical results and applicable limits.
[X]	[ ]	[ ]	Results and conclusions address all points required in the problem statement.
[X]	[ ]	[ ]	Format consistent with applicable guides or other standards.
[ ]		[X]**	Review calculations, comments, and/or notes are attached.
[X]	[ ]	[ ]	Document approved (for example., the reviewer affirms the technical accuracy of the document).

LETTER OF CERTIFICATION

This page intentionally left blank

HYDRO GeoLogic INC.

JAN 04 RECD.

Letter of Certification.

This is to certify that I have checked the decay chain option and the Polmann variable anisotropy option that have been programmed in the latest version of VAM3DF by Dr. Kim, and that they have been correctly implemented and verified.

Please call me at 703-736-4567 if you have any questions.

Sincerely

Sorab Panday

APPENDIX G

Geologic Data Package for 2001 Immobilized Low-Activity Waste Performance Assessment

S. P. Reidel
D. G. Horton

December 1999

Prepared for
the U.S. Department of Energy
under Contract DE-AC06-76RLO 1830

Pacific Northwest National Laboratory
Richland, Washington 99352

This page intentionally left blank.

Summary

This database is a compilation of existing geologic data from both the existing and new immobilized low-activity waste disposal sites for use in the 2001 Performance Assessment. Data were compiled from both surface and subsurface geologic sources. Large-scale surface geologic maps, previously published, cover the entire 200-East Area and the disposal sites. Subsurface information consists of drilling and geophysical logs from nearby boreholes and stored sediment samples. Numerous published geological reports are available that describe the subsurface geology of the area. Site-specific subsurface data are summarized in tables and profiles in this document.

Uncertainty in data is mainly restricted to borehole information. Variations in sampling and drilling techniques present some correlation uncertainties across the sites. A greater degree of uncertainty exists on the new site because of restricted borehole coverage. There is some uncertainty to the location and orientation of clastic dikes across the sites.

1.0 INTRODUCTION

The Office of River Protection at the Hanford Site is responsible for safe underground storage of liquid waste from previous Hanford Site operations, storage and disposal of immobilized tank waste, and closure of underground tanks. The current plan is to place immobilized low-activity tank waste (ILAW) in four existing vaults along the east side of 200-East Area and in new facilities in the south-central part of 200-East Area (Figure 1.1) (Mann et al. 1998).

This report is a compilation of geologic information for the existing disposal site and the new ILAW disposal site. This data package is being assembled for the 2001 ILAW Performance Assessment (PA). Basic requirements for the ILAW Performance Assessment are defined in Mann et al. (1998). Specific scenarios that will be considered in the 2001 PA are discussed in Mann (1999). These scenarios assume that the main pathway for exposure from the ILAW sites involves water movement into and through the disposal facilities with dissolution of waste followed by transport of contaminants through the vadose zone to the unconfined aquifer and transport in the aquifer to a water supply well. Estimates of possible exposure will be made from predictions of subsurface flow and contaminant transport using numerical simulations. The geologic framework for the numerical model will be developed from this report.

1.1 SCOPE

Data for the 2001 performance assessment will be derived from the following sources:

- **Geology**. Geologic Data Package for the 2001 Immobilized Low-Activity Waste Performance Assessment (this report).
- **Near-Field Hydrology**. Near-Field Hydrology Data Package for the Immobilized Low-Activity Waste 2001 Performance Assessment (Meyer and Serne 1999).
- **Far-Field Hydrology**. Far-Field Hydrology Data Package for the Immobilized Low-Activity Tank Waste Performance Assessment (Khaleel 1999).
- **Recharge**. Recharge Data Package for the Immobilized Low-Activity Waste 20001 Performance Assessment (Fayer et al. 1999).
- **Geochemistry**. Geochemical Data Package for the Immobilized Low-Activity Tank Waste Performance Assessment (Kaplan and Serne 1999).
- **Inventory**. Immobilized Low-Activity Waste Inventory Data Package (Wootan 1999).

The geology data provided in this report concentrate principally on stratigraphy and structure of the two areas. The mineralogy of sediments and their geochemistry is presented in the geochemistry data package. The physical, hydraulic, and transport properties of the soils sediments are presented in the far-field data package and the near-field data package.

This geology data package is a compilation of the basic stratigraphic and structural framework of the two sites and a description of the principal sediments. In addition, this report includes a summary on the sources and uncertainties of the data.

It is beyond the scope of this report to integrate the physical, hydraulic, and transport properties reported in the other data packages. An integration of all the physical, hydraulic, and transport properties of the stratigraphic layers from the ILAW sites will be done in preparation for the numerical simulations for the PA.

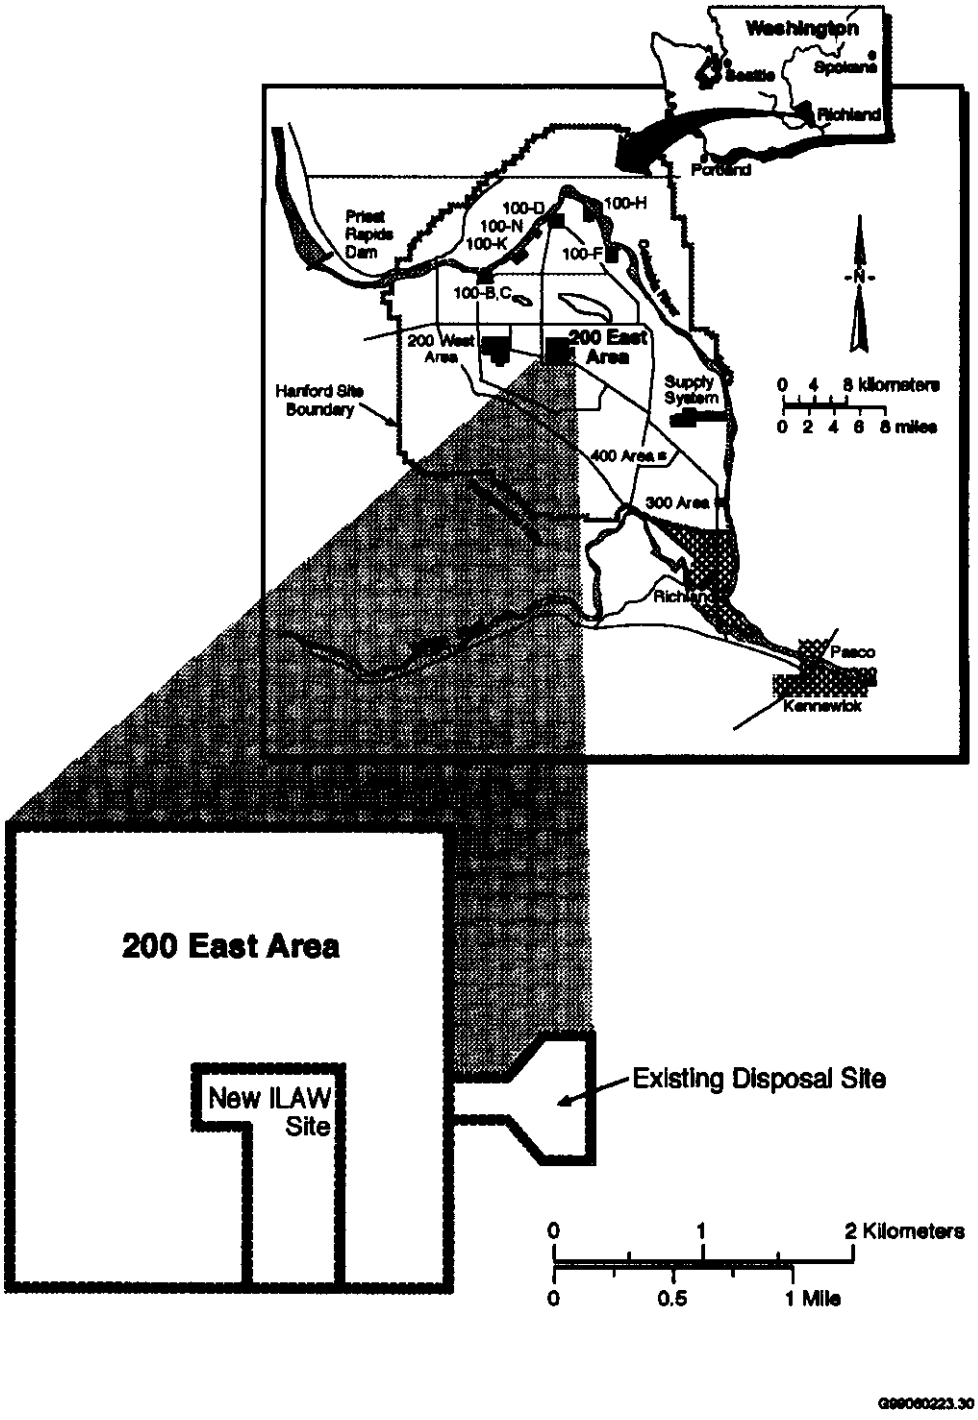

Figure 1.1. Location Map of the Existing Disposal Site and the New ILAW Disposal Site

2.0 SOURCE OF DATA

Data used in this compilation was obtained from surface geologic studies and from borehole data.

2.1 SURFACE DATA

The surface geology and geomorphology of the Hanford Site has been mapped and published by Reidel and Fecht (1994a, 1994b). The physiography of the Hanford Site is dominated by the low-relief plains of the Central Plains physiographic region and anticlinal ridges of the Yakima Folds physiographic region. Surface topography has been modified within the past several million years by geomorphic processes related to 1) Pleistocene cataclysmic floods, 2) Holocene eolian activity, and 3) landslides.

Cataclysmic flooding of the Hanford Site occurred when ice dams in western Montana and northern Idaho were breached, allowing large volumes of water to spill across eastern and central Washington. The last major flood occurred about 13,000 years ago, during the late Pleistocene Epoch. Anastomosing flood channels, giant current ripples, bergmounds, and giant flood bars are among the landforms created by the floods and are readily seen on Site. Most of the large landslides in the region occurred when these flood waters eroded steep slopes of the anticlinal ridges and along the White Bluffs.

The 200-East Area is located on the Cold Creek bar, one major Pleistocene flood bar. Since the end of the Pleistocene, winds have locally reworked the flood sediments, depositing sand dunes in the lower elevations and loess (windblown silt) around the margins of the Pasco Basin. Sand dunes have generally been stabilized by anchoring vegetation except where the dunes have been reactivated when vegetation is disturbed.

2.2 BOREHOLE SOURCES

Borehole data consisting of drilling logs, archive samples, and geophysical logs provide the principal data used to interpret the subsurface at the existing disposal site and the new ILAW disposal site. In addition, numerous reports describing the geology of the area and vicinity are available and a valuable source of information (e.g., Tallman et al. 1979; DOE 1988; Connelly et al. 1992; Lindberg et al. 1993; Lindsey et al. 1992, 1994b).

Tables 2.1 and 2.2 summarize information about the wells and boreholes used in this report. The north-south and east-west coordinates listed in Tables 2.1 and 2.2 were obtained from the well completion report for each borehole or, if no well completion report was available, from the well location database maintained by Pacific Northwest National Laboratory (PNNL). If several surveys for the same well were found in the database, the most recent survey was used. The specific survey associated with borehole locations obtained from well completion reports is not known but should not affect significantly the information in this data package.

Table 2.1. Borehole Information for Some Boreholes in and Adjacent to the Existing Disposal Site

Borehole #	Completion Date	Lambert Coordinates NS/EW (m)	Hanford Coordinates NS/EW (ft)	Casing Elevation (ft)	NAVD88, TOC[a] (m)	Ground Surface Elevation (ft) (brass plate)	Total Depth (ft)	Type of Log	Drilling Method[b]	Sieve	$CaCO_3$	Moisture	Gross Gamma-Ray Log	Neutron Log	Drill Cuttings

NA = Not available.

Elevation information listed in Tables 2.1 and 2.2 were obtained from well completion reports or as-built diagrams if available, or from Chamness and Merz (1993). Because several different borehole surveys have been used at the Hanford Site over the years, no attempt was made to assure consistency in the elevation survey data. However, differences among surveys are generally small (<3 feet [1 m]) compared to other uncertainties associated with the data (see discussion on uncertainties) and, except for water levels in areas with a relatively flat water table, will not affect significantly the information presented in this database. The well completion dates for the boreholes, the total depths, and the types of boreholes were obtained from well completion reports, as-built diagrams, and Chamness and Merz (1993).

Particle size distribution and calcium carbonate content information are available for some boreholes from the ROCSAN database. The database is no longer maintained but is on file at PNNL. Tables 2.1 and 2.2 indicate the drilling method used for each borehole. ROCSAN data was only considered for intervals in boreholes sampled by drive barrel because hard tool drilling pulverizes the sediments so that results are not representative of actual particle size distribution. The drilling method was obtained from geologists logs, well construction reports, and as-built diagrams for most boreholes. Appropriate particle size distribution data from ROCSAN was used as supplemental textural information but, because of varying data quality, it is not included in this report. The Khaleel (1999) and Fayer et al. (1999) report on particle size data from the two disposal sites are the best compilation of particle size information from the two sites for the ILAW 2001 PA. Meyer and Serne (1999) report similar data on near-field material for the two sites.

Calcium carbonate and moisture contents are available for some boreholes. Available data are in borehole packages on file at PNNL and in the ROCSAN database. The data were obtained from discrete samples collected by the borehole geologist during drilling. Moisture data were used to supplement the geologists log and the gross gamma-ray log in determining lithologic variations. For obvious reasons, moisture data is only valuable for samples collected above the water table. Khaleel (1999) and Fayer et al. (1999) report moisture data from the disposal sites and should be referred to for the best compilation of moisture data from these sites.

Gross gamma-ray logs and neutron moisture logs exist for many of the boreholes used for this report. If at all possible, logs obtained during drilling were used to supplement geologist logs. This is important for moisture measurements because most of the geophysical logs obtained subsequent to borehole completion reflect borehole construction materials more than they do geologic materials. Available logs listed in Tables 2.1 and 2.2 are on file at PNNL.

Finally, drill cuttings are available from most boreholes used for this report. The same precautions pertaining to ROCSAN data pertain to physical samples. That is, drill cuttings obtained from hard tool drilling methods will yield an unrepresentative particle size distribution. Uncertainties in these data are discussed in Section 3.0. All available physical samples are on file in the Hanford Geotechnical Sample Library under custody of PNNL.

2.3 METHODOLOGY

The process of building the data package followed a series of steps designed to ensure data were used properly. First, the main stratigraphic units and contacts were identified in boreholes with geologists logs and geophysical data. Gross gamma-ray logs were examined with respect to geologist logs for geophysical signatures of the stratigraphy. For many boreholes from both sites, chip samples from the Hanford Geotechnical Sample Library were examined to help control the location of contacts and lithologies of stratigraphic units and lateral changes in the percentage of silt, sand, and gravel. Next, boreholes with driller's logs and gross gamma-ray logs were examined and compared to nearby wells and boreholes. Lastly, boreholes with only driller's logs were given the least priority for constructing the geologic models. These data were then used to construct the maps and cross sections in Section 4.0.

3.0 UNCERTAINTY IN DATA

The principal source of uncertainty is in borehole data. Surface mapping is well controlled at Hanford and has been done by geologists with extensive mapping experience at Hanford and in the Columbia Basin. The quality of borehole data is related to drilling technique, logging of the boreholes, and sample collection. Borehole data collection methods (i.e., grab samples) make subtle differences between some stratigraphic units such as silty sandy layers of the Hanford formation and units of the underlying Ringold Formation (e.g., upper Ringold) difficult to identify. The use of geophysical logs is crucial to reducing uncertainty in poor quality driller and geologists logs.

In addition to the uncertainty in borehole data, there is uncertainty in the geometric shape of the sediment body. Lindsey (1996) provides a detailed depositional model for the Ringold Formation but few models are available on the Hanford formation. Borrow pits and excavation sites at Hanford (e.g., FFTF, tank farms, burial grounds, US Ecology) in the Pasco Basin provide information on the geometric shape of a sediment body but boreholes remain the principle means of collecting data to interpret the subsurface.

3.1 DRILLING METHODS

Most boreholes at and near the existing disposal site and the new disposal site have been drilled using cable tool techniques and, less often, air rotary techniques. Only the new ILAW borehole, 299-E17-21, was drilled using the Becker-Hammer technique that allowed high quality core samples to be recovered.

Cable tool drilling has been the standard technique from earliest drilling at Hanford because drilling can be done without adding water; unfortunately, many drillers routinely added water. Drilling techniques include use of drive barrel or hard tool and by driven temporary or permanent casing. The technique generally provides acceptable sample control and has proven successful. More recently, in uncontaminated areas, air rotary has been the preferred technique. Samples obtained from most drilling methods have inherent disadvantages. These disadvantages include:

- **Limited sample size**. The diameter of the borehole and length of the sampling device control the size of the sample.
- **Retention of samples**. Dry sediment samples are difficult to retain in any sampling device. This is especially true in drive barrels but also true of core barrels.
- **Gravel retrieval**. Unconsolidated gravels are not easily retained in drive barrels. Split spoon samples have better success.
- **Depth control**. Except for cored samples, the exact depth of a sample is not well controlled because part of the sample may be lost or sluffing may occur.

- **Cemented gravels.** Cemented gravels or large gravels must be sampled using a "hard tool." All drilling methods requiring hammered drilling and sampling including a split spoon breaks up the sample. Cemented gravels have been successfully cored but some loss is always to be expected.

Most boreholes prior to the 1980s were drilled without a well-site geologist to log samples. Thus, the only records of early drilling are driller's logs that vary in quality of the sample description. Driller's logs reflect lack of geologic knowledge, detailed descriptions, and accuracy of sampling interval. The quality of the geologists logs also varies from borehole to borehole. For example, a geologist new to the site will recognize the major sediment changes in drill cuttings but may not recognize the subtler changes that also represent changes in stratigraphy. Various procedures used to log sediments can result in different descriptions, which may not be directly comparable to other borehole sample descriptions.

Many boreholes at Hanford were completed without the benefit of being geophysically logged. Geophysical logging can be an important tool for determining lithologic changes. Geophysical logs show subtle lithology differences stemming from differing amounts of natural gamma-ray emitters (most commonly ^{40}K). At Hanford, gamma-ray logs typically indicate clay and silt abundance and can provide information on changes in grain size. When geophysical logs are used along with well-site geologist's logs and archived samples, the uncertainty of the depth of lithologic changes is reduced.

3.2 BOREHOLE LOCATION AND COVERAGE

Borehole coverage is usually dictated by factors other than just addressing a geologic problem. Therefore, the coverage of boreholes is generally inadequate to address many geologic problems. For the existing disposal site, there is borehole coverage for most of the area because of siting studies for the Grout Treatment project. Borehole coverage is less than adequate for the new ILAW disposal site because there are no existing waste disposal site studies. Borehole data is particularly poor on the east side of the new ILAW disposal site.

3.3 SAMPLING

Sample retrieval is often difficult and sample quantities are limited. Vadose zone drilling is difficult for sample recovery because the samples are typically dry and are not easily retained in the drive barrel. As indicated above, grain size of the sample can also be affected by drilling techniques such as in "hard tool" drilling or sonic drilling.

In order to perform certain tests, samples from several depths often must be composited. Also, certain tests performed on samples in the past may also have destroyed the integrity of the sample. In the past, particle size testing resulted in loss of fines, which were discarded before samples were returned to the Hanford Geotechnical Sample Library.

4.0 GEOLOGY

4.1 GENERAL HANFORD STRATIGRAPHY

4.1.1 Surface Geology and Geomorphology

Previous studies (DOE 1988) have discussed the general geomorphology of the 200 Areas. These studies describe the 200 Areas as a flood bar (200 Areas plateau) that formed as sediments were deposited by the Missoula floods during Pleistocene. The topographic low area immediately east of 200-East Area is an erosional channel cut by Missoula flood waters that moved south through Gable Gap.

The principal geologic units exposed at the surface are glacial fluvial and eolian sands (Reidel and Fecht 1994a, 1994b) (Figure 4.1). The fluvial sands were deposited by Missoula floods and have since been reworked by westerly winds to form a thin veneer of parabolic dunes.

4.1.2 Subsurface Geology

The existing and new disposal sites are in a sequence of sediments that overlie the Columbia River Basalt Group on the north limb of the Cold Creek syncline. These sediments include the upper Miocene to Pliocene Ringold Formation, Pleistocene cataclysmic flood gravels, sands and silt of the Hanford formation, and Holocene eolian deposits (Figures 4.1 and 4.2).

The main nomenclature employed in this report is consistent with the standardized use for the Hanford Site (i.e., Delaney et al. 1991; Reidel et al. 1992; Lindsey et al. 1994a, 1994b; Lindsey 1996) and the new ILAW disposal site (Reidel et al. 1998). Subdivision of some units is inconsistent across the sites because of the difficulty in correlating beds over great distances. Following geologic convention, the discussion in this report proceeds from oldest to youngest units. In addition, this report will use feet rather than meters following the convention used in borehole data.

Rocks underlying the 200-East Area consists of the Elephant Mountain Member of the Saddle Mountains Basalt, Columbia River Basalt Group overlain by the Ringold Formation and the Hanford formation. The Elephant Mountain Member consists of two lava flows totaling approximately 100 ft (30 m) in thickness and forms the base of the unconfined aquifer at 200-East Area.

The Ringold Formation consists of fluvial and lacustrine sediments deposited by the ancestral Columbia and Clearwater-Salmon river systems between about 3.4 and 8.5 Ma. Lindsey (1996) described the Ringold Formation in terms of three informal members: 1) the member of Wooded Island, 2) the member of Taylor Flat, and 3) the member of Savage Island. Of these, only the member of Wooded Island is present beneath the 200-East Area (Figure 4.2).

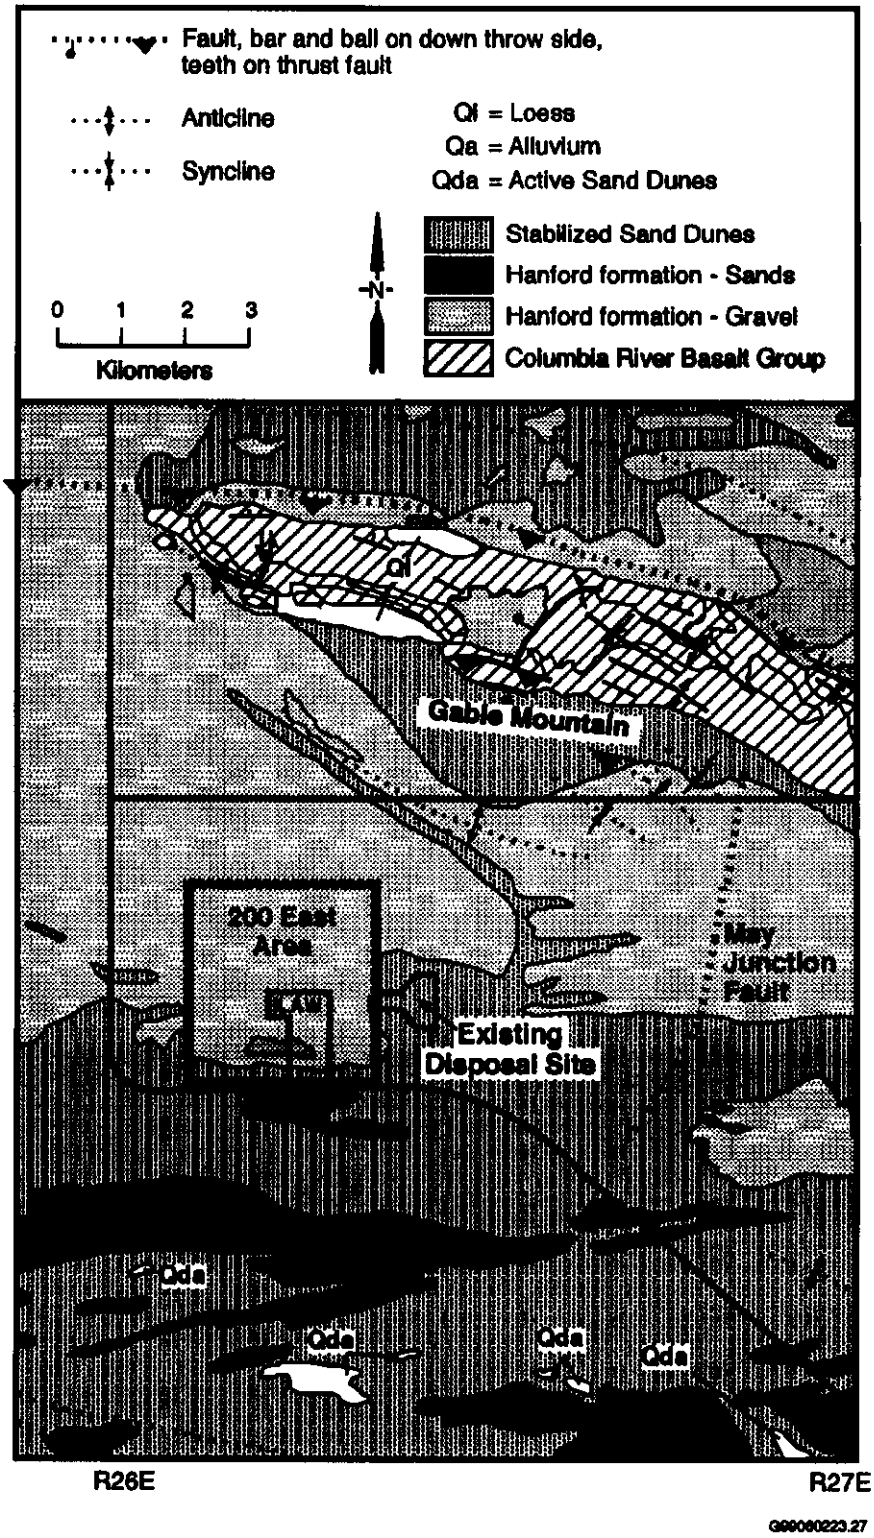

Figure 4.1. Geologic and Geomorphic Map of the 200-East Area (dashed geologic structures indicate they are buried by younger units) (From Reidel and Fecht [1994a, 1994b])

Figure 4.2. Generalized Stratigraphy of the Hanford Site and New ILAW Disposal Site

The member of Wooded Island consists of five separate units dominated by fluvial gravels (conglomerate). The gravels are designated (from bottom to top) as units A, B/D, C, and E. The gravel units are separated by fine-grained deposits typical of overbank and lacustrine environments. The lowermost of the fine-grained sequences is designated the lower mud unit. Only gravel units A and E are present beneath the 200-East Area and the Ringold Formation is entirely absent beneath the north and northeast parts of the 200-East Area (Lindsey et al. 1992, 1994b).

