D.4.01	Remove boat from furnace and let cool for one hour on boat stand.	Glove damage/operator burn	Boat removed from furnace too early or boat not allowed to cool on boat stand before handling.	Operator burns hole in glove and suffers injury while removing boat from furnace. Hole in glove compromises glovebox confinement.	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across hole in glove. Glovebox ventilation system removes enough heat to prevent overheating of glovebox air with furnace door open. Door/power interlock shuts off power to furnace coil when furnace door opened, minimizing radiant heat on gloves and glovebox panels. Furnace thermocouples and chart recorder indicate when it is safe to open furnace door.	By procedure, operators are not allowed to remove furnace boat until furnace is below 200 C. Hot mill gloves used with boat handling tool to remove boat from furnace. By procedure, boat is left on boat stand to cool for one hour before being handled by glove.	S1	F3	
D.4.02	Remove boat from furnace and let cool for one hour on boat stand.	Glovebox fire or radiant heat damage to glovebox confinement boundary	Door opened during heating cycle to remove boat	Radiant heat from coils melts gloves and burns operator, softens and potentially ignites glovebox panels Potential activation of glovebox dry fire suppression system (Halon system). Potential ignition of combustibles in glovebox. Release of Pu to room air and uptake by workers.	Furnace interior temp indication Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across hole in glove. Door/power interlock shuts off power to furnace coil when furnace door opened, minimizing radiant heat on gloves and glovebox panels. Furnace thermocouples and chart recorder indicate when it is safe to open furnace door.	Operators trained not to remove boat from furnace or to open furnace door until temperature has dropped below 200 C. Combustible loading in glovebox is controlled.	S1* S1	F2 F2	Each furnace produces about 1800 W of heat. From the PFP FHA, a 34 kW/m^2 heat flux is sufficient to ignite a polycarbonate panel in 10 minutes. S1*/F2 for glovebox fire S1/F2 for softening of panels or failure of port bags.

A. General Glove box Hazards									
F.3.01	Remove sieve tray(s) from shaker, remove pieces too large to fit through sieve (> 4 mesh) and grind using mortar and pestle for reprocessing through furnace, transfer contents that passed through sieve (< 4 mesh) to product can.	Spill/dispersal of Pu oxide powder in glovebox	Material spilled while transferring contents into product can.	Increased direct dose to workers working near glovebox due to increase in contamination level of glovebox.	Glovebox confinement boundary and E-4 ventilation system confine release. E-4 HEPA filters mitigate release to the environment through the 291-Z exhaust stack.	Housekeeping practices: spilled material is swept up, placed in cans, and sealed out of glovebox to minimize direct dose to workers. Institutional radiation protection program: radiological control technicians set glovebox dose rates to limit worker direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures the E-4 ventilation system is operating properly before initiating operations.	S0	F3	No hazards identified for weighing step. Pu Accountability error only.
F.3.02	Remove sieve tray(s) from shaker, remove pieces too large to fit through sieve (> 4 mesh) and grind using mortar and pestle for reprocessing through furnace, transfer contents that passed through sieve (< 4 mesh) to product can.	Pu metal added to product can causing rupture of container in storage vault.	Material not heated long enough or at high enough temperature in furnace to completely oxidize metal due to furnace failure or failure of furnace temperature controller. Sieve and size reduction step skipped due to human error results in metal pieces not being detected. Metal pieces not removed from oxide material before transferring material to product can.	Rupture of container in storage vault due to the formation of Pu oxide (assuming storage cans is not airtight). PuO_2 is less dense and takes up more volume than metal causing can rupture. Contamination of vault air. Potential uptake by workers on entry into vault. Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	Vault ventilation system and HEPA filters mitigate release to the environment. Pedestals in vault are instrumented to detect bulging cans. CAMs in vault alert workers to airborne contamination. Furnace chart recorder readings are used to verity proper furnace operation and soak time.	Operator training and procedures Radiological control program: Routine sampling of vault air. Blend plan identifies material processed in this campaign to be previously stabilized oxide material, minimizing likelihood of material containing excess moisture from being recanned even if undetected furnace upset occurs. Shift technical advisor sign off required by procedure.	S1	F2	S1/F2 based on no significant compressed gas present when can ruptures.

A. General Glove box Hazards									
F.7.02	Bag out of sample bottles from Glovebox HC-18M for transfer to the lab for LOI analysis Bag out of product cans from Glovebox HC-18M for transfer to storage vault.	Pu release from sample bottle or product can after bagout	Sample bottle or product can dropped after bagout causing bottle to break or slip lid to come off and bag to rupture.	Contamination of workers and potential uptake of radiological material	E-3 ventilation system filters mitigate release to environment should material be release to Zone 3 area. Room CAMs alert workers to airborne contamination.	Operator training and procedures Radiological control program. Survey of workers with alpha poppy probes to detect skin contamination. Worker decontamination by RCT if necessary. Bagged sample bottles are placed in ice cream carton and then in special wagon for transport to the analytical lab. Carton reduces chances of airborne release in a drop. Product cans are double bagged in the process of being sealed out of the glovebox. Taped slip lid can and double bag minimize the likelihood of a release should the container be dropped.	S1	F3	
G. Natural Phenomena									
G.1.01	Plutonium oxide being thermally stabilized.	Seismic event causes explosion and stagnet glovebox.	Seismic event results in loss of electrical power and potentially a loss of ventilation. Loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	Seismic ventilation supply shutdown switch. Building structure.	Emergency procedures for evacuation.	S1*	F2	S1*/F2 based on seismic initiator frequency. F2 frequency assumed to be on the low side of the range.
G.1.02	Plutonium oxide in any unconfined state in gloveboxes	Seismic event causes dispersal of plutonium oxide powder in glovebox.	Seismic event results in dispersal of plutonium oxide powder into glovebox atmosphere.	Potential additional exposure to workers due to cleanup requirements.	Seismic ventilation supply shutdown switch. Building structure Glovebox structure	Emergency procedures	S1	F2	S1/F2 based on seismic initiator frequency. F2 frequency assumed to be on high side of range for events that do not fail glovebox.

Table 9F.2
PHA - Thermal Stabilization of PuO_2

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
A. General Glove box Hazards									
G.2.01	Plutonium oxide being thermally stabilized.	NPH - Ash Fall		Ash Fall represents a roof loading concern, abrasive concern for moving equipment, and an electrical concern because of the conductivity of the ash.					
G.3.01	Plutonium oxide being thermally stabilized.	NPH - High Wind		High Wind represents a threat to the 234-5Z Building but not to an individual glovebox inside the building. Chapter 9.0 of the PFP FSAR considers the effect of a wind-driven plank striking the 234-5Z Building and concludes that no significant consequences result.					
External Events									
H.1.01	Plutonium oxide being thermally stabilized.	Facility wide external loss of power with subsequent return of power causes flammable gas deflagration in or around stabilization furnace in glovebox HC-21C.	External event causes facility wide loss of power resulting in loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	Building structure. Backup ventilation system connected to emergency.	Emergency procedures	S1*	F3	
H.2.01	Plutonium oxide being thermally stabilized.	Facility wide loss of powerdue to range fire with subsequent return of power causes flammable gas deflagration in or around stabilization furnace in glovebox HC-21C.	Range fire causes facility wide loss of power resulting in loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	Building structure.	Emergency procedures Vegitation control programs	S1*	F3	This is not a threat to the 234-5Z building due to the large open areas that are kept clear of vegitation or combustible material buildup.

H.1.01	Facility wide loss of power with subsequent return of power causes flammable gas deflagration in or around stabilization furnace in glovebox HC-21C.	Loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	S1*	F3
H.2.01	Facility wide loss of power due to range fire with subsequent return of power causes flammable gas deflagration in or around stabilization furnace in glovebox HC-21C.	Loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	S1*	F3
H.3.01	Aircraft crashes into facility causing fire and loss of confinement. (General to all gloveboxes)	Pilot error or mechanical failure	Significant release of material	S1*	F0

Table 9F.9. Flammable Gas Deflagration in Glove Box

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
B.2.01	Flammable gas (i.e. H_2) release and burn when overpack can opened in glovebox HC-21A.	Radiolysis of plastic bag around slip lid can and organic can seal during storage in vault. Ignition due to mechanical spark from can opener, static release from ejected powders, or electrical spark.	Potential deflagration involving H_2 released from can causing pressurization of glovebox, potential failure of port bags or gloves and release of Pu into the room air. Inhalation uptake of Pu by workers.	S1*	F2
B.4.02	Hydrogen gas release and burn when can opened in glovebox HC-21A.	Radiolytic degradation of plastic contaminant, brush bristles, tool handle, bottle caps, etc. in oxide during storage generates hydrogen in can. Hydrogen ignited during release from can due to static or electrical discharge High water content in oxide (above 1%) due to prior inadequate stabilization results in can pressurization due to hydrogen buildup from reaction of the water with PuO_2 and radiolysis of the water.	Potential deflagration involving H_2 released from can causing pressurization of glovebox, potential failure of port bags or gloves and release of Pu into the room air. Inhalation uptake of Pu by workers.	S1*	F2
B.4.04	Flammable gases (alkanes, H_2, etc) from organic in container released and ignited when can opened (can pressurized) in glovebox HC-21A.	Container containing organic (e.g., sludge, floor sweeps) inadvertently sealed into glovebox and opened. Wrong container selected due to inaccurate labeling or human error. Flammable gases generated due to radiolytic decay of organic material (e.g., sludge) in the container. Ignition due to mechanical or electrical spark, or static discharge.	Pressurization of glovebox Potential damage to glovebox confinement boundary Pu release into room and worker inhalation uptake	S1*	F2
B.6.01.b	Flammable gas deflagration due to plastic contaminants not identified or removed from oxide that result in reaction hazards in Glovebox HC-21C furnaces. Contaminants can include tool handles, brush bristles, PVC or polyethylene bag fragments, polycarbonate pieces, etc.	Human error; step not performed correctly Contaminants not readily identifiable due to color, size, etc. Poor visibility through glovebox windows.	Fires or deflagrations of flammables in the furnaces in Glovebox HC-21C. See item D.3.07.	S1*	F2
D.3.07	Plastic contaminants in Pu oxide feed result in fire/deflagration in stabilization furnace in glovebox HC-21C.	Plastic contaminants not noticed in feed or not removed by operator (plastic contaminants can include PVC, polyethylene, polycarbonate, polystyrene, Polymethyl Methacrylate).	Fire or deflagration involving flammable gases (alkanes, alkenes, hydrogen, carbon monoxide) generated inside the furnace. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	S1*	F2

Table 9F.9. Flammable Gas Deflagration in Glove Box

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
D.3.09	Glovebox sweeps containing organic (plastics or sludge) processed through furnace results in flammable gas deflagration in stabilization furnace in glovebox HC-21C.	Wrong can selected from storage area opened in Glovebox HC-21A due to mislabeling or human error. Plus Failure to notice plastic contaminant or sludge in furnace boat during visual inspection in Glovebox HC-21C.	Deflagration in furnace, failure of furnace, and potential burn through of gloves, bag ports, or glovebox panels. Release of Pu from glovebox and potential uptake by operators. Possibly more plastics than in normal oxide	S1*	F2

Table 9F.10. Flammable Gas Deflagration in Waste Drum

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
B.7.03	Hydrogen venting or deflagrating inside waste drum in 234-5Z satellite accumulation area.	Hydrogen generation from radiolysis in waste bags in waste drum. Ignition caused by spark generated while moving drum.	Pressurization of drum, drum damage and release of radiological material from waste drum in satellite accumulation area (Room 166) Potential worker injury.	S1	F2

Table 9F.11. Loss of Glove Box Confinement Due to Mechanical Breach

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
A.1.03	Hole in glovebox confinement boundary leads to spread of contamination from glovebox (general glovebox hazard).	Degradation of port bags, ice cream cartons used to seal sphincter port, or gloves due to aging, radiation, or heat.	Minor Spread of contamination from glovebox and potential uptake by workers.	S1	F3
A.1.04	Breach in glovebox confinement boundary during waste bagout, port bag replacement, or glove change (general glovebox hazard).	Sharp object punctures bag Bag not properly horse tailed or taped Bag inadvertently pulled off port Original or replacement bag glove tears Bungee chord used to hold replacement bag slips or fails while removing inner (original) bag Replacement glove inadvertently pull off lip of port Bag/glove pinched when tightening port ring Replacement bag/glove has undetected hole in it	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers	S1	F3
B.1.03	Glovebox HC-21A loss of confinement during seal in.	Sphincter seal failure Ice cream carton or can in sphincter seal inadvertently pushed into glovebox without can or carton behind it results in open sphincter seal. Seal in bag torn or pulled off port during seal in (also applies to changeout of port bags) (see item A.1.04). Pressurized glovebox during seal in (see item A.3.01)	Minor release of contamination from the glovebox into the room. Potential worker uptake of Pu.	S1	F3
B.2.02.a	Damage to glovebox glove compromising glovebox HC-21A confinement integrity.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Small hole in glovebox confinement boundary Small contamination release from glovebox as hands withdrawn from glovebox gloves	S1	F3
B.2.04.a	Damage to glovebox glove compromising glovebox HC-21A confinement integrity.	Operator ruptures glove while crushing empty can with hammer	Small hole in glovebox confinement boundary leading to contamination release from glovebox.	S1	F3
B.4.01.a	Damage to glovebox glove compromising glovebox HC-21A confinement integrity.	Worker penetrates glove while opening sealed can with can opener, taped slip lid can with scissors, while handling can or lid.	Small hole in glovebox confinement boundary Small contamination release from glovebox	S1	F3

Table 9F.11. Loss of Glove Box Confinement Due to Mechanical Breach

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
B.7.01	Breach in glovebox HC-21A confinement boundary during waste bagout or glove change.	Sharp object punctures bag Bag not properly horsetailed or taped Bag inadvertently pulled off port Original or replacement bag glove tears Bungee chord used to hold replacement bag slips or fails while removing inner (original) bag Replacement glove inadvertently pull off lip of port Bag/glove pinched when tightening port ring Replacement bag/glove has undetected hole in it	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers	S1	F3
C.1.01	Glove damaged during conveyor operation compromising glovebox HC-2 confinement	Glovebox glove(s) pinched in conveyor during transfer	Worker injury and contamination Potential spread of contamination from glovebox through hole in glove leading to potential inhalation uptake by workers	S1	F3
D.2.01	Glove damage during load in/ load out of the stabilization furnaces in glovebox HC-21C.	Glove pinched in furnace door when closed or glove punctured by sharp object.	Operator injury with contamination of wound Small hole in glovebox confinement boundary leading to contamination release from glovebox.	S1	F3
D.2.02	Breach in glovebox HC-21C confinement boundary during bagout of combustibles or while withdrawing gloves from glovebox.	Sharp object punctures port bag while bagging out combustibles or while changing bag. Bag not properly horsetailed or taped after removing combustibles from glovebox. Bag inadvertently pulled off port during bagout of combustibles. Glove tears while being pulled out of the glovebox to prevent contact with hot furnace.	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers	S1	F3
D.2.03	Gloves melted by contact with furnace compromising glovebox HC-21C confinement.	Gloves not withdrawn from glovebox before starting furnace; gloves contact hot surface of furnace and melts. Gloves not secured properly with bungee cords after being pulled out of the glovebox; negative pressure causes gloves to be pulled into glovebox contacting hot spot on furnace.	Burned out glove allows contamination to spread from glovebox; potential uptake by workers. Operator burned while trying to pull glove back from furnace.	S1	F3

Table 9F.11. Loss of Glove Box Confinement Due to Mechanical Breach

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
D.3.03	Reduced air flow or no air flow during stabilization of material in furnace in glovebox HC-21C.	Plugged ceramic filter. Vacuum system valved out or otherwise blocked. Failure of vacuum pump or loss of power to vacuum pump. Other loads placed on 26 in vacuum system reduce airflow through furnace. Airflow not set properly before operating furnace.	Hot air from furnace vents into glovebox while heating oxide. Furnace not cooled down in intended time period after stabilization oxide. Potential damage to glovebox gloves and operator burn when boat removed from furnace.	S1	F3
D.4.01	Glove damage/operator burn in glovebox HC-21C	Boat removed from furnace too early or boat not allowed to cool on boat stand before handling.	Operator burns hole in glove and suffers injury while removing boat from furnace. Hole in glove compromises glovebox confinement.	S1	F3
F.7.01	Breach in glovebox HC-18M confinement boundary during waste bagout, bag change, or glove change.	Bag punctured by sharp object Bag not properly horsetailed or taped Bag inadvertently pulled off port Original or replacement bag glove tears Bungee chord used to hold replacement bag slips or fails while removing inner (original) bag Replacement glove inadvertently pull off lip of port Bag/glove pinched when tightening port ring Replacement bag/glove has undetected hole in it.	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers.	S1	F3
D.4.02. b	Glovebox fire or radiant heat damage to glovebox HC-21C confinement boundary.	Door opened during heating cycle to remove boat	Radiant heat from coils melts gloves and burns operator, softens glovebox panels Potential activation of glovebox dry fire suppression system (Halon system). Potential ignition of combustibles in glovebox. Release of Pu to room air and uptake by workers.	S1	F2

Table 9F.12. Loss of Glove Box Confinement Due to Ventilation Failure

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
D.3.06	Overheating of glovebox HC-21C.	Loss of E-4 ventilation flow during operation of furnace due to equipment failures, damper closures, etc.	Overheating of glovebox leading to possible failure of port bags and gloves and inadvertent operation of the glovebox dry fire suppression system. Potential softening and sagging of glovebox windows. Release of contamination through failed gloves or bag ports (or failed windows). Potential Pu uptake by workers. Evacuation of Zone 3 process areas leading to unattended glovebox which could result in inability to control fire if combustibles ignited.	S1*	F3
A.3.01.b	Pressurized glovebox during operations causes spread of contamination from glovebox (general glovebox hazard)	Loss of E-4 ventilation flow or imbalance between E-4 supply and exhaust (caused by loss of power or equipment or control failures). Failure to detect HVAC upset during pre-job walkdown	Pressurized glovebox causing spread of contamination from glovebox during seal in or seal out of container, glove change, or change of port bag. Worker exposure to dispersible Pu. Overheating of Glovebox HC-21C during furnace operations (see item D.3.06).	S1*	F2
A.3.01.a	Stagnant glovebox during operations causes spread of contamination from glovebox (general glovebox hazard).	Loss of E-4 ventilation flow or imbalance between E-4 supply and exhaust (caused by loss of power or equipment or control failures). Failure to detect HVAC upset during pre-job walkdown	Spread of contamination from glovebox during seal in or seal out of container, glove change, or change of port bag. Worker exposure to dispersible Pu. Overheating of Glovebox HC-21C during furnace operations (see item D.3.06).	S1	F3

Table 9F.13. Natural Phenomena

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
G.1.01	Seismic event causes explosion and stagnet glovebox. (General to all gloveboxes)	Seismic event results in loss of electrical power and potentially a loss of ventilation. Loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	S1*	F2
G.1.02	Seismic event causes dispersal of plutonium oxide powder in glovebox. (General to all gloveboxes)	Seismic event results in dispersal of plutonium oxide powder into glovebox atmosphere.	Potential additional exposure to workers due to cleanup requirements.	S1	F2
G.2.01	Natural Phenomena - Ash Fall	Ash Fall effects are described in Chapter 3.0 of the PFP FSAR.	Ash Fall effects are described in Chapter 3.0 of the PFP FSAR. Ash Fall represents a roof loading concern, abrasive concern for moving equipment, and an electrical concern because of the conductivity of the ash.	S1	F2
G.3.01	Natural Phenomena - High Wind	High Wind effects are described in Chapter 3.0 of the PFP FSAR.	High Wind effects are described in Chapter 3.0 of the PFP FSAR. High Wind represents a threat to the 234-5Z Building but not to an individual glovebox inside the building. Chapter 9.0 considers the effect of a wind-driven plank striking the 234-5Z Building and concludes that no significant consequences result.	S0	F2

Table 9F.14. Occupational Hazards

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
A.1.02	Electrical shock to operator while working in glovebox HC-21A	Cord frayed in the glovebox Frayed cord contacts glovebox frame while operators body or leg is in contact with the glovebox frame.	Operator injury	S1	F5

Table 9F.15. Operational Upset

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
B.2.03	Outer cans not properly made into non- container in glovebox HC-21A result in operational upset.	Can not crushed and folded, can with bottom removed set upright instead of on its side, can not turned upside down.	CPS infraction Margin of criticality safety reduced	S0	F3
D.3.01	Stabilization furnace temperature ramped up too fast (temperature controller fails high) resulting in furnace failure in glovebox HC-21C and process upset.	Controller failure. Programmer error. Relay contact fails closed.	Burn out of furnace coils leading to shutdown of process. No hazard found for heating oxide too fast.	S0	F3
D.3.04	Excessive airflow through furnace in glovebox HC-21C resulting I elevated particulate release to vacuum system causes process upset.	Flow rate set too high by operator.	Entrainment of flighty Pu oxide powder in furnace. Elevated release of particulates to vacuum system. Potential pluggage of ceramic filter leading to loss of vacuum flow (see item D.3.03)	S0	F3
D.3.05	Unfiltered flow through/around ceramic filter in glovebox HC-21C results in operational upset.	Filter cracked due to thermal stress Filter cracked or not properly installed in canister during installation/replacement.	Pu release into vacuum system Potential plugging of vacuum line between furnace and vacuum header.	S0	F3
B.5.03	Material other than Pu oxide poured into furnace boat in glovebox HC-21A (e.g., metal button, sludge or glovebox floor sweeps) resulting in process upset.	Wrong can opened due to mislabeling of can or human error.	Process upset. Material would have to be canned up and bagged out of the glovebox for later processing. Potential adverse reactions in furnace in Glovebox HC-21C if wrong material not noticed by operator.	S0	F2
D.3.10	Pu fluoride powder processed through furnace causes corrosion damage to furnace in glovebox HC-21C results in operational upset..	Wrong can selected for processing due to mislabeling or human error.	Fluorine gas release due to reaction with water vapor in air run through furnace. Damage to furnace vacuum exhaust system. Increased direct dose to operators. Pu fluoride produces higher direct dose than oxide (due to alpha-n reactions). See item B.1.02.	S0	F2

Table 9F.16. Pyrophoric Reaction in Furnace

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
D.3.08	Metal contaminant in feed results in pyrophoric reactions in the furnace in glovebox HC-21C.	Metal turnings or pieces not noticed or removed from feed in Glovebox HC-21A.	Reaction of pyrophoric metal or hydrided metal contaminant in furnace, leading to hydrogen release and burn in the furnace. Potential furnace damage. Failure of glovebox not expected due to small quantity of hydrided metal expected in feed.	S1	F3
B.6.01.a	Contaminants not identified or removed from oxide result in reaction hazards in Glovebox HC-21C furnaces. Pyrophoric contaminants can include unburned metal pieces from prior stabilization run, metal hydrides, uranium hydrides, or Pu_2O_3.	Human error; step not performed correctly Contaminants not readily identifiable due to color, size, etc. Poor visibility through glovebox windows.	Pyrophoric reaction in furnace in Glovebox HC-21A. See item D.3.08. Fires in the furnaces in Glovebox HC-21C. See item D.3.07.	S1	F2

Table 9F.17. Pyrophoric Reaction in Glove Box

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
B.5.01.b	Pyrophoric reaction as material poured through air in glovebox HC-21A.	Pu metal, PuH_2, Uranium hydride; Pu_2O_3 contaminant in can Pu or U metal may be in can due to incomplete prior stabilization. PuH_2, UH_3 forms from metal if plastic or organic contaminants are also present in. Or if hydrogen from degradation of the plastic bag outside the can diffuses into the can.	Sparks potentially initiating a glovebox fire. Hot embers entrained in air may burn hole in glovebox HEPA filters. Dispersal of Pu in glovebox Potential burn through of gloves and operator injury due to contact with hot embers. Burn through of PVC port bags. Minor contamination spread from glovebox if gloves or port bags damaged Potential ignition of combustibles in glovebox producing glovebox fire If sufficient hydride contamination present, slight pressurization of the glovebox could occur	S1*	F2
B.4.05.a	Pyrophoric reaction and hydrogen burn when can opened in glovebox HC-21A.	PuH_2 hydride contaminant in can Pu metal may be in can due to incomplete prior stabilization. PuH_2 forms from metal if plastic or organic contaminants are also present in can. Or if hydrogen from degradation of the plastic bag outside the can diffuses into the can. Can under vacuum due to catalyzed formation of oxides and nitrides in the container. When can is opened air is sucked in which reacts with the hydrided material. Hyride reactions releases heat and hydrogen gas which is ignited on exiting the can.	If sufficient hydride contamination present, slight pressurization of the glovebox could occur. Potential burn through of gloves and operator injury due to contact with hot embers. Embers burn through PVC ports Minor contamination spread from glovebox if gloves or port bags damaged.	S1	F3

Table 9F.18. Radiation Protection

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
B.1.02	High worker direct dose during handling of cans in glovebox HC-21A.	Container containing metal or PuF_4 handled instead of PuO_2 (PuF_4 much higher dose than oxide from alpha-n reactions). Cans handled for extended time period during handling/seal-in of cans.	Worker dose rate limit (Radiological work permit) potentially exceeded	S1	F3