The Ringold Formation conglomerate is a variably indurated clast- and matrix-supported, pebble to cobble gravels with a fine to coarse sand matrix (Lindsey 1996). The most common lithologies are basalt, quartzite, and intermediate to felsic volcanics. Interbedded lenses of silt and sand are common. Cemented zones within the gravels are discontinuous and of variable thickness. In outcrop, the gravels are massive, planer bedded, or cross-bedded. Lying above the Ringold gravels are silts and sands of the upper Ringold, the member of Taylor Flats, which is not generally present beneath the 200-East Area.

The Hanford formation overlies the Ringold Formation. The Hanford formation consists of glacio-fluvial sediments deposited by cataclysmic floods from Glacial Lake Missoula, Pluvial Lake Bonneville, and ice-margin lakes. Hanford formation sediments resulted from at least four major glacial events and were deposited between about 1 Ma and 13 Ka. The formation consists of pebble- to boulder-gravel, fine- to coarse-grained sand, and silt- to clayey-silt. These deposits are divided into three facies: 1) gravel-dominated facies, 2) sand-dominated facies, and 3) silt-dominated facies (Reidel et al. 1992; Lindsey et al. 1992, 1994a, 1994b). These same facies are referred to as coarse-grained deposits, plane-laminated sand facies, and rhythmite facies, respectively, in Bjornstad et al. (1987) and Baker et al. (1992). The Hanford formation is present throughout the Hanford Site and is as much as 380 ft (116 m) thick (Delaney et al. 1991).

- Gravel-dominated facies - This facies generally consists of coarse-grained basaltic sand and granule to boulder gravel. These deposits display an open framework texture, massive bedding, plane to low-angle bedding, and large-scale planar cross bedding in outcrop. Silt content is variable and local interbedded silt and clay have been observed in outcrop. Clay and silt have been found as coatings on clasts but generally not filling open spaces between clasts. The gravel-dominated facies was deposited by high-energy floodwaters in or immediately adjacent to the main cataclysmic flood channelways.

- Sand-dominated facies - This facies consists of fine- to coarse-grained sand and granule gravel. The sands typically have a high basalt content and are commonly referred to as black, gray, or salt-and-pepper sands (Lindsey et al. 1992). They may contain small pebbles and rip-up clasts, pebble-gravel interbeds, and silty interbeds less than 3 ft (1 m) thick. The silt content of the sands is variable, but where it is low a well-sorted and open framework texture is common. The sand facies was deposited adjacent to main flood channelways during the waning stages of flooding. The facies is transitional between the gravel-dominated facies and the silt-dominated facies.

- Silt-dominated facies - This facies consists of thin bedded, plane-laminated and ripple cross-laminated silt and fine- to coarse-grained sand. Beds are typically a few centimeters to several tens of centimeters thick and commonly display normal grading (Myers et al. 1979; Bjornstad et al. 1987; DOE 1988). Local clay-rich beds occur in the silt-dominated facies and paleosols have been observed in core from the 200-East Area. Sediments of this facies were deposited under slack water conditions and in back flooded areas (DOE 1988).

4.1.3 Clastic Dikes

Clastic dikes are vertical to subvertical sedimentary structures that cross cut normal sedimentary layering and could effect the vertical movement of water and contaminants. Clastic dikes are a common geologic feature of Pleistocene flood deposits of the Hanford formation although they also have been found in the underlying Ringold Formation and in Columbia River Basalt Group and intercalated sedimentary interbeds. Clastic dikes at Hanford have been described in detail by Fecht et al. (1998).

Clastic dikes typically occur in swarms and occur as regular-shaped polygonal-patterns; irregular-shaped polygonal-patterns; pre-existing fissure fillings; and random occurrences. Regular polygonal networks resemble 4- to 8-sided polygons. Dikes in irregular-shaped polygon networks are generally crosscutting in both plan and cross-section resulting in extensive segmentation of the dikes. Where zones of pre-existing weakness occur, clastic dikes often occur in these zones.

Clastic dikes typically show a wide range in widths, depths, and lengths. The vertical extent of clastic dikes has been observed to range from 30 cm to greater than 55 m. Clastic dike widths ranges from about 1 mm to greater than 2 m and their length varies from as little as 0.3 m to more than 100 m.

In general, a clastic dike is composed of an outer skin of clay with coarser infilling material. Clay linings are commonly 0.03 mm to 1.0 mm thick, but linings up to about 10 mm are known. The clay skins may have a great influence on transport both within and adjacent to the clastic dikes. The width of individual infilling layers range from as little as 0.01 mm to more than 30 cm and their length can vary

from about 0.2 m to more than 20 m. Infilling sediments are typically poor to well-sorted sand, but may contain clay, silt, and gravel.

Clastic dikes have been noted in the Hanford formation sand sequence in the existing disposal site (Lindberg et al. 1993) and are suspected to occur but have not been identified at the new disposal site. At the existing disposal site, clastic dikes have not been mapped and their number and distribution are not known. Clastic dikes have been found in numerous locations on the 200 Area plateau where they occur primarily in polygonal networks with dimensions ranging from 30 to 240 m (Fecht et al. 1998). The total depth of the clastic dikes in the existing disposal site is also unknown but they extend below the bottom of the excavations for the former Grout Treatment Facility (Lindberg et al. 1993).

4.2 EXISTING DISPOSAL SITE

4.2.1 Previous Investigations

In 1988, Swanson et al. reported the existing knowledge of the subsurface geology of the existing disposal site area. Their report included geologic cross-sections, available particle size distribution data, chemical analyses of 47 sediment samples from boreholes, and sediment moisture data.

Swanson (1992) published the borehole completion package containing all known data from the then new RCRA borehole 299-E25-39 within the existing disposal facility. A gross gamma-ray borehole log, moisture and $CaCO_3$ contents, and a geologists log are included in that report. Similar reports are available for boreholes 299-E25-37 and 299-E25-38 (Swanson 1993) and boreholes 299-E25-49, -50, and -1000 (Swanson 1994).

Lindberg et al. (1993) updated Swanson's description of the geology and aquifer characteristics of the Grout Disposal site (now the existing disposal facility area). Using geologic logs from approximately 45 groundwater wells in the Grout Facility - B Pond - 241-A, AX area, they produced a set of isopach and structure contour maps for each of the geologic units in their interpretation of the subsurface geology. They also provided two cross-sections through the existing disposal site.

Rockhold et al. (1993) estimated the hydraulic properties of material and sediments that determine the movement of water at the existing disposal facility area. They present particle size, bulk density, and particle density data from selected samples from borehole 299-E25-234 in the existing disposal facility.

In 1998, the TWRS Phase 1 Privatization Site Preconstruction Characterization Report (Mitchell 1998) was issued for the existing disposal site and planned glass melter. That report included ground penetrating radar and electromagnetic induction surveys, and borehole geophysical surveys (spectral gamma-ray and neutron-moisture surveys). Unfortunately, most of the neutron moisture surveys from the existing disposal site are of little use because they reflect borehole construction characteristics rather than geologic characteristics.

Surface geophysical surveys reported by Mitchell (1998) for the existing disposal site interrogated the subsurface to a depth of about 13 ft (4 m). Most of the upper 13 ft (4 m) of the existing disposal facility area consisted of homogeneous sediment interpreted as wind blown Holocene sands and silts. In some areas, however, stratification was observed similar to what is found in inactive sand dunes or possibly the finer sediments of the Hanford formation (Mitchell 1998). In one area, geologically complex stratification was noted where soil stratification was laterally discontinuous possibly, in part, due to clastic dikes (Mitchell 1998). Several clastic dikes were noted in the excavation for the former Grout Treatment Facility.

4.2.2 Site Stratigraphy

Data reported in this document were compiled from 32 boreholes and monitoring wells in and around the existing disposal site. Figure 4.3 shows the location of the boreholes. Table 4.1 is a listing of the boreholes used along with their location, elevation, and construction information pertinent to this report. For this report, boreholes within the existing disposal facility are considered most important. The boreholes outside the existing disposal facility are used to supplement those within the existing disposal facility.

Six lithologic sequences are identified in this data package for performance assessment purposes. These are (from youngest to oldest):

- Recent surface deposits
- Hanford formation sand sequence
- Hanford formation gravel sequence
- Ringold Formation fine-grain sequence at top of Unit A
- Ringold Formation Unit A
- Columbia River Basalt Group.

The vadose zone beneath the existing disposal site is from approximately 250 ft (76 m) to 277 ft (84 m) thick. The vadose zone thins toward the northeast due to a decrease in elevation in that direction and an increase in the elevation of the water table beneath B Pond. With a few exceptions, the water table is in the Ringold Formation fine-grained sequence or just above the sequence in the Hanford formation gravel sequence.

Figure 4.3 shows the locations of the wells in the existing disposal site that were used to interpret the geology and construct the four cross-sections given in Figures 4.4 through 4.7. The cross sections depict the relationships of the lithologic sequences. All data used in constructing the cross sections (and the structure contour maps presented later) are given in Table 4.1. Appendix C provides a more generalized north-south and east-west cross sections depicting the primary features of the area.

The location of cross-section A-A' was chosen to illustrate the geology across the center of the existing disposal site. The exact location was influenced by the locations of existing and newer groundwater wells with the maximum of quality data. The location of cross-section B-B' was chosen to illustrate the geology along the southern portion of the existing disposal site. Likewise, the location of C-C' was

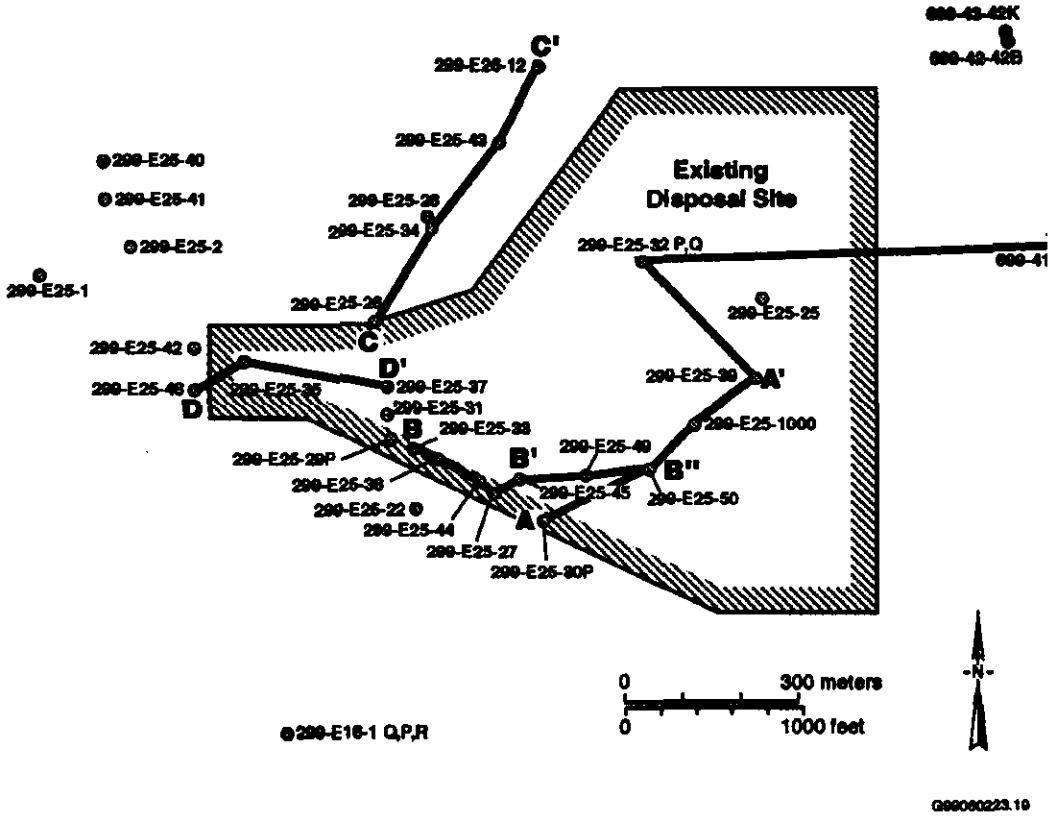

Figure 4.3. Map of the Existing Disposal Site Showing the Location of Boreholes and Cross-Sections

chosen to illustrate the geology along the northwestern edge of the site. The lack of suitable wells along the northern edge precluded extending the cross-section in that direction. Finally, cross-section D-D' is to illustrate the geology through the center of the waste transfer corridor.

4.2.2.1 Columbia River Basalt Group

The Elephant Mountain Member of the Saddle Mountains Basalt, Columbia River Basalt Group underlies the Ringold Formation. The top of the Elephant Mountain Member was penetrated in only 6 boreholes in the existing disposal facility area. A top of basalt map is shown in Figure 4.8.

4.2.2.2 Ringold Formation Unit A

The Ringold Formation Unit A overlies the Columbia River Basalt Group. This unit is equivalent to the Ringold Formation Unit A described in Lindberg et al. (1993).

The Ringold Formation Unit A is described on borehole logs of cuttings and samples as gravel, sandy gravel, and slightly sandy gravel to muddy sandy gravel at the existing disposal site. The gravels are

generally poorly sorted, subangular to rounded, and consist of pebbles and cobbles in a sand and mud matrix. Calcium carbonate is common but not abundant. These sediments are interpreted to represent fluvial gravels and sands.

Based on observations of outcrop and intact core, the Ringold Formation Unit A fluvial gravels consist of clast- and matrix-supported, pebble- to cobble-conglomerate with a fine- to coarse-sand matrix and interbedded fine- to coarse-sand and silt lenses (Lindsey 1996). The cement content ranges from absent to well developed. Cemented Ringold Formation conglomerates are discontinuous zones of variable thickness. The conglomerates exhibit massive, planer, and cross-bedding. Clast imbrication is common in the stratified sediments (Lindsey 1996).

Intercalated in the Ringold conglomerates are laterally discontinuous, fine- to coarse-grained, cross-bedded sand interbeds. Also interbedded in the conglomerates are thin, variably colored silty deposits, typically with disrupted bedding (Lindsey 1966).

The Ringold Formation Unit A is interpreted to represent rapid deposition of fluvial bed-load sediment in shallow channels across a gravelly floodplain.

The total thickness of the Ringold Formation Unit A at the existing disposal site is not known in most boreholes because most boreholes terminate before penetrating the lower contact. The lower contact is known, however, in 6 boreholes in the existing disposal facility area. In these boreholes, the Ringold Formation Unit A ranges from 55 to 100 ft (17 to 30 m) thick with an average thickness of 78 ft (23.7 m).

4.2.2.3 Ringold Formation Fine-Grained Sequence at Top of Unit A

A fine-grained sequence occurs as the uppermost Ringold Formation sediments in the existing disposal facility area. This sequence, along with the underlying gravels, is equivalent to the Ringold Formation Unit A described by Lindberg et al. (1993) and may be equivalent to a portion of the Ringold Formation Lower Mud. However, facies distribution maps shown in Lindberg et al. (1993) indicate that the Lower Mud has been eroded from most of the area beneath the existing disposal facility so that, if the Lower Mud is present, it is found only as erosional remnants.

The fine-grained sequence is described on borehole logs of cuttings and samples as sand and silty sand with minor silt/clay beds. The sequence is unconsolidated and generally lacks significant cement although it commonly has a variable but often strong reaction with HCl. On borehole logs, internal stratification and other internal features generally are not noted; however, the drilling method used to collect the samples has probably destroyed any internal structure that existed. The fine-grained sequence is represented by an increase in activity on the gross gamma-ray log from most but not all boreholes where it is present. The fine-grained sequence is interpreted to be fluvial sand deposits; possibly bedload deposits and/or proximal overbank deposits.

The fine-grained sequence varies in thickness from 0 to 27 ft (0 to 8 m) with an average thickness of 18 ft (5.5 m). The sequence is absent in boreholes 299-E25-25, -28, -31, -37, -42, and -43.

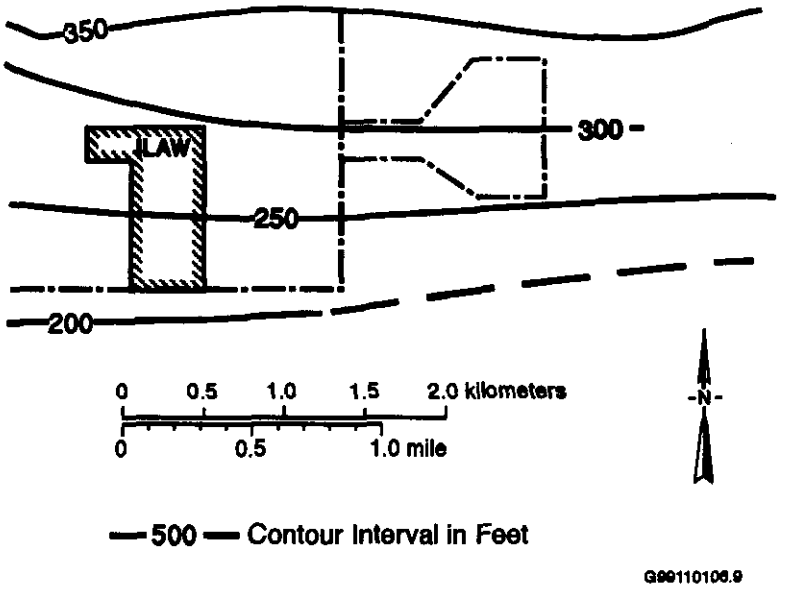

Figure 4.8. Generalized Elevation of the Top of the Columbia River Basalt Group Under the 200-East Area

Figure 4.9 is a structure contour map of the top of the Ringold Formation. The map shows a roughly northwest to southeast trending low across the center of the existing disposal site with about 66 ft (20 m) of relief in the area. The structural low may be due to post-depositional scouring by Pleistocene floods.

4.2.2.4 Hanford Formation Gravel Sequence

A thick sequence of Pleistocene Hanford formation flood gravels overlies the Ringold Formation. This sequence is equivalent, at least in part, to the lower gravel sequence of the Hanford formation of Lindberg et al. (1993) and Lindsey et al. (1992), to the Hanford formation H3 sequence of Lindsey et al. (1994a), and to the Qfg deposits of Reidel and Fecht (1994a, 1994b) (Figure 4.2).

The Hanford formation gravel sequence is described on borehole logs of cuttings and samples as dominantly sandy gravel and gravelly sand in the existing disposal site. Thin beds of sand, generally less than about 10 ft (3 m) in thickness, are common but not abundant. Silt lenses were not noted on the borehole logs of the gravel sequence at the existing disposal site. The gravels are generally poorly sorted, subrounded to subangular and have basalt content up to 80%. Calcium carbonate is common but the gravel sequence is not cemented.

Based on observation of outcrop and intact core, the gravel sequence sediments described on the borehole logs are interpreted to be gravel-dominated facies. This facies is typically open framework or matrix supported framework, granule to boulder gravel with massive bedding, plane to low-angle bedding, and cross-bedding. Lenticular and discontinuous units of sand-dominated facies are interbedded with gravel-dominated facies. The Hanford formation gravel sequence was deposited by high-energy, cataclysmic, Pleistocene floods.

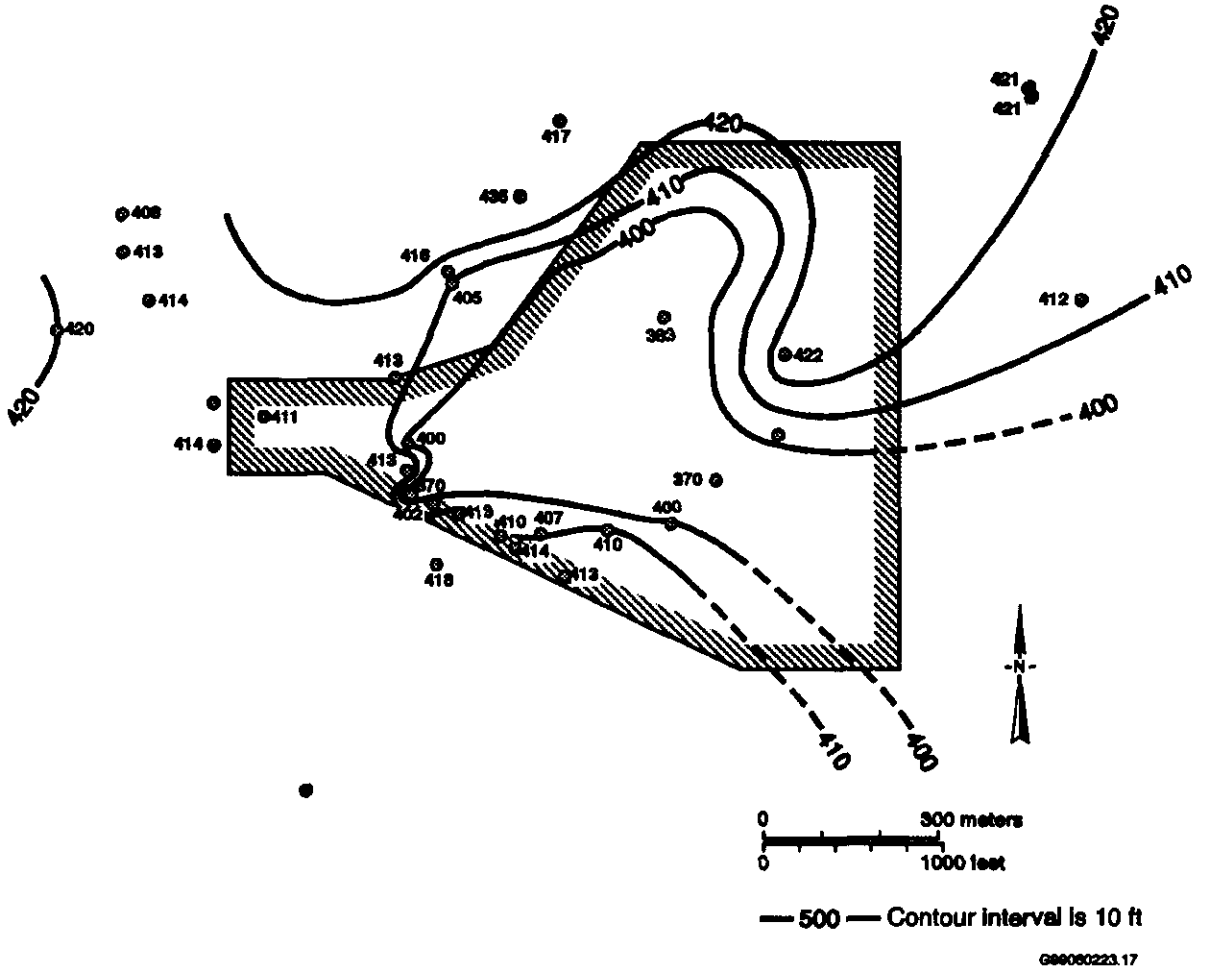

Figure 4.9. Structure Contour Map of the Top of the Ringold Formation in the Existing Disposal Site. Values are Elevations Above Sea Level.

The base of the Hanford formation gravel sequence was picked at the top of the silt, silty sand, or sand defining the top of the Ringold fine-grained sequence. In boreholes where the Ringold fine-grained sequence does not occur, the contact was chosen at a change in the degree of induration and/or change in the basalt content of the gravel. The lithology change was generally fairly dramatic going from about 50% or more basalt in the Hanford formation gravel sequence to about 10 to 15% basalt in the underlying Ringold Formation. In a few boreholes where neither the Ringold fine-grained sequence nor a dramatic change in lithology was evident, the base of the Hanford formation gravel sequence was taken from data in Lindberg et al. (1993).

Figure 4.10 shows a structure contour map on the top surface of the Hanford formation gravel sequence. The map shows that the top of the sequence has about 55 ft (17 m) of relief in the existing disposal site area and is highest through the center of the area in a north to north-northwest trend.

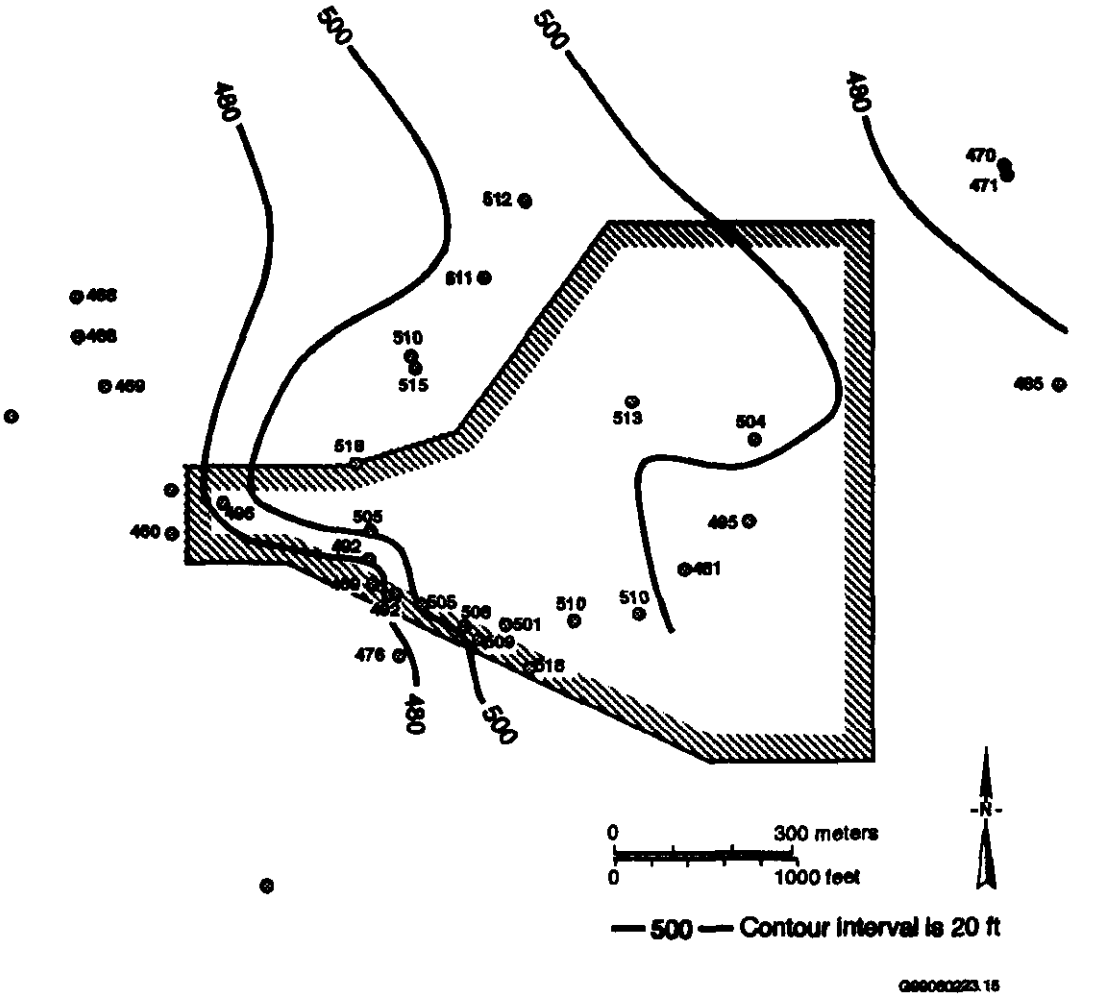

Figure 4.10. Structure Contour Map of the Top of the Hanford Formation Gravel Sequence in the Existing Disposal Site. Values are elevations in feet.

4.2.2.5 Hanford Formation Sand Sequence

The Hanford formation sand sequence overlies the Hanford formation gravel sequence. This sequence is equivalent to the sandy sequence of the Hanford formation of Lindberg et al. (1993) and Lindsey et al. (1992), the Hanford formation H2 sequence of Lindsey et al. (1994a), and to Qfs of Reidel and Fecht (1994a, 1994b) (Figure 4.2).

The Hanford formation sand sequence is described on borehole logs of cuttings as coarse to very fine sand. Beds of silty sand and gravelly sand are common; sandy gravels also exist but are less common. The composition of the sand sequence varies from typically 50 to 70% mafic and 30 to 50% felsic. Minor calcium carbonate is common in the sand sequence as indicated on the geologist's logs. Also, some caliche layers were noted on geologist's logs. The caliche is generally fine to medium pebble-sized cemented clasts.

The sand-sequence sediments are interpreted to consist of typical sand-dominated facies intercalated with beds of the silt-dominated and gravel-dominated facies. The amount of gravel-dominated facies sediment tends to increase toward the northwestern and western parts of the existing disposal site (see Figures 4.4 through 4.7) whereas the sequence is mostly sand-dominated with some silt-dominated beds in the central and eastern parts of the site.

Beds of silt-dominated facies were noted in the Hanford formation sand sequence from many geologist's logs. The beds are generally 6 in. (0.15 m) or less in thickness and in many boreholes were moist to wet relative to adjacent sediment. Silt-dominated units primarily were noted in three depth intervals: 10 to 15 ft (3 to 4.5 m), 20 to about 35 ft (6 to about 11 m), and 100 to 135 ft (30 to 41 m). However, many silt-dominated units were identified outside these depth intervals between 50 and 70 ft (15 and 21 m) and between 87 and 97 ft (26.5 and 29.5 m). Silt intervals were commonly noted as layered or bedded (with sand) by the geologist. In some boreholes, anomalies in gross gamma-ray logs and moisture content data reflect the presence of silt-dominated strata. In other boreholes, similar anomalies probably reflect silt-dominated strata that were not noted on the lithologic logs. Silt-dominated units cannot be correlated among boreholes and are interpreted to be lenticular. However, samples are normally collected every 5 ft (1.5 m) during drilling so most thin silt-dominated units would not get described.

The geologist's logs for two boreholes (299-E25-26 and 299-E25-220) indicate the presence of Mt. St. Helens set "S" ash at 14 to 15 ft (4.3 to 4.6 m) depth. If this horizon is Mt. St. Helens set "S" ash, it indicates an age of 13,000 years for the sediment at this depth.

The Hanford formation sand sequence in the existing disposal site varies from 134 to 220 ft (41 to 67 m) in thickness with an average thickness of 169 ft (51 m). Because of the difficulty in picking a contact between the Hanford formation sand sequence and the overlying surficial sands, both are included in the sand sequence thickness given in Table 4.1.

The bottom of the Hanford formation sand sequence was chosen as the top of the first, thick (>10 ft [3 m]), sandy gravel or gravelly sand underlying at least 25 ft (7.6 m) of sand, silty sand or slightly gravelly sand. Although there are some differences, this change in lithology agrees well with that used by Lindberg et al. (1993), who used the data set from Lindsey et al. (1992), to delineate the Hanford formation sand sequence from the underlying gravel sequence.

4.2.2.6 Recent Surface Deposits

Ground penetrating surveys conducted in 1998 found a variably thick sequence of surficial deposits across most of the existing disposal site. These deposits consist of Holocene wind blown sand and are typically about 10 ft (3 m) thick. Some geologist's logs and driller's logs note a surficial deposit but most do not. In some boreholes, the thickness of the surfical deposits can be established based on lithology where the eolian sands overly sandy gravel or gravelly sand. In those boreholes, the eolian deposits are between about 5 and 15 ft (1.5 and 4.5 m) in thickness. In other boreholes, the surfical sands overly the

Hanford formation sand sequence. The texture of the Hanford formation sand sequence is similar to the eolian material making it hard to differentiate the two without being able to observe the structures (laminations).

4.3 NEW ILAW DISPOSAL SITE

4.3.1 Previous Studies

The new ILAW disposal site is an area where no previous construction or disposal sites exist so no major geologic studies have been carried out there. Studies relevant to the site are summarized in Tallman et al. (1979), DOE (1988), Lindsey et al. (1993, 1994a, 1994b), Lindsey (1996), Reidel and Reynolds (1998), and Reidel et al. (1998). Less data are available for the new ILAW site and it is generally of poorer quality compared to data from the existing disposal site. The first major activity was the drilling of borehole 299-E17-21 in 1998 at the southwest end of the site and obtaining the first high-quality data from the area.

4.3.2 Site Stratigraphy

The stratigraphy at the new ILAW disposal site consists of the Hanford formation and Ringold Formation overlying the Columbia River Basalt Group. Surfacial sediments are mainly eolian deposits consisting of reworked Hanford sands and silts.

The stratigraphy and the stratigraphic model developed for this study is summarized in Figures 4.2 and 4.11. This diagram is based upon more detailed cross-sections (Figures 4.12 through 4.16).

The stratigraphy of the new ILAW disposal site is divided from youngest to oldest into the following units:

- Eolian Deposits
- Hanford formation, sandy unit (H2 of Lindsey et al. 1994b)
  - Layer 3 (extends into upper gravelly unit)
  - Layer 2
  - Layer 1
- Hanford formation, basal gravel units (H3 of Lindsey et al. 1994b)
- Ringold Formation
  - Unit E
  - Lower Mud
  - Unit A
- Columbia River Basalt Group.

Sequences of sandy gravels to gravelly sands (G1, G2, G3, G4) and sand to silty sand units (S, S1, S2, S3) can be recognized in the Hanford formation layers (Table 4.2) but correlation across the area is

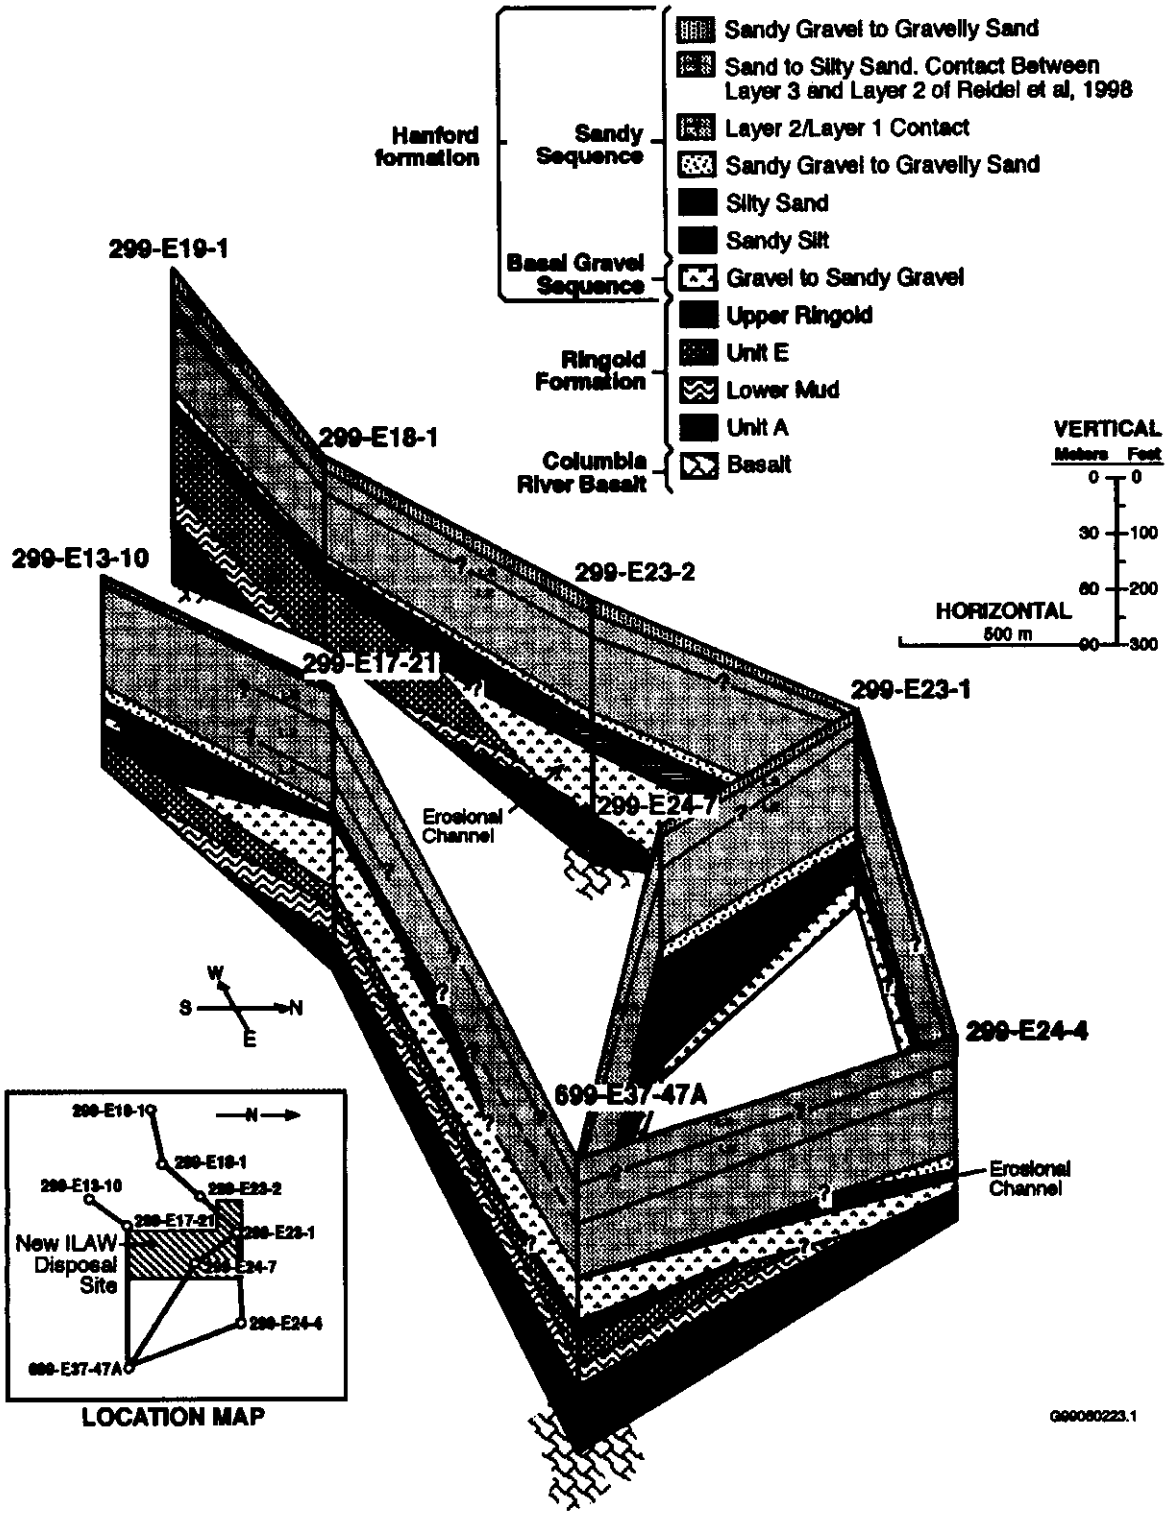

Figure 4.11. Fence Diagram of the New ILAW Disposal Site and Vicinity

Table 4.2. Stratigraphic Information from Boreholes in and Adjacent to the New ILAW Disposal Site

N = Not present. Letter number designations in table headings refer to cross section units (Figures 4.12, 4.13, 4.14, and 4.15).
ND = Not determined.
NP = Not penetrated.

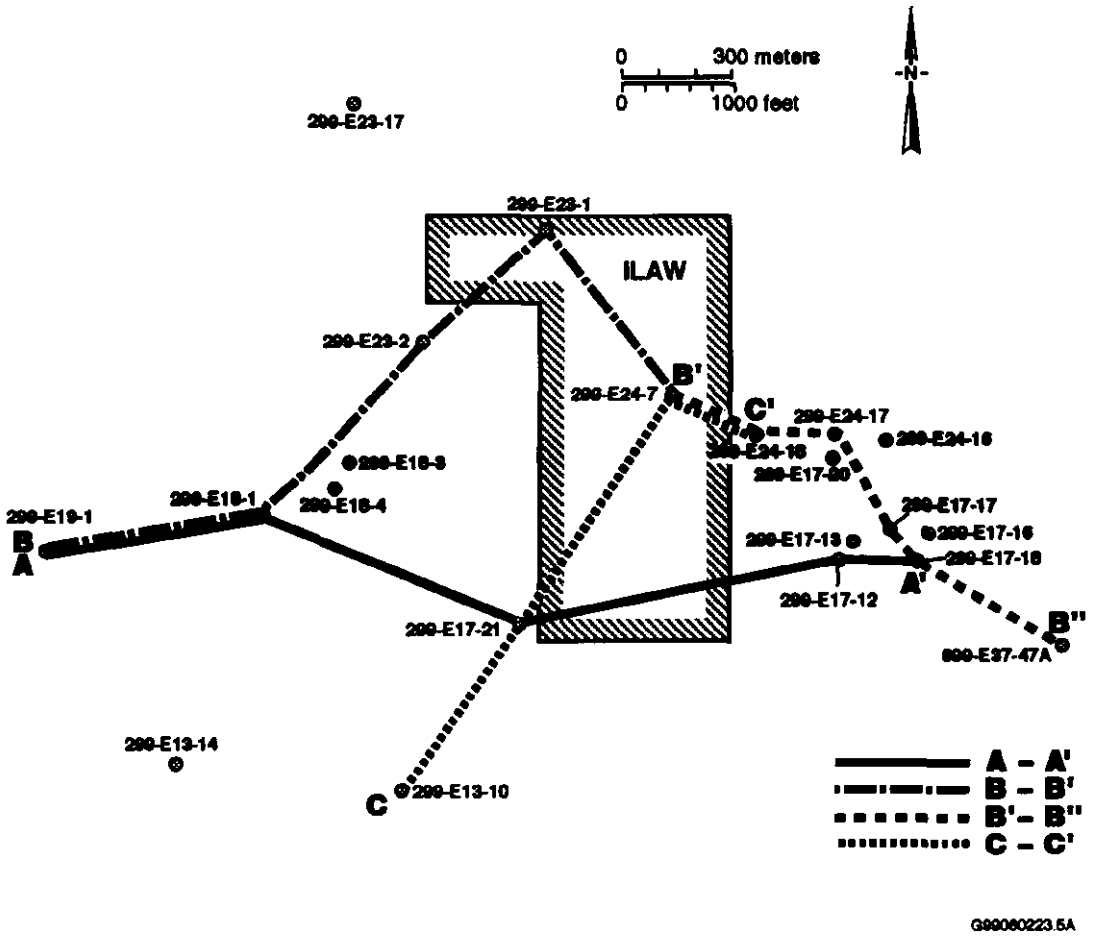

Figure 4.12. Map Showing Borehole Locations in the New ILAW Disposal Site and the Locations of Cross-Sections A-A', B-B', B'-B", and C-C'

tentative at this time because of the distance between boreholes, the poor quality of some data, and the local nature of thin units in the Hanford formation. Additional boreholes will be necessary to verify these correlations.

4.3.2.1 Columbia River Basalt Group

Previous studies (DOE 1988; Reidel and Fecht 1994a) have shown that the youngest lava flows of the Columbia River Basalt Group at the 200-East Area are those of the 10.5 million-year old Elephant Mountain Member. The Elephant Mountain Member is continuous beneath the new disposal site. No erosional windows are known or suspected to occur in the new ILAW disposal site area.