Table 9F.19. Rupture of Container In Storage Vault

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
D.3.02	Inadequate stabilization of material in glovebox HC-21C furnace leads to rupture of container in storage vault.	Failure of furnace heating element. Loss of power during stabilization. Temperature controller failure (temperature not held high enough for required 2 h). Power shut off early by operator.	Rupture of container sometime after it is place in storage vault if furnace upset not detected and LOI test fails to determine high moisture content. PuO_2 reacts with water to form a binary oxide and hydrogen gas which overpressurizes the container. Potential worker inhalation hazard upon entering vault.	S1*	F2
F.3.03	Non-representative sample taken from product can for LOI testing in glovebox HC-18M.	Material not heated long enough or at high enough temperature to be adequately stabilized due to furnace or temperature controller failure. Material not sieved or ground properly. Large (> 4 mesh) agglomerations of PuO_2 can give false high or false low LOI readings depending on furnace operation and how long the sample was exposed to humid air after removal from the furnace.	Rupture of container in storage vault due to presence of excess water in product can. PuO_2 reacts with water to form a binary oxide and hydrogen gas, which can overpressure the storage container. Contamination of vault air and potential inhalation uptake by workers entering vault Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	S1*	F2
F.4.01	"Wet" oxide transferred to product can in glovebox HC-18M and stored in vault, resulting in rupture of container in vault.	Material not stabilized long enough or at high enough temperature in furnace due to temperature controller or furnace failure. LOI test fails to detect inadequate stabilized material due to non-representative sample being taken or material canned without benefit of LOI testing due to human error. Or LOI test results or can labels mixed up resulting in wrong can being authorized for storage in vault.	Rupture of container in storage vault due to presence of excess water in product can. PuO_2 reacts with water to form a binary oxide and hydrogen gas, which can overpressure the storage container. Contamination of vault air and potential inhalation uptake by workers entering vault Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	S1*	F2
F.5.01	"Wet" oxide transferred to product can in glovebox HC-18M and stored in vault, resulting in rupture of container in vault.	Inadequately stabilized material not run back through the furnace due to human error.	Rupture of container in storage vault due to presence of excess water in product can. PuO_2 reacts with water to form a binary oxide and hydrogen gas, which can overpressure the storage container. Contamination of vault air and potential inhalation uptake by workers entering vault.	S1*	F2

Table 9F.19. Rupture of Container In Storage Vault

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
F.3.02	Pu metal added to product can in glovebox HC-18M causing rupture of container in storage vault.	Material not heated long enough or at high enough temperature in furnace to completely oxidize metal due to furnace failure or failure of furnace temperature controller. Sieve and size reduction step skipped due to human error results in metal pieces not being detected. Metal pieces not removed from oxide material before transferring material to product can.	Rupture of container in storage vault due to the formation of Pu oxide (assuming storage cans is not airtight). PuO_2 is less dense and takes up more volume than metal causing can rupture. Contamination of vault air. Potential uptake by workers on entry into vault. Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	S1	F2

Table 9F.20. Uncontrolled Fire in Glove Box

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
A.1.01	Fire in glove box HC-21A caused by electrical short.	Failure to properly inspect power cords or failure to identify frayed cords results in condition that leads to an electrical short that ignites combustibles in the glovebox Failure to control combustibles in glove box allows significant fire that damages glove box confinement.	Burn through of gloves seal out bags resulting in breach of containment Ignition of Polymethyl Methacrylate or Polycarbonate glove box panels and spread of fire to other gloveboxes Release of soot, hot embers, and water vapor to the E-3 and E-4 ventilation systems. Pluggage or failure of glovebox and E-4 filterbox HEPA filters. Potential pluggage of E-3 room prefilters or E-3 filterbox HEPA filters, with spread of contamination to clean portions of the plant. Worker uptake of airborne Pu	S1*	F3
B.4.05.b	Pyrophoric reaction and hydrogen burn when can opened which ignites combustibles in glovebox HC-21A.	PuH_2 hydride contaminant in can Pu metal may be in can due to incomplete prior stabilization. PuH_2 forms from metal if plastic or organic contaminants are also present in can. Or if hydrogen from degradation of the plastic bag outside the can diffuses into the can. Can under vacuum due to catalyzed formation of oxides and nitrides in the container. When can is opened air is sucked in which reacts with the hydrided material. Hyride reactions releases heat and hydrogen gas which is ignited on exiting the can. AND Combustible loading in glovebox not controlled.	Potential ignition of combustibles in glovebox producing glovebox fire.	S1*	F2
D.2.04	Fire in glovebox compromises glovebox HC-21C confinement.	Combustibles not controlled in glovebox come in contact with hot surface of furnace while it is operating. Combustible loading allows fire to spread. Port bag comes un-horsetailed and gets sucked in and contacts hot surface of furnace.	Potential burn through of gloves or port bags, softening or ignition of glovebox windows leading to spread of Pu from compromised glovebox confinement boundary.	S1*	F2
D.4.02.a	Glovebox fire or radiant heat damage to glovebox HC-21C confinement boundary.	Furnace door inadvertently opened during heating cycle to remove boat.	Radiant heat from coils potentially ignites glovebox panels Potential activation of glovebox dry fire suppression system (Halon system). Potential ignition of combustibles in glovebox. Release of Pu to room air and uptake by workers.	S1*	F2

Table 9F.20. Uncontrolled Fire in Glove Box

Item #	Failure/ Hazardous Condition	Causes	Consequences	Cons Rank	Freq Rank
B.5.01.a	Pyrophoric reaction as material poured through air in glovebox HC-21A.	Pu metal, PuH_2, Uranium hydride; Pu_2O_3 contaminant in can Pu or U metal may be in can due to incomplete prior stabilization. PuH_2, UH_3 forms from metal if plastic or organic contaminants are also present in. Or if hydrogen from degradation of the plastic bag outside the can diffuses into the can. S0 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.4.03	**DISPERSAL OF Pu OXIDE POWDER - INSIDE GB**	PuO_2 particulate release from pressurized can when it is opened in glovebox HC-21A	Can temperature higher than when canned causes pressurized can Alpha decay causing pressure buildup (Helium usually diffuses out of can) High water content in oxide (above 1%) due to prior inadequate stabilization results in can pressurization due to hydrogen buildup from reaction of the water with PuO_2 and radiolysis of the water.	Pu particulate release inside glovebox Increased dose rate to workers near glovebox from spilled PuO_2.	E-4 ventilation system and glovebox confines release E-4 ventilation system HEPA filters mitigate release to the environment through the facility exhaust stack.	Housekeeping; spilled material is swept up and placed in cans and sealed out of glovebox. Institutional radiation protection program: Radiological control technicians set glovebox dose rates to limit operator direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures ventilation is operating correctly.	F3
F.2.01	**DISPERSAL OF Pu OXIDE POWDER - INSIDE GB**	Dispersal of Pu oxide powder in glovebox HC-18M.	Cover left off sieve tray while shaker on produces dust that spreads Pu throughout glovebox.	Increased direct dose to workers working near glovebox due to increase in contamination level of glovebox.	Glovebox confinement boundary and E-4 ventilation system confine release. E-4 HEPA filters mitigate release to the environment through the 291-Z exhaust stack.	Housekeeping practices: spilled material is swept up, placed in cans, and sealed out of glovebox to minimize direct dose to workers. Institutional radiation protection program: radiological control technicians set glovebox dose rates to limit worker direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures the E-4 ventilation system is operating properly before initiating operations.	F3
F.3.01	**DISPERSAL OF Pu OXIDE POWDER - INSIDE GB**	Spill/dispersal of Pu oxide powder in glovebox HC-18M	Material spilled while transferring contents into product can.	Increased direct dose to workers working near glovebox due to increase in contamination level of glovebox.	Glovebox confinement boundary and E-4 ventilation system confine release. E-4 HEPA filters mitigate release to the environment through the 291-Z exhaust stack.	Housekeeping practices: spilled material is swept up, placed in cans, and sealed out of glovebox to minimize direct dose to workers. Institutional radiation protection program: radiological control technicians set glovebox dose rates to limit worker direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures the E-4 ventilation system is operating properly before initiating operations.	F3

Table 9F.21.

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.4.03	**DISPERSAL OF Pu OXIDE POWDER - INSIDE GB**	PuO_2 particulate release from pressurized can when it is opened in glovebox HC-21A	Can temperature higher than when canned causes pressurized can Alpha decay causing pressure buildup (Helium usually diffuses out of can) High water content in oxide (above 1%) due to prior inadequate stabilization results in can pressurization due to hydrogen buildup from reaction of the water with PuO_2 and radiolysis of the water.	Pu particulate release inside glovebox Increased dose rate to workers near glovebox from spilled PuO_2.	E-4 ventilation system and glovebox confines release E-4 ventilation system HEPA filters mitigate release to the environment through the facility exhaust stack.	Housekeeping; spilled material is swept up and placed in cans and sealed out of glovebox. Institutional radiation protection program: Radiological control technicians set glovebox dose rates to limit operator direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures ventilation is operating correctly.	F3
F.6.01.a	**DISPERSAL OF Pu OXIDE POWDER - INSIDE GB**	Spill/dispersal of Pu oxide powder in glovebox HC-18M	Furnace boat dumped off conveyor.	Added dose to workers in recovering from spill. Increased direct dose to workers working near glovebox due to increase in contamination level of glovebox.	Glovebox confinement boundary and E-4 ventilation system confine release. E-4 HEPA filters mitigate release to the environment through the 291-Z exhaust stack. Conveyor has special pedestals to hold furnace boats	Housekeeping practices: spilled material is swept up, placed in cans, and sealed out of glovebox to minimize direct dose to workers. Institutional radiation protection program: radiological control technicians set glovebox dose rates to limit worker direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures the E-4 ventilation system is operating properly before iniating operations. Boat is transferred in a "boat cover" which limits the potential for Pu oxide dispersal from the RMC line supply air or dispersal should the boat tip over on the conveyor.	F3
B.1.01	**DROPPED CONTAINERS OUTSIDE GB**	Drop of Pu storage container outside glovebox HC-21A during seal in.	Human error.	No significant release from Pu storage container expected.	Overpack containers protect inner container.	Operator training and procedures Inner containers have been drop tested and found not to leak.	F3
G.3.01	**NPH - High Wind**	Addressed in Chapter 3.0 of PFP FSAR		High Wind effects are described in Chapter 3.0 of the PFP FSAR. High Wind represents a threat to the 234-5Z Building but not to an individual glovebox inside the building. Chapter 9.0 considers the effect of a wind-driven plank striking the 234-5Z Building and concludes that no significant consequences result.			F2

Table 9F.21.
S0 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.4.03	**DISPERSAL OF Pu OXIDE POWDER - INSIDE GB**	PuO_2 particulate release from pressurized can when it is opened in glovebox HC-21A	Can temperature higher than when canned causes pressurized can Alpha decay causing pressure buildup (Helium usually diffuses out of can) High water content in oxide (above 1%) due to prior inadequate stabilization results in can pressurization due to hydrogen buildup from reaction of the water with PuO_2 and radiolysis of the water.	Pu particulate release inside glovebox Increased dose rate to workers near glovebox from spilled PuO_2.	E-4 ventilation system and glovebox confines release E-4 ventilation system HEPA filters mitigate release to the environment through the facility exhaust stack.	Housekeeping; spilled material is swept up and placed in cans and sealed out of glovebox. Institutional radiation protection program: Radiological control technicians set glovebox dose rates to limit operator direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures ventilation is operating correctly.	F3
B.2.03	**OPERATIONAL UPSET**	Outer cans not properly made into non-container in glovebox HC-21A	Can not crushed and folded, can with bottom removed set upright instead of on its side, can not turned upside down.	CPS infraction Margin of criticality safety reduced	None	Operator training and procedures Glovebox CPS posting (tells operator maximum open container volume to unit mass ratio)	F3
B.5.03	**OPERATIONAL UPSET**	Material other than Pu oxide poured into furnace boat in glovebox HC-21A (e.g., metal button, sludge or glovebox floor sweeps) resulting in process upset.	Wrong can opened due to mislabeling of can or human error.	Process upset. Material would have to be canned up and bagged out of the glovebox for later processing. Potential adverse reactions in furnace in Glovebox HC-21C if wrong material not noticed by operator.	--	Labeling and paperwork associated with each container identify contents making it unlikely for unapproved material to be processed. Operator training and procedures	F2
D.3.01	**OPERATIONAL UPSET**	Stabilization furnace temperature ramped up too fast (temperature controller fails high) resulting in furnace failure in glovebox HC-21C	Controller failure. Programmer error. Relay contact fails closed.	Burn out of furnace coils leading to shutdown of process. No hazard found for heating oxide too fast.	Furnace temperature controller and furnace thermocouples: Controller shuts off furnace if program temperature and furnace temperature differ by more than 200 C. Controller limits maximum current to 17 amps which prevents coil burnout. Temperature alarm switch (TAS) shuts off power to furnace if temperature exceeds 1050 C. Temperature deviation alarm provides indication of furnace temperature greater than 20 degrees from controller setpoint at any given time.	Operator training and procedures. Calibration of controller.	F3

Table 9F.21.
S0 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.4.03	**DISPERSAL OF Pu OXIDE POWDER - INSIDE GB**	PuO_2 particulate release from pressurized can when it is opened in glovebox HC-21A	Can temperature higher than when canned causes pressurized can Alpha decay causing pressure buildup (Helium usually diffuses out of can) High water content in oxide (above 1%) due to prior inadequate stabilization results in can pressurization due to hydrogen buildup from reaction of the water with PuO_2 and radiolysis of the water.	Pu particulate release inside glovebox Increased dose rate to workers near glovebox from spilled PuO_2.	E-4 ventilation system and glovebox confines release E-4 ventilation system HEPA filters mitigate release to the environment through the facility exhaust stack.	Housekeeping; spilled material is swept up and placed in cans and sealed out of glovebox. Institutional radiation protection program: Radiological control technicians set glovebox dose rates to limit operator direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures ventilation is operating correctly.	F3
D.3.04	**OPERATIONAL UPSET**	Excessive airflow through furnace in glovebox HC-21C resulting I elevated particulate release to vacuum system	Flow rate set too high by operator.	Entrainment of flighty Pu oxide powder in furnace. Elevated release of particulates to vacuum system. Potential pluggage of ceramic filter leading to loss of vacuum flow (see item D.3.03)	Baffle in furnace reduces airflow directly over furnace boat minimizing suspension of particulates. Ceramic offgas filter removes majority of particulates before they enter the vacuum system header. DP gauge across ceramic filter provides indication of plugging. Demister and HEPA filters in vacuum system remove residual particulates from vacuum system air before discharge to the environment. DP and orifice place in vacuum system indicate flowrate.	Operator verifies correct flowrate throughout the vacuum system via rotameter before operating furnace.	F3
D.3.05	**OPERATIONAL UPSET**	Unfiltered flow through/around ceramic filter in glovebox HC-21C.	Filter cracked due to thermal stress Filter cracked or not properly installed in canister during installation/replacement.	Pu release into vacuum system Potential plugging of vacuum line between furnace and vacuum header.	Ceramic filter designed for high heat environment. DP gauge across ceramic filter provides indication of plugging. DP and orifice place in vacuum system indicate flowrate to detect plugging of vacuum line. Demister and HEPA filters in vacuum system remove residual particulates from vacuum system air before discharge to the environment.	Maintenance procedure for proper replacement of ceramic filter Operator training and procedures	F3

S0 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.4.03	**DISPERSAL OF Pu OXIDE POWDER - INSIDE GB**	PuO_2 particulate release from pressurized can when it is opened in glovebox HC-21A	Can temperature higher than when canned causes pressurized can Alpha decay causing pressure buildup (Helium usually diffuses out of can) High water content in oxide (above 1 %) due to prior inadequate stabilization results in can pressurization due to hydrogen buildup from reaction of the water with PuO_2 and radiolysis of the water.	Pu particulate release inside glovebox Increased dose rate to workers near glovebox from spilled PuO_2.	E-4 ventilation system and glovebox confines release E-4 ventilation system HEPA filters mitigate release to the environment through the facility exhaust stack.	Housekeeping; spilled material is swept up and placed in cans and sealed out of glovebox. Institutional radiation protection program: Radiological control technicians set glovebox dose rates to limit operator direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures ventilation is operating correctly.	F3
D.3.10	**OPERATIONAL UPSET**	Pu fluoride powder processed through furnace causes corrosion damage to furnace in glovebox HC-21C.	Wrong can selected for processing due to mislabeling or human error.	Fluorine gas release due to reaction with water vapor in air run through furnace. Damage to furnace vacuum exhaust system. Increased direct dose to operators. Pu fluoride produces higher direct dose than oxide (due to alpha-n reactions). See item B.1.02.	None	Labeling and paperwork associated with each container identify contents making it unlikely for wrong material to be processed.	F2

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
B.2.04.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator suffers injury and ruptures glove while crushing empty can with hammer	Operator injury with contamination of wound	Glovebox ventilation system maintains confinement velocity across hole in glove	Operator training and procedures HPT deconning of skin or injury Leather gloves used when crushing or folding cans	F3
B.4.01.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Worker penetrates glove while opening sealed can with can opener, taped slip lid can with scissors, while handling can or lid.	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves use when opening cans HPT deconning of skin or injury Leather gloves used when crushing or folding cans	F3
B.7.02	**DISPERSAL OF Pu OXIDE POWDER - OUTSIDE GB**	Spread of contamination from waste bag during bagout of waste from glovebox HC-21A	Waste bag squeezed causing release of radiological material through taped vent Isolated Transport Container (ITC) dropped during handling causing bag to vent or rupture	Contamination of workers and potential uptake of radiological material	E-3 ventilation system filters release to environment. Room CAMs alert workers to airborne contamination.	Operator training and procedures Waste bags are put in Isolated Transport Container (ITC) immediately after applying second bag. ITCs have lids to minimize spread of release from pail. Radiological control program. Survey of workers with alpha poppy probes to detect skin contamination. Worker decontamination by RCT if necessary.	F3

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
F.7.02	**DISPERSAL OF Pu OXIDE POWDER - OUTSIDE GB**	Pu release from sample bottle or product can after bagout from glovebox HC-18M	Sample bottle or product can dropped after bagout causing bottle to break or slip lid to come off and bag to rupture.	Contamination of workers and potential uptake of radiological material	E-3 ventilation system filters mitigate release to environment should material be release to Zone 3 area. Room CAMs alert workers to airborne contamination.	Operator training and procedures Radiological control program. Survey of workers with alpha poppy probes to detect skin contamination. Worker decontamination by RCT if necessary. Bagged sample bottles are placed in ice cream carton and then in special wagon for transport to the analytical lab. Carton reduces chances of airborne release in a drop. Product cans are double bagged in the process of being sealed out of the glovebox. Taped slip lid can and double bag minimize the likelihood of a release should the container be dropped.	F3
B.7.03	**FLAMMABLE GAS DEFLAGRATION IN WASTE DRUM**	Hydrogen venting or deflagrating inside waste drum in 234-5Z satellite accumulation area.	Hydrogen generation from radiolysis in waste bags in waste drum. Ignition caused by spark generated while moving drum.	Pressurization of drum, drum damage and release of radiological material from waste drum in satellite accumulation area (Room 166) Potential worker injury	Waste drum is vented through a filter to prevent hydrogen accumulation Room CAMs alert workers of airborne contamination in room 166 Room 166 ventilated by the E-3 system which confines and filters any release from waste drum.	Drum seal is verified. Periodic surveillance of rooms to detect bulging drums.	F2

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
D.4.02.b	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Glovebox fire or radiant heat damage to glovebox HC-21C confinement boundary.	Door opened during heating cycle to remove boat	Radiant heat from coils melts gloves and burns operator, softens glovebox panels Potential activation of glovebox dry fire suppression system (Halon system). Potential ignition of combustibles in glovebox. Release of Pu to room air and uptake by workers.	Furnace interior temp indication Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across hole in glove. Door/power interlock shuts off power to furnace coil when furnace door opened, minimizing radiant heat on gloves and glovebox panels. Furnace thermocouples and chart recorder indicate when it is safe to open furnace door.	Operators trained not to remove boat from furnace or to open furnace door until temperature has dropped below 200 C. Combustible loading in glovebox is controlled.	F2

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
A.1.03	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Hole in glovebox confinement boundary leads to spread of contamination from glovebox (general glovebox hazard).	Degradation of port bags, ice cream cartons used to seal sphincter port, or gloves due to aging, radiation, or heat.	Minor Spread of contamination from glovebox and potential uptake by workers.	E-4 ventilation system maintains negative pressure in glovebox and maintains confinement velocity across small holes	Gloves and bags have scheduled replacement dates which minimizes likelihood of degradation. Pre-job walkdown visual inspection of gloves, bags, and ice cream cartons. Air flow through leaks can cause a whistling sound which aids in detecting leaks in gloves, port bags, etc. during pre-job walkdown. Radiological control program: operators hands are surveyed every 15 minutes during glovebox operations and when changing glovebox locations to identify leaks. Surveys with alpha poppy probes before leaving radiological control area prevents spread of contamination to clean areas of the plant.	F3

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
A.1.04	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Breach in glovebox confinement boundary during waste bagout, port bag replacement, or glove change (general glovebox hazard).	Sharp object punctures bag Bag not properly horse tailed or taped Bag inadvertently pulled off port Original or replacement bag glove tears Bungee chord used to hold replacement bag slips or fails while removing inner (original) bag Replacement glove inadvertently pull off lip of port Bag/glove pinched when tightening port ring Replacement bag/glove has undetected hole in it	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers	Glovebox (E-4) ventilation system maintains glovebox negative pressure and confinement velocity across small holes; minimizes potential spread of contamination from glovebox Glovebox port designed to minimize likelihood of loss of confinement during bag changes (notches, ridges to facilitate, 2 bags or gloves)	Workers on mask during bag out of waste, bag/glove changes Room put on ARA status during bagouts, bag changes, glove changes. Operator certification.	F3

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
B.1.03	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Glovebox HC-21A loss of confinement during seal in.	Sphincter seal failure Ice cream carton or can in sphincter seal inadvertently pushed into glovebox without can or carton behind it results in open sphincter seal. Seal in bag torn or pulled off port during seal in (also applies to changeout of port bags) (see item A.1.04). Pressurized glovebox during seal in (see item A.3.01)	Minor release of contamination from the glovebox into the room. Potential worker uptake of Pu.	Glovebox ventilation system maintains negative pressure and confinement velocity across failed sphincter seal or port bag which minimizes the potential contamination spread. Backup glovebox (E-4) ventilation system maintains confinement on loss of primary ventilation. Room CAMs alert operators to presence of airborne contamination. PRV on supply restricts flowrate on low glovebox DP. Emergency exhaust valves open on low glovebox negative. Sphincter seal design prevents release unless no can or carton in seal.	Operator training and procedures	F3
B.2.02.a	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Damage to glovebox glove compromising glovebox HC-21A confinement integrity.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Small hole in glovebox confinement boundary Small contamination release from glovebox as hands withdrawn from glovebox gloves	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans Operators are surveyed for contamination every 15 minutes while working in glovebox gloves. Self survey on exit from radiological area to detect skin contamination HPT deconning of skin Leather gloves used when crushing or folding cans	F3

Table 9F.22.

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
D.2.01	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Glove damage during load in/ load out of the stabilization furnaces in glovebox HC-21C.	Glove pinched in furnace door when closed or glove punctured by sharp object.	Operator injury with contamination of wound Small hole in glovebox confinement boundary leading to contamination release from glovebox.	Glovebox ventilation system maintains confinement velocity across hole in glove	Operator training and procedures Operators are surveyed for contamination every 15 minutes while working in glovebox gloves. Self survey on exit from radiological area to detect skin contamination HPT deconning of skin or injury Leather gloves used when crushing or folding cans	F3
D.2.02	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Breach in glovebox HC-21C confinement boundary during bagout of combustibles or while withdrawing gloves from glovebox.	Sharp object punctures port bag while bagging out combustibles or while changing bag. Bag not properly horsetailed or taped after removing combustibles from glovebox. Bag inadvertently pulled off port during bagout of combustibles. Glove tears while being pulled out of the glovebox to prevent contact with hot furnace.	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers	Glovebox (E-4) ventilation system maintains glovebox negative pressure and confinement velocity across small holes; minimizes potential spread of contamination from glovebox Glovebox port designed to minimize likelihood of loss of confinement during bag changes (notches, ridges to facilitate, 2 bags or gloves)	Workers on mask during bag out of waste, bag/glove changes Room put on ARA status during bagouts, bag changes, glove changes. Operator certification.	F3

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
D.2.03	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Gloves melted by contact with furnace compromising glovebox HC-21C confinement.	Gloves not withdrawn from glovebox before starting furnace; gloves contact hot surface of furnace and melts. Gloves not secured properly with bungee cords after being pulled out of the glovebox; negative pressure causes gloves to be pulled into glovebox contacting hot spot on furnace.	Burned out glove allows contamination to spread from glovebox; potential uptake by workers. Operator burned while trying to pull glove back from furnace.	Glovebox (E-4) ventilation system maintains negative pressure in glovebox and prevents contamination spread unless several gloves are lost. Emergency exhaust valves on RMC line opens up on low glovebox vacuum. Fire brick insulates outer surfaces of furnace from the intense heat produced in the furnace. Only limited areas around the door of the furnace are hot enough to melt or burn gloves. Room CAMs alert workers to presence of airborne contamination. E-3 ventilation system filters any release from Zone 3 area to the environment.	Operator training and procedures. Gloves are pulled out of glovebox and secured with bungee cords before operating furnaces.	F3

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
D.3.03	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Reduced air flow or no air flow during stabilization of material in furnace in glovebox HC-21C.	Plugged ceramic filter. Vacuum system valved out or otherwise blocked. Failure of vacuum pump or loss of power to vacuum pump. Other loads placed on 26 in vacuum system reduce airflow through furnace. Airflow not set properly before operating furnace.	Hot air from furnace vents into glovebox while heating oxide. Furnace not cooled down in intended time period after stabilization oxide. Potential damage to glovebox gloves and operator burn when boat removed from furnace.	DP across ceramic filter allows identification of plugged filter. Flow meter on vacuum line. Glovebox (E-4) ventilation system adequately removes hot air vented from furnace preventing overheating of glovebox. Temperature recorder tells operator when furnace is cooled down. DP and orifice place in vacuum system indicate flowrate.	Flow through vacuum system is verified to be in proper range before each furnace use. By procedure, operators are not allowed to remove furnace boat until furnace is below 200 C.	F3
D.4.01	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Glove damage/operator burn in glovebox HC-21C	Boat removed from furnace too early or boat not allowed to cool on boat stand before handling.	Operator burns hole in glove and suffers injury while removing boat from furnace. Hole in glove compromises glovebox confinement.	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across hole in glove. Glovebox ventilation system removes enough heat to prevent overheating of glovebox air with furnace door open. Door/power interlock shuts off power to furnace coil when furnace door opened, minimizing radiant heat on gloves and glovebox panels. Furnace thermocouples and chart recorder indicate when it is safe to open furnace door.	By procedure, operators are not allowed to remove furnace boat until furnace is below 200 C. Hot mill gloves used with boat handling tool to remove boat from furnace. By procedure, boat is left on boat stand to cool for one hour before being handled by glove.	F3

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
F.7.01	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Breach in glovebox HC-18M confinement boundary during waste bagout, bag change, or glove change.	Bag punctured by sharp object Bag not properly horsetailed or taped Bag inadvertently pulled off port Original or replacement bag glove tears Bungee chord used to hold replacement bag slips or fails while removing inner (original) bag Replacement glove inadvertently pull off lip of port Bag/glove pinched when tightening port ring Replacement bag/glove has undetected hole in it	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers.	Glovebox (E-4) ventilation system maintains glovebox negative pressure and confinement velocity across small holes; minimizes potential spread of contamination from glovebox Glovebox port designed to minimize likelihood of loss of confinement during bag changes (notches, ridges to facilitate, 2 bags or gloves)	Workers on mask during bag out of waste, bag/glove changes Room put on ARA status during bagouts, bag changes, glove changes. Operator certification.	F3

Table 9F.22.