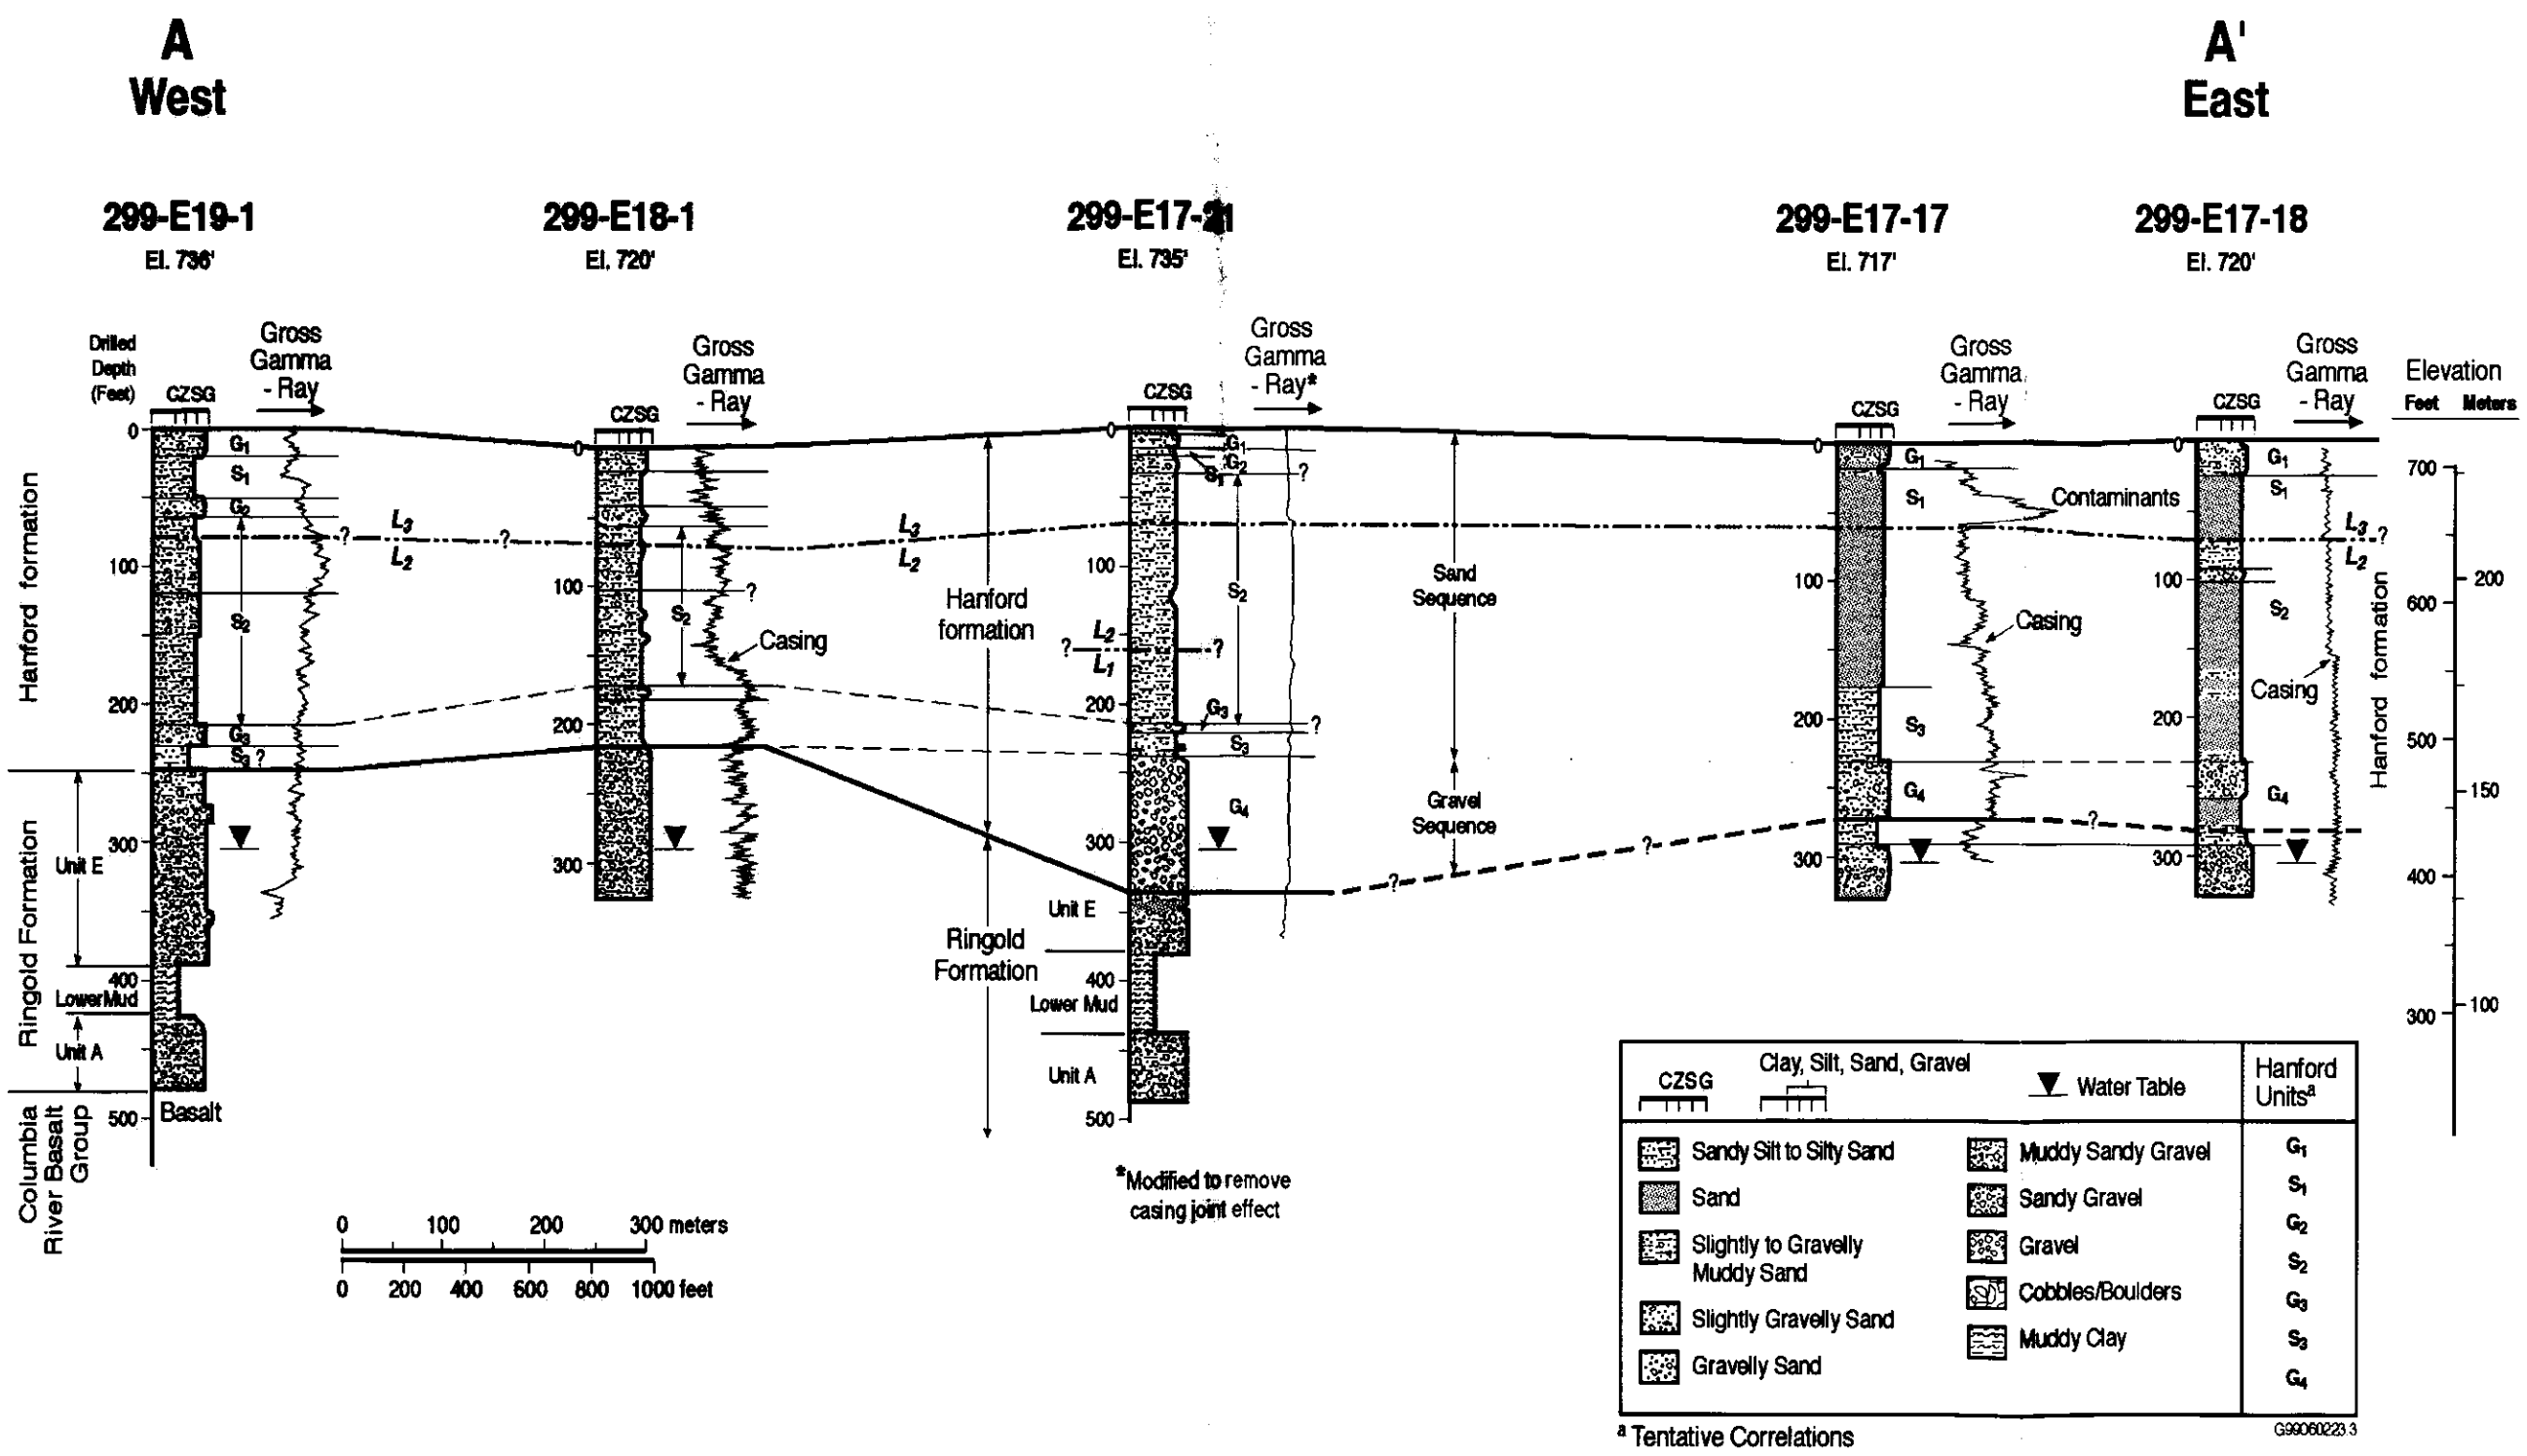

Figure 4.13. Cross-Section A-A' Across the New ILAW Disposal Site

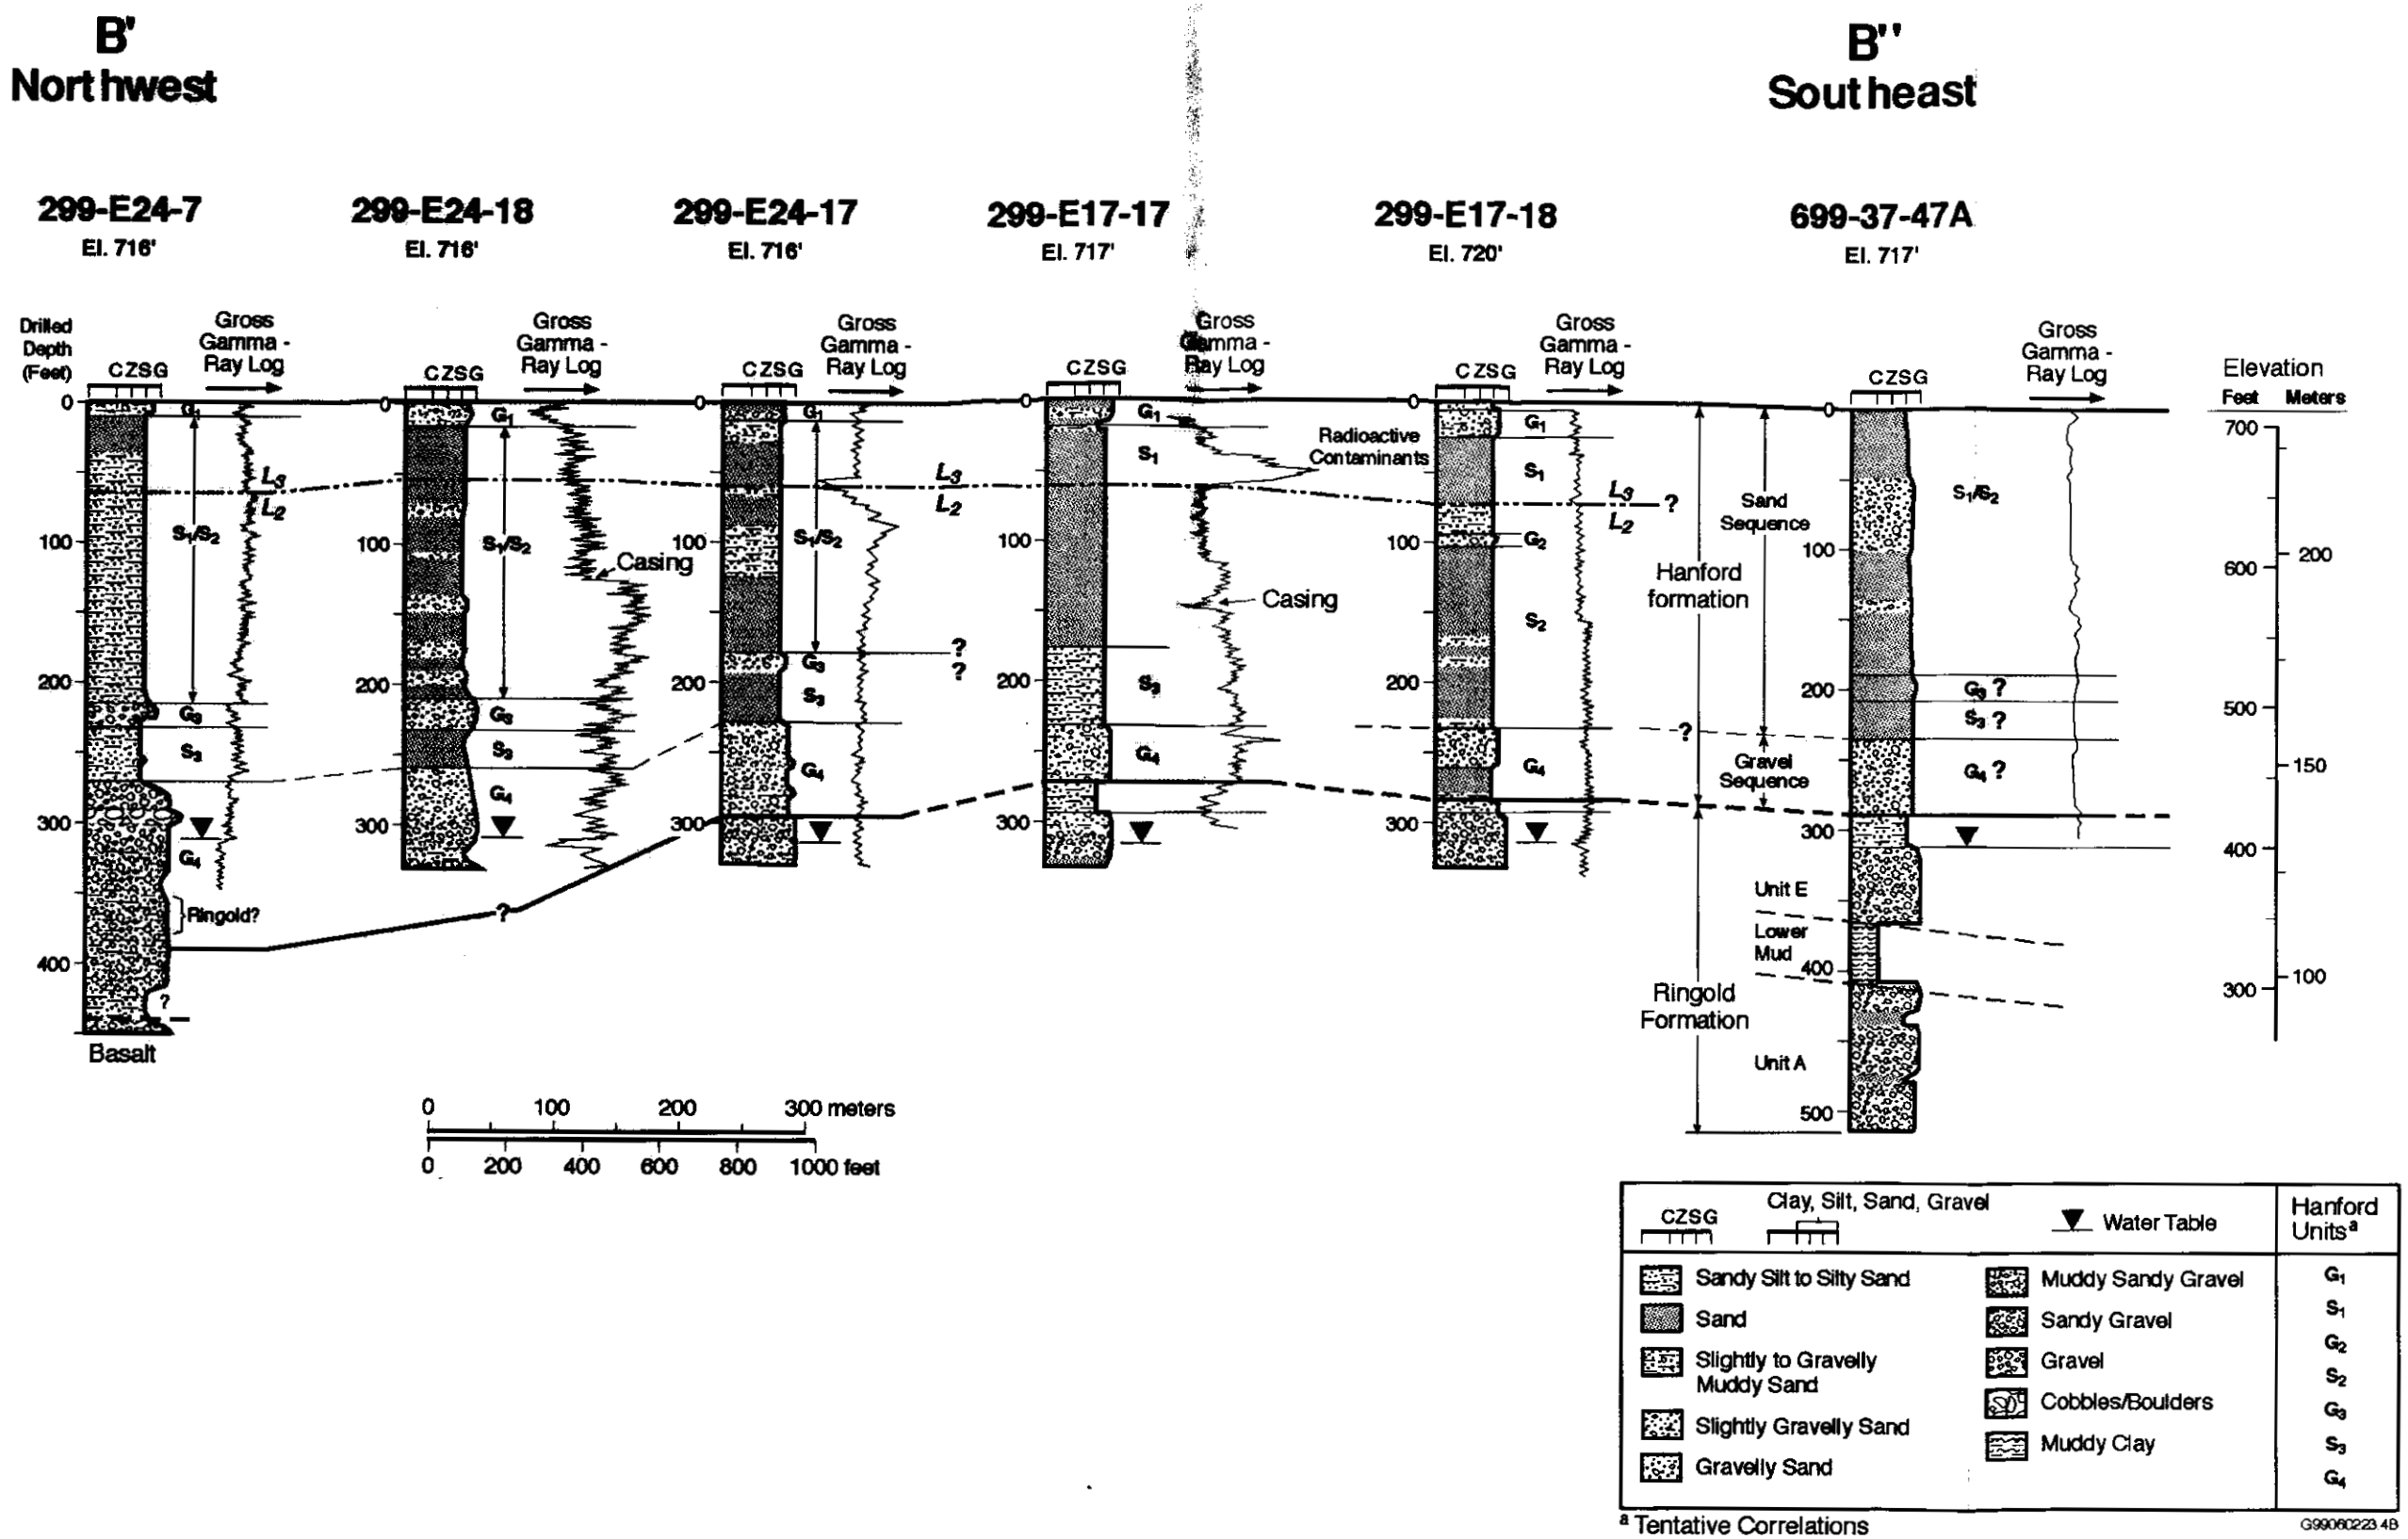

Figure 4.15. Cross-Section B'-B" Across the New ILAW Disposal Site

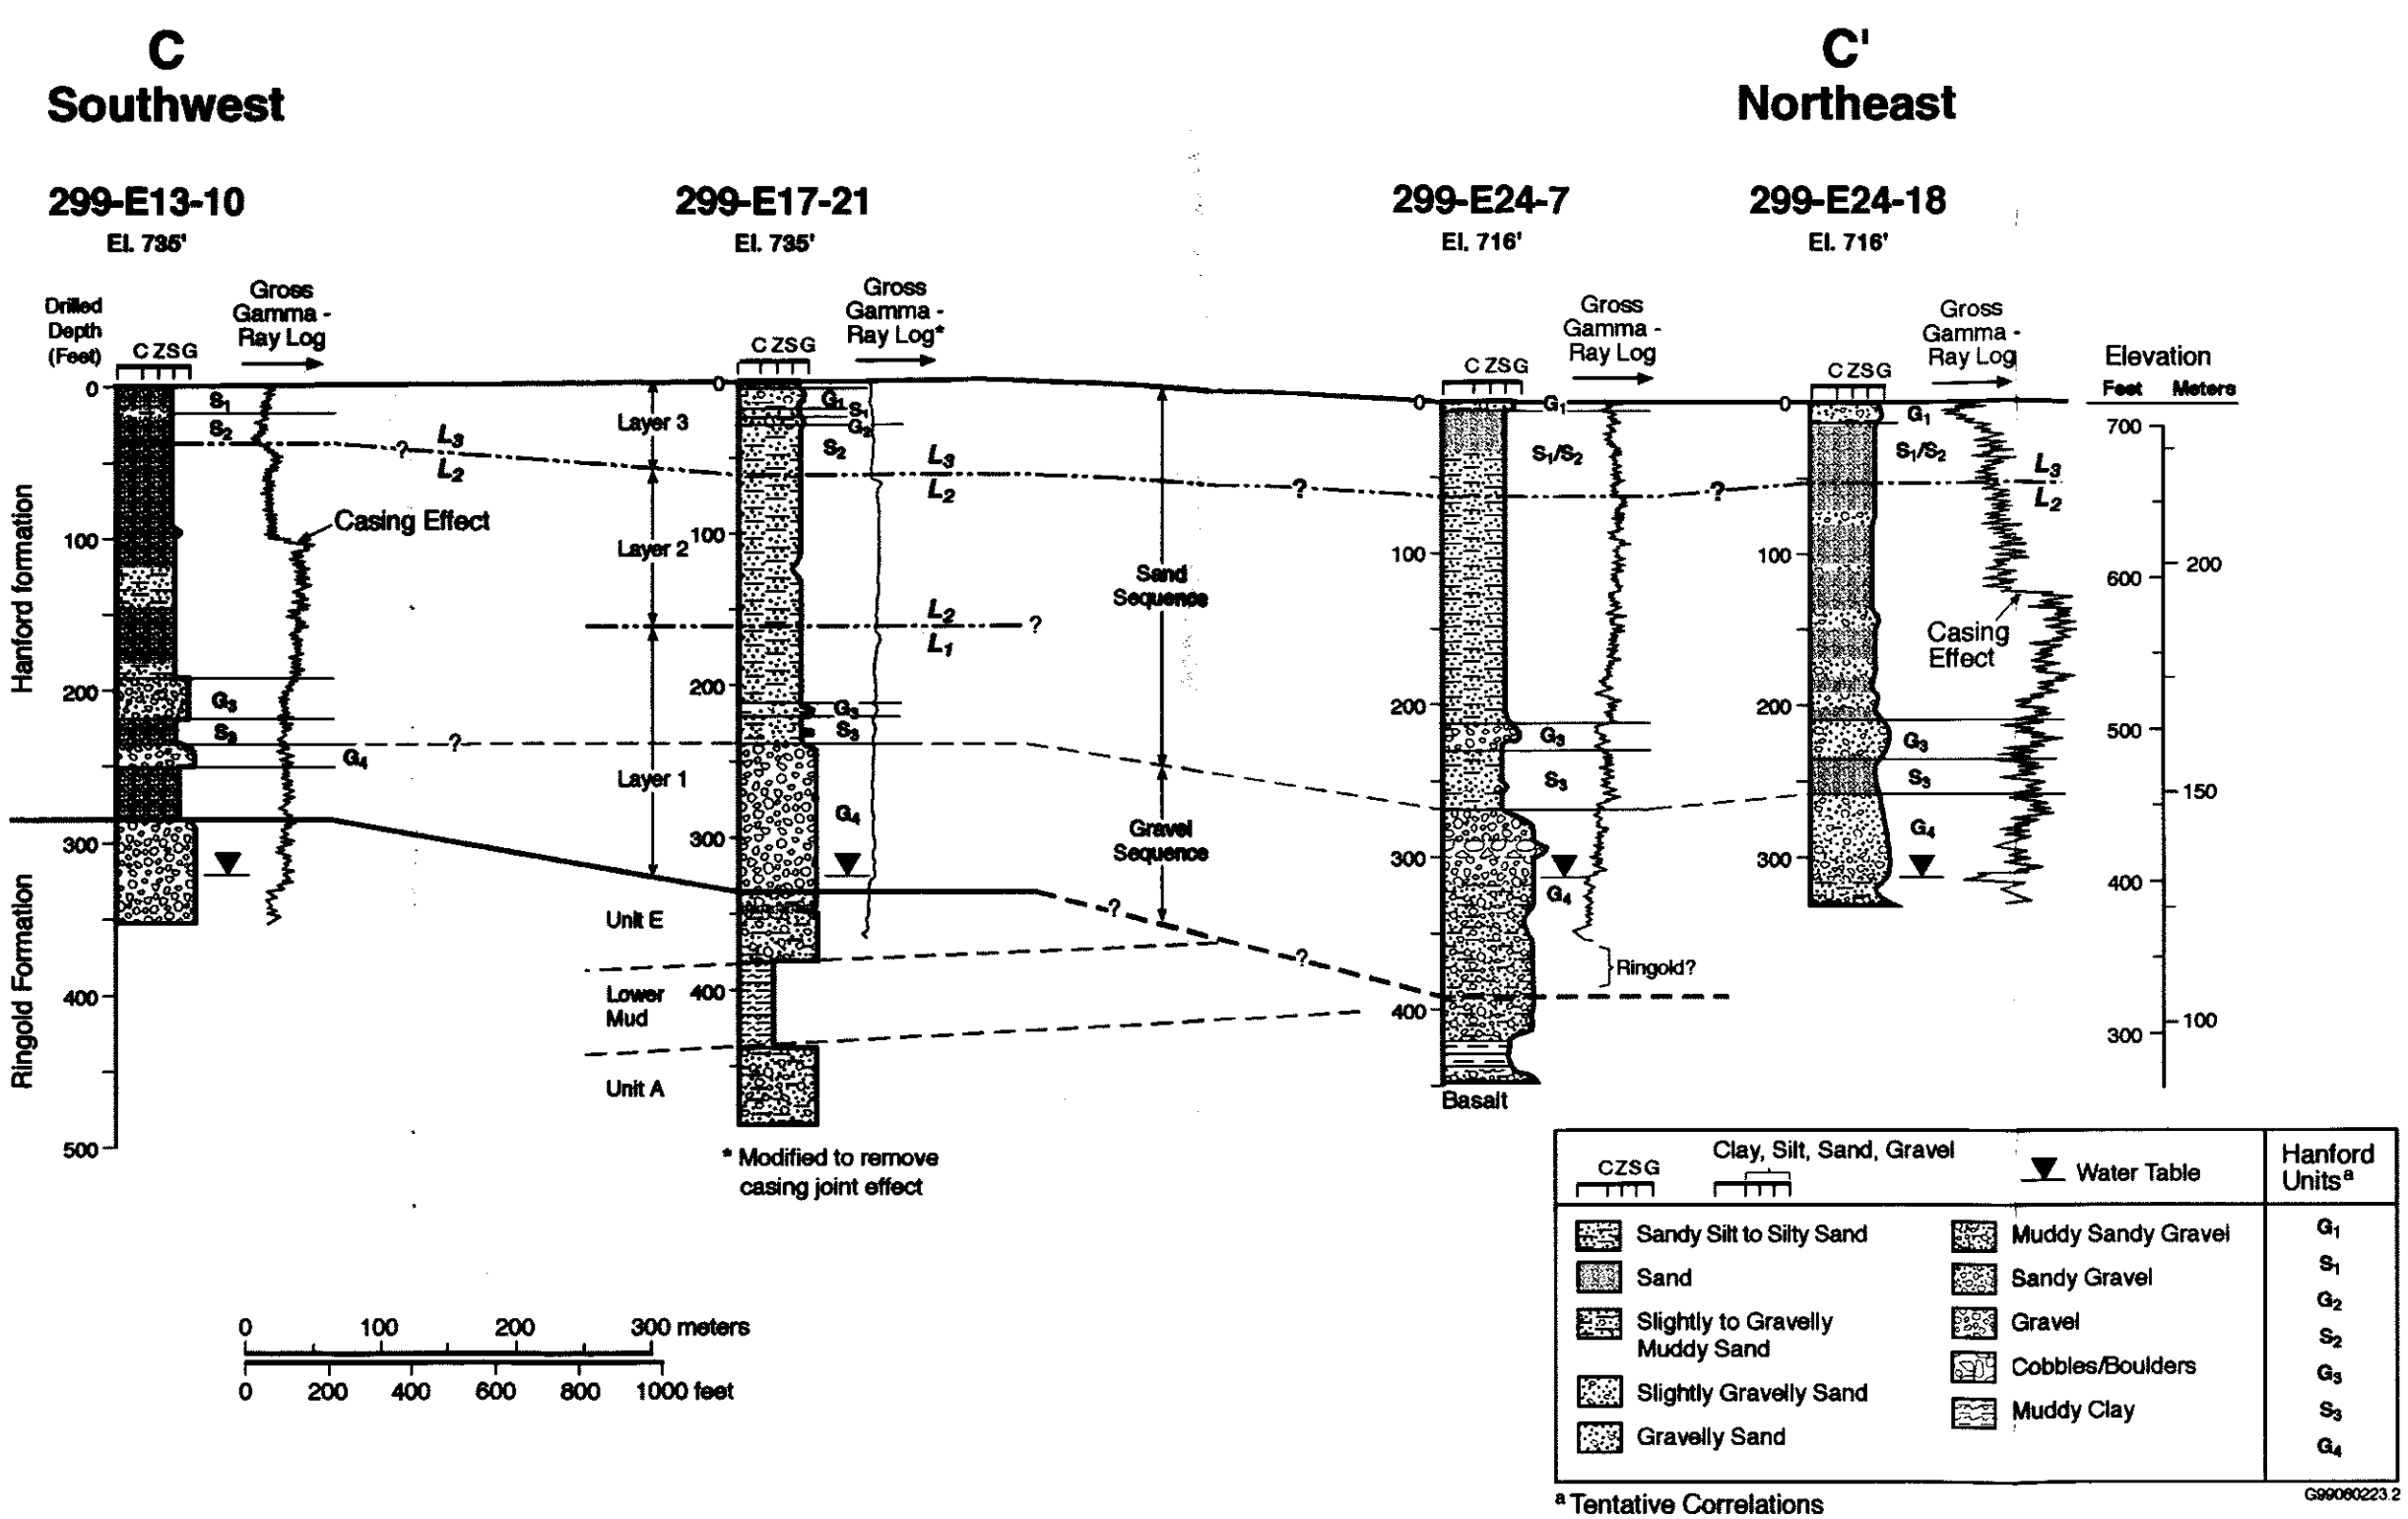

Figure 4.16. Cross-Section C-C' Across the New ILAW Disposal Site

4.3.2.2 Ringold Formation

Because few boreholes penetrate much of the entire Ringold Formation at the new ILAW disposal site (Figure 4.17), data are limited. The Ringold Formation reaches a maximum thickness of 285 ft (95 m) on the west side of the new ILAW disposal site and thins eastward. It consists of three units of Lindsey's (1996) member of Wooded Island. The member of Taylor Flats has been identified in borehole 699-47-37A (Lindberg et al. 1997) east of the site but this correlation was tentative. The deepest unit encountered is the lower gravel, Unit A. Lying above Unit A is the Lower Mud and overlying the Lower Mud is an upper gravel, Unit E. The upper Ringold (sand and silt of the member of Taylor Flat) is not present at the new ILAW disposal site (Figure 4.11). Unit A and Unit E are equivalent to mapping unit PLMcg (Figure 4.2), Pliocene-Miocene continental conglomerates of Reidel and Fecht (1994a, 1994b). The Lower Mud is equivalent the mapping unit PLMc, Pliocene-Miocene continental sand, silt, and clay beds of Reidel and Fecht (1994a, 1994b).

4.3.2.2.1 Unit A

Only 3 boreholes penetrated Unit A in the study area (Table 4.2). Unit A is 61 ft (19 m) thick on the west side of the new ILAW site but thins to the northeast (Figure 4.11). Unit A is described on borehole

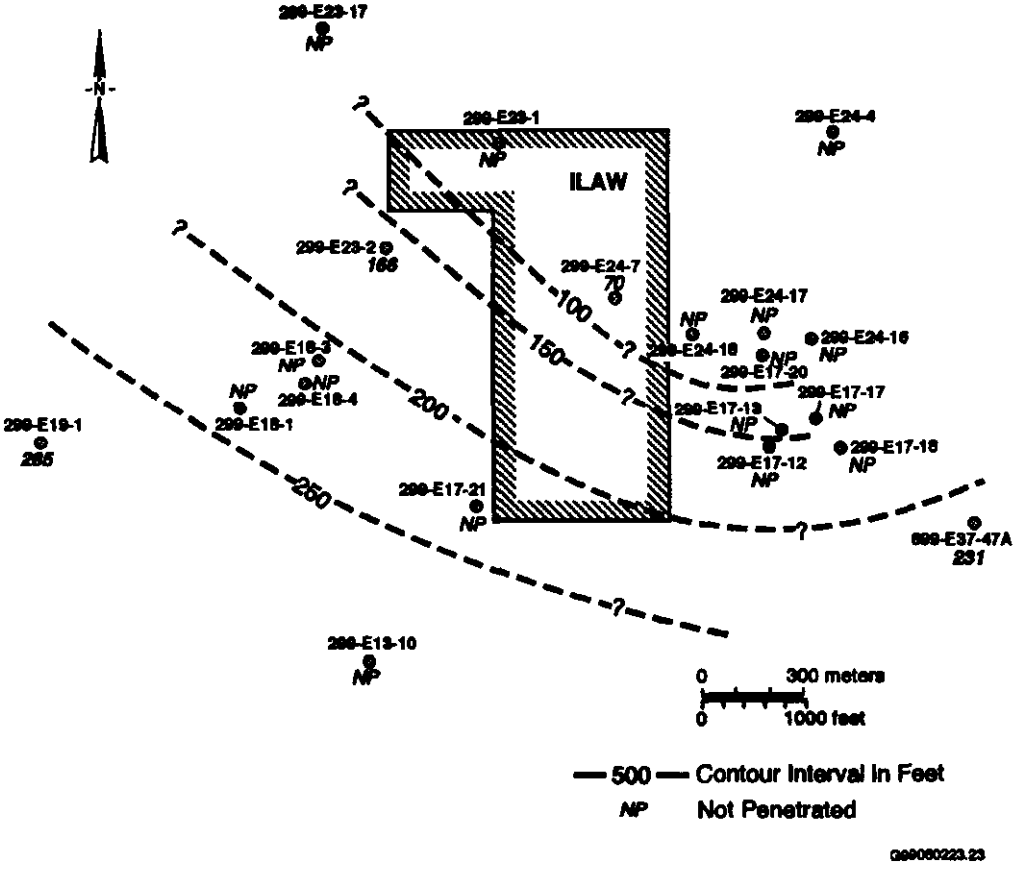

Figure 4.17. Isopach Map of the Ringold Formation at the New ILAW Disposal Site

logs as a sandy gravel consisting of both felsic and basaltic rocks. It is interpreted as Lindsey's (1996) fluvial gravel facies, which consists of conglomerates and is interpreted to be similar to Unit A in the existing disposal site (Section 4.2.2.2). There are sporadic yellow to white interbedded sands and silts with silt and clay lenses. Green-colored, reduced-iron stain is present on some grains and pebbles. Although the entire unit appears to be partially cemented, the zone produced abundant water in borehole 299-E17-21 (Reidel et al. 1998).

4.3.2.2.2 Lower Mud

Sixty-one feet (19 m) of the Lower Mud was encountered at the new ILAW site characterization borehole (299-E17-21). The upper most part (about 4 ft [1 m]) is described on borehole logs as a yellow sandy to silty mud and is interpreted as Lindsey's (1996) lacustrine facies, which consists of clays, silts, and silty sands. The silty clay grades downward into about 34 ft (10 m) of blue clay with beds of silt to slightly silty clay. The blue clay, in turn, grades down into 23 ft (7 m) of brown silty clay with organic rich zones and occasional wood fragments. The Lower Mud is absent in the center of the new ILAW site (Figure 4.11; boreholes 299-E23-1 and 299-E24-7).

4.3.2.2.3 Unit E

Unit E is described on borehole logs as a sandy gravel to gravelly sand. It is interpreted to consist of as much as 50 ft (15 m) of conglomerate with scattered cobbles up to 10 in. (25 cm) in size. The conglomerate consists of both felsic and basaltic clasts which are well rounded with a sand matrix supporting the cobbles and pebbles. Cementation of this unit ranges between slight and moderate. The upper contact of Unit E is not easily identified at the new ILAW site. In the western part of the study area, unconsolidated gravels of the Hanford formation directly overly the Ringold Unit E gravels. The dominance of basalt in the Hanford formation and the absence of any cementation are the key criteria used for distinguishing them here (Reidel et al. 1998). In the central and northeast part of the study area, Unit E is interpreted to have been eroded (e.g., boreholes 299-E24-7 and 299-E17-21, Figure 4.11). Unconsolidated gravels and sands typical of the Hanford formation replace them.

4.3.2.2.4 Upper Ringold (Member of Taylor Flat)

The upper Ringold is not present at the new ILAW disposal site but has been tentatively identified in the southeast corner of 200-East Area in borehole 699-E37-47A (Lindberg et al. 1997). These sediments do not appear to be present at the new ILAW disposal site (Figure 4.11).

4.3.2.2.5 Unconformity at Top of Ringold Formation

The surface of the Ringold Formation is irregular in the new ILAW disposal site area (Figure 4.18). A NW-SE trending erosional channel or trough is centered along the northeast portion of the site (Figures 4.11 and 4.18). The deepest portion of the trough occurs near borehole 299-E24-7 in the northern portion of the new ILAW disposal site. This trough is interpreted to be a smaller part of a much larger trough under the 200-East Area resulting from scouring by the Missoula floods or post-Ringold fluvial incision prior to the Missoula floods.

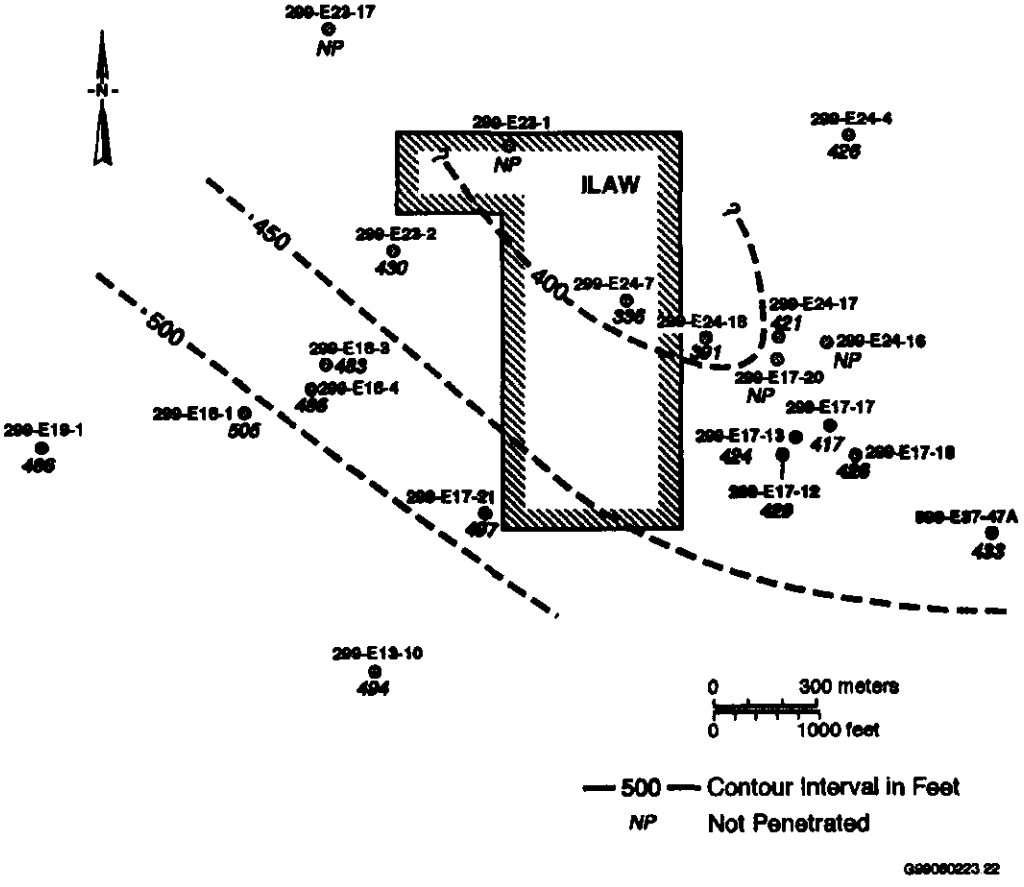

Figure 4.18. Structural Contour Map on the Surface of the Ringold Formation

4.3.2.3 Hanford Formation

The Hanford formation is as much as 380 ft (116 m) thick in and around the new ILAW disposal site (Figures 4.11 and 4.19). It thickens in the erosional channel cut into the Ringold Formation and thins to the southwest along the margin of the trough. It may thin northeast of the trough but this is based on only one data point (Figure 4.19).

At the new ILAW site, the Hanford formation consists mainly of sand-dominated facies and lesser amounts of silt-dominated and gravel-dominated facies. It has been described on borehole logs as poorly sorted pebble to boulder gravel and fine- to coarse-grained sand, with lesser amounts of interstitial and interbedded silt and clay. In previous studies of the new ILAW disposal site (Reidel et al. 1998), the Hanford formation was described as consisting of three units: an upper and lower gravel-dominated facies and a sand-dominated facies between the two gravel facies. The upper gravel-dominated facies appears to be thin or absent in the new ILAW disposal area. In Table 4.2, the elevations of the tops of several tentatively correlated units of the Hanford formation are given.

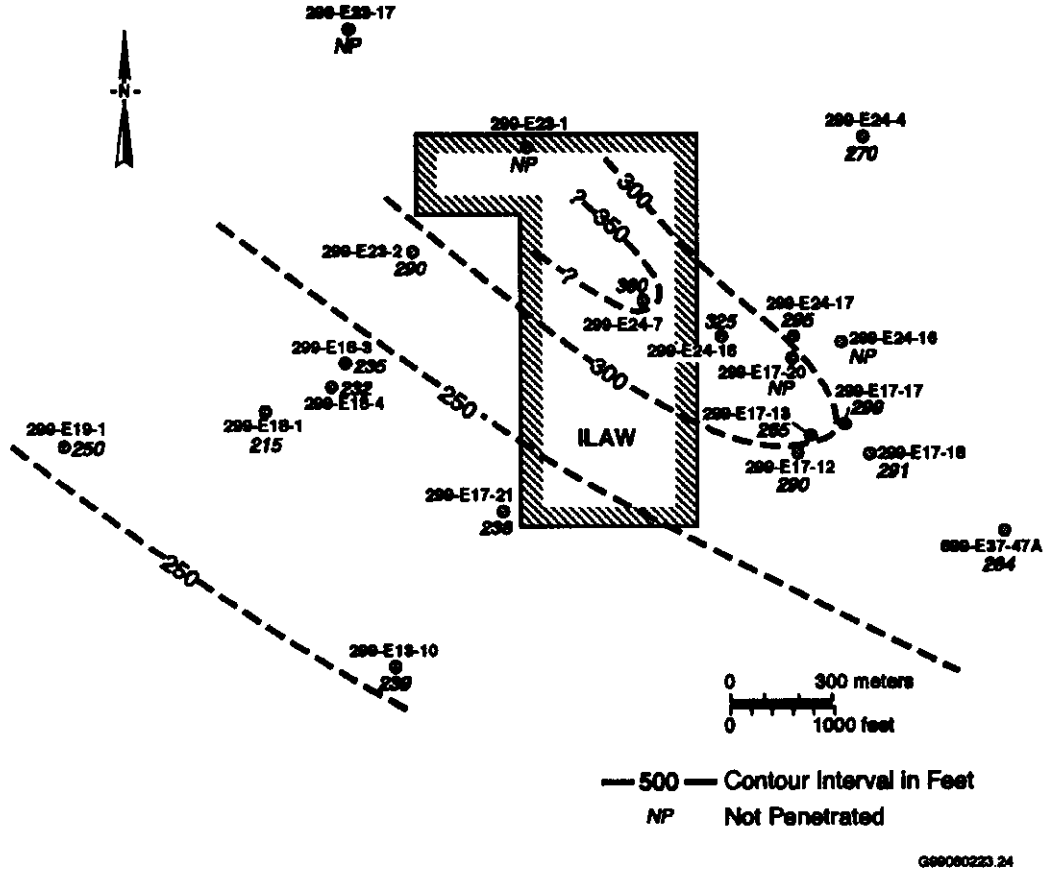

Figure 4.19. Isopach Map of the Hanford Formation at the New ILAW Disposal Site

4.3.2.3.1 Basal Gravel Sequence

The lowermost 88 ft (27 m) of the Hanford formation encountered in borehole 299-E17-21 consists of gravel-dominated facies. Drill core and cuttings from this borehole indicate that the unit is clast-supported pebble- to cobble-gravel with minor amounts of sand in the matrix. Cobbles and pebbles are almost exclusively basalt with no cementation. In outcroppings these deposits display massive bedding, plane to low-angle bedding and large-scale planar forset cross-bedding, but such features typically cannot be observed in borehole core. This unit either pinches out west of the new ILAW disposal site or becomes more sand rich. It thickens to the northeast. The gravel is interpreted to be Missoula flood gravels deposited in the erosional channel carved into the underlying Ringold Formation (Figure 4.18).

This basal gravel sequence is equivalent to unit H3 of Lindsey et al. (1994b) (Figure 4.2), and is equivalent to mapping unit Qfg1, Missoula Outburst flood gravel deposits of Reidel and Fecht (1994a, 1994b). The sand unit overlying this gravel has reversed polarity (Appendix B), indicating that these units are older than 780 ka.

4.3.2.3.2 Sandy Sequence

The upper portion of the Hanford formation consists of at least 240 ft (73 m) of sand-dominated and silt-dominated facies. These deposits have been described as fine- to coarse-grained sand with minor amounts of silt and clay and some gravelly sands. This sequence is equivalent to unit H2 of Lindsey et al. (1994a), and is equivalent to the following mapping units of Reidel and Fecht (1994a,b): Qfs1, Qfs2, and Qfs3, Missoula Outburst Flood Deposits consisting of sand, silt, and clay (Figure 4.2).

Three paleosols (soils) were identified in core and drill cuttings from borehole 299-E17-21 (Reidel et al. 1998). Paleosol Horizon 1 occurs at 163 ft (49 m) drilled depth (Figure 4.11), paleosol Horizon 2 at 58 ft (18 m) drilled depth, and paleosol Horizon 3 at 5 ft (1.5 m). The paleosol horizons are as much as 6 in. (15 cm) thick with a sharp upper surface. The horizons have a light brown color compared to the darker sands below and some $CaCO_3$ cementation. The lack of well-defined bedding laminations rhythmics like the sands below suggests some bioturbation but no root casts were observed in the core. The paleosol grades downward into normal sands.

The three paleosol horizons represent time intervals when soil development took place and are interpreted to represent three time periods between Missoula flood deposition. Reidel et al. (1998) called the layers defined by the paleosols: Layer 1 as that part of the Hanford formation extending from the paleosol horizon at 163 ft (49 m) to the top of the basalt gravel at 247 ft (75 m). Layer 2 extends from the top of the second paleosol horizon 58 ft (18 m) to the top of the first paleosol at 163 ft (49 m). Layer 3 extends from the top of the third paleosol horizon at 5 ft (1.5 m) depth to the second paleosol horizon at 58 ft (18 m) drilled depth. The presence or exact depth of these layers is known elsewhere at the new ILAW site and can only be inferred.

Layer 1. Layer 1 is 84 ft (26 m) thick in borehole 299-E17-21. It is a zone of sand and silt with a poorly developed caliche layer at the top. Only the upper several inches are cemented but $CaCO_3$ extends to a depth of about 10 ft (3.3 m) below the top. $CaCO_3$ fragments or grain coatings were found to a depth of at least 218 ft (66 m).