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
A.3.01.a	**LOSS OF GB CONFINEMENT - VENTILATION FAILURE**	Stagnant glovebox during operations causes spread of contamination from glovebox (general glovebox hazard).	Loss of E-4 ventilation flow or imbalance between E-4 supply and exhaust (caused by loss of power or equipment or control failures). Failure to detect HVAC upset during pre-job walkdown	Spread of contamination from glovebox during seal in or seal out of container, glove change, or change of port bag. Worker exposure to dispersible Pu. Overheating of Glovebox HC-21C during furnace operations (see item D.3.06).	E-4 HVAC controls Interlock shuts off supply fans if exhaust fans go down, which prevents glovebox pressurization. Pressure regulating valve on supply air regulates pressure in RMC line gloveboxes. Addition exhaust capacity provided via emergency exhaust valves in Room 228A should imbalance develop between supply and exhaust flow. Alarm activates in power control room on detection of low glovebox negative in control room. PAX announcement made if alarm activates. Plant is evacuated if E-3/E-4 exhaust is lost, which minimizes potential worker inhalation doses. E-3 filter room filters mitigate release to environment if only E-4 ventilation is lost. Building shell mitigates release if glovebox and building goes stagnant. Backup power operates emergency exhaust fans that maintain negative pressure in gloveboxes if plant loses primary power. Room CAMs alert workers to airborne	Pre-job walkdown to verify proper glovebox ventilation flow and DP Operator training and procedures	F3

B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
G.2.01	**NPH - Ash Fall**	Addressed in Chapter 3.0 of PFP FSAR		Ash Fall effects are described in Chapter 3.0 of the PFP FSAR. Ash Fall represents a roof loading concern, abrasive concern for moving equipment, and an electrical concern because of the conductivity of the ash.			F2
G.1.02	**NPH - Seismic**	Seismic event causes dispersal of plutonium oxide powder in glovebox. (General to all gloveboxes)	Seismic event results in dispersal of plutonium oxide powder into glovebox atmosphere.	Potential additional exposure to workers due to cleanup requirements.	Seismic ventilation supply shutdown switch. Building structure Glovebox structure	Emergency procedures	F2
A.1.02	**OCC**	Electrical shock to operator while working in glovebox HC-21A	Cord frayed in the glovebox Frayed cord contacts glovebox frame while operators body or leg is in contact with the glovebox frame.	Operator injury	None	Senior supervisory watch OSHA inspections can identify frayed cords. Electrical safety program of cord inspection reduces the likelihood of the presence of frayed cords. Institutional occupational safety program of requirements and inspections reduces the likelihood of the presence of frayed cords.	F3
B.6.01.a	**PYROPHORIC REACTION IN FURNACE**	Contaminants not identified or removed from oxide result in reaction hazards in Glovebox HC-21C furnaces. Pyrophoric contaminants can include unburned metal pieces from prior stabilization run, metal hydrides, uranium hydrides, or Pu_2O_3.	Human error; step not performed correctly Contaminants not readily identifiable due to color, size, etc. Poor visibility through glovebox windows.	Pyrophoric reaction in furnace in Glovebox HC-21A. See item D.3.08. Fires in the furnaces in Glovebox HC-21C. See item D.3.07.	See items D.3.07 and D.3.08 for engineered features to mitigate reactions in the HC-21C furnaces.	Previous LOI testing results provide confidence that significant quantities of plastic contaminant are not in product to be stabilized in this campaign. Procedures with sign off by Shift Technical Advisor.	F2

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
D.3.08	**PYROPHORIC REACTION IN FURNACE**	Metal contaminant in feed results in pyrophoric reactions in the furnace in glovebox HC-21C.	Metal turnings or pieces not noticed or removed from feed in Glovebox HC-21A.	Reaction of pyrophoric metal or hydrided metal contaminant in furnace, leading to hydrogen release and burn in the furnace. Potential furnace damage. Failure of glovebox not expected due to small quantity of hydrided metal expected in feed.	Glovebox ventilation system confines material dispersed from furnace.	Visual identification of "non oxides" in Glovebox HC-21A when material poured into furnace boat. Blend plan identifies previously stabilized oxide to restabilize in this campaign.	F3
B.4.05.a	**PYROPHORIC REACTION IN GB**	Pyrophoric reaction and hydrogen burn when can opened in glovebox HC-21A.	PuH_2 hydride contaminant in can Pu metal may be in can due to incomplete prior stabilization. PuH_2 forms from metal if plastic or organic contaminants are also present in can. Or if hydrogen from degradation of the plastic bag outside the can diffuses into the can. Can under vacuum due to catalyzed formation of oxides and nitrides in the container. When can is opened air is sucked in which reacts with the hydrided material. Hyride reactions releases heat and hydrogen gas which is ignited on exiting the can.	If sufficient hydride contamination present, slight pressurization of the glovebox could occur. Potential burn through of gloves and operator injury due to contact with hot embers. Embers burn through PVC ports Minor contamination spread from glovebox if gloves or port bags damaged.	Glovebox (E-4) ventilation system maintains confinement if damage limited to holes in gloves E-3 ventilation system filters release to environment if glovebox confinement lost Rooms CAMs alert worker to airborne contamination Glovebox dry fire suppression system for putting out glovebox fire Glovebox high temperature alarm	MgO sand for putting out small fire Bayonet fire extinguishers available near glovebox for putting out small fire Operator training and procedures Only material passing previous LOI test will be processed through the furnaces during this campaign. Blend plan identifies which containers are acceptable for processing. Container labeling and material processing records identify contents of containers. Shift technical advisor sign off for material acceptability required by procedure. Combustible loading in glovebox is controlled by procedure.	F3

Table 9F.22.
S1 Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
B.1.02	**RADIATION PROTECTION**	High worker direct dose during handling of cans in glovebox HC-21A.	Container containing metal or PuF_4 handled instead of PuO_2 (PuF_4 much higher dose than oxide from alpha-n reactions). Cans handled for extended time period during handling/seal-in of cans.	Worker dose rate limit (Radiological work permit) potentially exceeded	Leaded gloves limit dose when handling cans inside the glovebox. Glovebox structure shields body of operator Inner can and first overpack are wrapped with leaded tape to minimize direct dose	ALARA principles applied to Pu storage container handling process. Periodic dose measurements taken on glovebox to establish acceptable worker exposure periods. Labeling of cans in vault (RAM tags) Cans surveyed for contact dose several times during movement and before loading into HC-21A. Blend plan identifies intended cans Institution radiological control program	F3
F.3.02	**RUPTURE OF CONTAINER IN STORAGE VAULT**	Pu metal added to product can in glovebox HC-18M causing rupture of container in storage vault.	Material not heated long enough or at high enough temperature in furnace to completely oxidize metal due to furnace failure or failure of furnace temperature controller. Sieve and size reduction step skipped due to human error results in metal pieces not being detected. Metal pieces not removed from oxide material before transferring material to product can.	Rupture of container in storage vault due to the formation of Pu oxide (assuming storage cans is not airtight). PuO_2 is less dense and takes up more volume than metal causing can rupture. Contamination of vault air. Potential uptake by workers on entry into vault. Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	Vault ventilation system and HEPA filters mitigate release to the environment. Pedestals in vault are instrumented to detect bulging cans. CAMs in vault alert workers to airborne contamination. Furnace chart recorder readings are used to verity proper furnace operation and soak time.	Operator training and procedures Radiological control program: Routine sampling of vault air. Blend plan identifies material processed in this campaign to be previously stabilized oxide material, minimizing likelihood of material containing excess moisture from being recanned even if undetected furnace upset occurs.	F2

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
B.2.02.b	**CONTAMINATED WOUND**	Operator injury in glovebox HC-21A.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans HPT deconning of skin or injury Surgical excision of contaminated tissue Leather gloves used when crushing or folding cans	F3
B.5.01.a	**UNCONTROLLED FIRE IN GB**	Pyrophoric reaction as material poured through air in glovebox HC-21A.	Pu metal, PuH_2, Uranium hydride; Pu_2O_3 contaminant in can Pu or U metal may be in can due to incomplete prior stabilization. PuH_2, UH_3 forms from metal if plastic or organic contaminants are also present in. Or if hydrogen from degradation of the plastic bag outside the can diffuses into the can. AND Combustible loading in glovebox not controlled.	Sparks potentially initiating a glovebox fire. Hot embers entrained in air may burn hole in glovebox HEPA filters. Dispersal of Pu in glovebox Potential burn through of gloves and operator injury due to contact with hot embers. Burn through of PVC port bags. Minor contamination spread from glovebox if gloves or port bags damaged Potential ignition of combustibles in glovebox producing glovebox fire If sufficient hydride contamination present, slight pressurization of the glovebox could occur	Glovebox (E-4) ventilation system maintains confinement if damage limited to holes in gloves E-3 ventilation system filters release to environment if glovebox confinement lost Rooms CAMs alert worker to airborne contamination Glovebox dry fire suppression system for putting out glovebox fire Glovebox high temperature alarm	MgO sand for putting out small fire Bayonet fire extinguishers available near glovebox for putting out small fire Operator training and procedures Only material passing previous LOI test will be processed through the furnaces during this campaign. Blend plan identifies which containers are acceptable for processing. Container labeling and material processing records identify contents of containers. Cans with relatively large quantities of hydride will be "paneled" and easily identified. Combustible loading in glovebox is controlled by procedure	F3

Table 9F.23.
S1* Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
A.2.01	**CRITICALITY**	Violation of criticality safety mass or spacing limit. Violation of dispersible inventory limit. (General glovebox hazard)	Failure to check or adhere to CPS or dispersible limit postings on glovebox	Potential Criticality in glovebox with worker exposure to ionizing radiation and fission product gasses. Release in seismic event above current accepted levels	None	CSER controls on mass of Pu allowed in glovebox, spacing of containers in glovebox, etc. CPS posting on glovebox Operator training.	F2
E.2.01	**CRITICALITY**	Violation of criticality safety mass limit or violation of glovebox HC-18BS dispersible inventory limit.	Too many containers stored too close together. Failure to check or adhere to CPS or dispersible limit postings on glovebox	Potential Criticality in glovebox with worker exposure to ionizing radiation and fission product gasses. Release in seismic event above current accepted levels	None	CSER controls on mass of Pu allowed in glovebox, spacing of containers in glovebox, etc. CPS posting on glovebox Operator training	F2
F.6.01.b	**CRITICALITY**	Violation of criticality safety mass limit or violation of glovebox HC-18M dispersible inventory limit	Failure to check or adhere to CPS or dispersible limit postings on glovebox	Potential Criticality in glovebox with worker exposure to ionizing radiation and fission product gasses. Release in seismic event above current accepted levels	None	CSER controls on mass of Pu allowed in glovebox, spacing of containers in glovebox, etc. CPS posting on glovebox Operator training.	F2
B.6.01.b	**FLAMMABLE GAS DEFLAGRATION IN GB**	Plastic contaminants not identified or removed from oxide result in reaction hazards in Glovebox HC-21C furnaces. Contaminants can include tool handles, brush bristles, PVC or polyethylene bag fragments, polycarbonate pieces, etc.	Human error; step not performed correctly Contaminants not readily identifiable due to color, size, etc. Poor visibility through glovebox windows.	Fires or deflagrations of flammables in the furnaces in Glovebox HC-21C. See item D.3.07.	See items D.3.07 for engineered features to mitigate reactions in the HC-21C furnaces.	Previous LOI testing results provide confidence that significant quantities of plastic contaminant are not in product to be stabilized in this campaign. Procedures with sign off by Shift Technical Advisor.	F2
B.2.01	**FLAMMABLE GAS DEFLAGRATION INSIDE GB**	Flammable gas (i.e. H_2) release and burn when overpack can opened in glovebox HC-21A.	Radiolysis of plastic bag around slip lid can and organic can seal during storage in vault. Ignition due to mechanical spark from can opener, static release from ejected powders, or electrical spark.	Potential deflagration involving H_2 released from can causing pressurization of glovebox, potential failure of port bags or gloves and release of Pu into the room air. Inhalation uptake of Pu by workers.	Glovebox and E-4 ventilation system confine release unless deflagration large enough to fail port bags or gloves. E-3 ventilation system filters mitigate release to the environment. Room CAMs alert workers to presence of airborne radiological material	Operators verify glovebox DP and filter DP before opening cans. Pressurized cans containing a dangerous amount of hydrogen are easily identified due to bulging.	F2

Table 9F.23.
S1* Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
A.2.01	**CRITICALITY**	Violation of criticality safety mass or spacing limit. Violation of dispersible inventory limit. (General glovebox hazard)	Failure to check or adhere to CPS or dispersible limit postings on glovebox	Potential Criticality in glovebox with worker exposure to ionizing radiation and fission product gasses. Release in seismic event above current accepted levels	None	CSER controls on mass of Pu allowed in glovebox, spacing of containers in glovebox, etc. CPS posting on glovebox Operator training.	F2
B.4.02	**FLAMMABLE GAS DEFLAGRATION INSIDE GB**	Hydrogen gas release and burn when can opened in glovebox HC-21A.	Radiolytic degradation of plastic contaminant, brush bristles, tool handle, bottle caps, etc. in oxide during storage generates hydrogen in can. Hydrogen ignited during release from can due to static or electrical discharge High water content in oxide (above 1%) due to prior inadequate stabilization results in can pressurization due to hydrogen buildup from reaction of the water with PuO_2 and radiolysis of the water.	Potential deflagration involving H_2 released from can causing pressurization of glovebox, potential failure of port bags or gloves and release of Pu into the room air. Inhalation uptake of Pu by workers.	Glovebox and E-4 ventilation system confine release unless deflagration large enough to fail port bags or gloves. E-3 ventilation system filters mitigate release to the environment. Room CAMs alert workers to presence of airborne radiological material	Operators verify glovebox DP and filter DP before opening cans. Pressurized cans containing a dangerous amount of hydrogen are easily identified due to bulging.	F2

Table 9F.23.
S1* Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
A.2.01	**CRITICALITY**	Violation of criticality safety mass or spacing limit. Violation of dispersible inventory limit. (General glovebox hazard)	Failure to check or adhere to CPS or dispersible limit postings on glovebox	Potential Criticality in glovebox with worker exposure to ionizing radiation and fission product gasses. Release in seismic event above current accepted levels	None	CSER controls on mass of Pu allowed in glovebox, spacing of containers in glovebox, etc. CPS posting on glovebox Operator training.	F2
B.4.04	**FLAMMABLE GAS DEFLAGRATION INSIDE GB**	Flammable gases (alkanes, H_2, etc) from organic in container released and ignited when can opened (can pressurized) in glovebox HC-21A.	Container containing organic (e.g., sludge, floor sweeps) inadvertently sealed into glovebox and opened. Wrong container selected due to inaccurate labeling or human error. Flammable gases generated due to radiolytic decay of organic material (e.g., sludge) in the container. Ignition due to mechanical or electrical spark, or static discharge.	Pressurization of glovebox Potential damage to glovebox confinement boundary Pu release into room and worker inhalation uptake	Glovebox and E-4 ventilation system confine release unless deflagration large enough to fail port bags or gloves. E-3 ventilation system filters mitigate release to the environment. Room CAMs alert workers to presence of airborne radiological material	Operators verify glovebox DP and filter DP before opening cans. Pressurized cans containing a dangerous amount of flammable are easily identified due to bulging. Blend plan identifies appropriate cans to stabilize in PuO_2 campaign. Labeling of containers Operator training and procedures Shift technical advisor sign off for material acceptability required by procedure. Sludges which may contain organic are stored in vented polyjars which are easily distinguishable from cans containing PuO_2.	F2
D.3.07	**FLAMMABLE GAS DEFLAGRATION INSIDE GB**	Plastic contaminants in Pu oxide feed result in fire/deflagration in stabilization furnace in glovebox HC-21C.	Plastic contaminants not noticed in feed or not removed by operator (plastic contaminants can include PVC, polyethylene, polycarbonate, polystyrene, Polymethyl Methacrylate).	Fire or deflagration involving flammable gases (alkanes, alkenes, hydrogen, carbon monoxide) generated inside the furnace. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	Furnace door does not latch and thereby provides vent path to prevent catastrophic explosion of the furnace. Furnace vacuum system sweeps air through the furnace to dilute flammable gas concentration or to completely oxidize (burn) plastic contaminant in a controlled manner.	Plastic contaminants are looked for and removed when the oxide is poured into the furnace boat in Glovebox HC-21A. Previous LOI testing results provide confidence that significant quantities of plastic contaminant are not in product to be stabilized in this campaign.	F2

Table 9F.23.
S1* Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
A.2.01	**CRITICALITY**	Violation of criticality safety mass or spacing limit. Violation of dispersible inventory limit. (General glovebox hazard)	Failure to check or adhere to CPS or dispersible limit postings on glovebox	Potential Criticality in glovebox with worker exposure to ionizing radiation and fission product gasses. Release in seismic event above current accepted levels	None	CSER controls on mass of Pu allowed in glovebox, spacing of containers in glovebox, etc. CPS posting on glovebox Operator training.	F2
D.3.09	**FLAMMABLE GAS DEFLAGRATION INSIDE GB**	Glovebox sweeps containing organic (plastics or sludge) processed through furnace results in flammable gas deflagration in stabilization furnace in glovebox HC-21C.	Wrong can selected from storage area opened in Glovebox HC-21A due to mislabeling or human error. Plus Failure to notice plastic contaminant or sludge in furnace boat during visual inspection in Glovebox HC-21C.	Deflagration in furnace, failure of furnace, and potential burn through of gloves, bag ports, or glovebox panels. Release of Pu from glovebox and potential uptake by operators. Possibly more plastics than in normal oxide	E-3 ventilation system filters release to environment should Pu be released into room from glovebox.	Labelling and paperwork associated with each can identify contents: glovebox sweeps are indicated in labelling and paperwork minimizing likelihood or processing wrong material. Glovebox sweeps are not stored in same vault with Pu oxides to be processed in this campaign. Sweeps from wet gloveboxes are stored in polyjars which are difficult to mistake for a PuO_2 container.	F2
D.4.02.a	**LOSS OF GB CONFINEMENT - MECHANICAL BREACH**	Glovebox fire or radiant heat damage to glovebox HC-21C confinement boundary.	Furnace door inadvertently opened during heating cycle to remove boat.	Radiant heat from coils potentially ignites glovebox panels Potential activation of glovebox dry fire suppression system (Halon system). Potential ignition of combustibles in glovebox. Release of Pu to room air and uptake by workers.	Furnace interior temp indication Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across hole in glove. Door/power interlock shuts off power to furnace coil when furnace door opened, minimizing radiant heat on gloves and glovebox panels. Furnace thermocouples and chart recorder indicate when it is safe to open furnace door.	Operators trained not to remove boat from furnace or to open furnace door until temperature has dropped below 200 C. Combustible loading in glovebox is controlled.	F2

A.3.01.b	**LOSS OF GB CONFINEMENT - VENTILATION FAILURE**	Pressurized glovebox during operations causes spread of contamination from glovebox (general glovebox hazard)	Loss of E-4 ventilation flow or imbalance between E-4 supply and exhaust (caused by loss of power or equipment or control failures). Failure to detect HVAC upset during pre-job walkdown	Pressurized glovebox causing spread of contamination from glovebox during seal in or seal out of container, glove change, or change of port bag. Worker exposure to dispersible Pu. Overheating of Glovebox HC-21C during furnace operations (see item D.3.06).	E-4 HVAC controls Interlock shuts off supply fans if exhaust fans go down, which prevents glovebox pressurization. Pressure regulating valve on supply air regulates pressure in RMC line gloveboxes. Addition exhaust capacity provided via emergency exhaust valves in Room 228A should imbalance develop between supply and exhaust flow. Alarm activates in power control room on detection of low glovebox negative in control room. PAX announcement made if alarm activates. E-3 filter room filters mitigate release to environment if only E-4 ventilation is lost. Building shell mitigates release if glovebox and building goes stagnant. Backup power operates emergency exhaust fans that maintain negative pressure in gloveboxes if plant loses primary power. Room CAMs alert workers to airborne contamination.	Pre-job walkdown to verify proper glovebox ventilation flow and DP Operator training and procedures Plant is evacuated if E-3/E-4 exhaust is lost, which minimizes potential worker inhalation doses.	F2

Table 9F.23.
S1* Hazardous Conditions

Item #	Acc Cat	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Freq Rank
A.2.01	**CRITICALITY**	Violation of criticality safety mass or spacing limit. Violation of dispersible inventory limit. (General glovebox hazard)	Failure to check or adhere to CPS or dispersible limit postings on glovebox	Potential Criticality in glovebox with worker exposure to ionizing radiation and fission product gasses. Release in seismic event above current accepted levels	None	CSER controls on mass of Pu allowed in glovebox, spacing of containers in glovebox, etc. CPS posting on glovebox Operator training.	F2
D.3.06	**LOSS OF GB CONFINEMENT - VENTILATION FAILURE**	Overheating of glovebox HC-21C.	Loss of E-4 ventilation flow during operation of furnace due to equipment failures, damper closures, etc.	Overheating of glovebox leading to possible failure of port bags and gloves and inadvertent operation of the glovebox dry fire suppression system. Potential softening and sagging of glovebox windows. Release of contamination through failed gloves or bag ports (or failed windows). Potential Pu uptake by workers. Evacuation of Zone 3 process areas leading to unattended glovebox which could result in inability to control fire if combustibles ignited.	Insulating blankets protect glovebox panels from heat damage from nearby hot vacuum lines. Backup E-4 exhaust fans run by emergency generators or steam kicks on on loss of normal exhaust flow protecting glovebox from overheating. Alarms if dP is lost Halon system designed to put out fire by displacing a fraction of the air in the glovebox. It is designed not to discharge enough material to pressurize the glovebox. .	Alarms in power control room activate on loss of E-4 exhaust flow. Process areas are evacuated on loss of E-4 ventilation protecting workers from Pu potentially released from the glovebox. Work to restore ventilation flow on dampers or other equipment can occur as they are outside process areas. Operators are trained to hit "kill switch" shutting down furnaces before evacuating. Emergency plan	F3
G.1.01	**NPH - Seismic**	Seismic event causes explosion and stagnet glovebox. (General to all gloveboxes)	Seismic event results in loss of electrical power and potentially a loss of ventilation. Loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	Seismic ventilation supply shutdown switch. Building structure.	Emergency procedures for evacuation.	F2

Table 9F.23.

APPENDIX 9G

Preliminary Hazards Analysis for Thermal Stabilization of Non-Product Quality Oxide Feed Materials

This page intentionally left blank.

PRELIMINARY HAZARDS ANALYSIS FOR THERMAL STABILIZATION OF NON-PRODUCT QUALITY OXIDE FEED MATERIAL

9G.1 STABILIZATION OF NON-PRODUCT QUALITY OXIDE FEED MATERIAL PHA

The hazards associated with thermally stabilizing non-product quality oxide feed materials in Glovebox HC-21C muffle furnaces were identified and evaluated using a Preliminary Hazards Analysis (PHA) approach. A detailed discussion of the PHA technique can be found in Guidelines for Hazard Evaluation Procedures (AIChE 1992). Non-product quality oxide feed materials are defined as:

* impure plutonium oxides
* mixed uranium and plutonium oxide
* floor sweepings
* plutonium oxalate
* Plutonium Reclamation Facility (PRF) sludges.

9G.2 PHA METHODLOGY

The PHA process is a systematic approach in which a system or process is broken down into basic elements and the hazards associated with operations in the system or process are identified, potential causes of those hazards are determined, potential consequences of the hazards are evaluated, and possible corrective and/or preventative measures are examined. The PHA was developed using a table to guide and record the results of a "brainstorming" process. Brainstorming was performed by individuals with detailed knowledge of the system or process being examined, and was supported by a multi-disciplinary team.

9G.2.1 PHA Data Description

The purpose and contents of each column in the PHA table, Table 9G-1, are described in detail in the following paragraphs.

Column 1, Item #: This column provides an alpha-numeric identifier for each hazard postulated in the table. The identifier is primarily used for cross referencing within the table and as an identifier for accident sequences discussed in Chapter 9 of the PFP FSAR.

Column 2, Process Step/Equipment: The step or steps and the important equipment involved in performing each set of operations is identified in this column. Listing each piece of equipment involved ensures that all relevant hardware failures are considered in the analysis and that the operational faults associated with use of each piece of equipment are considered.

Column 3, Failure/hazardous condition: The hardware failures or operational faults of concern are identified in this column. The hazards are identified first by postulating failures of the safety function(s) listed in the previous column. Simply postulating functional failure of hardware, however, is insufficient for identifying the wide range of things that can go wrong.

Additional hazards are identified by asking "what-if" type questions, such as, "what if the operation is not performed," "what if the operation is performed out of order," "what if the operation is performed too fast". Guideword deviations such as are used in HAZOP analysis (AIChE 1992) were also utilized to identify hazardous conditions. Guidewords are process parameters such as pressure, temperature, flow, concentration etc. Relevant deviations include "low/no," "high," "other than."

Column 4, Causes: This column identifies the causes for the failures/hazardous conditions postulated in Column 4. Identifying causes is important to identifying potential preventative controls for significant hazards. In many cases, multiple hardware or operational faults are required to produce a hazardous event. This column identifies the sequence of hardware and operational faults required to produce the postulated hazardous event.

Column 5, Consequences: This column describes the potential consequences that could result from the postulated hazards identified in Column 4. The focus of this column is to identify effects to the glovebox confinement system and to facility workers. None of the hazards associated with opening cans containing Pu metal and with processing the metal were found to be energetic enough to compromise building confinement or to pose a threat to onsite workers outside the plant or to the offsite public.

Column 6, Existing Engineered Features: This column identifies the engineered features (hardware items) intended or available to prevent or mitigate the consequences identified in Column 6. The engineered features in this column are candidates for designation as Safety Significant items for hazards that pose a significant threat to the health of facility workers.

Column 7, Existing Administrative Controls: This column identifies the administrative requirements that reduce the likelihood of the hazardous event identified in Column 4, or that help minimize the potential consequences of the hazardous event. The controls listed in this column are candidates for operational safety requirement (OSR) designation for hazardous events with the potential to significantly harm facility workers.

Column 8, Consequence Rank: This column is used to capture a code designator for the level of consequence associated with a hazardous event. The consequence ranking is a "first cut," qualitative estimate of the safety severity of the consequences. An alphanumeric system has been used at the PFP to designate the severity of hazardous events. The system has the following "S" rankings characterizing safety consequences:

S0 No effect outside the glovebox confinement systems; negligible safety concerns for the facility worker.

S1 Potential industrial injury, low radiological or chemical exposure dose consequences to the facility worker. Such a hazard would be an operator injury where glovebox gloves are penetrated by the can punch causing worker injury and possible skin/wound contamination.

S1* Potential severe harm or potential death from industrial injury, radiological dose or chemical exposure to the facility worker. Hazards of this severity level warrant Safety Significant controls. Hazards at this severity level for the process examined in this analysis are typically those that result in significant

pressurization or damage to the glovebox structure causing release of radiological material from the glovebox. All events with enough energy to cause a significant release of radiological material from the glovebox are assigned an S1* consequence rank. This is conservative as such events will not necessarily cause severe harm to facility workers.

S2 Potential significant radiological dose consequences or chemical exposure to onsite workers located outside the facility. No hazards postulated for processing non-product quality oxide feed material were found to be energetic enough to compromise building confinement and lead to an S2 consequence.

S3 Potential significant radiological dose consequences or chemical exposure to the offsite population. No events were postulated with potential S3 consequences.

The engineered safety features and controls specific to the processing of non-product oxide feed material are not credited in assigning the above consequence rankings. This is to allow determination of whether the controls warrant Safety Significant designation.

The mitigative effects of features previously designated as Safety Significant or Safety Class in the PFP FSAR (WHC 1995) are credited in assigning the consequence rankings. For example, the glovebox structure E-4 ventilation system, and E-4 HEPA filters are credited with mitigating the effects of releases inside gloveboxes. This means that a spill of Pu oxide powder inside a glovebox (e.g., due to dumping the furnace boat after removal from the furnace) results in an S0 consequence ranking because the glovebox structure and E-4 ventilation system can be expected to prevent a significant exposure to facility workers. The effects of energetic events (such as flammable gas deflagration in a muffle furnace) on the glovebox structure, however, are assessed to determine if the hazardous event can compromise the Safety Significant confinement function provided by the glovebox structure and ventilation system. Similarly, the Safety Class Building 234-5Z structure and E-3 ventilation system are credited with protecting onsite workers and the offsite public outside the PFP from accidents that breach glovebox confinement.

Column 9, Frequency Ranking: The frequency ranking is a first cut, qualitative estimate of the likelihood of the hazardous event. The following ranking system is used.

F3 Events that are expected to occur one or more times during the lifetime of the facility, categorized as "anticipated" events. The frequency range associated with this category is 1E-02/yr to 0.1/yr.

F2 Events that could occur during the lifetime of the facility, but with low probability. Such events are categorized as "unlikely" and fall in the range of 1E-04/yr to 1E-02/yr.

F1 Events not expected to occur during the lifetime of the facility, categorized as "extremely unlikely." The frequency range associated with this category is 1E-06/yr to 1E-04/yr.

F0 Events categorized as "beyond extremely unlikely," with a frequency less than 1E-06/yr. Events in this category (such as meteor strike) are so unlikely they generally do not require special controls.

The frequency estimate, like the consequence ranking, is assigned taking no credit for active engineered features. The frequency ranges shown above are based on the risk acceptance criteria for the onsite receptor from the PFP FSAR (WHC 1995).

Column 10, Comments: This column contains miscellaneous observations or clarifying comments for a given hazard. There are many hazards identified in the PHA that are adequately covered in the PFP FSAR (WHC 1995) or in other authorization basis documents (e.g., CSERs). The comments column is used to flag those hazards that are adequately addressed in other documentation.

9G.2.2 SCOPE OF THE PRELIMINARY HAZARDS ANALYSIS

The PHA covers the operations performed within the RMC line glove boxes, from seal-in of containers of non-product quality oxide feed material into Glovebox HC-21A to bag-out of the thermally stabilized product oxide from Glovebox HC-18M. Within the RMC Line glove boxes, the non-product quality oxide is handled, thermally stabilized, and placed in sealed containers. Storage of containers in vaults (before and after thermal stabilization) is not covered in this PHA, as the hazards associated with these operations are adequately covered in the PFP FSAR (WHC 1995). The specific activities evaluated within this PHA are identified in Section 9G.3.

9G.3 PHA ORGANIZATION

The PHA table used in this analysis is provided in Table 9G.1. The PHA table is structured to ensure a systematic and thorough review of potential hazards. The thermal stabilization of non-product oxide feed materials is broken down into logical sets of operations performed at specific locations. The breakdown of operational steps covered in the analysis were identified from verbal descriptions provided by the cognizant engineers, and other available information. The operational steps evaluated and documented in the PHA table (Table 9G.2) are identified with an alpha-numeric designator in rows that traverse the width of the table. The thermal stabilization of non-product quality oxide feed materials was broken down into the following basic process elements:

- general glovebox hazards
- transfer of feed materials from vault storage to Glovebox HC-21A
- transfer of feed materials from glovebox storage to Glovebox HC-21A
- charge preparation activities in Glovebox HC-21A (impure oxide and MOX feed materials from vault storage)
- charge preparation activities in Glovebox HC-21A (PRF sludge, floor sweeps, and oxalate feed materials from glovebox storage)

- transfer of prepared charge from Glovebox HC-21A to HC-21C
- thermal stabilization activities in Glovebox HC-21C
- interim storage in Glovebox HC-18BS
- sampling and packaging activities in Glovebox HC-18M.

In addition, the PHA evaluated the impact of severe natural phenomena (e.g., a seismic event) and external events (e.g., facility-wide loss of power) on thermal stabilization operations.

9G.4 HAZARDS EVALUATION RESULTS

The PHA results in Table 9G.2 identify 22 S0 items, 50 S1 items, 26 S1* items, and 1 S2 item. To facilitate further evaluation, the identified events were grouped into 18 categories based on similarities in phenomenology and consequence. These groupings are presented in Tables 9G.3 through 9G.20.

Events designated as S0 and S1 are evaluated as abnormal operations; and S1* and S2 events are evaluated as accidents. Categorizing hazardous events as either "abnormal operations" or "accidents" is consistent with the NRC Regulatory Guide 3.39 (NRC 1976) format of the PFP FSAR. In instances where a given group contains both S1 and S1* events, the group is collectively evaluated as an accident.

Three groupings of events; Occupational Hazards (Table 9G.14), Operational Upsets (Table 9G.15), and Radiation Protection (Table 9G.18), were not further evaluated as either abnormal operations or accidents. Occupational hazards and direct radiation exposure hazards are not unique to thermal stabilization operations and are adequately covered by existing PFP industrial safety and hygiene and radiation protection programs. The operational upsets identified are unique to thermal stabilization operations but do not pose hazards to facility workers or onsite or offsite individuals.

9G.4.1 Abnormal Operations

9G.4.1.1 Contaminated Wound

The potential for a contaminated wound (Table 9G.3) exists whenever operators work in gloveboxes. This event is not unique to thermal stabilization operations. Principal preventive controls including minimizing, to the extent practicable, sharp objects within gloveboxes and the use of protective gloves over glovebox gloves. Chapter 9, Section 9.1.9 of the PFP FSAR evaluates the penetration of a glovebox glove and an associated puncture wound.

9G.4.1.2 Dispersal of Plutonium Inside Glovebox

The hazards analysis identified numerous events resulting in a spill and dispersal of Pu inside gloveboxes (Table 9G.5). These events, which are not

unique to thermal stabilization operations, were assigned a consequence rank of S0, i.e., resulting in negligible safety concerns to facility workers.

9G.4.1.3 Dispersal of Plutonium Outside Glovebox

The potential for a release of plutonium during seal-out operations (Table 9G.6) exists at all PFP gloveboxes. The principal preventive and mitigative controls are operator training and procedures, a negative pressure differential between gloveboxes and the surrounding room, and the use of respirators during seal-out operations. This event is not a unique to thermal stabilization operations and is adequately covered by existing PFP controls. This event is considered a serious operational event, but it poses essentially no risk to onsite or offsite individuals. Chapter 9, Section 9.1.9 of the PFP FSAR discusses such events in greater detail.

9G.4.1.4 Dropped Container Outside Glovebox

The potential for dropping a container in an operating area (Table 9G.7) exists whenever containers are handled outside of gloveboxes. The principal mitigative controls are packaging and CAMs. This event is not unique to thermal stabilization operations and is adequately addressed by the analysis of a plutonium powder spill outside of a glovebox presented in Chapter 9, Section 9.1.3 of the PFP FSAR.

9G.4.1.5 Flammable Gas Deflagration in Glovebox

Flammable gases are potentially present in crimp-sealed containers due to the thermal and radiolytic decomposition of plastic contaminants and water. These gases could be released and burn when containers are opened in glovebox HC-21A (Table 9G.9). Chapter 9, Section 9.1.4 of the PFP FSAR evaluates the failure of a pressurized container as an abnormal operation but does not postulate ignition of flammable gases. Chapter 9, Section 9.1.9 of the PFP FSAR identifies an explosion or rapid release of gas pressure as a potential cause of a glovebox glove breach. Chapter 9, Section 9.1.11 of the PFP FSAR analyses?????, as an abnormal event, a release and burn of flammable gas upon opening a crimp sealed container. This event bounds S1 events identified in Table 9G.16, Pyrophoric Reaction in a Furnace, and Table 9G.17, Pyrophoric Reaction in Glovebox.

9G.4.1.6 Flammable Gas Deflagration in a Waste Drum

A flammable gas deflagration in a waste drum (Table 9G.10) due to the presence of radiolytically-generated hydrogen was postulated as a potential event resulting from various waste disposal activities associated with thermal stabilization operations. The activity of handling and disposing of plutonium contaminated material is not unique to thermal stabilization operations. This event is considered to be adequately addressed by the consideration of waste drum handling accidents in Chapter 9, Section 9.2.2D of the PFP FSAR.

9G.4.1.7 Loss of Glovebox Confinement Due to Mechanical Breach

Many causes of a loss of glovebox confinement due to mechanical breach (Table 9G.11) have been postulated. The principal mitigative controls are maintaining a negative pressure differential between the gloveboxes and surrounding room, and CAMs. This event is not unique to thermal stabilization operations and is considered to be adequately addressed by the analysis of a glovebox breach in Chapter 9, Section 9.1.9 of the PFP FSAR.

9G.4.1.8 Loss of Glovebox Confinement Due to Ventilation Failure

The E-4 ventilation maintains a negative pressure differential between gloveboxes and the surrounding operational areas. Either a loss of both supply and exhaust ventilation resulting in stagnant conditions, or a loss of only exhaust ventilation resulting in a pressurized glovebox, could result in a spread of contamination from the gloveboxes (Table 9G.12). This hazard is not unique to thermal stabilization operations and is considered to be adequately addressed by the analysis of a loss of ventilation in Chapter 9, Section 9.1.8, and the analysis of a glovebox breach in Chapter 9, Section 9.1.9 of the PFP FSAR.

In Glovebox HC-21C the ventilation system also serves to remove heat generated by furnace operation. Loss of the E-4 system could result in overheating of the glovebox leading to a breach of confinement. This hazard is also considered to be adequately addressed by Chapter 9, Sections 9.1.8 and 9.1.9 of the PFP FSAR.

9G.4.1.9 Rupture of Container in Storage Vault

The PHA identified numerous process upsets and failures that could result in inadequately stabilized product oxide. If this condition was not detected before the oxide was packaged, the container could rupture in storage due to internal pressurization (Table 9G.19). Should a container rupture while being handled in the 234-5Z Building, any airborne plutonium would be filtered by the E-3 ventilation exhaust system prior to release. In Building 2736-Z, many storage vault pedestals are instrumented to detect bulging cans. Those without this instrumentation are visually inspected monthly. A release from a ruptured can would be confined and filtered by the vault ventilation system.

Chapter 9, Section 9.1.4 of the PFP FSAR analyzes the rupture of a pressurized plutonium powder container outside of a glovebox. The impact of the thermal stabilization of non-product quality oxide feed materials on the prior FSAR analysis is presented in Chapter 9, Section 9.1.11**????** of the PFP FSAR. Note that the PFP FSAR categorized and evaluated the rupture of a pressurized container as an abnormal operation.

9G.4.2 Accidents

All S1* and S2 events warrant consideration for detailed accident analysis (the exception would be events with a corresponding frequency rank of F0).

9G.4.2.1 Criticality

Relatively large masses of plutonium will be handled during thermal stabilization operations. Placing too much of plutonium in a glovebox or having a sufficient amount of plutonium in a non-safe geometry could result in an accidental nuclear criticality (Table 9G.4). Controls to prevent criticality include administratively controlled mass and spacing limits, hardware that physically separates plutonium containers, limited quantities of water in the gloveboxes, controlled water addition by fire protection systems, and limits on the size and number of containers in gloveboxes. Criticality Safety Evaluations Reports are written establishing specific controls that provide double-contingency protection.

Chapter 9, Section 9.2.3 of the PFP FSAR quantitatively analyses the probability and consequences of a nuclear criticality. Plutonium handling operations associated with thermal stabilization operations do not differ from other PFP plutonium handling activities and do not warrant additional analysis as established controls have been determined to provide an adequate degree of protection.

9G.4.2.2 Uncontrolled Fire in Glovebox

The PHA identified numerous causes of a glovebox fire (Table 9G.20) including electrical shorts, the presence of pyrophoric materials in the feed, or combustible materials coming into contact with hot furnace surfaces. Controls to prevent or mitigate fires include controlling the quantity of combustible materials in gloveboxes, maintaining a safe separation between combustible materials and ignition sources, and fire suppression systems.

Chapter 9, Section 9.2.2A of the PFP FSAR analyses a fire in the RMC line as the bounding PFP fire hazard. The impact of the thermal stabilization of non-product quality oxide feed materials on the existing FSAR RMC line fire analysis is presented in Chapter 9, Section 9.2.10 of the PFP FSAR.

9G.4.2.3 Flammable Gas Deflagration/Energetic Chemical Reactions

The hazards analysis identified the potential for flammable gas deflagrations resulting from the thermal decomposition of TBP (and its degradation products) known to be present in PRF sludges or from the thermal decomposition of plastic or other organic materials potentially present in impure oxide, MOX, floor sweeps, and oxalates (Table 9G.9). Examples of controls for deflagrations include minimizing the quantity of TBP, plastics, and other organic contaminants present in the feeds, maintaining airflow and CO_2 flow through the furnaces, and slowly increasing the furnace temperature when processing PRF sludges

In addition to flammable gas deflagrations, the PHA identified the potential for energetic chemical reactions between incompatible chemicals potentially present as contaminants (Tables 9G.16 and 9G.17). This event was selected for detailed analysis in Chapter 9, Section 9.2.10 ????. Note that PFP processes are small in size relative to many chemical plants and that the processes generally employ low energy level chemistry.

9G.4.2.4 Natural Phenomena

The PHA identified three natural phenomena events: earthquake, high wind, and ashfall. The PHA identified four seismically induced events: an explosion, a fire, a loss of confinement, and a criticality (Table 9G.13).

Chapter 9, Section 9.2.4.1 of the PFP FSAR analyzes the response of PFP structures and gloveboxes, including those operated in support of thermal stabilization, to a seismic event, and calculates the consequences based on loss of confinement and criticality scenarios. The impact of the thermal stabilization of non-product quality oxide feed materials on the existing FSAR analyses is presented in Chapter 9, Section 9.2.10 of the PFP FSAR.

Chapter 9, Section 9.2.5 of the PFP FSAR analyzes the impact of a design basis wind. The 234-5Z Building is capable of withstanding both the wind forces and wind-generated missile associated with the design basis wind. Evaluation of this event with respect to thermal stabilization operations is not warranted.

Ash fall represents a roof loading concern and an abrasive concern for moving equipment. Evaluation of this event with respect to thermal stabilization operations is not warranted.

9G.4.3 External Events

The PHA identified facility-wide loss of power due to external events as an initiator to a flammable gas deflagration (Table 9G.8). The combination and sequencing of specific events is such that the probability is considered to be bounded by operator error or equipment failure initiators considered in Section 9G.4.2.3 above.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
A. General Glovebox Hazards – Applicable to all Feed Materials									
A.1.01	Electrical Equipment in glove box.	Fire in glove box caused by electrical short	Failure to properly inspect power cords or failure to identify frayed cords results in condition that leads to an electrical short that ignites combustibles in the glovebox Failure to control combustibles in glove box allows significant fire that damages glove box confinement.	Burn through of gloves seal out bags resulting in breach of containment Ignition of Polymethyl Methacrylate or Polycarbonate glove box panels and spread of fire to other gloveboxes Release of soot, hot embers, and water vapor to the E-3 and E-4 ventilation systems. Pluggage or failure of glovebox and E-4 filterbox HEPA filters. Potential pluggage of E-3 room prefilters or E-3 filterbox HEPA filters, with spread of contamination to clean portions of the plant. Worker uptake of airborne Pu	Halon fire suppression system in Gloveboxes HC-21A, HC-21C, HC-18M, HC-18BS, HC-2, and HC-3 Dry fire suppression system in Gloveboxes HA-23S, HC-28, and HC-4 Wet pipe fire suppression system in rooms 228C, 230A, B, C, and Room 235B Glovebox (E-4) ventilation system maintains negative glovebox pressure and confines release until several gloves or bag ports are burned out or window panels are breached, giving operators time to manually extinguish fire. Long length of E-3/E-4 ductwork between RMC line and filter room filters and dilution airflow from other E-3/E-4 areas of the plant are expected to cool offgasses from the fire enough to prevent heat damage to, or plugging of the E-3/E-4 filter-room HEPA filters. E-3/E-4 filter-room HEPA filters mitigate release to the environment CAMS alert workers to presence of airborne contamination.	MgO sand available in gloveboxes for extinguishing small fires Bayonet fire extinguisher is near glovebox for manually extinguishing fire. Housekeeping practices minimize combustible loading in glovebox. Senior supervisory watch OSHA inspections can identify frayed cords. Electrical safety program of cord inspection reduces the likelihood of the presence of frayed cords. Institutional occupational safety program of requirements and inspections reduces the likelihood of the presence of frayed cords. Hanford fire department located within a few miles of PFP	S1*	F3	Polymethyl Methacrylate panels are easier to ignite and spread flames more readily than Polycarbonate panels. Polymethyl Methacrylate panels have been replaced by Polycarbonate panels in Gloveboxes HC-21A and HC-21C. Several kg of burning plastic can generate enough radiant heat to ignite Polycarbonate panels. See RMC line fire accident analysis in Section 9.2.2 of the PFP FSAR.
A.1.02	Electrical Equipment in glovebox	Electrical shock to operator	Cord frayed in the glovebox Frayed cord contacts glovebox frame while operators body or leg is in contact with the glovebox frame.	Operator injury	None	Senior supervisory watch OSHA inspections can identify frayed cords. Electrical safety program of cord inspection reduces the likelihood of the presence of frayed cords. Institutional occupational safety program of requirements and inspections reduces the likelihood of the presence of frayed cords.	S1	F3	Commonly accepted industrial hazard. The likelihood of electrical shock injury is reduced by the presence of rubber mats that are placed on floor grating to protect shoe covers Hypalon glovebox gloves may provide some protection

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
A.1.03	Glovebox Confinement Boundary	Hole in glovebox confinement boundary leads to spread of contamination from glovebox	Degradation of port bags, ice cream cartons used to seal sphincter port, or gloves due to aging, radiation, or heat.	Minor Spread of contamination from glovebox and potential uptake by workers.	E-4 ventilation system maintains negative pressure in glovebox and maintains confinement velocity across small holes	Gloves and bags have scheduled replacement dates which minimizes likelihood of degradation. Pre-job walkdown visual inspection of gloves, bags, and ice cream cartons. Air flow through leaks can cause a whistling sound which aids in detecting leaks in gloves, port bags, etc. during pre-job walkdown. Radiological control program: operators hands are surveyed every 15 minutes during glovebox operations and when changing glovebox locations to identify leaks. Alpha contamination survey on exit from radiological control area prevents spread of contamination to clean areas of the plant.	S1	F3	Ice cream cartons currently are replaced with each successive seal-in.
A.1.04	Glovebox Confinement Boundary	Breach in glovebox confinement boundary during waste bagout, port bag replacement, or glove change.	Sharp object punctures bag Bag not properly horse tailed or taped Bag inadvertently pulled off port Original or replacement bag glove tears Bungee chord used to hold replacement bag slips or fails while removing inner (original) bag Replacement glove inadvertently pull off lip of port Bag/glove pinched when tightening port ring Replacement bag/glove has undetected hole in it	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers.	Glovebox (E-4) ventilation system maintains glovebox negative pressure and confinement velocity across small holes; minimizes potential spread of contamination from glovebox Glovebox port designed to minimize likelihood of loss of confinement during bag changes (notches, ridges to facilitate, 2 bags or gloves)	Workers wear respirators during bag out of waste, bag/glove changes Room put on ARA status during bagouts, bag changes, glove changes. Operator certification.	S1	F3	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
A.2.01	Glovebox CPS	Violation of criticality safety mass or spacing limit, loss of contingency	Failure to check or adhere to CPS postings on glovebox	Potential Criticality in glovebox with worker exposure to ionizing radiation and fission product gasses.	None	CSER controls on mass of Pu allowed in glovebox, spacing of containers in glovebox, etc. CPS posting on glovebox Operator training.	S1*	F2	Controls providing double contingency protection against criticalities are identified in separate CSER reports for each glovebox. S1* is consequence for a criticality, not a loss of contingency.
A.3.01	Glovebox (E-4) ventilation system	Stagnant glovebox or pressurized glovebox during operations causes spread of contamination from glovebox	Loss of E-4 ventilation flow or imbalance between E-4 supply and exhaust (caused by loss of power or equipment or control failures). Failure to detect HVAC upset during pre-job walkdown	Spread of contamination from glovebox during seal in or seal out of container, glove change, or change of port bag. Worker exposure to dispersible Pu. Overheating of Glovebox HC-21C during furnace operations (see item E.3.04).	E-4 HVAC controls Interlock shuts off supply fans if exhaust fans go down, which prevents glovebox pressurization. Pressure regulating valve on supply air regulates pressure in RMC line gloveboxes. Addition exhaust capacity provided via emergency exhaust valves in Room 228A should imbalance develop between supply and exhaust flow. Alarm activates in power control room on detection of low glovebox negative in control room. PAX announcement made if alarm activates. E-3 filter room filters mitigate release to environment if only E-4 ventilation is lost. Building shell mitigates release if glovebox and building goes stagnant. Backup power operates emergency exhaust fans that maintain negative pressure in gloveboxes if plant loses primary power. Room CAMs alert workers to airborne contamination.	Pre-job walkdown to verify proper glovebox ventilation flow and DP Operator training and procedures	S1 S1	F3 F2	S1/F3 for stagnant glovebox case. S1/F2 for pressurized glovebox case (pressurization is not large). Plant is evacuated if E-3/E-4 exhaust is lost, which minimizes potential worker inhalation doses.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
B. Transfer Items from Vault Storage to Glovebox HC-21A									
B.1.01	Remove item from storage location and place on fixed array wagon	Breach of container	Operator drops container Pressurized container fails during handling	Spread of contamination, worker uptake	Multiple overpack containers Room CAMs alert workers to presence of airborne contamination Suspected pressurized containers (i.e., B, C, and D cans) placed in ITC HEPA filtered ventilation system	Training and procedures	S0	F3	None
B.1.02	Remove item from storage location and place on fixed array wagon	Violation of mass or spacing limits, loss of contingency	Operator placed too many items on wagon	Potential criticality with worker exposure to ionizing radiation and fission product gases	Fixed array wagon that limits the number of containers and establishes spacing	Training and procedures CPS limits	S1*	F2	Controls providing double contingency protection identified in applicable CSERs. S1* is consequence for a criticality, not a loss of contingency.
B.2.01	Transfer item to Glovebox HC-21A	Breach of container	Wagon tips over, container falls out and opens	Spread of contamination, worker uptake	Fixed array wagon holds cans in storage positions if tipped over Multiple overpack containers Room CAMs alert workers to presence of airborne contamination HEPA filtered ventilation system	Training and procedures	S0	F3	None
B.2.02	Transfer item to Glovebox HC-21A	Violation of spacing limits, loss of contingency	Wagon tips over, containers fall out	Potential criticality with worker exposure to ionizing radiation and fission product gases	Fixed array wagon holds can in storage positions if tipped over	Training and procedures	S1*	F2	Controls providing double contingency protection identified in applicable CSERs. S1* is consequence for a criticality, not a loss of contingency.
BB. Transfer Items from Glovebox Storage to Glovebox HC-21A									
BB.1.01	Transfer polyjar or slip-lid can from glovebox storage to HC-21A via glovebox conveyor system (transfer will primarily be from HA-23S via conveyors HA-28, HC-4, HC-3, airlock, HC-2)	Polyjar crumbles in worker hands during handling or is damaged in drop or by conveyor malfunction	Radiolytic/thermal degradation of polyjar	Spill of material to glovebox floor, entrainment of material into glovebox air Plastic contaminant in cleaned-up material potentially results in flammable gas burn during subsequent thermal stabilization (see E.3.04)	Glovebox confinement boundary and ventilation system confine release See E.3.04 for potential flammable gas hazard	Procedure requires sieving of material during transfer to furnace boat. Plastics and other contaminants visually detected by workers	S0 S1*	F3 F2	S0/F3 for spilling S1*/F2 for flammable gas burn See E.3.04