The lower 20 ft (6 m) of Layer 1 consists of interbedded sands and gravels. The basal gravel sequence underlying Layer 1 appears to grade upward into a sequence of interbedded sands and gravels. At least three upward fining zones of gravels to sands were recognized in Layer 1. These zones are equivalent to unit H2A of Lindsey et al. (1994a).

Planar-laminar sands with minor silt lenses dominate the upper 54 ft (16 m) of Layer 1. This sequence consists of fining upward sands, well-compacted, slightly $CaCO_3$-cemented sands, and well-laminated sands. $CaCO_3$ associated with development of the paleosol extends well down into this layer.

Layer 1 is part of unit H2 of Lindsey et al. (1994a), and is equivalent to mapping unit Qfs1 of Reidel and Fecht (1994a, 1994b) (Figure 4.2). Mapping unit Qfs1 is a Missoula Outburst Flood Deposits consisting of sand, silt, and clay that is 780 ka and has a reversed magnetic polarity. Paleomagnetic studies by the University of California, Santa Cruz, has shown that this layer has reversed magnetic polarity (Appendix B). Layer 1 has only been identified in borehole 299-E17-21. Data from surrounding boreholes is of too poor of quality to identify this layer.

Layer 2. The upper 90 ft (27 m) of Layer 2 is principally the sand- and silt-dominated facies. They have been described as fine- to medium-grained sand with minor amounts of interstitial silt. Throughout the sands are disseminated flakes of $CaCO_3$ and $CaCO_3$-cemented sand grains. Several fining upward zones were recognized as well as highly-compacted zones of sand and silt with faint laminations. Layer 2 was correlated to other boreholes using geologists logs and archived chip samples. In addition, the paleosol that forms the top of this layer appears to responsible for zones of lateral spreading of contaminants under waste disposal sites immediately east of the new ILAW disposal site.

Layer 2 is also part of unit H2 of Lindsey et al. (1994a), and may be equivalent to mapping unit Qfs2 of Reidel and Fecht (1994a, 1994b) (Figure 4.2). The mapping unit is a Missoula Outburst Flood Deposits consisting of sand, silt and clay that is older than 13 ka and younger than 780 ka. Mapping unit Qfs2 has a normal magnetic polarity.

Layer 3. Layer 3 is 53 ft (16 m) thick in borehole 299-E17-21. The paleosol at the top of Layer 3 is a 1.1 ft (3 cm) thick, oxidized and leached zone of pebbly, fine-grained sand and silt with some pebbles with a 4-in. (10-cm) poorly developed caliche zone (sand and silt cemented by $CaCO_3$). Several distinct gravelly sands are present within several feet of the paleosol at the top of this layer. This forms the surface of much of the new ILAW disposal site north of the eolian deposits.

The lower 25 to 30 ft (8 to 10 m) of Layer 3 consists principally of sand with interstitial silt and minor silt beds that are interpreted as lenses. Several minor silt beds are locally present. Gravelly sand as described on geologists logs marks a transition to finer-grained sand with more silt at a drilled depth of approximately 25 ft (8 m).

Layer 3 is interpreted to consist of the upper gravelly sequence and the upper part of the sandy sequence defined in previous studies. It is part of unit H2 of Lindsey et al. (1994) and is equivalent to mapping unit Qfs3 of Reidel and Fecht (1994a, 1994b) - Outburst Flood Deposits consisting of sand, silt and clay that is about 13 ka. An ash from the 13 ka eruption of Mt. St. Helens (Set S Ash) is typically found near the top of this unit in many places throughout the Pasco basin. The ash was not recognized in any of the boreholes near the new ILAW disposal site but has been identified as an excavation 100 m west of the site.

4.3.2.4 Eolian Unit

Eolian deposits cover the southern part of the new ILAW disposal site. Borehole 299-E17-21 was sited on a stabilized sand dune. The eolian unit is composed of fine- to coarse-grained sands with abundant silt. Calcium-carbonate coating found on the bottom of pebbles and cobbles in drill core through this unit is typical of Holocene caliche development in the Columbia Basin. This unit is equivalent to mapping unit Qd, Holocene Dune Sand, of Reidel and Fecht (1994a, 1994b) (Figure 4.2).

4.3.2.5 Clastic Dikes at the New ILAW Site

Clastic dikes have not been observed at the new ILAW site. Clastic dikes, however, have been observed in excavations surrounding the site (e.g., PUREX, US Ecology, and Canister Storage excavation). At the new ILAW site, clastic dikes are probably not observed because they are covered by wind

blown sediments and a cover of "old growth" sagebrush. The ubiquitous presence of clastic dikes in the 200-East Area suggests that they are probably present at the site.

5.0 SEISMIC DATA

Earthquake activity at the new and existing disposal sites is typical of the Hanford Site. Figure 5.1 shows the location of earthquakes that have occurred near the 200-East Area since monitoring began at Hanford in 1969. Table 5.1 summarizes the pertinent data for the earthquakes shown on Figure 5.1. Most of the earthquakes have been less than coda magnitude 3.0. Coda magnitude is a local magnitude and is an estimate of the Richter magnitude. Thirty-three percent of the earthquakes shown on Figure 5.1 occurred in the Columbia River Basalt Group. Sixteen percent were in the sub-basalt sediments and 51% were in the crystalline basement.

The principal geologic structures from Reidel and Fecht (1994a) are reproduced on Figure 5.1. A comparison of the location of earthquakes to the geologic structures indicates that there is no apparent pattern.

Appendix A

Quality Assurance and Safety

Appendix A

Quality Assurance and Safety

All laboratory and field experiments are conducted under PNNL quality assurance (QA) requirements as described in the guidance provided in PNNL's Standards Based Management System (SBMS) and as specified in the Project QA Plan. Significant modifications to the QA plan are made in accordance with the guidance in the SBMS.

Project staff members are qualified and receive any training needed to carry out their assigned responsibilities.

Staff use equipment of known accuracy for data collection. For measurements necessary to substantiate test results, staff ensure that standards used for calibration are traceable to nationally recognized standards. Measuring and Test Equipment (M&TE) lists are generated by each task and maintained in the project files applicable to the specific task. M&TE used is identified in the laboratory record books or other data recording location to provide traceability to instrument calibrations.

Test procedures and methods are documented and deviations noted. New methods developed during the course of this work are documented and reviewed. All test procedures, data processing software, and supporting documentation undergo independent technical review by qualified PNNL staff.

Staff maintain records necessary to substantiate results and processes of research activities. After activities are completed, records are filed and maintained per the project Records Inventory and Disposition Schedule (RIDS).

All precautionary measures are taken in accordance with standard PNNL safety procedures to ensure that field work is conducted in a safe manner. No hazardous wastes have been generated during the conduct of work described in this report.

Paleomagnetic Study

Paleomagnetism of Borehole 299-E17-21 Sediments, Hanford, WA

prepared by Christopher J. Pluhar
under the supervision of Professor Robert S. Coe

University of California, Santa Cruz
Earth Sciences Dept.
1156 High St.
Santa Cruz, CA 95064-1077

Abstract

We have completed paleomagnetic analysis of seventeen sediment samples of the Hanford Formation from a drill core recovered from borehole 299-E17-21 at the Hanford DOE site. These analyses reveal dominantly reversed polarity directions, including that these sediments are older than the Brunhes-Matuyama magnetic reversal (780 ka).

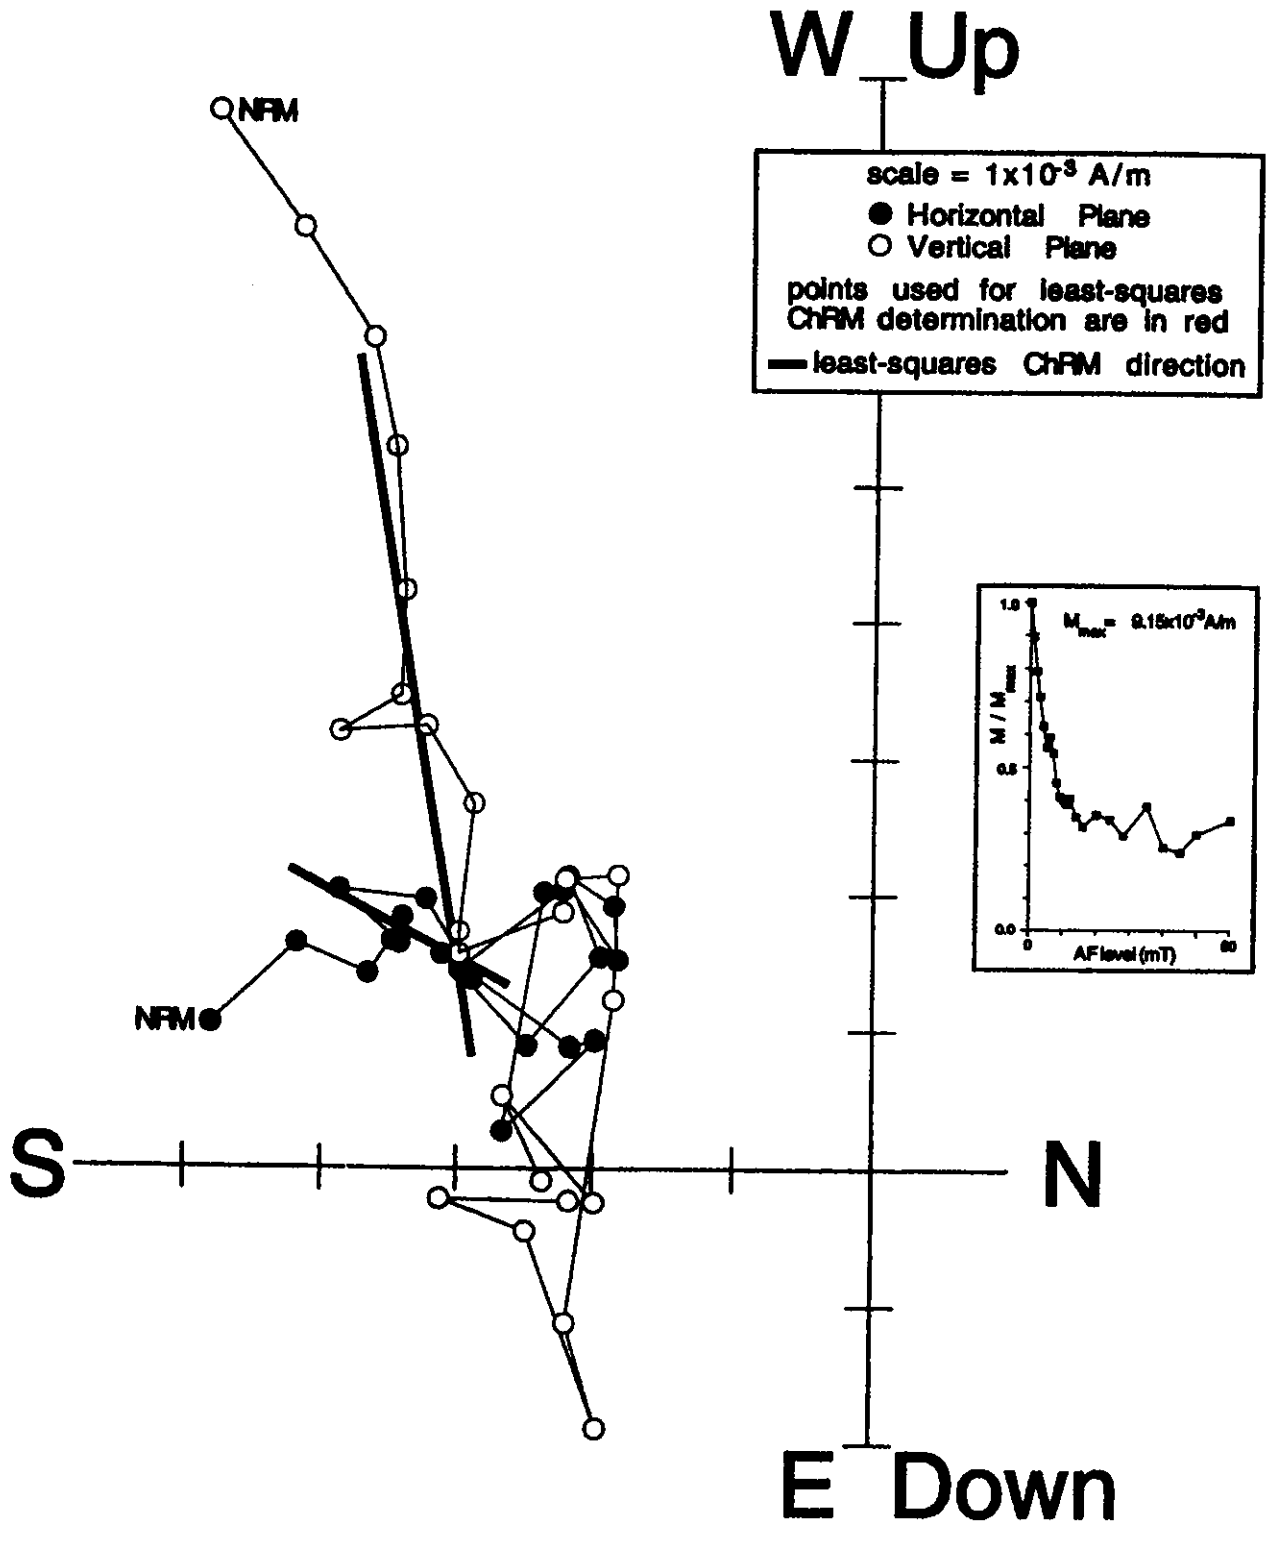
Introduction

Seventeen minimally-consolidated, oriented samples were collected from the most fine-grained segments of the drill core (Table 1). The samples consisted of cubes "carved" from the drill core. Plastic sample boxes were placed over/around each cube before it was detached from the core. Sample lithology varied between fine and coarse grained sand, but in all cases was very loose and therefore likely sustained some randomization from shaking in transit from Washington to Santa Cruz. Upon arrival, samples were cemented with sodium silicate solution and in some cases were capped with alumina cement to prevent the loss of sample. Samples were analyzed in a 3-axis DC SQUID cryogenic magnetometer, housed in a shielded room at the UC Santa Cruz paleomagnetism lab.

Demagnetization Experiments

We conducted unusually detailed alternating field (AF) demagnetization experiments on the samples to reveal their characteristic remanent magnetization (ChRM) directions. Typical AF demag steps were; NRM, 1, 2, 3, 4, 5, 6, 7, 8, 10, 13, 16, 20, 25, 30, 35, 40,... milli-Tesla (mT). Demagnetization was considered complete when the remaining sample magnetization intensity was <10% of NRM, or more than 3 consecutive directions along a sample's demag path were highly scattered and non-collinear. Typically, samples dropped below 50% of their NRM intensity before the 10 mT AF step and the ChRM is at least partially revealed by 10 mT. This indicates low coercivity magnetization of the samples, leading to concern about the samples being overprinted *in situ*, or during drilling, transportation and storage. None of the rigorous paleomagnetic tests for sample overprinting (reversal test, fold test, conglomerate test) are available to us due to the nature of the samples (derived from one drill core and apparently containing no magnetic reversals). However, any *in situ* overprinting with a reversed-polarity direction would require that the samples existed during a reversed chron of significant length, still making them >780 ka. Furthermore, the observed ChRM is of similar inclination to that expected for the Hanford geographic area. Overprinting during drilling could have induced a uniform overprint, but since the observed ChRM is not parallel to the drill string (inclination direction ±90), it is unlikely caused by drilling. Overprinting by the earth's field during sample storage is possible, if the core segments were all stored parallel, and with their tops all toward the same direction. However, to produce the observed ChRM the cores would have to be stored flat side down with the core tops pointing in a northerly direction. This is not the case. The cores were stored flat side up and therefore overprinting during storage is unlikely unless the storage location possesses a uniform ambient field opposed to the earth's field.

Thermal demagnetization experiments were not conducted since the samples were extremely friable and contained in plastic sample boxes. It is very possible that thermal demag would yield superior results if samples could be cemented prior to removal from the drill core.



Least-squares Sample Analysis

We obtained the ChRM directions by fitting least-squares lines to the demagnetization data (see Zijderveld diagrams on the following pages). Typically, higher level demag segments of the demagnetization paths degenerated to highly-scattered, semi-random collections of points. Thus points chosen for least-squares fitting are at relatively low demag levels, although generally we

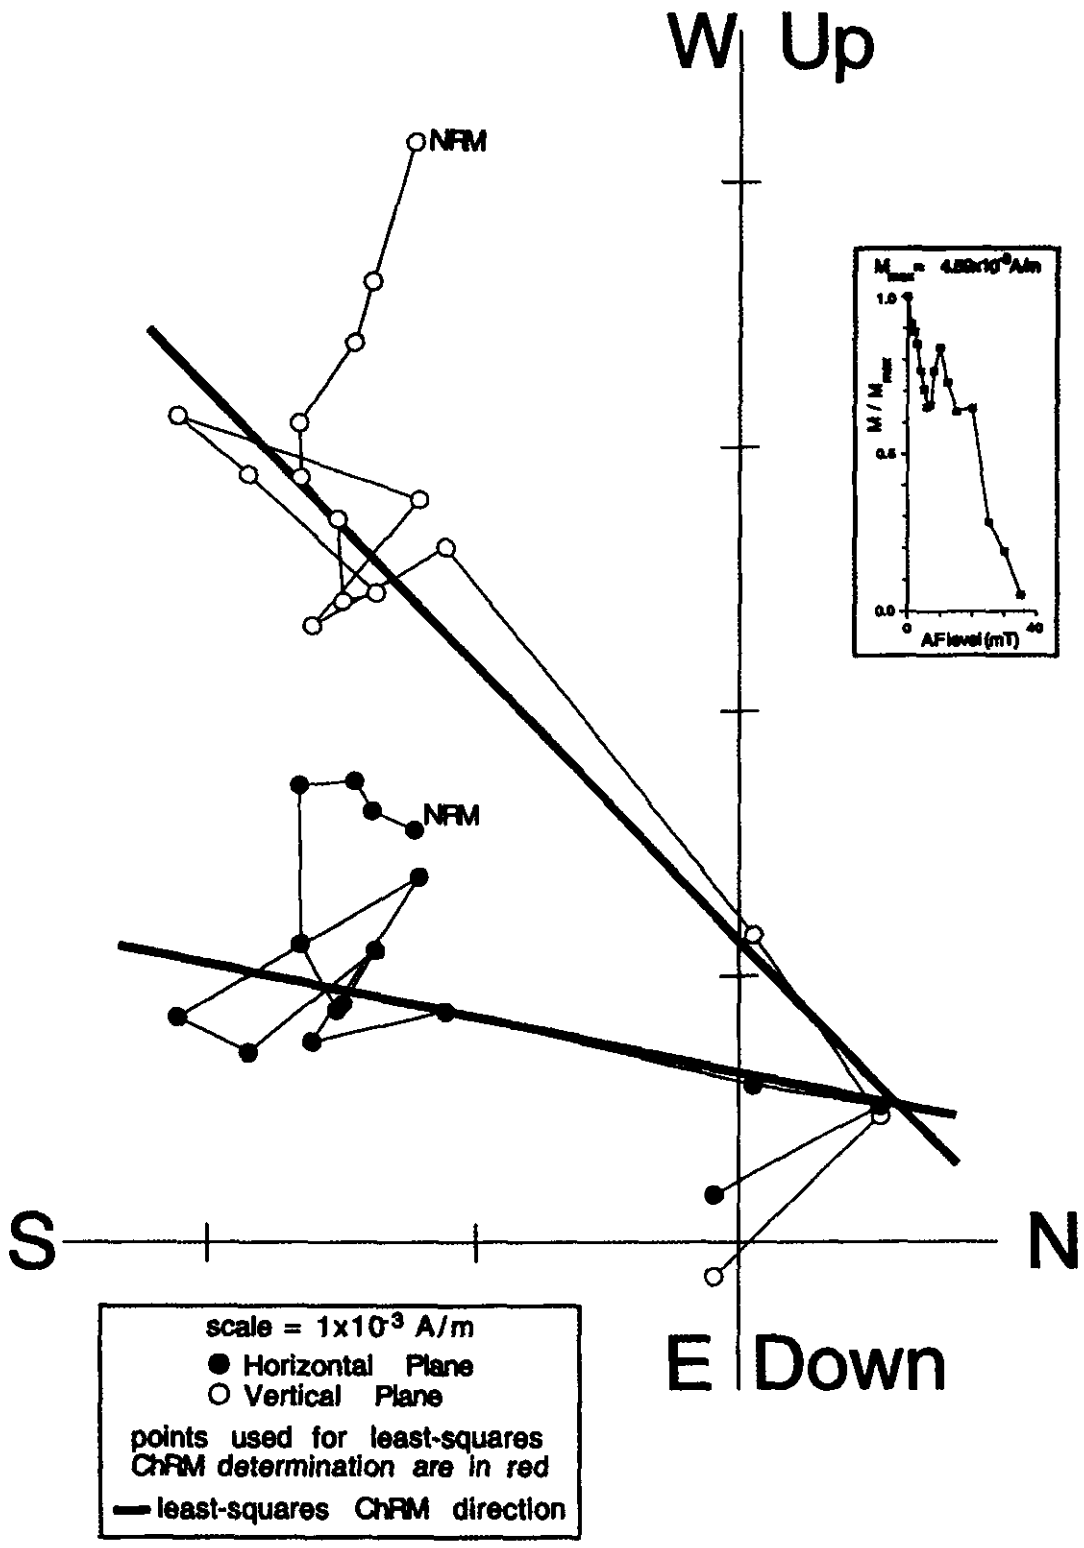


Table 1 - Borehole 299-E17-21 Stratigraphic, Lithologic and Paleomagnetic Summary

magnetic overprints. While least-squares analysis of some points is rather questionable, all such ChRM directions were chosen because of favorable agreement with samples derived from the same drill-core segment, creating the most plausible magnetostratigraphy.

Least-squares analysis was not performed on core segment 26A because of the highly scattered nature of the data and lack of a consistent ChRM for the core segment. Either magnetic overprint or physical disruption has degenerated the paleomagnetic quality of these samples. However, it is noteworthy that these samples nonetheless possess an upward inclination or the demag path heads towards an upwards inclination. We therefore interpret this core segment to be of reversed polarity.