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
BB.1.02		Airlock between conveyors HC-2 and HC-3 left open, deminishes effectiveness of Halon system, loss of fire separation	Operator error results in airlock doors being left open	No consequence unless concurrent RMC line fire Reduced ability to Halon system to suppress fire	Operator training and procedures	Operator training and procedures	S2	F1	None
C. Activities in Glovebox HC-21A – PuO2 and MOX Feed Materials from Vault Storage (multiple overpack containers)									
C.1.01	Seal container into Glovebox HC-21A through bag in port or sphincter seal	Drop of Pu storage container outside glovebox during seal in.	Human error.	No significant release from Pu storage container expected.	Overpack containers protect inner container.	Operator training and procedures Inner containers have been drop tested and found not to leak.	S0	F3	Hazards associated with handling containers of Pu outside gloveboxes is adequately covered in the PFP FSAR.
C.1.02	Seal container into Glovebox HC-21A through bag in port or sphincter seal	High worker direct dose during handling of cans	Container containing PuF_4 handled instead of PuO_2 or MOX (PuF_4 much higher dose than oxide from alpha-n reactions). Cans handled for extended time period during handling/seal-in of cans.	Worker dose rate limit (Radiological work permit) potentially exceeded	Leaded gloves limit dose when handling cans inside the glovebox. Glovebox structure shields body of operator Inner can and first overpack are wrapped with leaded tape to minimize direct dose	ALARA principles applied to Pu storage container handling process. Periodic dose measurements taken on glovebox to establish acceptable worker exposure periods. Labeling of cans in vault (RAM tags) Cans surveyed for contact dose several times during movement and before loading into HC-21A. Blend plan identifies intended cans Institution radiological control program	S1	F3	None
C.1.03	Seal container into Glovebox HC-21A through bag in port or sphincter seal	Glovebox loss of confinement during seal in.	Sphincter seal failure Ice cream carton or can in sphincter seal inadvertently pushed into glovebox without can or carton behind it results in open sphincter seal. Seal in bag torn or pulled off port during seal in (also applies to change out of port bags) (see item A.1.04). Pressurized glovebox during seal in (see item A.3.01)	Minor release of contamination from the glovebox into the room. Potential worker uptake of Pu.	Glovebox ventilation system maintains negative pressure and confinement velocity across failed sphincter seal or port bag which minimizes the potential contamination spread. Backup glovebox (E-4) ventilation system maintains confinement on loss of primary ventilation. Room CAMs alert operators to presence of airborne contamination. PRV on supply restricts flow rate on low glovebox DP. Emergency	Operator training and procedures	S1	F3	S1 ranking assumes minor release of contamination from glovebox. Hazards associated with seal in of containers into gloveboxes is covered in the PFP FSAR. This accident is not unique to seal in of containers containing thermal stabilization feed materials. Room CAMs are designated safety significant in the PFP FSAR.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
					exhaust valves open on low glovebox negative. Sphincter seal design prevents release unless no can or carton in seal.				
C.2.01	Open outer cans and make empty cans into Non containers	Flammable gas (i.e. H_2) release and burn when overpack can opened.	Radiolysis of plastic bag around slip lid can and organic can seal during storage in vault. Ignition due to mechanical spark from can opener, static release from ejected powders, or electrical spark.	Potential deflagration involving H_2 released from can causing pressurization and potential failure of seal-in ports or sphincter ports with release of Pu into the room air. Inhalation uptake of Pu by workers.	Glovebox and E-4 ventilation system confine release unless deflagration large enough to fail port bags or gloves. E-3 ventilation system filters mitigate release to the environment. Room CAMs alert workers to presence of airborne radiological material	Operators verify glovebox DP and filter DP before opening cans. Pressurized cans containing potentially significant amounts of hydrogen are identified by visual detection of bulging.	S1	F2	Catastrophic failure of glovebox structure not expected due to limited quantity of H_2 possible in the can. Many pressurized cans have been opened at PFP without a resultant deflagration. Ignition of hydrogen released from the can by the can opener or static discharge is unlikely.
C.2.02	Open outer cans and make empty cans into Non containers	Operator injury and damage to glovebox glove compromising glovebox confinement integrity.	Operator punches through glove with can opener or cuts glove on sharp edges of the can or can lid	Operator injury with contamination of wound Small hole in glovebox confinement boundary Small contamination release from glovebox as hands withdrawn from glovebox gloves	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves are used over glovebox gloves when opening cans Operators are surveyed for contamination every 15 minutes while working in glovebox gloves. Self survey on exit from radiological area to detect skin contamination HPT deconning of skin or injury Surgical excision of contaminated tissue. Leather gloves used when crushing or folding cans	S1	F3	None
C.2.03	Open outer cans and make empty cans into Non containers	Outer cans not properly made into non- container, loss of contingency	Can not crushed and folded, can with bottom removed set upright instead of on its side, can not turned upside down.	CPS infraction Margin of criticality safety reduced	None	Operator training and procedures Glovebox CPS posting (tells operator maximum open container volume to unit mass ratio)	S1*	F3	None S1* is consequence for a criticality, not a loss of contingency.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
C.2.04	Open outer cans and make empty cans into □Non containers□	Operator injury and damage to glovebox glove compromising glovebox confinement integrity.	Operator suffers injury and ruptures glove while crushing empty can with hammer	Operator injury with contamination of wound Small hole in glovebox confinement boundary leading to contamination release from glovebox.	Glovebox ventilation system maintains confinement velocity across hole in glove	Operator training and procedures Operators are surveyed for contamination every 15 minutes while working in glovebox gloves. Self survey on exit from radiological area to detect skin contamination HPT deconning of skin or injury Leather gloves used when crushing or folding cans	S1	F3	None
C.3.01	Weigh storage container (inner and overpacks) and furnace boat (before and after filling) for Pu accountability and operational requirements	No safety hazard identified for this step.	--	--	--	--	--	--	Pu content of item is set by Accountability prior to placing container in vault. Scale can□t necessarily detect overbatch of Pu or potential criticality hazard since it only measures gross weight.
C.4.01	Open innermost can (can containing feed material)	Operator injury and damage to glovebox glove compromising glovebox confinement integrity.	Worker penetrates glove while opening sealed can with can opener, taped slip lid can with scissors, while handling can or lid.	Operator injury with contamination of wound Small hole in glovebox confinement boundary Small contamination release from glovebox	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves use when opening cans Operators are surveyed for contamination every 15 minutes while working in glovebox gloves. Self survey on exit from radiological area to detect skin contamination HPT deconning of skin or injury Leather gloves used when crushing or folding cans	S1	F3	None
C.4.02	Open innermost can (can containing feed material)	Hydrogen gas release and burn when can opened	Radiolytic degradation of plastic contaminant, brush bristles, tool handle, bottle caps, etc. in oxide during storage generates hydrogen in can. Hydrogen ignited during release from can due to static or electrical discharge High water content in oxide (above 1%) due to prior inadequate stabilization results in can pressurization	Potential deflagration involving H_2 released from can causing pressurization and potential failure of seal-in ports or sphincter ports with release of Pu into the room air. Inhalation uptake of Pu by workers.	Glovebox and E-4 ventilation system confine release unless deflagration large enough to fail port bags or gloves. E-3 ventilation system filters mitigate release to the environment. Room CAMs alert workers to presence of airborne radiological material	Operators verify glovebox DP and filter DP before opening cans. Pressurized cans containing potentially significant amounts of hydrogen are identified by visual detection of bulging.	S1	F2	Catastrophic failure of glovebox structure not expected due to limited quantity of H2 possible in the can. Many pressurized cans have been opened at PFP, all without a resultant deflagration. Ignition of hydrogen released from the can by the can opener or static discharge is unlikely.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
			due to hydrogen buildup from reaction of the water with Pu and radiolysis of the water.						
C.4.03	Open innermost can (can containing feed material)	Pu particulate release from pressurized can when it is opened	Can temperature higher than when canned causes pressurized can Alpha decay causing pressure buildup (Helium usually diffuses out of can) High water content in oxide (above 1%) due to prior inadequate stabilization results in can pressurization due to hydrogen buildup from reaction of the water with Pu and radiolysis of the water.	Pu particulate release inside glovebox Increased dose rate to workers near glovebox from spilled Pu	E-4 ventilation system and glovebox confines release E-4 ventilation system HEPA filters mitigate release to the environment through the facility exhaust stack.	Housekeeping; spilled material is swept up and placed in cans and sealed out of glovebox. Institutional radiation protection program: Radiological control technicians set glovebox dose rates to limit operator direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures ventilation is operating correctly.	S0	F3	None
C.4.04	Open innermost can (can containing feed material)	Flammable gases (alkanes, H_2, etc) from organic in container released and ignited when can opened (can pressurized)	Container containing organic (e.g., sludge, floor sweeps) inadvertently sealed into glovebox and opened. Wrong container selected due to inaccurate labeling or human error. Flammable gases generated due to radiolytic decay of organic material (e.g., sludge) in the container. Ignition due to mechanical or electrical spark, or static discharge.	Pressurization of glovebox Potential damage to glovebox confinement boundary Pu release into room and worker inhalation uptake.	Glovebox and E-4 ventilation system confine release unless deflagration large enough to fail port bags or gloves. E-3 ventilation system filters mitigate release to the environment. Room CAMs alert workers to presence of airborne radiological material.	Operators verify glovebox DP and filter DP before opening cans. Pressurized cans containing a dangerous amount of flammable are easily identified due to bulging. Labeling of containers Operator training and procedures Shift technical advisor sign off for material acceptability required by procedure. Sludges which may contain organic are stored in vented polyjars which are easily distinguishable from multiple overpack cans containing PuO_2 and MOX	S1	F2	Recommend bulged containers not be opened in air. []Ruler test[] can be used to eliminate highly pressurized cans. Catastrophic failure of glovebox structure not expected due to limited quantity of flammable gas possible in the can. Many pressurized cans have been opened at PFP, all without a resultant deflagration. Ignition of flammable gas released from the can by the canopener or static discharge is unlikely.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
C.4.05	Open innermost can (can containing feed material)	Pyrophoric reaction and hydrogen burn when can opened	Pu metal, PuH_2 hydride contaminant in can Pu metal may be in can due to incomplete prior stabilization. PuH_2 forms from metal if plastic or organic contaminants are also present in can. Or if hydrogen from degradation of the plastic bag outside the can diffuses into the can. Can under vacuum due to catalyzed formation of oxides and nitrides in the container. When can is opened air is sucked in which reacts with the hydrided material. Hydride reactions releases heat and hydrogen gas which is ignited on exiting the can.	If sufficient hydride contamination present, slight pressurization of the glovebox could occur. Potential burn through of gloves and operator injury due to contact with hot embers. Embers burn through PVC ports Minor contamination spread from glovebox if gloves or port bags damaged. Potential ignition of combustibles in glovebox producing glovebox fire.	Glovebox (E-4) ventilation system maintains confinement if damage limited to holes in gloves E-3 ventilation system filters release to environment if glovebox confinement lost Rooms CAMs alert worker to airborne contamination Glovebox dry fire suppression system for putting out glovebox fire Glovebox high temperature alarm	MgO sand for putting out small fire Bayonet fire extinguishers available near glovebox for putting out small fire Operator training and procedures Only material passing previous LOI test will be processed through the furnaces during this campaign. Blend plan identifies which containers are acceptable for processing. Container labeling and material processing records identify contents of containers. Shift technical advisor sign off for material acceptability required by procedure. Combustible loading in glovebox is controlled by procedure.	S1 S1*	F3 F2	S1/F3 for sparking reaction and small hydrogen flash with maximum consequence being burn through of glove or port bag S1*/F2 for ignition of significant combustibles in the glovebox causing glovebox fire. Evaluate use of Pu net wt% to detect presence of Pu hydride in can before opening. Cans with relatively large quantities of hydride will be □panelled,□ making them easy to identify and not open in this campaign.
C.5.01	Transfer contents to furnace boat	Pyrophoric reaction as material poured through air	Pu metal, PuH_2, Uranium hydride; Pu_2O_3 contaminant in can Pu or U metal may be in can. PuH_2/ UH_3 forms from metal if plastic or organic contaminants are also present, or if hydrogen from degradation of the plastic bag outside the can diffuses into the can.	Sparks potentially initiating a glovebox fire. Hot embers entrained in air may burn hole in glovebox HEPA filters. Dispersal of Pu in glovebox Potential burn through of gloves and operator injury due to contact with hot embers. Burn through of PVC port bags. Minor contamination spread from glovebox if gloves or port bags damaged Potential ignition of combustibles in glovebox producing glovebox fire If sufficient hydride contamination present, slight pressurization of the glovebox could occur	Glovebox (E-4) ventilation system maintains confinement if damage limited to holes in gloves E-3 ventilation system filters release to environment if glovebox confinement lost Rooms CAMs alert worker to airborne contamination Glovebox dry fire suppression system for putting out glovebox fire Glovebox high temperature alarm	MgO sand for putting out small fire Bayonet fire extinguishers available near glovebox for putting out small fire Operator training and procedures Only material passing previous LOI test will be processed through the furnaces during this campaign. Blend plan identifies which containers are acceptable for processing. Container labeling and material processing records identify contents of containers. Cans with relatively large quantities of hydride will be □panelled□ and easily identified. Combustible loading in glovebox is controlled by procedure	S1 S1*	F3 F2	Evaluate use of Pu net wt% to detect presence of Pu or U metal in can before opening. S1/F3 for sparking reactions with maximum consequence being burn through of glove or port bag. S1*/F2 for ignition of significant combustibles in the glovebox.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
C.5.02	Transfer contents to furnace boat	Can/boat contents spilled to glovebox floor	Human error	Violation of criticality prevention specification limit regarding depth of powder allowed on glovebox floor Increased operator exposures during cleanup of spill	E-4 ventilation system and glovebox confinement release	Housekeeping Operator training and procedures	S0	F3	Operational upset only Significant dose to operator in cleaning up spill not expected.
C.5.03	Transfer contents to furnace boat	Material other than Pu oxide or MOX poured into furnace boat (e.g., metal button, sludge or glovebox floor sweeps) resulting in process upset.	Wrong can opened due to mislabeling or human error.	Process upset. Material would have to be canned up and bagged out of the glovebox for later processing. Potential adverse reaction in furnace in Glovebox HC-21C if wrong material not noticed by operator.	--	Labeling and paperwork associated with each container identify contents making it unlikely for wrong material to be processed. Operator training and procedures.	S0	F2	X-ray or Pu mass ratio information could be used to provide added assurance against processing materials other than Pu oxide. Sludges are stored in polyjars in Glovebox HA-23S, not in the vaults with the Pu oxide. Highly unlikely that container of sludge would get mixed up with container of oxide. Glovebox floor sweeps are stored in gloveboxes, not in the vaults with the Pu oxide, making selection of can with floor sweeps very unlikely. H/X ratio on sludges will indicate high organic loading. Hazards associated with inadvertently processing Pu fluoride are covered in this PHA since it may be difficult to visually tell the difference between fluoride and oxide through the yellowed glovebox windows (see items B.1.02 and D.3.10).

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
C.6.01	Identify and remove contaminants from oxide in furnace boat	Contaminants not identified or removed from oxide result in reaction hazards in Glovebox HC-21C furnaces. Contaminants can include unburned metal pieces from prior stabilization run, metal hydrides, and plastics including: tool handles, brush bristles, PVC or polyethylene bag fragments, polycarbonate pieces, etc.	Human error; step not performed correctly Contaminants not readily identifiable due to color, size, etc. Poor visibility through glovebox windows.	Pyrophoric reaction in furnace in Glovebox HC-21C. See item E..3.05. Fires or deflagrations of flammables the furnaces in Glovebox HC-21C. See item E.3.04.	See items E.3.04 and E.3.05 for engineered features to mitigate reactions in the HC-21C furnaces.	Procedures with sign off by Shift Technical Advisor.	S1 S1*	F2 F2	S1/F2 for pyrophoric reactions in furnace. S1*/F2 for flammable gas deflagration in furnace resulting from excessive plastic contaminant in oxide feed to furnace.
C.7.01	Bag out waste (crushed cans, tape, plastic); replace port bag.	Breach in glovebox confinement boundary during waste bagout or glove change.	Sharp object punctures bag Bag not properly horsetailed or taped Bag inadvertently pulled off port Original or replacement bag glove tears Bungee chord used to hold replacement bag slips or fails while removing inner (original) bag Replacement glove inadvertently pull off lip of port Bag/glove pinched when tightening port ring Replacement bag/glove has undetected hole in it	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers	Glovebox (E-4) ventilation system maintains glovebox negative pressure and confinement velocity across small holes; minimizes potential spread of contamination from glovebox Glovebox port designed to minimize likelihood of loss of confinement during bag changes (notches, ridges to facilitate, 2 bags or gloves)	Workers on mask during bag out of waste, bag/glove changes Room put on ARA status during bagouts, bag changes, glove changes. Operator certification.	S1	F3	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
C.7.02	Bag out waste (crushed cans, tape, plastic); replace port bag.	Spread of contamination from waste bag	Waste bag squeezed causing release of radiological material through taped vent Isolated transport container (ITC) dropped during handling causing bag to vent or rupture	Contamination of workers and potential uptake of radiological material	E-3 ventilation system filters release to environment. Room CAMs alert workers to airborne contamination.	Operator training and procedures Waste bags are put in isolated transport container (ITC) immediately after applying second bag. ITCs have lids to minimize spread of release from pail. Radiological control program. Survey of workers with alpha poppy probes to detect skin contamination. Worker decontamination by RCT if necessary.	S1	F3	None
C.7.03	Bag out waste (crushed cans, tape, plastic); replace port bag.	Hydrogen deflagration inside waste drum in satellite accumulation area.	Hydrogen generation from radiolysis in waste bags in waste drum. Ignition caused by spark generated while moving drum.	Pressurization of drum, drum damage and release of radiological material from waste drum in satellite accumulation area (Room 166) Potential worker injury	Waste drum is vented through a filter to prevent hydrogen accumulation Room CAMs alert workers of airborne contamination in Room 166 Room 166 ventilated by the E-3 system which confines and filters any release from waste drum.	Drum seal is verified. Periodic surveillance of rooms to detect bulging drums.	S1	F2	S1 ranking instead of S1* due to small quantity of Pu in drum. This hazard is not unique to the thermal stabilization process as it applies to drums containing bagged out waste from all gloveboxes. Hazards associated with drum storage are covered in the PFP FSAR. The Pu content of the bagged waste is so low that significant pressurization of a drum is not expected during its storage life at PFP even if vent plugs.
CC. Activities in Glovebox HC-21A – Sludges, Floor Sweeps, and Oxalates from Glovebox Storage (polyjars or slip-lid cans)									
CC.1.01	Weigh polyjar or slip-lid can and furnace boat (before and after filling) for Pu accountability and operational requirements	No safety hazard identified for this step	–	–	–	–	–	–	–