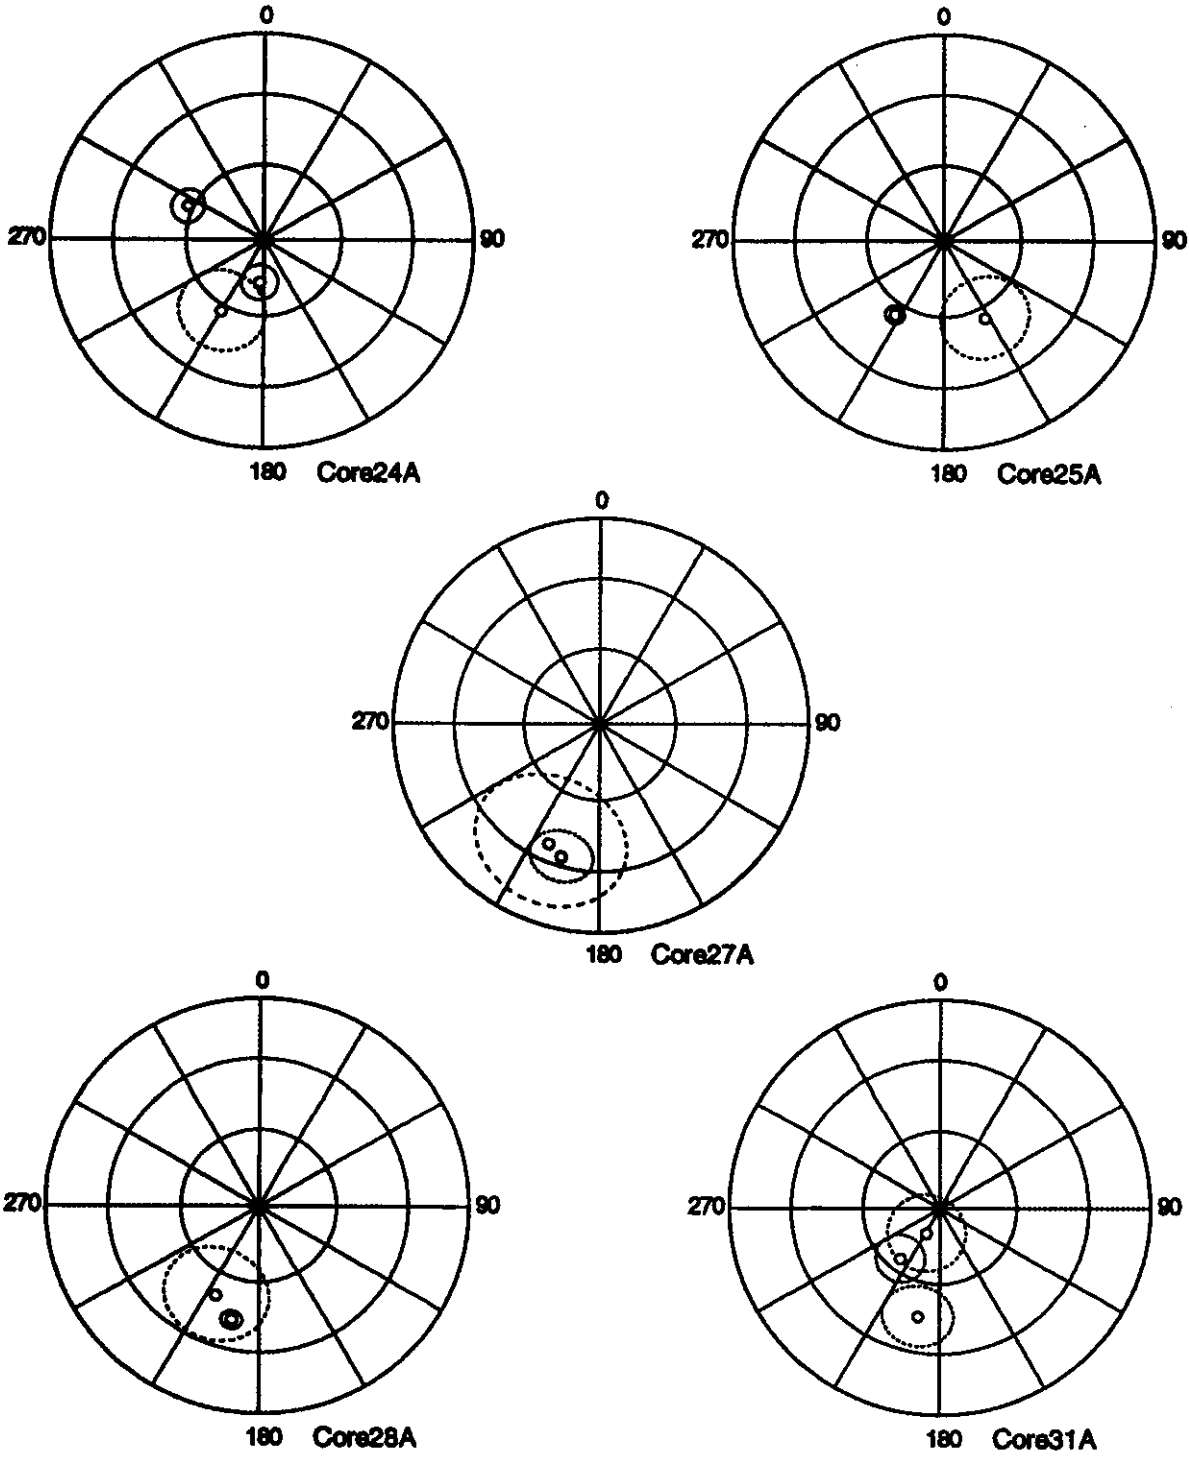
Lithology only somewhat controls the quality of individual sample results. Samples 1-3 are the finest-grained and yield some of the best results (Table 1). However, samples 8-12 are the next-finest-grained and yield the poorest results, with very coarse-grained samples 4-7 and 13-18 yielding fair to good results.

Magnetostratigraphy

The figure on the next page shows the ChRMs of each core segment in equal area stereographic projection. Presumably, within each core segment there has been a minimum of disruption from drilling and therefore the ChRMs from each segment will be oriented consistently relative to each other. As one can see, this is plausibly true - each cluster of directions only occupies approximately one quadrant. The ChRM inclination is essentially that expected for the geographic latitude of the drilling site during a reversed-polarity chron. Note that only core 26A fails to provide well-grouped, easily-interpreted directions. We believe this results from disruption of the core while drilling, rather than the samples indicating some normal polarity chron.

Orientation between core segments should be random, as we understand it, due to the method of core retrieval. However, this appears not to be the case, resurrecting the possibility that the ChRM is some sort of uniformly-induced overprint like that which might be acquired from earth's field applied to a neatly stored drill core.

Observations



1. All but three samples have reversed polarity (i.e., upward) remanent magnetizations.
2. Of the three normal polarity samples, the demagnetization paths of two appear headed towards reversed polarity.
3. Essentially the demagnetization paths of all seventeen samples miss the origin.

Interpretations

1. The samples we have analyzed were magnetized mainly in a reversed polarity magnetic field, and was probably also deposited in a reversed field. Therefore, the age of these sediments is greater than 780 ka.
2. Only 5 of the seventeen samples have a low-coercivity normal-polarity overprint (samples 6, 9, 10, 11, 13).
3. Some samples appear to have a small, high-coercivity normal overprint, possibly resulting from the mineral geothite. While almost all samples become unstable at the higher AF levels, and therefore fail to decay smoothly to the origin.

Conclusions

Despite the lack of consolidation, paucity of fine-grained material, and non-ideal demagnetization behavior, the reversed paleomagnetic signal strongly suggests that this core is older than 780 ka. Either it is a primary magnetization acquired at or shortly after deposition (our preferred interpretation) or it is a secondary overprint. In either case it was acquired in a reversed polarity chron, the youngest known of which ended 780 ka ago.

Sample Characteristic Remanent Magnetization Directions
Presented in equal-area stereographic projections and plotted separately for each core segment, except Core 26A which did not yield ChRMs (see text). Open circles signify projection onto the upper-hemisphere, and each direction is accompanied by an alpha 95.

Summary Stratigraphic Cross Sections for the Existing and New Immobilized Low-Activity Waste Disposal Sites

Appendix C

Summary Stratigraphic Cross Sections for the Existing and New Immobilized Low-Activity Waste Disposal Sites

This appendix provides summary diagrams showing cross sections for the existing and new Immobilized Low-Activity Waste (ILAW) disposal sites based on the more detailed geology presented in Section 4.0. Figures C.1, C.2, and C.3 are for the existing ILAW disposal site. Figures C.4, C.5, and C.6 are for the new ILAW disposal site. These figures were constructed to show the principal features of both sites for use in the ILAW Performance Assessment. Thin, local layers or layers with uncertain extent that depicted in the cross sections in Section 4.0 were omitted. Clastic dikes are not shown because their locations are not known even though they are suspected of being present.

IMMOBILIZED LOW ACTIVITY WASTE INVENTORY DATA PACKAGE

1.0 INTRODUCTION

1.1 BACKGROUND

Radionuclide and chemical inventories in the Immobilized Low Activity Waste (ILAW) product are needed to support the 2001 Low Level Tank Waste Performance Assessment (ILAW PA). Previously, radionuclide inventories were generated for the Performance Assessment (Mann 1998) based on ORIGEN2 calculations of total radionuclide production, with adjustments for estimated losses to obtain total glass inventories (Schmittroth 1995). New inventories are needed that reflect current operational planning and include nominal and reasonable bounding values that account for the variability between individual ILAW packages.

1.2 OBJECTIVES

The objective of this study is to provide radionuclide and chemical inventories for the 2001 ILAW PA that are based on 1) the Tank Waste Retrieval System (TWRS) Characterization Program tank-by-tank Best Basis Inventories (BBI), 2) the latest U.S. Department of Energy – Office of River Protection guidance, 3) the privatization contract for Phase 1 waste retrieval and vitrification, 4) available information on the BNFL, Inc. pretreatment and vitrification processes, and 5) proposed operating scenarios for retrieval of waste from double shell tanks (DST) and single shell tanks (SST) and delivery of feed to BNFL, Inc. and future low level waste vitrification contractors. These inventories address variability between individual ILAW packages as a function of time due to processing sequence. Both nominal and reasonable upper bounding values, along with a general assessment of uncertainties for key inventory components, are provided.

1.3 APPROACH

Nominal ILAW package radionuclide and chemical inventories are based on the latest edition of the Tank Waste Remediation System Operation and Utilization Plan (TWRSO&UP) (Kirkbride 1999), which incorporates BBI tank inventories, DOE guidance, the privatization contract requirements for Phase 1, and waste retrieval operations planning studies. The project planning case (Case 3) is used, which is based on the April 1, 1999, DOE Guidance (Taylor 1999), and completes processing in 2034. The TWRSO&UP provides processed inventories at the time of vitrification for each batch of LAW feed vitrified into ILAW. These batchwise inventories included losses associated with tank retrieval and feed preparation, but did not include offgas losses. For this study, the ILAW inventories were adjusted for estimated losses of volatile species during the vitrification process.

Inventories of trace organic and dangerous waste constituents not covered by the TWRSO&UP are treated as bounded by the land disposal restriction treatment standards

described in the Tank Waste Remediation System - Privatization Project Dangerous Waste Permit Application (BNFL 1999).

Reasonable upper bounds are developed for the total ILAW inventory and representative ILAW package inventory for key inventory components based on Best Basis tank inventories, global process based tank inventories, total reactor production, batch-to-batch variations from the tank processing operations, and Phase 1 contract specifications. The bounding values and uncertainties are based on qualitative considerations and conservative assumptions since consistent quantitative uncertainty information on the tank inventories, separation factors, and process losses are not available at this time.

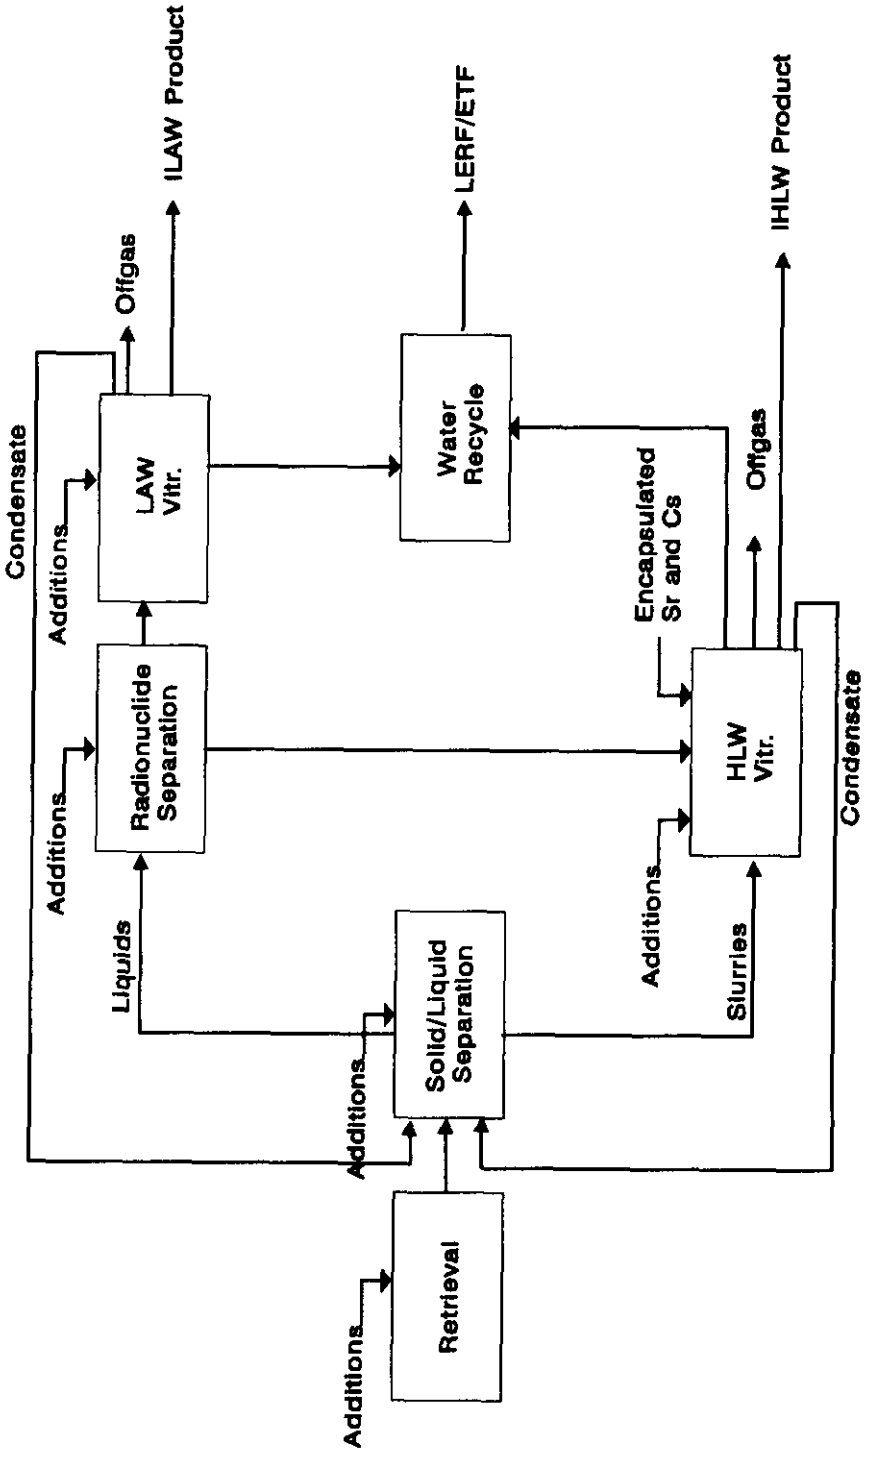
2.0 LAW PROCESSING

The LAW processing involves 1) retrieval of tank contents, 2) producing LAW feed through separation of solid and liquid components by water washing and caustic leaching, 3) pretreating the liquid LAW feed to concentrate and remove selected components as required in the Phase 1 contract, and 4) vitrification of the pretreated LAW feed with recycle of captured offgasses. Figure1 provides a simplified process flow diagram for the ILAW processing.

Feed material transferred to BNFL Inc. and Phase 2 treatment contractors is subjected to a series of pretreatment and treatment operations, such as caustic leaching, radionuclide separations, and immobilization. Current models are based on the Project Hanford Management Contract (PHMC) understanding of these operations (Kirkbride 1999). As discussed in Kirkbride 1999,

"It is unlikely that future Private Contractors will propose drastically different flowsheets or come to drastically different conclusions about the final product volume unless DOE's long term strategy undergoes major changes. Those volumes are driven by a relatively small number of parameters that are for the most part understood and not expected to change."

These models could be improved by more specific details of the Phase 1 and Phase 2 processes from BNFL Inc. and the Phase 2 contractor as they become available.



2.1 TANK INVENTORIES

The DST and SST inventories developed for the TWRSO&UP (Kirkbride 1999) provide the starting point for the ILAW inventories. The tank inventory for the TWRSO&UP is based on the tank-by-tank best basis inventory (BBI) data as of October 1, 1998, (LMHC 1998). The BBI includes 46 radionuclides and 25 chemicals. For the TWRSO&UP studies, the BBI values were adjusted for waste transfers not accounted for in the BBI, data were added for non-BBI analytes that are in the BNFL contract, and the BBI inventories were adjusted to a common date (October 1, 1998). Details of these adjustments can be found in the TWRSO&UP (Kirkbride 1999).

The BBIs were developed by considering and reconciling all sources of tank inventory information (sample results, engineering assessments, and inventory predictions from the

Hanford Defined Waste (HDW) model). The HDW model (Agnew 1997) supports the BBI effort by providing the basis for distribution on a tank-by-tank basis for radionuclides that were not represented by tank specific sample data.

Figure 1 Simplified Process Flowsheet for ILAW Processing

2.2 LIQUID AND SOLID PARTITIONING

In the TWRSO&UP the BBI tank-by-tank inventories were partitioned into water soluble and water-insoluble phases using the most recent water wash data for each tank (Hendrickson 1998). Caustic wash data (Colton 1997) were applied to the HLW feed calculations (Kirkbride 1999). The tank inventory components were distributed between liquid and solid phases in the TWRSO&UP by applying tank specific wash factors for every BBI analyte (Hendrickson 1998). Global caustic leach factors were applied to the water-insoluble phases to model the LAW generated as part of the HLW feed preparation.

2.3 FEED DELIVERY

The project planning case (Case 3) in the TWRSO&UP is based on the April 1, 1999, DOE Guidance (Taylor 1999). This option completes processing in 2034 assuming Glass Property Model oxide loadings in HLW (Kirkbride 1999).

This processing scenario assumes the following (Kirkbride 1999):

- BNFL Inc. will start processing by their Integrated Master Plan (IMP) dates.
- The BNFL Inc. facilities can start up and operate at their proposed maximum production rates (i.e., no capacity ramp up) as given in the contract.
- BNFL Inc. stores the entrained solids at their facility rather than returning them to the DST system.
- Phase 2 starts in 2018 with 60 MT ILAW/day rates
- A transition period (Phase 1B-Prime) bridges the completion of Phase 1 contract quantities in 2012 and the start of Phase 2 in 2018.

2.4 PHASE 1 AND PHASE 2

Based on Case 3 of the TWRSO&UP, Phase 1 produces a total of 117,605 MT of ILAW, which corresponds to approximately 19,295 ILAW packages. The Phase 1 contractor will deliver the ILAW product in 1.4 m cubic packages. Each package contains 2.3 m^3, or 6095 kg, of glass. Phase 2 produces a total of 301,374 MT of ILAW, which corresponds to approximately 49,446 ILAW packages. Since no specific guidance is provided for Phase 2 ILAW packaging, the Phase 1 standard package was used for Phase 2. Table 2.1 summarizes the ILAW volume, mass, and number of packages for the reference case (Case 3 of the TWRSO&UP) (Kirkbride 1999).

Table 2.1. Summary of Phase 1 and Phase 2 ILAW Package Production

	Total m^3 glass	Total MT glass	Total Packages
Phase 1	44379	117605	19295
Phase 2	113726	301374	49446
Total	158105	418979	68741

Phase 1 actually consists of two phases, as specified in the BNFL contract. Phase 1B meets minimum order quantities specified by contract and Phase 1B-Prime is for additional BNFL Inc. operations through February 2018, the period of performance for the Phase 1 contract.

2.5 PRETREATMENT

The following description of the LAW pretreatment process is summarized from the TWRS-P Project Dangerous Waste Permit Application (BNFL 1999). Pretreatment of LAW feed involves concentrating the waste feed and removing strontium, transuranics (TRU), cesium, technetium, sulfates, and entrained solids from the waste feed prior to vitrification. The LAW feed stream is concentrated in the LAW Feed Evaporator. The LAW Feed Evaporator is a continuous, forced-circulation evaporator that concentrates the feed to provide consistent feed for the ion-exchange process. Condensate is collected, analyzed, and transferred to the 200 Area Effluent Treatment Facility. Non-condensable gases extracted from the evaporator system are routed to the pretreatment building offgas treatment system. Following evaporation, the concentrated LAW is sent to the ultrafiltration process to separate entrained solids. For certain wastes, strontium and TRU removal is accomplished by adding reagents to precipitate the strontium and TRU out of solution, where they are removed by ultrafiltration. The liquid fraction is passed through successive ion exchange systems to remove cesium and technetium. If required, sulfate is removed by a further ion exchange process.

2.6 VITRIFICATION

The concentrated LAW from the melter feed evaporator is combined with glass forming chemicals and mixed. Dry glass formers (e.g., silica, alumina, boric acid, calcium silicate) are tailored to the waste feed of each batch to obtain the desired glass formulation. The waste and glass former slurry is transferred as a continuous feed to LAW joule-heated melters. The operating temperature in the LAW melters is expected to be approximately 1050-1200 °C. The chemically active region of the melt is the cold cap, which will be at 600-800 °C. Superheated gases and volatile feed components are released into the melter offgas treatment system. The solids and a fraction of the semi-volatile components entrained in the offgas are captured and recycled back into the process. The glass content of an ILAW package is 6095 kg. The density of the LAW glass is 2.65 MT/m^3 which correlates with the net glass volume per package of 2.3 m^3 (Kirkbride 1999). The ILAW package is a 1.4 m cube with an external volume of 2.74 m^3 (Kirkbride 1999).

2.7 OFFGAS LOSSES AND RECYCLE

Pretreated LAW vitrification feed contains large amounts of material that, because of boiling point, decomposition temperature, or low solubility in the glass melt, become volatile during vitrification. Over half of the mass in LAW feed is volatile under melter conditions. Nearly all inorganic constituents (e.g., carbonate, nitrate, nitrite, water) and perhaps small molecular weight organics containing carbon, hydrogen, and nitrogen are likely to volatize or

decompose, and be released as an emission source during vitrification. Steam distillation is another pathway for analytes to be transported from the melter (cold cap) to the offgas treatment system. Some semi-volatile components are partially recaptured and recycled so there is a net loss to the volatiles streams. The balance of the semi-volatiles is completely recaptured and vitrified. Table 2.2 shows the fraction of each volatile or semi-volatile feed component that is retained in the ILAW product based on current limited knowledge of the BNFL Inc. offgas treatment process (Kirkbride 1999).

Table 2.2. Net Volatility Around Low-Activity Waste Vitrification

Feed Component	Fraction Retained in ILAW
Volatiles lost during vitrification	
Water	0.0
Carbon	0.0
Hydrogen	0.0
Nitrogen	0.0
Noble gases	0.0
Hydroxide	0.0
Nitrite	0.0
Nitrate	0.0
Cyanide	0.0
Carbonate	0.0
Ammonia	0.0
Semi volatiles partially captured and recycled	
Sulfur	0.9
Mercury	0.2
Iodine	0.25
Selenium	0.9
Semi volatiles captured by offgas scrubbing and recycled	
Cesium	1.0
Technetium	1.0
Boron	1.0
Silver	1.0
Ruthenium	1.0
Molybdenum	1.0
Chlorine	1.0
Fluorine	1.0

2.8 PHASE 1 PRIVATIZATION CONTRACT LIMITATIONS

The Phase 1 privatization contract with BNFL Inc. (DOE-RL 1996 MOD A006 1998) specifies radionuclide and dangerous waste concentration limits in the ILAW product. These specifications include:

- Class C limits as defined in 10 CFR 61.55 and as described in NRC's Branch Technical Position on Concentration Averaging and Encapsulation. (alpha emitting transuranic nuclides with half-life greater than 5 years < 100 nCi/g)
- Average concentration of ^{137}Cs <3 Ci/m^3, average concentration of ^{90}Sr < 20 Ci/m^3, and average concentration of ^{99}Tc < 0.1 Ci/m^3.
- On average, remove at least 80% of the ^{99}Tc present in the LAW feed.
- The ILAW product shall be acceptable for land disposal under the State of Washington Dangerous Waste Regulations, WAC 173-303, and RCRA LDR in 40 CFR 268.

Phase 2 requirements are assumed to be the same as Phase 1.

3.0 NOMINAL INVENTORIES

The batch-by-batch ILAW radionuclide and chemical inventories are listed in Appendix HA for the reference Phase 1 and Phase 2 operating scenario. These are based on the TWRSO&UP inventory that was the basis for Table 3.5.1 in Kirkbride 1999, with additional factors from Table 2.2 applied to account for offgas losses during vitrification. These are based on processing both the water-soluble and insoluble fractions of the tank inventories, with sufficient pretreatment to remove technetium, cesium, strontium, and TRU to meet specifications on average concentrations. The requirement to remove 80% of the ^{99}Tc in the LAW feed was not imposed on these batch inventories. Every batch is at or below the average concentration specification limit for ^{99}Tc, ^{137}Cs, ^{90}Sr, and TRU. No hazardous organic chemicals are included in the nominal inventories because they are not expected to survive the vitrification process (Kirkbride 1999). Radionuclide batch inventories have been decayed to the time of processing. These inventory values represent partitioning of the tank wastes, and do not include any additives to the waste feed such as glass formers or other chemicals for removals (except for sodium added for feed processing).

The following components of the original batch inventories were reduced to zero by the offgas removal correction: ^{14}C, ^{3}H, CO_3, H, H_2O, NO_2, NO_3, OH, NH_3, and TOC.

The batch inventory data values were zero for several components that were identified in Kirkbride 1999 as being required for characterizing the HLW feed Envelope D. These components included CN-, Co+3, Nd+3, Pd+2, Pr+3, Pu+4, Rb+, Rh+3, Ru+3, Sb+5, Ta+5, Tc+7, Te+6, Th+4, Tl+3, V+5, W+6, and Y+3.

The TWRSO&UP inventory as currently configured does not remove ^{134}Cs or Cs+ from the LAW feed along with ^{137}Cs removals. Therefore the ^{134}Cs and Cs+ values were adjusted so that the ILAW to BBI ratios were the same as for ^{137}Cs. This adjustment was also applied to the Appendix HA values.

The batch inventory values for ^{79}Se and ^{126}Sn have the same half-life basis as the BBI, which are based on ORIGEN2 values (see Appendix HC for a list of relevant half lives from the ORIGEN2 library). Recent studies have indicated that improved half-life values could be used

for these radionuclides (Harmsen 1998). Table 3.1 shows the old and new half-life values and the factor that could be used to adjust the activity values for these radionuclides. The amounts of ^{79}Se and ^{126}Sn expressed in curies in Appendix HA and in the remaining tables in this report should be multiplied by the adjustment factor in Table 3.1 to reflect these improved half-lives. The values in this report are based on the old half-lives for consistent comparisons with the BBI and existing data.

Table 3.1 Half-Life Corrections for ^{79}Se and ^{126}Sn

Component	ORIGEN2 Half-life (years)	New Half-life (years)	Activity Adjustment Factor
^{79}Se	6.50E+04	8.05E+05	0.08
^{126}Sn	1.00E+05	2.46E+05	0.40

4.0 UPPER BOUNDS FOR RADIONUCLIDES AND CHEMICALS

4.1 TOTAL ILAW INVENTORIES

The major sources of uncertainty for the total ILAW inventory are the uncertainties in the tank inventories, the split between HLW and LAW (the wash and leach factors and radionuclide removal factors, and offgas losses of volatile and semi-volatile components. Currently, uncertainties for the total tank inventories, wash and leach factors, and offgas losses during vitrification have not been consistently quantified. Therefore, the approach was taken to estimate bounding inventories for most components by neglecting the processing losses.

The batchwise nominal inventories described in Section 3 are decayed to the processing date. For comparison with other inventory values and the development of bounding values, each batch inventory was decay corrected to a common date of 1/1/94, the date for the BBI radionuclide values. The individual batch inventories were then summed for Phase 1, Phase 2, and total ILAW inventories. The chemical inventories were also converted from kg-moles to kg.

For comparison, the total tank inventories (adjusted tank-by-tank BBI from the TWRSO&UP, including both LAW and HLW feed tanks) were separated into Phase 1 and Phase 2 inventories. The Phase 1 tanks are those shown in Table 4.1, which are based on the Case 3 tank operations described in Kirkbride 1999. The tanks are shown in the approximate order of retrieval. All other tanks were taken to be Phase 2. This is not precise, since some of the wastes in these tanks will be processed in phase 2, and some of the wastes will end up in HLW. The actual tank retrieval sequence and selection of tanks for Phase 1B and Phase 1B-Prime has not been approved by DOE. The tank sequence will be finalized in the multiyear work plan. It is likely that some changes will be made to the tanks listed in Table 4.1. Such changes may affect the distribution of inventory between Phase 1 and Phase 2 but should not affect the total inventory.

Table 4.1 Phase 1 Tanks

	LAW Tanks	HLW Tanks
Phase 1B	AN107 AN104 AN102 AN105 SY101 AN103 AZ101* AZ102*	AZ101 SY102 AW103 AZ102 AY102 C106 AY101
Phase 1B-Prime	AW101 AW104 AP105 AP104 AP101	C104 AW104 C102 AW105

*pretreated, staged waste

Note: The actual tank retrieval sequence and selection of tanks for Phase 1B and Phase 1B-Prime has not been approved by DOE.

Table 4.2 lists these ILAW inventories and compares them with the TWRSO&UP total tank inventories, the Global tank inventories based on process knowledge (Kupfer 1999), and the total radionuclide production in the fuel in the reactors before it was processed (Watrous 1997). The difference between the ILAW inventory and the tank inventory can be attributed to the high level waste (HLW) fraction, residual tank heel, radionuclide separations to meet contract specifications, and losses to the offgas stream. The global tank inventory values and the reactor production values generally provide support to the BBI sum-of-tank values. Additional discussion for selected components can be found in Appendix HB.

Table 4.3 shows the resulting upper bounding values for Phase 1, Phase 2, and Total ILAW inventories based on these comparisons. For most components, the upper bound limit on total ILAW inventory was taken as the BBI tank inventory, neglecting any processing and separations losses. For radionuclides limited by the contract specifications (^{99}Tc, ^{137}Cs, ^{90}Sr, and TRU), the contract limits were used as upper bounds. Neglecting the processing losses between the tank inventory and the ILAW inventory provides a very conservative bounding value, but was used to compensate for the lack of uncertainty information on the separations factors (wash and leach effectiveness, offgas treatment, solids retention). Additional discussion for several special case components follows.

^{99}Tc

The ^{99}Tc values for the batch-by-batch Phase 1 and Phase 2 ILAW inventories from the TWRSO&UP did not include the contract requirement to reduce the feed ^{99}Tc by 80%. Therefore, The ^{99}Tc summation value for the total ILAW was adjusted downward to be 20% of the BBI total tank inventory. The Phase 1 and Phase 2 totals for ^{99}Tc were scaled proportionately. This overestimates the ILAW inventory since it assumes that all of the ^{99}Tc in

the tanks is represented in the feed. The resulting total inventory is 48% less than the total of the TWRSO&UP ILAW inventory in Appendix HA (1.21E4 Ci). Users should be aware that use of the ^{99}Tc values from Appendix HA will result in a total inventory that is high by about a factor of 2. It is likely that BNFL will meet the 80% reduction requirement by applying separations to selected batches or types of feed, so that many of the batch inventories may not be affected. Upper bound values in Table 4.3 are 15% higher than the nominal inventories to allow for uncertainties in the tank inventories, but not exceed the total reactor production. Consistent with the assumption that the Phase 1 requirements will be applied to Phase 2 as well, these limitations provide reasonable bounding inventory values.

The best basis value for ^{99}Tc agrees reasonably well with the process knowledge based (global) estimate. The best basis value is likely the more valid since the global estimate does not account for known losses of ^{99}Tc that occurred during fuel separation operations (Kupfer 1999). There is good evidence that 20% or more of the technetium produced was separated from the waste stream during initial fuel reprocessing, mainly co-processed with the UO_3 and sent offsite, but with minor losses to the environment as well (Schmittroth 1995). The HDW global inventory for ^{99}Tc may be biased high by about 32% due to it's not accounting for the fractional separation of Tc to the uranium product stream in the uranium recovery, PUREX and REDOX processes (cribbing, offsite shipment, U contaminant). Approximately 60% of the tank summation inventory is based on the HDW model (Kupfer 1999). The BBI ^{99}Tc total tank inventory of 28,900 Ci is 87% of the total reactor production. The total production value for ^{99}Tc is likely known within 10% since it depends primarily on well known fission product yields and the production reactor histories.

The only way the nominal total ^{99}Tc ILAW inventory could be larger would be for the tank inventory to be higher. However, the tank inventory is constrained by the total reactor production. The ILAW inventory could be smaller due to any ^{99}Tc not retrieved from the tanks or incorporated into IHLW, or to smaller than expected tank inventories. A reasonable estimated uncertainty in the ILAW ^{99}Tc total inventory would be on the order of 15% to account for these effects, with the assumption that the Phase 1 requirements will be applied to Phase 2 as well.

^{137}Cs, ^{90}Sr

The ^{137}Cs and ^{90}Sr inventory in the ILAW are also constrained by the BNFL Inc. Phase 1 contract specifications. The ILAW inventory values are the sum of the batch values that include the decay correction to the reference date of 1/1/1994. This explains why they are higher than strictly applying the concentration limit to the entire ILAW volume at the reference date. BNFL could exceed the ^{137}Cs and ^{90}Sr ILAW inventory in Table 4.2 by simply making more glass at the concentration limit. The upper bound values in Table 4.3 were created by increasing the contract limited values based on the nominal ILAW glass volume of 158105 m^3 by a factor of 1.3 to allow for uncertainty in the total volume of ILAW glass produced. Based on these constraints, the uncertainty in the ^{137}Cs and ^{90}Sr total ILAW inventory in Table 4.2 is estimated to be on the order of 30%.

The best-basis values for ^{137}Cs and ^{90}Sr agree with the global values. The majority of the tank summation inventory is based on samples.

The TWRSO&UP inventory as currently configured does not remove ^{134}Cs or Cs+ from the LAW feed along with ^{137}Cs removals. Therefore the ^{134}Cs and Cs+ values were adjusted so that the ILAW to BBI ratios were the same as for ^{137}Cs. This adjustment was also applied to the Appendix HA values.

TRU

Bounding values for the TRU isotopes (as defined in the Phase 1 privatization contract limits for TRU isotopes with half-lives greater than five years as interpreted in Kirkbride 1999) neptunium, plutonium, americium, and curium inventories (except ^{242}Cm and ^{241}Pu) were developed by adjusting the sum of these component inventories to the contract limit of 100 nCi/g (contract limit). The upper bound values in Table 4.3 were created by increasing the contract limited values based on the nominal ILAW mass of 418979 metric tons by a factor of 1.3 to allow for uncertainty in the total mass of ILAW glass produced. The relative proportions of these components were kept the same as in the sum of batch inventory. The inclusion of ^{241}Pu in the TRU limits in the TWRSO&UP is questionable because ^{241}Pu decays primarily by emitting a beta particle. Only 0.0024% of the decays result in alpha particle emission. Since the ^{241}Pu curie inventory is comparable to the major TRU isotopes ^{239}Pu and ^{241}Pu, the ILAW inventory values for the TRU isotopes could be as much as 30% higher than the values in Appendix HA and still be within the 100 nCi/g limit. An overall uncertainty for the total TRU would thus be on the order of 30 %. Individual component uncertainty could be higher.

^{126}Sn

Most of the best-basis (tank-by-tank summation) and all of the global inventory estimate for ^{126}Sn are based on the HDW model. The HDW curie value of ^{126}Sn could be reduced by a factor of 0.4 to account for a recently updated half life value, and by a factor of 0.78 to account for a better fission yield value. The nominal ILAW inventory value of 423 Ci is approximately 36% of the tank inventory. The tank inventory is approximately 75% of the total reactor production. An overall uncertainty on the order of 300% is likely for the ^{126}Sn inventory to cover the uncertainty in the fraction of the tank waste that makes it to the ILAW product.

^{79}Se

Most of the best-basis (tank-by-tank summation) and all of the global inventory estimate for ^{79}Se are based on the HDW model. These ORIGEN2 based calculations of ^{79}Se production could be reduced by a factor of 0.85 to account for a lower fission yield and by a factor of 0.08 to account for a recently updated half life value. The total BBI tank value is only 20% greater than the ILAW inventory. To provide an additional safety margin, the upper bounding ILAW inventory was created by increasing the tank inventory by a factor of 1.3 to be comparable to the total production value. The uncertainty in the nominal ILAW inventory is estimated to be on the order of 70% to account primarily for the tank inventory uncertainties.

^{129}I

The best-basis of ^{129}I is somewhat larger than the global estimate. The global (HDW model) estimate conservatively assumes that all of the ^{129}I in the fuel was routed to the waste tanks. Thus the reason for the higher tank sum is not inherently obvious. The difference could be due to sample error, but is likely not due to underestimated model values. Both best basis and global inventory values are likely to be significantly higher than actual values (Kupfer 1999). The calculated ^{129}I production in the fuel could be reduced by a factor of 0.76 to account for a better fission yield value (Harmsen 1998). The nominal ILAW inventory is based on the TWRSO&UP assumption that only a fraction of the ^{129}I would be incorporated into the ILAW product, with the bulk of the ^{129}I diverted through the offgas system to the atmosphere or other solid waste forms. If the ^{129}I cannot be released to atmosphere or a secondary waste product, then the ILAW inventory would be comparable to the tank inventory. The BBI sum of tank value was used as the upper bound total ILAW ^{129}I inventory. Since this 101 Ci value is a factor of 1.6 higher than the total produced, an adequate safety margin is assured to account for uncertainties in production and tank inventories. The uncertainty in the nominal ILAW ^{129}I inventory is large, in the range of 300-500%, to reflect the uncertainty in the amount of ^{129}I returned to the ILAW glass from the offgas treatment system.

^{226}Ra, ^{228}Ra, ^{227}Ac, ^{229}Th, ^{231}Pa

The tank summation inventories for these isotopes (alpha decay chain daughters of uranium and thorium isotopes) are based essentially on the HDW model estimates, due to lack of any direct analytical data from samples. The estimate for these daughter radionuclides is substantially overpredicted due to the lack of proper second-order decay functions in the HDW model (Kupfer 1999). The buildup of these daughter products from decay of the uranium and thorium in the ILAW will overshadow the initial inventories (Kupfer 1999).

Table 4.2 Comparison of Nominal ILAW Inventory With Tank Inventory and Total Production

	ILAW Inventory (radionuclides are in Ci at 1/1/94 chemicals are in kg)			BBI Sum of Tanks (radionuclides are in Ci at 1/1/94 chemicals are in kg)			Global Inventory (Kupfer 1999)	Total Produced (Watrous 1997)

a) These were corrected values based on improved activation calculations described in Harmsen 1998.
b) These are daughter products of uranium and thorium that were not treated correctly in the HDW model because uranium, thorium, and plutonium were decayed prior to separations (Kupfer 1999). The inventory values for these radioisotopes may be significantly in error and their long term growth should be calculated concurrently with the calculation of waste migration and elemental retardation. The reason for the discrepancy between BBI and Global Inventory needs further investigation.
c) These are total production values with no product separations.
d) Isotope quantity limited by contract (see Section 2.8). Values in table for ILAW inventory may exceed contract concentration limits due to decay between the reference date (1/1/94) and the date of batch processing.
e) The TWRSO&UP inventory as currently configured does not remove ^{134}Cs or Cs+ from the LAW feed. Therefore the ^{134}Cs and Cs+ ILAW values were adjusted so that the ILAW to BBI ratio was the same as for ^{137}Cs.
f) ^{241}Am is overestimated by approximately a factor of 10 in Watrous 1997 because the parent ^{241}Pu was not separated. The HDW model corrected for this.
g) Zero entries in the ILAW inventory indicate the component was 100% released to the offgas system.
h) NA entries refer to components where inventory information is not available.
i) The ^{90}Sr will have ^{90}Y daughter in equilibrium. The ^{137}Cs will have ^{137m}Ba daughter in equilibrium.
j) U (total) was treated in TWRSO&UP as Total U - U radionuclides

Table 4.3 Upper Bound Inventories for ILAW

4.2 ILAW PACKAGE UPPER BOUNDS

The main contributor to the variability in the inventory in an ILAW package or group of packages are the tank-to-tank variations in inventories. Each batch of LAW feed represents one or more tank contents after it has been retrieved and subjected to the wash and leach processes. The approach taken was to combine the bounding ILAW total inventory and batch-to-batch variations in inventory values along with the Phase 1 BNFL Inc. contract radionuclide limits to determine bounding concentrations for the ILAW packages. The Phase 2 limits are assumed to be the same as for Phase 1. The intent was not to identify the extreme concentration limits of an individual package, but to provide reasonable bounding values. There could be situations where recycle buildup, filter cleanouts, or other situations provide small amounts of ILAW that approach the acceptability limits for some components. However, reasonable variations for groups of packages were judged to be adequately represented by the batch to batch variability, which primarily reflects the variability in the tank concentrations.

Table 4.4 shows concentration values for the average Phase 1, average Phase 2, and the maximum batch concentration based on the batchwise inventories described in Section 3, but decay corrected to the reference date of 1/1/94. The processing assumptions used in the TWRSO&UP for Case 3 included both small batches representing internal processing by BNFL Inc. as well as the major batches. Individual batches may be pretreated LAW, ion exchange column wash, HLW caustic wash, etc. As such the averaging effect that normally occurs due to the internal parallel treatment and blending operations of the vitrification facility are not apparent. Thus the maximum to average ratio shown in Table 4.4 should be greater than what actually will occur in the vitrification plant. With the exception of Be, which has a maximum to average concentration ratio of 140, caused by the segregation of zirconium cladding waste, the ratios are all well under 100 and frequently under 10.

The second and third columns of Table 4.5 show the average concentrations based on the total nominal ILAW inventory and the total upper bound inventory from Table 4.3. The nominal average package concentration is determined by dividing the total nominal ILAW inventory (Table 4.2) by the total volume of waste produced (Table 2.1). The upper bound for a package or group of packages was determined by increasing the average concentration based on the total upper bound inventory by the ratio of the maximum batch concentration to the average batch concentration. An additional multiplicative factor representing the uncertainty in an individual tank inventory was then applied. This approach is shown in Table 4.5. The ratio of the

maximum batch to average batch was taken from Table 4.4. The tank uncertainty factors were roughly based on the BBI tank inventory uncertainties (Ferryman 1998). These tank-by-tank uncertainties were examined for the major components of concern to the performance assessment, and in general, a factor of 3 characterized the typical variations between the 90% confidence values and the nominal values for tanks with substantial inventories of a given component. Much larger values can be found, but these generally applied to tanks with relatively small inventories of the given component, or where discrepancies exist between the inventory used in the uncertainty studies and the BBI tank inventories used for this study. This factor was assumed to be a factor of 10 for the components that were not based on BBI data. The contract limits for ^{99}Tc, ^{90}Sr, and ^{137}Cs of 0.1, 20, and 3 Ci/m^3 can be exceeded as long as the average is maintained below these values. The 10CFR 61.55 Class C limits cannot be exceeded. The Class C limits for ^{99}Tc, ^{90}Sr, and ^{137}Cs are 3, 7000, and 4600 Ci/m^3. Other radionuclides with Class C limits are ^{129}I (0.08 Ci/m^3), ^{14}C (8 Ci/m^3, ^{63}Ni (700 Ci/m^3), ^{241}Pu (3500 nCi/g - which corresponds to 9.28 Ci/m^3 at 2.65 MT/m^3 glass density), and ^{242}Cm (20,000 nCi/g – which corresponds to 53 Ci/m^3 at 2.65 MT/m^3 glass density). The Class C limits provide the ultimate upper bounds for these isotopes for a single package or group of packages. The TRU (alpha emitting Np, Pu, Am, and Cm radionuclides with half life greater than 5 years) concentration is limited by contract to 100 nCi/g (this is also the Class C limit). There is no exception within the contract for ILAW with greater than 100 nCi/g TRU. With a glass density of 2.65 MT/m^3, the 100 nCi/g limit corresponds to 0.265 Ci/m^3. Thus, the sum of the ^{237}Np, ^{238}Pu, ^{239}Pu, ^{240}Pu, ^{242}Pu, ^{241}Am, ^{243}Am, ^{242}Cm, and ^{244}Cm curie inventory must be within this limit for every package. The upper bound for a package or group of packages is shown in the last column of Table 4.5

a) Class C Limits

4.3 HAZARDOUS CHEMICALS

The ILAW packages must meet the land disposal restriction (LDR) treatment standards for compliance with the Washington State Dangerous Waste Regulations contained in Chapter 173-303 of the Washington Administrative Code (WAC). The LDR regulations are found in 40 CFR 268 and WAC173-303-140. The privatization regulatory Data Quality Objectives (DQO) (Wiemers 1998) identified a set of regulatory constituents plausible to be in the tank waste and which might be considered during permitting activities in support of the treatment facility. The TWRS-P Project Dangerous Waste Permit Application (BNFL 1999) compared these constituents to the "Universal Treatment Standards" (40 CFR 268.48) and provided a list of components and LDR treatment standards. These LDR treatment standards provide an upper bound concentration for acceptability of the ILAW product. These maximum concentrations were multiplied by the glass mass produced in Phase 1 and Phase 2 from Table 2.1, along with a safety factor of 1.3 to allow for uncertainty in the total glass mass, to provide bounding inventories of trace hazardous organic chemicals in the ILAW product. These are summarized in Table 4.6 for Phase 1, Phase 2, and total ILAW inventories. The 1,160,000 kg total inventory of organic chemicals is a little more than half of the total 2,000,000 kg tank inventory of TOC.

Table 4.6 Bounding Limits for Organic Chemicals in ILAW Packages

Organic Compounds	LDR Treatment Standard (mg/kg)	Upper Bound Organic ILAW Inventory (MT)

5.0 CONCLUSIONS

Nominal and bounding inventories for radionuclides, tank chemicals, and organic chemicals for the Phase 1, Phase 2, and total ILAW processing have been generated. Uncertainties in the nominal ILAW inventory were addressed qualitatively using engineering judgement for selected components. Nominal and bounding concentrations for ILAW packages have also been generated. The bounding values and uncertainties were based on qualitative considerations and conservative assumptions since consistent quantitative uncertainty information on the tank inventories, separation factors, and process losses are not available at this time.

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with ofgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date.

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory
TWRS0&UP Case 3 by LAW feed batch with offgas losses
(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Batch	Starting Date	Total m3 glass	Processing Days	Days to fill cask	Al(OH)4- kg-mol	Al+3 kg-mol	As+5 kg-mol	B+3 kg-mol	Ba+2 kg-mol	Be+2 kg-mol	Bi+3 kg-mol	Ca+2 kg-mol	Cd+2 kg-mol	Ce+3 kg-mol	Cl- kg-mol	CO3-2 kg-mol	Cr(OH)4- kg-mol	Cr(TOTAL) kg-mol	Cs+ kg-mol

Appendix A Nominal ILAW Inventory

TWRSO&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are *Ci for radionuclides and kg-mol for chemicals*)

Batch	Starting Date	Total m3 glass	Processing Days	Days to fill cask	Cu+2	F-	Fe+3	H+	H2O	Hg+2	K+	La+3	Li+	Mg+2	Mn+4	Mo+6	Na+	NH3	Ni+2

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS0&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date.

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Batch	Starting Date	Total m3 glass	Processing Days	Days to fill cask	3-H	14-C	59-Ni	60-Co	63-Ni	79-Se	90-Sr	93-Zr	93m-Nb	99-Tc	106-Ru	113m-Cd	125-Sb	126-Sn	129-I

Appendix A Nominal ILAW Inventory
TWRSO&UP Case 3 by LAW feed batch with offgas losses
(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory
TWRS O&UP Case 3 by LAW feed batch with offgas losses
(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS0&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory
TWRSO&UP Case 3 by LAW feed batch with offgas losses
(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS/O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date.

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS0&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS0&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Batch	Starting Date	Total m3 glass	Processing Days	Days to fill cask	NO2- kg-mol	NO3- kg-mol	OH(BOUND) kg-mol	OH- kg-mol	Pb+2 kg-mol	PO4-3 kg-mol	Se+6 kg-mol	Si+4 kg-mol	SO4-2 kg-mol	Sr+2 kg-mol	Ti+4 kg-mol	TOC kg-mol	U(TOTAL) kg-mol	Zn+2 kg-mol	Zr+4 kg-mol

Appendix A Nominal ILAW Inventory
TWRS O&UP Case 3 by LAW feed batch with offgas losses
(Components are decayed to starting date.
units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRSO&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date.

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Batch	Starting Date	Total m3 glass	Processing Days	Days to fill cask	3-H	14-C	59-Ni	60-Co	63-Ni	79-Se	90-Sr	93-Zr	93m-Nb	99-Tc	106-Ru	113m-Cd	125-Sb	126-Sn	129-I

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory
TWRS O&UP Case 3 by LAW feed batch with offgas losses
(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory
TWRSO&UP Case 3 by LAW feed batch with offgas losses
(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Batch	Starting Date	Total m3 glass	Processing Days	Days to fill cask	Al(OH)4-	Al+3	As+5	B+3	Ba+2	Be+2	Bi+3	Ca+2	Cd+2	Ce+3	Cl-	CO3-2	Cr(OH)4-	Cr(TOTAL)	Cs+

Appendix A Nominal ILAW Inventory
TWRSO&UP Case 3 by LAW feed batch with offgas losses
(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,
units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS O&UP Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)

Appendix A Nominal ILAW Inventory

TWRS Case 3 by LAW feed batch with offgas losses

(Components are decayed to starting date,

units are Ci for radionuclides and kg-mol for chemicals)