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
CC.1.02	Transfer container into Glovebox HC-21A via conveyor	High worker direct dose during handling of container	Container containing PuF4 instead of sludges, floor sweeps and oxalates	Worker dose rate limit (radiological work permit) potentially exceeded.	Leaded gloves limit dose when handling containers Glovebox structure shields body of operator	ALARA principles applied to Pu storage container handling process. Periodic dose measurements taken on glovebox to establish acceptable worker exposure periods. Labeling of cans in vault (RAM tags) Cans surveyed for contact dose several times during movement and before loading into HC-21A. Blend plan identifies intended cans Institution radiological control program	S1	F3	None
CC.2.01	Open polyjar or slip-lid can	Operator injury and damage to glovebox glove compromising glovebox confinement integrity	Polyjar crumbles, worker glove penetrated by shard. Worker glove penetrated by scissors while opening taped slip-lid can.	Operator injury with contamination of wound. Small hole in glovebox confinement boundary Small contamination release from glovebox	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across small holes preventing release of Pu to room.	Leather gloves use when opening cans Operators are surveyed for contamination every 15 minutes while working in glovebox gloves. Self survey on exit from radiological area to detect skin contamination HPT deconning of skin or injury	S1	F3	None
CC.2.02	Open polyjar or slip-lid can	Hydrogen gas release when polyjar or slip-lid can opened	Radiolytic degradation of plastic contaminant, brush bristles, tool handle, bottle caps, etc. in oxide during storage generates hydrogen in can. Hydrogen ignited during release from can due to static or electrical discharge	Potential deflagration involving H_2 released from can causing pressurization and potential failure of seal-in ports or sphincter ports with release of Pu into the room air. Inhalation uptake of Pu by workers.	Glovebox and E-4 ventilation system confine release unless deflagration large enough to fail port bags or gloves. E-3 ventilation system filters mitigate release to the environment. Room CAMs alert workers to presence of airborne radiological material	Operators verify glovebox DP and filter DP before opening cans. Pressurized cans containing a dangerous amount of hydrogen are easily identified due to bulging.	S1	F2	Polyjars and slip-lid cans not likely to hold pressure. Catastrophic failure of glovebox structure not expected due to limited quantity of H2 possible in the can. Many pressurized cans have been opened at PFP, all without a resultant deflagration. Ignition of hydrogen released from the can by the can opener or static discharge is unlikely.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
CC.3.01	Sample sludge for organic content	Flammable gas above LFL	Operator fails to sample or collects non-representative sample	Potential flammable gas (butene) concentration greater than LFL. Possible fire or deflagration. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	Furnace door does not latch and thereby provides vent path to prevent catastrophic explosion of the furnace. Furnace vacuum system sweeps air through the furnace that serves to dilute flammable gas concentration.	Operator training and procedures	S1*	F2	None
CC.3.02	Transfer contents to furnace boat	Polyjar or slip-lid can contents spilled to glovebox floor	Human error	Potential violation of criticality prevention specification limit regarding depths of powder allowed on glovebox floor. Increased operator exposure during cleanup of spill	E-4 ventilation system and glovebox serve to confine release	Housekeeping Operator training and procedures	S0	F3	Operational upset only. Significant dose to operator in cleanup of spill not expected/
CC.4.01	Identify and remove contaminants from feed in furnace boat	Contaminants not identified or removed from feed result in reaction hazards in Glovebox HC-21C furnaces. Contaminants can include plastics including: RTV, tool handles, brush bristles, PVC or polyethylene bag fragments, polycarbonate pieces, etc.	Human error; step not performed correctly Contaminants not readily identifiable due to color, size, etc. Poor visibility through glovebox windows.	Pyrophoric reaction in furnace in Glovebox HC-21C. See item E.3.05. Fires or deflagrations of flammables the furnaces in Glovebox HC-21C. See item E.3.04.	See items E.3.04 and E.3.05 for engineered features to mitigate reactions in the HC-21C furnaces.	Procedures with sign off by Shift Technical Advisor.	S1 S!*	F2 F2	S1/F2 for pyrophoric reaction in furnace. S1*/F2 for flammable gas deflagration in furnace resulting from excessive plastic contaminant in oxide feed to furnace.
CC.5.01	Make polyjar or slip-lid can into a noncontainer	Polyjar or slip-lid can not properly made into non-container, loss of contingency	Polyjar or slip-lid can not turned upside down or on side Polyjar or slip-lid can not cut or crushed	CPS infraction Margin of criticality safety reduced	None	Operator training and procedures Glovebox CPS posting (informs operator maximum open container volume to unit mass ratio)	S1*	F3	None S1* is consequence for a criticality, not a loss of contingency.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
CC.5.02	Make polyjar or slip-lid can into a noncontainer	Operator injury and damage to glovebox glove compromising glovebox confinement integrity	Operator injures self and ruptures glove while cutting or crushing polyjars or slip-lid cans	Operator injury with contamination of wound Small hole in glovebox confinement boundary leading to contamination release from glovebox	Glovebox ventilation system maintains confinement velocity across hole in glove	Leather gloves use when cutting polyjars or crushing slip-lid cans Operators are surveyed for contamination every 15 minutes while working in glovebox gloves. Self survey on exit from radiological area to detect skin contamination HPT deconning of skin or injury	S1	F3	None
CC.6.01	Bag out waste (cut polyjars, crushed cans); replace bagport.	See C.7.01 through C.7.03	See C.7.01 through C.7.03	See C.7.01 through C.7.03	See C.7.01 through C.7.03	See C.7.01 through C.7.03	See C.7.01 through C.7.03	See C.7.01 through C.7.03	See C.7.01 through C.7.03
D. Activities in Glovebox HC-2									
D.1.01	Transfer furnace boat down conveyor to Glovebox	Glove damaged during conveyor operation compromising glovebox confinement	Glovebox glove(s) pinched in conveyor during transfer.	Worker injury and contamination Potential spread of contamination from glovebox through hole in glove leading to potential inhalation uptake by workers	Glovebox (E-4) ventilation system maintains negative pressure in glovebox and confinement velocity across ruptured gloves. CAMs alert workers to presence of airborne contamination.	Conveyor disabled when workers have hands in gloves - 3 key interlocks (in different rooms) must be enabled to operate conveyor. Gloves secured outside conveyor glovebox with bungee cords before conveyor is turned on. Operator training and certification.	S1	F3	None
D.1.02	Transfer furnace boat down conveyor to Glovebox	Spill/dispersal of Pu bearing material in glovebox	Furnace boat dumped off conveyor .	Added dose to workers in recovering from spill. Increased direct dose to workers working near glovebox due to increase in contamination level of glovebox.	Glovebox confinement boundary and E-4 ventilation system confine release. E-4 HEPA filters mitigate release to the environment through the 291-Z exhaust stack.	Housekeeping practices: spilled material is swept up, placed in cans, and sealed out of glovebox to minimize direct dose to workers. Institutional radiation protection program: radiological control technicians set glovebox dose rates to limit worker direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures the E-4 ventilation system is operating properly before initiating operations. Boat is transferred in a boat cover which limits the potential for Pu oxide dispersal from the RMC line supply air or dispersal	S0	F3	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
						should the boat tip over on the conveyor.			
E. Activities in Glovebox HC-21C									
E.1.01	Remove boat cover, adjust furnace hearth, and place boat in furnace	Spill/dispersal of Pu bearing material in glovebox	Furnace boat spilled while loading into furnace	Added dose to workers in recovering from spill. Increased direct dose to workers working near glovebox due to increase in contamination level of glovebox.	Glovebox confinement boundary and E-4 ventilation system confine release. E-4 HEPA filters mitigate release to the environment through the 291-Z exhaust stack.	Housekeeping practices: spilled material is collected, placed in cans, and sealed out of glovebox to minimize direct dose to workers. Institutional radiation protection program: radiological control technicians set glovebox dose rates to limit worker direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures the E-4 ventilation system is operating properly before initiating operations. "Boat cover" limits the potential for Pu dispersal should the boat tip over on the conveyor.	S0	F3	None
E.2.01	Prepare for furnace operation, includes: - close furnace door	Operator injury/glove damage	Glove pinched in door when closed or glove punctured by sharp object.	Operator injury with contamination of wound Small hole in glovebox confinement boundary leading to contamination release from glovebox.	Glovebox ventilation system maintains confinement velocity across hole in glove	Operator training and procedures Operators are surveyed for contamination every 15 minutes while working in glovebox gloves. Self survey on exit from radiological area to detect skin contamination HPT deconning of skin or injury Leather gloves used when crushing or folding cans	S1	F3	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
E.2.02	Prepare for furnace operation: - adjust offgas (vacuum), flowrate typically 2-3 cfm	Buildup of flammable gas	Operator error in adjusting flow, valve failure	Potential flammable gas concentration greater than LFL. Possible fire or deflagration. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	Flow meter on vacuum line	Operator training and procedures	S1*	F2	None
E.2.03	Prepare furnace for operation: - check ceramic filter DP	Buildup of flammable gases	Operator fails to check ceramic filter DP combined with buildup of solids on filter reduces air flow	Potential flammable gas concentration greater than LFL.. Possible fire or deflagration. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	None	Operator training and procedures	S1*	F3	None
E.2.04	Prepare furnace for operation: - Turn on and adjust CO_2 flowrate if processing sludge, flowrate typically 0.5 cfm.	No CO_2 purge during sludge processing	CO_2 not turned on Bottle runs empty CO_2 valved to wrong furnace	Potential flammable gas (butene) concentration greater than LFL.. Possible fire or deflagration. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	Alarm on CO_2 tank switching Furnace door does not latch and thereby provides vent path to prevent catastrophic explosion of the furnace. Furnace vacuum system sweeps air through the furnace that serves to dilute flammable gas concentration.	Verification of CO_2 supply prior to conduct of furnace operations Quantity of organic in sludge limited to 10 g Ramp/dwell furnace operation controls rate at which flammable gases are generated.	S1*	F2	Ramp/dwell provides primary control, CO_2 provides defense in depth. Loss of CO_2 only not likely to result in flammable gas deflagration

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
E.2.05a	Prepare furnace for operation: - Remove combustibles (e.g. tools, cartons if present) from glovebox	Breach in glovebox confinement boundary during bagout of combustibles or while withdrawing gloves from glovebox.	Sharp object punctures port bag while bagging out combustibles or while changing bag. Bag not properly horsetailed or taped after removing combustibles from glovebox. Bag inadvertently pulled off port during bagout of combustibles. Glove tears while being pulled out of the glovebox to prevent contact with hot furnace.	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers	Glovebox (E-4) ventilation system maintains glovebox negative pressure and confinement velocity across small holes; minimizes potential spread of contamination from glovebox Glovebox port designed to minimize likelihood of loss of confinement during bag changes (notches, ridges to facilitate, 2 bags or gloves)	Workers wear respirators during bag out of waste, bag/glove changes Room put on ARA status during bagouts, bag changes, glove changes. Operator certification.	S1	F3	None
E2.05b	Prepare furnace for operation: - Remove combustibles (e.g. tools, cartons if present) from glovebox	Fire in glovebox compromises glovebox confinement.	Combustibles not controlled in glovebox come in contact with hot surface of furnace while it is operating. Combustible loading allows fire to spread. Port bag comes un-horsetailed gets sucked in and contacts hot surface of furnace.	Potential burn through of gloves or port bags, softening or ignition of glovebox windows leading to spread of Pu from compromised glovebox confinement boundary.	Glovebox (E-4) ventilation system maintains negative pressure in glovebox and prevents contamination spread unless several gloves or port bags are lost. Emergency exhaust valves on RMC line opens up on low glovebox vacuum. Fire brick insulates outer surfaces of furnace from the intense heat produced in the furnace. Only limited areas around the door of the furnace are hot enough to ignite combustibles. Room CAMs alert workers to presence of airborne contamination. E-3 ventilation system filters any release from Zone 3 area to the environment.	Operator training and procedures. Combustible loading in glovebox is minimized by procedure.	S1*	F2	None
E.2.06	Prepare furnace for operation: - Pull gloves out of glovebox an secure with bungee cords	Gloves melted by contact with furnace compromising glovebox confinement.	Gloves not withdrawn from glovebox before starting furnace; gloves contact hot surface of furnace and melts. Gloves not secured properly with bungee cords after being pulled out of the glovebox; negative pressure causes gloves to be pulled into glovebox contacting hot spot on furnace.	Burned out glove allows contamination to spread from glovebox; potential uptake by workers. Operator burned while trying to pull glove back from furnace.	Glovebox (E-4) ventilation system maintains negative pressure in glovebox and prevents contamination spread unless several gloves are lost. Emergency exhaust valves on RMC line opens up on low glovebox vacuum. Fire brick insulates outer surfaces of furnace from the intense heat	Operator training and procedures. Gloves are pulled out of glovebox and secured with bungee cords before operating furnaces.	S1	F3	Hypalon gloves are expected to melt not burn on contact with hot surface of furnace.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
			on furnace.		produced in the furnace. Only limited areas around the door of the furnace are hot enough to melt or burn gloves. Room CAMs alert workers to presence of airborne contamination. E-3 ventilation system filters any release from Zone 3 area to the environment.				
E.3.01a	PU OXIDE, MOX, FLOOR SWEEPINGS: (Temperature controller upsets) Select furnace program for Pu oxide/MOX/floor sweepings, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Temperature ramped up too fast (temperature controller fails high)	Controller failure. Programmer error. Relay contact fails closed.	Burn out of furnace coils leading to shutdown of process. No hazard found for heating Pu oxide, MOX, or floor sweepings too fast.	Furnace temperature controller and furnace thermocouples: Controller shuts off furnace if program temperature and furnace temperature differ by more than 200 °C. Controller limits maximum current to 17 amps which prevents coil burnout. Temperature alarm switch (TAS) shuts off power to furnace if temperature exceeds 1050 °C. Temperature deviation alarm provides indication of furnace temperature greater than 20 degrees from controller setpoint at any given time.	Operator training and procedures. Calibration of controller.	S0	F3	None
E.3.01b	PRF SLUDGES (Temperature controller upsets) Select furnace program for PRF sludges, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Temperature ramped up too fast, no dwell times	Temperature controller fails high, wrong controller program selected, programming error, relay contact fails closed.	Potential flammable gas (butene) concentration greater than LFL. Possible fire or deflagration. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	Furnace door does not latch and thereby provides vent path to prevent catastrophic explosion of the furnace. Furnace vacuum system sweeps air through the furnace that serves to dilute flammable gas concentration.	Operator training and procedures 10 g TBP control limits the quantity of butene generated Controller operational test procedures Controller calibration	S1	F3	Oxycarbonate program ramp/dwell times and temperatures approximate those for sludge. Hazard remains relatively unchanged if oxycarbonate program selected instead of sludge
E.3.01c	PU OXALATES (Temperature controller upsets) Select furnace program for Pu oxalates, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C.	Temperature ramped up too fast, no dwell times	Temperature controller fails high, wrong controller program selected, programming error, relay contact fails closed.	Process material boils/foams over boat into furnace	No hazard	Operator training and procedures Controller operational test procedures Controller calibration	S0	F3	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
E.3.01d	ALL FEED MATERIALS (Temperature controller upsets) Select furnace program for feed material, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Inadequate stabilization of material leads to rupture of container in storage vault.	Failure of furnace heating element. Loss of power during stabilization. Temperature controller failure (temperature not held high enough for required 2 h). Power shut off early by operator.	Rupture of container sometime after it is place in storage vault if furnace upset not detected and LOI test fails to determine high moisture content. PuO_2 reacts with water to form a binary oxide and hydrogen gas which overpressurizes the container. Potential worker inhalation hazard upon entering vault.	Vault ventilation system and HEPA filters mitigate release to the environment. Pedestals in vault are instrumented to detect bulging cans. CAMs in vault alert workers to airborne contamination. Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product. Temperature deviation alarm provides indication of furnace temperature greater than 20 degrees from controller setpoint at any given time.	Operator training and procedures. Radiological control program: Routine sampling of vault air. Furnace chart recorder readings are used to verify proper furnace operation and soak time. LOI testing is performed on representative sample of material after stabilization in the furnace. Material found to lose more than 0.5 wt% in LOI testing will be run back through the furnace.	S1*	F2	None
E.3.02a	PU OXIDE, MOX, PU OXALATES, FLOOR SWEEPIONGS (Furnace vacuum system upsets) Select furnace program for feed material, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Reduced air flow or no air flow during stabilization of material in furnace.	Plugged ceramic filter. Vacuum system valved out or otherwise blocked. Failure of vacuum pump or loss of power to vacuum pump. Other loads placed on 26 in vacuum system reduce airflow through furnace. Airflow not set properly before operating furnace.	Hot air from furnace vents into glovebox while heating oxide. Furnace not cooled down in intended time period after stabilization oxide. Potential damage to glovebox gloves and operator burn when boat removed from furnace.	DP across ceramic filter allows identification of plugged filter. Flow meter on vacuum line. Glovebox (E-4) ventilation system adequately removes hot air vented from furnace preventing overheating of glovebox. Temperature recorder tells operator when furnace is cooled down. DP and orifice place in vacuum system indicate flowrate.	Flow through vacuum system is verified to be in proper range before each furnace use.	S1	F3	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
E.3.02b	PRF SLUDGE (Furnace vacuum system upsets) Select furnace program for PRF sludge, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Reduced air flow or no air flow during stabilization of material in furnace.	Plugged ceramic filter. Vacuum system valved out or otherwise blocked. Failure of vacuum pump or loss of power to vacuum pump. Other loads placed on 26 in vacuum system reduce airflow through furnace. Airflow not set properly before operating furnace.	Potential flammable gas (butene) concentration greater than LFL. Possible fire or deflagration. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	DP across ceramic filter allows identification of plugged filter. Flow meter on vacuum line. DP and orifice place in vacuum system indicate flowrate. Furnace door does not latch and thereby provides vent path to prevent catastrophic explosion of the furnace.	Flow through vacuum system is verified to be in proper range before each furnace use.	S1*	F3	None
E.3.02c	ALL FEED MATERIALS (Furnace vacuum system upsets) Select furnace program for feed material, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Excessive airflow through vacuum system	Flow rate set too high by operator.	Entrainment of flighty Pu oxide powder in furnace. Elevated release of particulates to vacuum system. Potential pluggage of ceramic filter leading to loss of vacuum flow (see item D.3.03)	Baffle in furnace reduces airflow directly over furnace boat minimizing suspension of particulates. Ceramic offgas filter removes majority of particulates before they enter the vacuum system header. DP gauge across ceramic filter provides indication of plugging. Demister and HEPA filters in vacuum system remove residual particulates from vacuum system air before discharge to the environment. DP and orifice place in vacuum system indicate flowrate.	Operator verifies correct flowrate throughout the vacuum system via rotameter before operating furnace.	S0	F3	None
E.3.02d	ALL FEED MATERIALS (Furnace vacuum system upsets) Select furnace program for feed material, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Unfiltered flow through/around ceramic filter.	Filter cracked due to thermal stress Filter cracked or not properly installed in canister during installation/replacement.	Pu release into vacuum system Potential plugging of vacuum line between furnace and vacuum header.	Ceramic filter designed for high heat environment. DP gauge across ceramic filter provides indication of plugging. DP and orifice place in vacuum system indicate flowrate to detect plugging of vacuum line. Demister and HEPA filters in vacuum system remove residual particulates from vacuum system air before discharge to the environment.	Maintenance procedure for proper replacement of ceramic filter Operator training and procedures	S0	F3	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
E.3.03	ALL FEED MATERIALS (E-4 ventilation upsets) Select furnace program for feed material, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Overheating of glovebox	Loss of E-4 ventilation flow during operation of furnace due to equipment failures, damper closures, etc.	Overheating of glovebox leading to possible failure of port bags and gloves and inadvertent operation of the glovebox fire suppression system. Potential softening and sagging of glovebox windows. Release of contamination through failed gloves or bag ports (or failed windows). Potential Pu uptake by workers. Evacuation of Zone 3 process areas leading to unattended glovebox which could result in inability to control fire if combustibles ignited.	Insulating blankets protect glovebox panels from heat damage from nearby hot vacuum lines. Backup E-4 exhaust fans run by emergency generators or steam kicks on, on loss of normal exhaust flow protecting glovebox from overheating. Alarms if dP is lost Halon system designed to suppress fire by displacing a fraction of the air in the glovebox. It is designed not to discharge enough material to pressurize the glovebox. .	Alarms in power control room activate on loss of E-4 exhaust flow. Process areas are evacuated on loss of E-4 ventilation protecting workers from Pu potentially released from the glovebox. Work to restore ventilation flow on dampers or other equipment can occur as they are outside process areas. Operators are trained to hit "kill switch" shutting down furnaces before evacuating. Emergency plan	S1	F3	None
E.3.04	ALL FEED MATERIALS (Plastic/organic contaminants in feed materials) Select furnace program for feed material, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Plastic/organic contaminants in feed result in fire/deflagration in furnace.	Plastic/organic contaminants not noticed in feed or not removed by operator (plastic/organic contaminants can include PVC, polyethylene, polycarbonate, polystyrene, polymethyl methacrylate, RTV sealant, hydraulic oil)	Fire or deflagration involving flammable gases (alkanes, alkenes, hydrogen, carbon monoxide) generated inside the furnace. Fire extending out from gaps around furnace door can ignite combustibles, burn through gloves or port bags. Deflagration can damage furnace, throw furnace door open and produce a jet of flames that can burn through gloves, or port bags.	Furnace door does not latch and thereby provides vent path to prevent catastrophic explosion of the furnace. Furnace vacuum system sweeps air through the furnace to dilute flammable gas concentration or to completely oxidize (burn) plastic contaminant in a controlled manner. Furnace controller program of sludges and Pu oxalate have ramp/dwell times. CO_2 purge gas when processing sludges	Plastic contaminants are looked for and removed when the oxide is poured and sieved into the furnace boat in Glovebox HC-21A.	S1*	F2	Combination of airflow rate and ramp up rate should be used to ensure complete and controlled oxidation of plastic in furnace, taking into account the maximum quantity of plastic likely to slip past detection in Glovebox HC-21A.
E.3.05	PU OXIDE (Pyrophoric metal contaminants in feed materials) Select furnace program for feed material, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Metal contaminant in feed results in pyrophoric reactions in the furnace.	Metal turnings or pieces not noticed or removed from feed in Glovebox HC-21A.	Reaction of pyrophoric metal or hydrided metal contaminant in furnace, leading to hydrogen release and burn in the furnace. Potential furnace damage. Failure of glovebox not expected due to small quantity of hydrided metal expected in feed.	Glovebox ventilation system confines material dispersed from furnace.	Visual identification of "non oxides" in Glovebox HC-21A when material poured into furnace boat. Blend plan identifies previously stabilized oxide to restabilize in this campaign. Labeling of cans. Operator training and procedures.	S1	F3	Pyrophoric metals are not expected to be present in MOX, floor sweepings, or PRF sludges.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
E.3.06	ALL FEED MATERIALS (Pu fluoride processed through furnace) Select furnace program for feed material, ramp up furnace temperature and stabilize material for 2 hours at 1,000 °C	Pu fluoride powder processed through furnace.	Wrong can selected for processing due to mislabeling or human error.	HF gas release due to reaction with water vapor in air run through furnace. Damage to furnace vacuum exhaust system. Increased direct dose to operators. Pu fluoride produces higher direct dose than oxide (due to alpha-n reactions). See item B.1.02.	None	Labeling and paperwork associated with each container identify contents making it unlikely for wrong material to be processed.	S0	F2	PuF_4 powders may be difficult to distinguish from PuO_2 through yellow glovebox windows.
E.4.01	Remove boat from furnace and let cool for one hour on boat stand.	Glove damage/operator burn	Boat removed from furnace too early or boat not allowed to cool on boat stand before handling.	Operator burns hole in glove and suffers injury while removing boat from furnace. Hole in glove compromises glovebox confinement.	Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across hole in glove. Glovebox ventilation system removes enough heat to prevent overheating of glovebox air with furnace door open. Door/power interlock shuts off power to furnace coil when furnace door opened, minimizing radiant heat on gloves and glovebox panels. Furnace thermocouples and chart recorder indicate when it is safe to open furnace door.	By procedure, operators are not allowed to remove furnace boat until furnace is below 200 °C. Hot mill gloves used with boat handling tool to remove boat from furnace. By procedure, boat is left on boat stand to cool for one hour before being handled by glove.	S1	F3	None
E.4.02	Remove boat from furnace and let cool for one hour on boat stand.	Glovebox fire or radiant heat damage to glovebox confinement boundary	Door opened during heating cycle to remove boat	Radiant heat from coils melts gloves and burns operator, softens and potentially ignites glovebox panels Potential activation of glovebox dry fire suppression system (Halon system). Potential ignition of combustibles in glovebox. Release of Pu to room air and uptake by workers.	Furnace interior temp indication Glovebox (E-4) ventilation system maintains negative pressure and confinement velocity across hole in glove. Door/power interlock shuts off power to furnace coil when furnace door opened, minimizing radiant heat on gloves and glovebox panels. Furnace thermocouples and chart recorder indicate when it is safe to open furnace door.	Operators trained not to remove boat from furnace or to open furnace door until temperature has dropped below 200 °C. Combustible loading in glovebox is controlled.	S1* S1	F2 F2	Each furnace produces about 1800 W of heat. From the PFP FHA, a 34 kW/m^2 heat flux is sufficient to ignite a polycarbonate panel in 10 minutes. S1*/F2 for glovebox fire S1/F2 for softening of panels or failure of port bags.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
E.5.01	Place cover on boat and transfer boat to Glovebox HC-18BS through Conveyor Glovebox	Spill/dispersal of Pu oxide powder in glovebox	Furnace boat dumped off conveyor Air supply to RMC line blows powder out of boat near Glovebox HC-18BS.	Added dose to workers in recovering from spill. Increased direct dose to workers working near glovebox due to increase in contamination level of glovebox.	Glovebox confinement boundary and E-4 ventilation system confine release. E-4 HEPA filters mitigate release to the environment through the 291-Z exhaust stack. Conveyor has special pedestals to hold furnace boats	Housekeeping practices: spilled material is swept up, placed in cans, and sealed out of glovebox to minimize direct dose to workers. Institutional radiation protection program: radiological control technicians set glovebox dose rates to limit worker direct dose exposure. Operators verify glovebox DP and filter DP during pre-job walkdown which ensures the E-4 ventilation system is operating properly before initiating operations. Boat is transferred with a "boat cover" which limits the potential for Pu oxide dispersal from the RMC line supply air or dispersal should the boat tip over on the conveyor.	S0	F3	None
E.6.01	CO_2 supply system	Leak of CO_2 from liquid cylinder or transfer line	Handing accident, overpressurization, cylinder or line failure, PRV failure	Potential cryogenic burns to operators. Potential asphyxiation hazard	Cylinder restrained within storage cabinet. Ring at top of cylinder protects valve connections Cylinders vent approximately 2lb of CO_2 per days via PRV to reduce pressure build-up Room ventilation dilutes CO_2	Procedure governing transportation and storage of cylinders	S1	F2	None

Operators verify glovebox DP and filter DP during pre-job walkdown which ensures the E-4 ventilation system is operating properly before initiating operations.	S0	F3	No hazards identified for weighing step. Pu Accountability error only.
G.3.02	Remove sieve tray(s) from shaker, remove pieces too large to fit through sieve (> 4 mesh) and grind using mortar and pestle for reprocessing through furnace, transfer contents that passed through sieve (< 4 mesh) to product can.	Pu metal added to product can causing rupture of container in storage vault.	Material not heated long enough or at high enough temperature in furnace to completely oxidize metal due to furnace failure or failure of furnace temperature controller. Sieve and size reduction step skipped due to human error results in metal pieces not being detected. Metal pieces not removed from oxide material before transferring material to product can.	Rupture of container in storage vault due to the formation of Pu oxide (assuming storage cans is not airtight). PuO_2 is less dense and takes up more volume than metal causing can rupture. Contamination of vault air. Potential uptake by workers on entry into vault. Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	Vault ventilation system and HEPA filters mitigate release to the environment. Pedestals in vault are instrumented to detect bulging cans. CAMs in vault alert workers to airborne contamination. Furnace chart recorder readings are used to verify proper furnace operation and soak time.	Operator training and procedures Radiological control program: Routine sampling of vault air. Oxide known be generated by button burning is recycled by procedure Shift technical advisor sign off required by procedure.	S1*	F2	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
G.3.03	Remove sieve tray(s) from shaker, remove pieces too large to fit through sieve (> 4 mesh) and grind using mortar and pestle for reprocessing through furnace, transfer contents that passed through sieve (< 4 mesh) to product can.	Non-representative sample taken from product can for LOI testing.	Material not heated long enough or at high enough temperature to be adequately stabilized due to furnace or temperature controller failure. Material not sieved or ground properly. Large (> 4 mesh) agglomerations of PuO_2 can give false high or false low LOI readings depending on furnace operation and how long the sample was exposed to humid air after removal from the furnace.	Rupture of container in storage vault due to presence of excess water in product can. PuO_2 reacts with water to form a binary oxide and hydrogen gas, which can overpressure the storage container. Contamination of vault air and potential inhalation uptake by workers entering vault Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	Vault ventilation system and HEPA filters mitigate release to the environment. Pedestals in vault are instrumented to detect bulging cans. CAMs in vault alert workers to airborne contamination. Furnace chart recorder readings are used to verify proper furnace operation and soak time	Operator training and procedures Radiological control program: routing sampling of vault air. Blend plan identifies material processed in this campaign to be previously stabilized oxide material, minimizing likelihood of material containing excess moisture from being recanned even if undetected furnace upset occurs.	S1*	F2	None
G.4.01	Take 5 to 10 g sample for LOI test and perform LOI test	□Wet□ oxide transferred to product can and stored in vault, resulting in rupture of container in vault.	Material not stabilized long enough or at high enough temperature in furnace due to temperature controller or furnace failure. LOI test fails to detect inadequate stabilized material due to non-representative sample being taken (see above) or material canned without benefit of LOI testing due to human error. Or LOI test results or can labels mixed up resulting in wrong can being authorized for storage in vault.	Rupture of container in storage vault due to presence of excess water in product can. PuO_2 reacts with water to form a binary oxide and hydrogen gas, which can overpressure the storage container. Contamination of vault air and potential inhalation uptake by workers entering vault Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	Vault ventilation system and HEPA filters mitigate release to the environment. Pedestals in vault are instrumented to detect bulging cans. CAMs in vault alert workers to airborne contamination. Furnace chart recorder readings are used to verify proper furnace operation and soak time	Operator training and procedures. Radiological control program: Routine sampling of vault air. Blend plan identifies material processed in this campaign to be previously stabilized oxide material, minimizing likelihood of material containing excess moisture from being recanned even if undetected furnace upset occurs.	S1*	F2	Oxidation of U can mask loss of water (due to U going to higher oxidation state) such that analysis may be indicate less than 5% LOI when it is actually greater.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
G.5.01	If material found to contain greater than 0.5 wt% water by LOI test, reprocess material through furnace and repeat LOI testing.	"Wet" oxide transferred to product can and stored in vault, resulting in rupture of container in vault.	Inadequately stabilized material not run back through the furnace due to human error.	Rupture of container in storage vault due to presence of excess water in product can. PuO_2 reacts with water to form a binary oxide and hydrogen gas, which can overpressure the storage container. Contamination of vault air and potential inhalation uptake by workers entering vault.	Vault ventilation system and HEPA filters mitigate release to the environment. Pedestals in vault are instrumented to detect bulging cans. CAMs in vault alert workers to airborne contamination. Thermocouples monitor furnace temperature. Temperature is recorded as a function of time using a chart recorder. The chart recorder readings reveal furnace upsets that could result in moisture not being adequately driven off the oxide product.	Operator training and procedures. Radiological control program: Routine sampling of vault air. Blend plan identifies material processed in this campaign to be previously stabilized oxide material, minimizing likelihood of material containing excess moisture from being re-canned even if undetected furnace upset occurs. Furnace chart recorder readings are used to verity proper furnace operation and soak time	S1*	F2	None
G.6.01	Temporarily store Pu oxide material in product cans in Glovebox HC-18BS pending results of LOI testing.	Covered in items F.1.01 and F.2.01	Covered in items F.1.01 and F.2.01	Covered in items F.1.01 and F.2.01	Covered in items F.1.01 and F.2.01	Covered in items F.1.01 and F.2.01	–	–	Covered in items F.1.01 and F.2.01
G.7.01	Bag out of sample bottles from Glovebox HC-18M for transfer to the lab for LOI analysis Bag out of product cans from Glovebox HC-18MM or HC-1 in Room 228A for transfer to storage vault.	Breach in glovebox confinement boundary during waste bagout, bag change, or glove change.	Bag punctured by sharp object Bag not properly horsetailed or taped Bag inadvertently pulled off port Original or replacement bag glove tears Bungee chord used to hold replacement bag slips or fails while removing inner (original) bag Replacement glove inadvertently pull off lip of port Bag/glove pinched when tightening port ring Replacement bag/glove has undetected hole in it	Spread of contamination to room, external contamination of workers, and potential inhalation uptake by workers.	Glovebox (E-4) ventilation system maintains glovebox negative pressure and confinement velocity across small holes; minimizes potential spread of contamination from glovebox Glovebox port designed to minimize likelihood of loss of confinement during bag changes (notches, ridges to facilitate, 2 bags or gloves)	Workers wear respirators, during bag out of waste, bag/glove changes Room put on ARA status during bagouts, bag changes, glove changes. Operator certification.	S1	F3	By moving items down HC-1 conveyor to Room 228A for seal out, only Room 228A would be placed on mask such that primary thermal stabilization processing areas (Rooms 230A, B, and 228C) do not need to be put on mask.

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
G.7.02	Bag out of sample bottles from Glovebox HC-18M for transfer to the lab for LOI analysis Bag out of product cans from Glovebox HC-18M for transfer to storage vault.	Pu release from sample bottle or product can after bagout	Sample bottle or product can dropped after bagout causing bottle to break or slip lid to come off and bag to rupture.	Contamination of workers and potential uptake of radiological material	E-3 ventilation system filters mitigate release to environment should material be release to Zone 3 area. Room CAMs alert workers to airborne contamination.	Operator training and procedures Radiological control program. Alpha contamination survey to detect contamination spill. Worker decontamination by RCT if necessary. Bagged sample bottles are placed in ice cream carton and then in special wagon for transport to the analytical lab. Carton reduces chances of airborne release in a drop. Product cans are heat sealed in a polyethylene bag in the process of being sealed out of the glovebox. Taped slip lid can and double bag minimize the likelihood of a release should the container be dropped.	S1	F3	None
H. Natural Phenomena									
H.1.01	Plutonium feed material being thermally stabilized.	Seismic event causes fire or explosion and stagnant glovebox.	Seismic event results in loss of electrical power and potentially a loss of ventilation. Loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	Seismic ventilation supply shutdown switch. Building structure.	Emergency procedures for evacuation.	S1*	F2	S1*/F2 based on seismic initiator frequency. F2 frequency assumed to be on the low side of the range.
H.1.02	Plutonium feed material in any unconfined state in gloveboxes	Seismic event causes dispersal of plutonium oxide powder in glovebox.	Seismic event results in dispersal of plutonium oxide powder into glovebox atmosphere.	Potential additional exposure to workers due to cleanup requirements.	Seismic ventilation supply shutdown switch. Building structure Glovebox structure	Emergency procedures	S1*	F2	S1*/F2 based on seismic initiator frequency. F2 frequency assumed to be on high side of range for events that do not fail glovebox.
H.1.03	Plutonium feed material in any unconfined state in gloveboxes	Seismic event causes criticality.	Seismic induced failure of Gloveboxes results in accumulation of a critical mass of Pu.	Worker exposure to ionizing radiation and fission product gasses	Glovebox HC-4 and HC-18BS seismically qualified.	CSER controls on mass of Pu in Gloveboxes. CPS Posting on Glovebox operator training.	S1*	F2	S1*/F2 based on seismic initiator frequency. F2 frequency assumed to be on the low side of the range.
H.2.01	Plutonium feed material being thermally stabilized.	NPH - Ash Fall	None	Ash Fall represents a roof loading concern, abrasive concern for	None	None	None	None	None

Table 9G.2. PHA – Thermal Stabilization of Non-Product Quality Oxide Feed Material

Item #	Process Step/ Equipment	Failure/ Hazardous Condition	Causes	Consequences	Existing Engineered Features	Existing Administrative Controls	Cons Rank	Freq Rank	Comments
	thermally stabilized.			moving equipment, and an electrical concern because of the conductivity of the ash.					
H.3.01	Plutonium feed material being thermally stabilized.	NPH - High Wind	None	High Wind represents a threat to the 234-5Z Building but not to an individual glovebox inside the building. Chapter 9.0 of the PFP FSAR considers the effect of a wind-driven plank striking the 234-5Z Building and concludes that no significant consequences result.	None	None	None	None	None
I External Events									
I.1.01	Plutonium feed material being thermally stabilized.	Facility wide external loss of power with subsequent return of power causes flammable gas deflagration in or around stabilization furnace in Glovebox HC-21C.	External event causes facility wide loss of power resulting in loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	Building structure. Backup ventilation system connected to emergency.	Emergency procedures	S1*	F1	F1 frequency considers negative specific sequencing of events.
I.2.01	Plutonium feed material being thermally stabilized.	Facility wide loss of power due to range fire with subsequent return of power causes flammable gas deflagration in or around stabilization furnace in Glovebox HC-21C.	Range fire causes facility wide loss of power resulting in loss of airflow in muffle furnace combined with material in furnace boat that produces ethylene gas. Spark source assumed present.	Damage to glovebox confinement with release of plutonium oxide to facility. Potential contamination of workers and uptake of radiological material.	Building structure.	Emergency procedures Vegetation control programs	S1*	F1	This is not a threat to the 234-5Z building due to the large open areas that are kept clear of vegetation or combustible material buildup.
I.3.01	Plutonium feed material being thermally stabilized.	Aircraft crashes into facility causing fire and loss of confinement. (General to all gloveboxes)	Pilot error or mechanical failure	Significant release of material		Controls preventing overflight of facility	S1*	F0	This event is considered to be beyond extremely unlikely in the PFP FSAR and therefore is not being considered for further analysis.

APPENDIX 9H

Hazards Evaluation of Plutonium Metal Opening and Stabilization

This page intentionally left blank.

HAZARDS EVALUATION OF PLUTONIUM METAL OPENING AND STABILIZATION

9H.1 INTRODUCTION

A Hazards Evaluation (HE) was done for the opening of containers of Pu metal, conversion of the metal and corrosion products to plutonium oxide product, and sampling, testing and packaging the product. Hazards evaluation is the analysis of the significance of hazardous situations associated with an activity or process. The HE used the qualitative techniques of Hazard and Operability (HazOp) analysis and What-If analysis to identify those elements of handling and thermal stabilization processing that could lead to accidents

9H.2 METAL OPENING AND STABILIZATION ACTIVITY ANALYZED

9H.2.1 Operations in Glovebox 636

The following is a sequential listing of the metal opening operations that will normally be done in the 636 Glovebox. These steps were identified during the HE team meetings and are the substance of the activity rather than the final procedural form and format. These are the steps that are identified in the HE worksheets with an "OM" identifier in the "Node ID" column.

1. Segregate, remove or minimize all combustibles to far end of glovebox.

2. Inspect outermost can to determine if it's a suspect (bulged, paneled, weight gained) can.

3. If suspect, punch can and wait until no further obvious reactions ongoing.

4. Open can with can opener.

5. If lid falls in can, remove lid from can with dulled screwdriver or tweezers.

6. Inspect material within can.

7. If contents are another can, go to step 2.

8. If contents are burning product, place slip-lid on top of product can. (may curtail operations until burning stops) -Seal it into a slip-lid can, bag it out, can it, and transfer it directly to Glovebox HC-21A to be thermally stabilized.

9. If contents appear to be normal product, pour contents into open container (tray, boat, can).

10. Separate corrosion products from metal:

    a. brush whole, stable button with bristle brush

b. move clean stable button to a new can.

11. If contents are not a whole, stable button (per STA/Operator decision); re-can for transfer to Glovebox HC-21A.

12. When a maximum of 200 g of brushings have accumulated, can and transfer to Glovebox HC-21A.

Note: differences in operation in this GB636 & Glovebox HC-21A - 636 handles it more, no canning in Glovebox HC-21A, when opened in Glovebox HC-21A, it's poured into a boat, then conveyed to Glovebox HC-21C & thermally stabilized, and conveyed to and finally canned in GB18M.

9H.2.2 Subsequent stabilization operations in Gloveboxes HC-21A, HC-21C, and HC-18M

The following is a sequential listing of the metal opening operations that will normally be done in the Glovebox HC-21A. These steps were identified during the HE team meetings and are the substance of the activity rather than the final procedural form and format. These are the steps that are identified in the HE worksheets with an "TS" identifier in the "Node ID" column.

1. Seal-in Pu container into Glovebox HC-21A, weigh Pu container, and furnace boat for Pu material accountability purposes.

2. Punch suspect (bulged or paneled) outer containers to relieve pressure or vacuum (typically performed in GB636).

3. Open Pu containers (includes punching and opening, if necessary, of overpack containers and inner container of Pu metal).

4. Remove materials (maybe corrosion products, metal or any combination of both) from containers and place in furnace boat.

5. Transfer furnace boat with boatcover to HC-2. Bag-out empty cans, plastic bags and tape as needed.

6. Transfer furnace boat with cover from Glovebox HC-21A to Glovebox HC-21C via conveyor or passed by hand via conveyor glovebox.

7. Remove the boatcover from the furnace boat, place boat in the furnace and operate the furnace.

8. At the end of the cool down cycle, open furnace and remove boat. After further cooling, inspect for degree of stabilization and reprocess as necessary.

9. Upon completion of stabilization and cool down, transfer furnace boat to HC-18M via HC-2 for sieve/grinding, place in can and sample.

10. Transfer can to Glovebox HC-18BS for interim storage pending sampling results.

11. If the sample passes LOI, transfer to HC-18M, bag-out and can. If the sample does not pass LOI, return material to Glovebox HC-21A for reprocessing.

In addition to the above operations, the relevant utilities associated with the plutonium metal stabilization process were examined. The specific utilities evaluated were the glovebox fire suppression system, the E-4 ventilation system that exhausts the gloveboxes, the power supply to the RMC Line equipment, and the 26-inch-Hg vacuum system that exhausts the muffle furnaces in Glovebox HC-21C.

9H.3 HAZARD EVALUATION METHODLOGY

The HE process is one that employs a systematic approach in the identification of hazards associated with a system, or process. The process is one in which the system or process is broken down into its basic elements and the hazards associated with each element are identified. Potential causes of those hazards are determined, potential consequences estimated and evaluated and possible corrective and/or preventative measures are considered. The HE was developed using a table to guide and record the results of a What-If brainstorming process. The What-If technique was combined with Hazard and Operability analysis system of using guidewords in conjunction with process parameters or procedure activities to arrive at an unintended deviation. By this method, structure was given to the otherwise unstructured What-If analysis technique. This guided What-If brainstorming was performed by individuals with detailed knowledge of the system or processes being examined, and was supported by a multi-disciplinary team familiar with the operation. A detailed discussion of the HE techniques of HazOp analysis and What-If analysis can be found in *Guidelines for Hazard Evaluation Procedures* (AIChE 1992).

The purpose and contents of each column in the HE sample table, Table B-1, are described in detail in the following paragraphs.

Column 1, Node ID: This column provides an alpha-numeric identifier for each hazard postulated in the table. The identifier is primarily used for cross-referencing within the table and as an identifier for accident sequences.

Column 2, Step #: The step or steps involved in performing each set of operations is identified in this column

Column 3, "What-If" question: The deviation from the intended action put in the form of a "what if" question. The questions being generated using a set of deviation guide words. The deviation guides are the same as those used in a HazOp analysis.

Column 4, Consequence: Both the immediate and ultimate consequence of the activity/operational "What-If" deviation that could result are recorded in this column

Column 5, Causes: This column identifies the causes for both the What-If and the ultimate accident sequence conclusion.

Column 6, Engineered Safety Feature(s) for "What-If" and Accident: This column identifies the engineered features (hardware items) intended or available to prevent or mitigate the consequences identified in Column 4.

Column 7, Administrative Safety Feature(s) for "What-If" and Accident: This column identifies the administrative requirements that reduce the likelihood of both the What-If event (if applicable) and the Accident event consequences identified in Column 4, or that help minimize the potential consequences of the Accident event

Column 8, Consequence Category: This column is used to capture a code designator for the level of consequence associated with a hazardous event. The consequence ranking is the initial, qualitative estimate of the safety severity of the consequences. An alpha-numeric system has been used at the PFP to designate the severity of hazardous events. The system has the following "S" rankings characterizing safety consequences:

S0 No effect outside the glovebox confinement systems; negligible safety concerns for the facility worker.

S1 Potential industrial injury, low radiological or chemical exposure dose consequences to the facility worker

S1* Potential severe harm or potential death from industrial injury, radiological dose or chemical exposure to the facility worker

S2 Potential significant radiological dose consequences or chemical exposure to onsite workers located outside the facility

S3 Potential significant radiological dose consequences or chemical exposure to the offsite population

Column 9, Frequency Ranking: This column shows the estimated frequency of occurrence. The frequency ranking is a first cut, qualitative estimate of the likelihood of the hazardous event. The following ranking system is used.

F3 Events that are expected to occur one or more times during the lifetime of the facility, categorized as "anticipated" events. The frequency range associated with this category is 1E-02/yr to 0.1/yr.

F2 Events that could occur during the lifetime of the facility, but with low probability. Such events are categorized as "unlikely" and fall in the range of 1E-04/yr to 1E-02/yr.

F1 Events not expected to occur during the lifetime of the facility categorized as "extremely unlikely." The frequency range associated with this category is 1E-06/yr to 1E-04/yr.

F0 Events categorized as "beyond extremely unlikely," with a frequency less than 1E-06/yr. Events in this category (such as meteor strike) are so unlikely they generally do not require special controls.

The frequency estimate, like the consequence ranking, is assigned taking no credit for active engineered features.

Column 10, Remarks: This column contains miscellaneous observations or clarifying comments for a given hazard.

9H.4 HAZARDS EVALUATION WORKSHEET ORGANIZATION

The HE table structure used in this analysis is provided in Table 9H-T-1. The HE table is structured to ensure a systematic and thorough review of potential hazards. The thermal stabilization of metal and metal corrosion products is broken down into logical sets of operations performed at specific locations. The operational steps covered in the analysis were identified from verbal descriptions provided by the cognizant engineers and other available information and were identified in section 9H.2.

"What If" Hazards Evaluation Work Sheets

Deviation Guides: (1) No, None (2) Less, Lower (3) More, Higher (4) Part of (5) As Well As (6) Reverse (7) Other Than, Sooner, Later, Where Else

Node ID	Step #	"What If" question	Consequence	Cause(s) of "What If"	Engineered Safety Feature(s) for "What If" and Accident	Administrative Safety Feature(s) for "What If" and Accident	Cons Cat	Freq Cat	Remarks
OM-4c	4	What if the inmost can is turned upside-down, agitated, dropped, turned sideways, etc., before being opened?	Suspension of more particulate, which may escape and react – "Sparky". A: See OM-3b.	See OM-3b.	See OM-3b.	See OM-3b.	WI: S0 A: 1)S0 2)S0 3)S0	WI: F3 A: 1)F3 2)F3 3)F3	Calculations show ~ 0.75 g could be released from a pressurized can; this amount will likely be less than that.
OM-5	5								Inconsequential
OM-6a	6	What if the contents are not inspected before being dumped, and the material is burning?	Larger surface area available for reaction, greater exposure to oxygen. A: Fire in glovebox, assuming contact with sufficient combustibles.	See OM-1a.	See OM-1a.	See OM-1a.	WI: S0 A: S1	WI: F3 A: F2	Single container will not contain more than 200 g of Pu hydride, and this quantity of hydride reacting anywhere in the glovebox is not enough to pressurize glovebox. This can be proven scientifically within a can, and by ~50 years of processing experience for outside the can, in the glovebox. (See Thurman for details). This is the highest likelihood for a fire in the glovebox – lots of glowing, burning, sparking material spread around.
OM-6b	6	What if foreign (e.g., aluminum foil) material is in the can?	WI: none A: foreign material trapping corrosion products and igniting while it is mixed with combustibles and causing a glovebox fire	WI: foreign material originally packaged with Pu metal	WI: none A: See OM-1a.	WI: none A: See OM-1a.	See OM-1a.	See OM-1a.	It is not anticipated that foreign materials will be present.
OM-7	7								Nothing to evaluate.

PLUTONIUM FINISHING PLANT
FINAL SAFETY ANALYSIS REPORT

CHAPTER 10.0

CONDUCT OF OPERATIONS

FEBRUARY 2001

This page intentionally left blank.

PREFACE

Revision 2 of Chapter 10.0 of the Plutonium Finishing Plant (PFP) Final Safety Analysis Report (FSAR) incorporates the following:

- Significant revision in the Organizational Structure to reflect recent changes in Fluor Hanford's responsibilities
- Significant revision in the PFP's management and operations structure
- Revision of the emergency preparedness description including the BED
- Additional discussion regarding conduct of operations

Other minor changes include editorial changes and additional clarifications.

The significant areas of change in Revision 2 are indicated by vertical bars in the margin of each page.

This page intentionally left blank.

REFERENCES R10-1

10.0 CONDUCT OF OPERATIONS

This chapter outlines the Plutonium Finishing Plant (PFP) administrative and operating elements, and activities that ensure continued and safe plant operations. The specific elements and activities presented are the organizational structure, operating startup plans, the PFP training program, standard plant operations, emergency preparedness, and plant decommissioning.

The following paragraphs identify the responsibilities and standards of operation required in the performance of all work at the PFP. The PFP Transition Project organization manages PFP in a safe, efficient, and environmentally sound manner and ensures that all activities at PFP are conducted in compliance with applicable DOE Directives and federal, state, and local regulations. The Nuclear Material Stabilization organization is composed of organizations that report directly to the PFP Transition Project Director and line organizations that are administered by the PFP Plant Manager. The organization structure at PFP is provided in FSP-PFP-5-8, *Plutonium Finishing Plant Administration*, Volume 1, Section A, *Organizational Charts*.

For each management position at PFP there is a set of functional responsibilities. The incumbent manager and the key functions for that position are listed in FSP-PFP-5-8, Volume 1, Section B, *Nuclear Material Stabilization - Key Functions*. Managers are held accountable to carry out their responsibilities in completing their assigned tasks. Every manager and employee has a prime responsibility to carry out their assigned tasks in a manner that ensures personnel safety, environmental compliance, criticality safety, protection of plutonium material, and responsibility is the need to perform all activities with good Conduct of Operations principles. Line management is responsible for assuring the quality and safety of work performed. PFP personnel are responsible for doing it right the first time. Managers have the responsibility to ensure that all operations are accomplished by qualified personnel in accordance with company/plant policies and procedures. When there is a concern or question with a procedure, work must be stopped to establish a safe condition.

Plant and area status is monitored and understood by personnel assigned responsibility for the area control. Understanding of plant conditions is paramount for effective and proper response to abnormal plant conditions. All activities that occur at PFP are under the control of the shift manager. The shift manager must be aware of, in control of, and accountable for all activities, including operations, maintenance, testing, and other work. Plant conditions and configurations are the responsibility of the shift manager and their permission is required prior to making any changes in the plant status. PFP personnel are accountable for their performance and for the implementation of the plant standards. All personnel are responsible for maintaining cleanliness in their spaces and work areas. PFP will take positive action to address all known employee concerns, procedural deficiencies, and facility deficiencies (e.g., leaks, broken equipment).

A single Building Emergency Director (BED) is designated for all buildings and facilities within the PFP. The BED is assigned to emergency response duties on the basis of the similarity of their normal daily responsibilities to the emergency response duties, and their demonstrated

ability to properly analyze data, assess situations, and make decisions under high stress conditions. In the event of an emergency, the BED assumes control over all facility occupants. As specified in FSP-PFP-5-8, Volume 1, Section B, the on-duty PFP Surveillance Shift Team Leader is the PFP BED. Consequently, the position of BED is staffed 24 hours per day, seven days per week. The BED is responsible for assessing and categorizing an event, and if the event is categorized as an emergency, classifying the event and initiating appropriate protective actions for the welfare and safety of facility occupants and affected areas. The BED communicates with emergency staff and directs subsequent actions at the event site. The specific authority and responsibilities of the BED are defined in FSP-PFP-0821, *PFP Conduct of Operations*, Chapter 1, "Operations Organization."

10.1 ORGANIZATIONAL STRUCTURE

The following sections outline the PFP Nuclear Materials Stabilization Project organizational structure, and those functions and responsibilities which relate to maintenance of the facility Authorization Basis. The Plutonium Finishing Plant Director and the Nuclear Material Stabilization Deputy Manager report directly to the Vice President for the Nuclear Material Stabilization Project as shown in FSP-PFP-5-8, Volume 1, Section A. The key functions for the Vice President and Director offices are specified in FSP-PFP-5-8, Volume 1, Section B. Some of the specific responsibilities include: Coaches/mentoring supervision, startup team management/ coordination, ISMS program management, ESH&QA policies, hazard communication program direction, corrective action management program monitoring, and oversight of other safety program elements.

10.1.1 PFP Business Management

The Manager of PFP Business Management reports directly to the Vice President for the Nuclear Material Stabilization Project as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Business Management organization includes the following functional organizations: Financial Integration and Administration Team, Project Scheduling Team, and Project Management Support Team. The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.2 PFP Environmental, Safety, Health, and Quality Assurance (ESH&QA)

The Manager of PFP Environmental, Safety, Health, and Quality Assurance (ESH&QA) reports directly to the Vice President for the Nuclear Material Stabilization Project as shown in FSP-PFP-5-8, Volume 1, Section A. The ESH&Q organization includes the following functional organizations: Health and Safety Team, Quality Team, Environmental Team, and Safeguards and Security Team. The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.3 PFP Thermal Stabilization and Polycubes Project

The Manager of PFP Thermal Stabilization and Polycubes Project reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The Thermal Stabilization and Polycubes Project organization includes the following functional organizations: Thermal Stabilization Support Team, P Shift Team, and Q Shift Team. The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.4 PFP Vaults

The Manager of PFP Vaults reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Vaults organization includes the following functional organizations: Solid Waste Operations Team, Vault Operations Team, and Stabilization and Packaging Team. The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.5 PFP Surveillance

The Manager of PFP Surveillance reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Surveillance organization includes the following functional organizations: A Shift Team, B Shift Team, C Shift Team, D Shift Team, Operations Support Team, Special Tasks Team, and Plastic Shop/Storeroom Team. The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.6 PFP Infrastructure Services

The Manager of PFP Infrastructure Services reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Infrastructure Services organization includes the following functional organizations: Water, Air, Vacuum and Steam (WAVS) Team, HVAC Control Team, HEPA Filters Team, Safety Systems Team, Electrical Team, and Infrastructure Support Team. The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.7 PFP Project Management

The Manager of PFP Project Management reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Project Management organization provides programmatic guidance/support and project management support for the PFP. The functional responsibilities are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.8 PFP Contracts and Procurement

The Manager of PFP Contracts and Procurement reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Contracts and Procurement organization facilitates procurement of good and services, and administers contracts and subcontracts in support of the Nuclear Material Stabilization Project. The functional responsibilities are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.9 PFP Solutions/Residues Stabilization Project

The Manager of PFP Solutions/Residues Stabilization Project reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Solutions/Residues Stabilization Project organization includes the following functional organizations: Solutions Handling Team and Solutions Project Management Team The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.10 PFP Radiological Control

The Manager of PFP Radiological Control reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Radiological Control organization includes the following functional organizations: Radiological Control Technician Team and Radiological Engineering Team. The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.11 PFP Near Term Planning Team

The Manager of PFP Near Term Planning Team reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The functional responsibilities for this team are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.12 PFP Analytical Laboratory

The Manager of PFP Analytical Laboratory reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Analytical Laboratory organization includes the following functional organizations: Analytical Services Team, XYZ Shift Team, and Waste Packaging and NDA Team The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.13 PFP Pu Process Support Labs

The Manager of PFP Pu Support Labs reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Pu Support Labs performs chemical process development and bench scale

testing, and operates and maintains the PPSL. Each of the functional responsibilities is specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.14 PFP Technical Support

The Manager of PFP Technical Support reports directly to the Plutonium Finishing Plant Director as shown in FSP-PFP-5-8, Volume 1, Section A. The PFP Technical Support organization includes the following functional organizations: Authorization Basis Team, Engineering Team, Materials Planning and Disposition Team, Technical Services Team, and Training Team The functional responsibilities for each of the individual teams are specified in FSP-PFP-5-8, Volume 1, Section B.

10.1.15 Standing Plant Committees

The following standing plant committees serve as integral parts of the PFP organization that aid in establishing the PFP ALARA program in accordance with *Occupational Radiation Protection*, Title 10, *Code of Federal Regulations*, Part 835 (DOE 1993) and *Hanford Site Radiological Control Manual*, HSRCM-1 (DOE-RL 1994).

The Enhanced ALARA Review Committee reviews and provides approval of work documents for jobs or activities involving estimated individual or collective doses >1 person-rem, infrequent or first time activities for recurring process operations, and results of ALARA design reviews for new designs and major modifications.

The PFP ALARA Committee addresses personnel awareness and concerns. The PFP ALARA Committee also assists radiological work planners to complete an ALARA Management Worksheet (AMW) or equivalent ALARA review. They also review high-risk radiological work.

The Nuclear Material Stabilization Plant Review Committees (PRC) at PFP serves as the Safety Review Board (SRB). The purpose is to provide a global over view, an independent review, and, if necessary, provide additional subject matter experts (FSP-PFP-5-8, Vol 1, Section 2.43 "Plant Review Committee).

10.1.16 Support Interfaces

The PFP operating contractor interfaces with many organizations. Fluor Hanford, Inc. (FH) is the Hanford Site integrating contractor as described in section 10.1.17.1 along with its project organizations and major Hanford subcontractors. Besides the integrating contractor, project organizations and major subcontractors, several separate Enterprise Companies support Hanford programs and projects as described in Section 10.1.17.2. Finally, there are three other organizations that contract directly with DOE-RL for specific services as described in section 10.1.17.3.

10.1.16.1 Integrating Contractor and Major Subcontractors. Fluor Hanford, Inc. (FH) is the integrating contractor for the Project Hanford Management Contract (PHMC). FH is responsible for planning, integrating, managing, and

executing the Hanford programs, projects, operations, and other activities at the Hanford Site. FH also operates several major cleanup projects and provides quality assurance services. The FH project team includes FH project organizations and major subcontractors, which are briefly described below.

The FH Nuclear Material Stabilization (NMS) organization is responsible for the Facility Stabilization Project. In this role, it examines all highly contaminated structures and makes the appropriate recommendations as to the best remediation action. Nuclear Material Stabilization is responsible for the Plutonium Finishing Plant.

The FH Spent Nuclear Fuel (SNF) organization work at Hanford involves managing the SNF Project. The scope of the SNF Project includes removing spent nuclear fuel from the present deficient storage conditions (basins), conditioning (drying and sealing in containers) the fuel, transferring the fuel to an interim storage, removing the sludge and debris from the basins, and treating the basin water.

The FH Waste Management (WM) organization is responsible for 200 Area liquids disposal (low level), solid waste storage and disposal, and Waste Retrieval and Packaging (WRAP) facilities.

DynCorp Tri-Cities Services (DYN) provides all essential infrastructure service in support of the Hanford Site. These services include Facility Maintenance and Site Services, Real Estate and Property Management, Landlord Program Management and Emergency Preparedness and Emergency Response Services.

Three Johnson Controls Package boilers that are sited north of PFP and west of 231-Z (Figure 1-1) provide the steam supply for the Plutonium Finishing Plant. These oil-fired boilers have a capacity to supply up to 100 psi steam. The 100 psi steam system can be used to operate the steam driven turbine exhaust fans in the 234-5Z building. The steam system delivers to the turbines approximately 85 psi steam which tests have demonstrated is sufficient for the steam turbines to meet or exceed minimum exhaust plenum pressure differentials. These local individual boilers have a thermal efficiency of approximately 75% and replace the central steam boiler in 200 West area which had an efficiency of about 33%. Additional information about the Johnson Controls Package boilers can be found in Section 1.5.1.1.

CH2M Hill Hanford Group, Inc. (CHG) is the Hanford Prime Contractor in charge of the River Protection Project (RPP), including 177 underground high-level waste tanks. CHG ascertains the contents and determines what is necessary for continued safe management of the tank waste. CHG pre-processes waste for disposition through DOE's privatization contracts and stores the stabilized waste on an interim basis until permanent facilities are available.

The Numatec Hanford Corporation (NHC) mission is to provide best-in-class engineering and project management services and technical expertise to Fluor Hanford, Inc. and its other major subcontractors, and to implement relevant technologies to accelerate cleanup at the Hanford Site.

Protection Technology Hanford (PTH) provides facility and/or system design and installation, security assessments, security program development and implementation to government and industrial markets. PTH will provide, manage, operate and integrate all safeguards and security services of the

Hanford Site, except Pacific Northwest National Laboratory, including function design, testing and upgrade of safeguards and security systems.

Waste Management Federal Services of Hanford, Inc. (WMH) is responsible for the Waste Management Project. The company uses existing and new technology to accelerate treatment and disposal of waste, reduce need for waste storage and minimize waste through partnerships with waste generators.

10.1.16.2 Enterprise Companies. Fluor Hanford and its major subcontractors established several new companies in the local area. These enterprise companies are described below and are separate businesses with the flexibility to pursue and perform Hanford and non-Hanford work.

COGEMA Engineering Corporation (COGEMA) will develop and design waste sampling characterization and retrieval equipment, specialized analytical methods and techniques development. The company will design environmental monitoring equipment and develop and design vitrification technology and processes. COGEMA Engineering will apply its expertise in field screening and sampling at the Hanford Site, as well as its special welding technique development and application.

Fluor Federal Services (FFS) is part of Fluor Daniel, Inc., the core engineering and construction business of Fluor Corporation. FFS provides engineering, procurement, construction, project management, project controls, and environmental, safety, health, and quality (ESH&Q) services. FFS's initial client base consists of the PHMC subcontractors listed in section 1.4.2

Lockheed Martin Services, Inc. (LMSI) provides telecommunications and network engineering, Internet technology integration, software modernization, maintenance and support, engineering computational resources, data center management, imaging and document management and multimedia services.

Waste Management Technical Services, Inc. (WMTS) role includes privatization of a select group of premier capabilities that were developed for use at Hanford but also have applications throughout the DOE complex or in the private sector. They include: transportation logistics; waste management engineering; environmental monitoring and investigations; well services; sampling and mobile laboratories; and integrated pest management.

10.1.16.3 Other Department of Energy Contractors. Three additional onsite contractors provide services to DOE-RL as described below.

Bechtel Hanford, Inc. (BHI), a division of Bechtel National, Inc., is the environmental restoration contractor at Hanford. BHI plans, manages, executes, and integrates a full range of activities for the cleanup of groundwater, contaminated soils, and inactive nuclear facilities under DOE's Environmental Restoration Program.

Hanford Environmental Health Foundation (HEHF) provides personnel health and occupational medical services to DOE and the site contractors. The HEHF provides on-call emergency medical support and operates the Emergency Decontamination Facility.

Pacific Northwest National Laboratory (PNNL), a division of Battelle Memorial Institute, is a research and development facility that provides contract work. PNNL also provides the Hanford Site-wide radiological and environmental surveillance programs, portable radiation detection instrument maintenance and the calibration laboratory.

10.1.17 Plutonium Finishing Plant Staffing Requirements

Staffing requirements for safe and efficient operation of the PFP are a function of the specific mission requested by the DOE-RL. The current mission is as follows:

- Addition of stabilization operations to permit safe storage of reactive Plutonium materials
- Long-term storage of plutonium material
- Laboratory facility support of Hanford Site programs
- Facility cleanup to minimize levels of contamination and quantities of hazardous chemicals
- Shutdown of plutonium recovery and conversion operations
- Other miscellaneous changes related to facilities and operations.

The number of personnel required by plant operations and by technical support is established through preparation of resource-loaded schedules that satisfy the requirements and commitments as determined by DOE and agreed to by Contractor management. See *Administrative Controls*, WHC-SD-CP-OSR-010, for the minimum staffing requirements.

The resource-loaded schedules are reviewed and approved by the Plant Manager and by the managers of the respective organizations providing support for the specific mission. These managers are responsible for ensuring that their staffs are of adequate size and have the required training and experience to operate the facility safely.

Staffing needs for shipping and receiving activities vary, depending on the plutonium material handling/inventory requirements of the DOE complex. Staffing needs for remediation and construction activities are also driven by the plutonium material handling/inventory requirements of the DOE complex and the need to upgrade or modify the plant and equipment. Consequently, the required plant operations and technical support staff varies according to the operating schedule. Evolving operations, safety, security, ALARA, training and environmental orders, directives, and requirements also affect the staffing requirements needed to satisfy a particular mission.

The determination of staffing requirements for specific unit operations and tasks considers job/task requirements, plutonium material security, industrial safety, radiation protection, management and quality oversight requirements, and other considerations. Technical Training performs detailed job analyses and identifies staffing requirements for PFP operational activities. The job/task analysis, the identification of job skills/crafts

needed to perform the task/operation, and administrative and regulatory requirements are used by management to establish staffing requirements for safe operations and tasks in specific units.

Confirmation that staffing levels are sufficient for safe operation is verified by an operational readiness review (ORR) conducted in accordance with *Startup and Restart of Facilities*, HNF-PRO-055. The types and numbers of personnel needed to perform a given activity are often specified by plant procedures (e.g., operating, maintenance, and administrative).

For short periods of time (i.e., less than one shift) and during facility weekend shutdown, the facility can be maintained in a safe configuration and can support limited operation with a minimum level of operating staff. This minimum staffing level maintains the essential building support systems and allows operations in a reduced mode for short periods of time.

10.1.18 Personnel Qualification and Responsibilities

Qualification requirements for key management personnel assigned to the PFP are based on the responsibilities of the position and organization. Individuals deemed qualified to assume and discharge the responsibilities of the position must complete plant-specific training as noted in Section 10.3. Personnel qualification and training programs are under continuous review and modification to reflect DOE-RL guidance and added responsibilities arising from the changing regulatory/industrial environment.

DOE Order 5480.20A, *Personnel Selection, Qualification and Training Requirements*, Chapter IV specifies education and experience requirements for nonreactor nuclear facility personnel.

10.2 PREOPERATIONAL TESTING AND OPERATION

At the PFP, preoperational testing is the second phase of testing that supports the plant readiness process. The readiness process includes all the steps necessary to ensure that those systems that already have been operated, and those systems/operations that represent a new technology not previously applied in the plant, can be operated safely and reliability. The depth and content of the readiness process is based upon a graded approach that considers the facility hazard category, system complexity, and facility life cycle stage. The extent of testing and/or review is determined by the type of operation, the technology used, the potential risk associated with the operation, the degree and complexity of control required, facility or process modifications, the knowledge and skill of the personnel, and the length of time since the operation was last active.

At the PFP, the Readiness Process consists of four general phases.

The first phase is acceptance testing, which demonstrates that fabrication, assembly, installation, and construction requirements have been met as defined in the procurement specifications. The acceptance test procedures (ATPs) are prepared and/or performed by the vendor/supplier to assure the facility custodian that the equipment, materials, etc. meet the procurement specifications.

Preoperational testing is the second phase, and is performed on the equipment and the process systems in preparation for operational testing. The operability test procedures (OTPs) assure the facility custodian that the system operates in the context of the actual process under real or simulated conditions.

Operational testing is the third phase, and is prepared and conducted by facility operators against the final in-service process/facility configuration. This testing is a cold run.

The Readiness Assessment (RA) or Operational Readiness Review (ORR) is the final phase; which verifies that all elements (plant, procedures, and personnel) are in conformance with process specifications. A graded approach determines the depth and breadth of the review, as delineated in FSP-PFP-5-8.

The purpose, scope, definitions, responsibilities, and procedures associated with the assessment of facility readiness are delineated in HNF-PRO-055. The readiness program relies on acceptance, preoperational, and operational testing as the primary source of information for determining operational readiness.

The purpose, scope, definitions, responsibilities, requirements, and procedures to a broad range of testing activities, including acceptance, preoperational and operational testing, are found in *Testing Requirements*, HNF-PRO-446. Acceptance, preoperational, and operational testing are used to determine the readiness of process systems before production operation.

Acceptance testing is the first step of testing used when new fabrication, assembly, or construction is associated with the process or system startup. Acceptance testing demonstrates that parts, equipment, and systems have met procurement, fabrication, and/or construction specifications. The supplier or vendor prepares and performs acceptance testing of parts and equipment; onsite acceptance testing is conducted for parts and equipment from Contractor sources to ensure that fabrication, assembly, and construction specifications have been met.

Preoperational testing is performed in preparation for operational testing. Operational testing is to ensure that equipment, systems, or processing lines function in compliance with specifications, procedures, and plant standards. During preoperational testing, components, subsystems, and systems are operated at reduced parameters to ensure that they are ready for full operational testing. When the components, subsystems, and systems have been tested sufficiently at the reduced parameters to indicate that the normal operating parameters can be achieved, they are tested at designated higher parameters. At the completion of preoperational testing, the test results are evaluated, and a determination is made to move into operational testing.

Primary emphasis is placed on the safety class equipment during preoperational testing. (For information about what constitutes safety class equipment, see *Hazard and Accident Analysis Process*, HNF-PRO-704.) The specific requirements of operability of the following safety systems are found in WHC-SD-CP-OSR-010, *Plutonium Finishing Plant Operational Safety Requirements*.

- Criticality prevention, detection and alarm systems

- Facility confinement and ventilation systems
- Dispersible plutonium inventory.

Operational testing demonstrates operational readiness through extensive testing conducted before process operation. During the test, the operating configuration of all equipment is readied. In the liquid systems, process flows are tested using a dilute solution, and other chemical solutions as appropriate, to simulate the process. In the dry areas, mechanical equipment can be tested through simulated operations without process chemicals. Instruments and interlocks are functionally tested to verify proper response during operations and in problem situations.

Reviews of the acceptance, preoperational, and operational tests are conducted before, during, and after testing is conducted. These reviews confirm test requirements and proper test performance, and verify the results. The type and extent of test reviews conducted are determined by the scope, complexity, and technical risk associated with the testing program. Test reviews confirm that a test meets established requirements, which include OSRs in the case of preoperational tests. Test reviews are typically conducted by representatives from facility engineers, Safety, QA, and Operations. Nonconformances associated with ATPs and OTPs are tracked to ensure their correction.

The contractor performs ORRs before the initial startup or before restart following major modification, significant interruption, or activity scope change, of all activities that have the potential for environmental, health, safety, safeguards and security, or operational risk.

A Readiness Review Board is convened by the plant manager to conduct the ORR of the operation/process to be started up. Using the procedures and criteria established in FSP-PFP-5-8, a thorough review is conducted. The results of the ORR include documentation of operational readiness, a punch list of nonconforming items, and a recommendation to the plant manager on whether to start up.

10.3 TRAINING PROGRAMS

The training programs for PFP personnel are designed to provide the knowledge required to operate the plant in a safe, efficient manner. DOE Order 5480.20A, presents the training requirements. Specific training procedures (i.e., HNF-PRO series of procedures) provide the Hanford Site requirements which are applicable to PFP. For the PFP, FSP-PFP-1121, *Plutonium Finishing Plant Training Administration*, implements these requirements and has the following objectives:

- Define a process for selection of personnel based on the ability to meet job performance requirements
- Specify minimum job qualifications and/or certification requirements for all positions with duties that could affect safe operation of the PFP

- Specify management and supervisory training as appropriate to assigned responsibilities
- Establish a qualification program for operators, maintenance, and technical support positions
- Develop requalification/recertification and continuing training programs to ensure personnel meet job performance requirements
- Ensure that sufficient qualified facility and support staff are available to ensure safe operation
- Formally document qualification, certification, requalification, recertification, and continuing training programs
- Maintain auditable records of training programs and personnel qualifications and training.

10.4 NORMAL OPERATIONS

All operations for the PFP are defined, controlled, and conducted by written procedures that include administrative/implementing procedures, technical documents (operating, maintenance, etc.), and work instructions that are included in work packages. The ensuing discussion in this chapter will describe the development, review, verification and validation, and configuration management of each of these document types.

10.4.1 Administrative Procedures

Administrative procedures and the development, review, publication, and control of these procedures are outlined and contained in FSP-PFP-5-8. The need to develop a new procedure must first be justified to and approved by the PFP Director. The content typically includes purpose, scope, responsibilities, requirements, procedures, review organizations, and references, as appropriate. In addition to editorial review, the draft procedure is reviewed by the organization that is assigned a responsibility or task in the procedure, the organization accountable for requirements or processes established in the procedure, and appropriate quality, environmental, and safety oversight organizations. All draft administrative procedures are coordinated through the review, approval, and publication cycle by the Manual Administrator who forwards the approved procedure to Unclassified Document Control for printing and release. Each administrative procedure is assigned a title, unique identifier, revision number, and effective date. This information is shown in the header.

FSP-PFP-5-8 is a controlled manual and its configuration management is in accordance with *Document Control*, HNF-PRO-224 and *Distributing Copy - Controlled Unclassified Documents*, HNF-PRO-225. All changes are sent to the holder of the manual, who must sign and return each change notice indicating that the change has been entered into the controlled manual. Each change notice has an effective list of pages and is consecutively numbered. The current approved copy of FSP-PFP-5-8 and associated administrative procedures

can be accessed electronically (read-only) on a dedicated computer file server.

10.4.2 Technical Documents

Technical documents provide the procedural basis used to support the operation of the PFP, regardless of the specific document type (i.e., maintenance procedures, operating procedures, specific manuals, and operating specifications).

The methods for preparing, validating, and approving technical documents, and for the implementation of document changes, is outlined in FSP-PFP-5-8, Volume 2, Section 13.5, "Processing PFP Technical Documents." The procedures for control, release, and distribution of these technical documents is contained in FSP-PFP-5-8, Volume 2, Section 13.6, "Technical Document Control System." The cognizant engineer is responsible for providing the procedural basis, which furnishes the justification for significant safety and technical elements of a procedure. These include administrative, technical (FSAR and/or federal, state and local laws and regulations) and design bases. The procedural basis is recorded on the Document Approval Form, which is the QA record for documenting the review, validation, verification, and approval process.

The PFP follows the guidance of DOE-STD-1029-92, *DOE Writer's Guide for Technical Procedures* (DOE 1992), in developing technical documents.

Validation is performed by a team of individuals, one of which must be an individual who would normally perform the task. The intended user takes the document to the location where the task is to be performed and (without actually performing the operation) ensures that each step is correct and readily usable as written.

Approval is the process by which each document is reviewed, verified, and approved by personnel designated by the cognizant engineer. Depending upon the nature of the document and its contribution to the safe operation of the plant, the review organizations could include QA, Safety, and Environmental. The cognizant engineer and cognizant manager are normally the last individuals to review the document before it is sent to the approval authority, who is a designated individual qualified in the operation to be performed.

The process for both permanent and temporary changes to technical documents is also outlined in FSP-PFP-5-8, Volume 2, Sections 13.5 and 13.6. If the change is technical in nature, the process is similar to that of a new technical document.

PFP Facility Engineering is responsible for the generation of these technical documents, and initiates the review, verification, and approval cycle of a technical document. The cognizant engineers are responsible for providing technical guidance and specifically to review the technical document for technical accuracy as it applies to systems, structures, or components (SSCs) and/or processes. PFP Facility Engineering Administration is responsible for formatting, incorporating changes and ensuring approvals are properly obtained. The cognizant engineer is responsible for conducting the

unreviewed safety question (USQ) screening in accordance with FSP-PFP-5-8, Section 2.23, "Identification and Resolution of Unreviewed Safety Questions."

All properly approved technical documents are maintained by PFP Facility Engineering Administration on a central computer file server in password-protected, "read-only" files. In addition, hard copies stamped with "Official Release" are distributed to locations requested by the approval authority. Only "Controlled Copy" documents are authorized for use within the PFP; "Working Copy" or "Information Copy" technical documents are not authorized for use. Each technical document is uniquely identified by title, number, revision/modification, pagination, issue date, and review date.

Before a document is used in the field, the document user is required to verify through a computerized listing that the document in use is the current revision. It is the responsibility of the manager to inform their personnel of changes, and to turn over information concerning a temporary change to a procedure to the incoming manager.

A graded approach is used to schedule periodic review of technical documents, and depending upon the approval designator, the frequency may vary from annually to every five years. The verification method is the same as for a new procedure. PFP Facility Engineering Administration provides the user organization with a copy of the procedure and a validation checklist two months before the required review completion date.

10.4.2.1 Technical Procedures. According to FSP-PFP-5-8, compliance with technical procedures is mandatory within the PFP. The procedure use method depends on risk implications to the facility, risk to the individual performer, quality implications, training of the performer, complexity of the procedure, and frequency of use of the procedure. There are three types of procedure use methods at the PFP: (1) step by step, (2) general use, and (3) routine use, in order of lessening strictness in application.

10.4.2.1.1 Step by step. Step by step procedures requires a step by step approach in the execution of the procedure and requires those performing the task to read through the procedure as the task is being performed.

10.4.2.1.2 General use. The individuals performing the task(s) outlined in the procedure are required to have the procedure available and should have read through the procedure prior to performing the task.

10.4.2.1.3 Routine use. The individuals performing the task have been trained for the procedure and have frequently performed the procedure in the past.

10.4.3 Work Instructions

Management of work activities within the PFP is accomplished through formalized procedures under the auspices of the Job Control System (JCS). For the PFP, this effort is managed by the Maintenance Administration and Support organization and is implemented by FSP-PFP-5-8, Section 13.4, "Job Control System Process Description." The JCS provides a formal, disciplined approach to the control of work to ensure all work is performed using appropriate instructions to assure personnel safety, equipment protection, and facility

configuration control. The JCS uses a graded approach to originating, planning, verifying, preparing, reviewing, approving, scheduling, releasing, performing, retesting, completing, and recording work efforts within the plant. The JCS uses automatic data processing (ADP) to facilitate the development, approval, documentation, and close-out of work packages.

Work packages that modify the plant configuration require an engineering change notice (ECN) that is prepared in accordance with *Engineering Documents Change Control Requirements*, HNF-PRO-440. A USQ screening is also required. Written procedures for conducting the work are reviewed, verified, and approved in much the same manner as any technical document. As part of the pre-job review, the job is walked down to ensure the task can be accomplished as detailed in the work instructions. Approved work packages are scheduled in the Plan of the Day and the person in charge (PIC) of the work to be performed is notified. The work packages are provided to the shift manager, who ensures that all prerequisite conditions are established and authorizes the work packages to be released during the next 24-h period. Once the authorized work has been performed per the work instructions, the PIC or the Maintenance Manager reviews the work package to ensure all required work activities were performed, required information was recorded, all appropriate signatures were obtained, and acceptance criteria were met. As directed by the Shift Manager, the equipment and facility is restored and/or retested and the work package returned to Work Control for close-out and transcription of the record copy into the JCS ADP (see Section 10.4.5 below).

10.4.4 Plant Records

The establishment of a system for creating and preserving records is a fundamental management responsibility. A sitewide records management system was developed and is maintained as described in *Records Management Program*, HNF-PRO-210.

10.4.4.1 Records Maintenance and Retention. The Contractor Records Management Program has been established and is devised to comply with the contractual requirements of the DOE. The program outlines the requirements for the maintenance and disposal of "record" and "nonrecord" material. This procedure defines the responsibilities and procedures for records management, assignment of retention periods, transfer of records, records disposition, and approval and disposition of the Records Inventory and Disposition Schedule (RIDS).

Records that pertain to organizational functions, policies, decisions, procedures, operations, or other activities of the PFP are considered "record" material and are preserved in accordance with the RIDS.

The RIDS is a listing of the filing units and general files of an organization, setting forth their mandatory disposition in terms of retirement, disposal, or transfer to storage after specified retention periods. The schedule includes all file material, whether record, nonrecord, classified, or unclassified. It includes records designated for permanent retention as well as those scheduled for disposal.

Operations, maintenance, engineering, and radiological control records that may be designated for retention include the following:

- Operations
  - Daily log (shift-to-shift reports/turnovers)
  - Hazardous Waste Storage Area Inspection Checklist
  - Sample graphs and data sheets
  - Surveillance sheets (operator reports, weekend readings, OSR data sheets)
  - Security Alarm Functional Test Records (functional tests on door and room alarms)
  - Reportable Occurrence Logs
  - Emergency supply check sheets
  - Safety showers check sheets
  - Essential Materials Checklist
  - Valve verification sheets
  - Item Transfer Sheets (custodians)
  - OSRs surveillance sheets
  - Strip charts
  - Sample logs, letterbooks
- Maintenance
  - Daily logs (shift-to-shift reports/turnovers)
  - Work packages (for preventive maintenance and corrective maintenance, as well as facility equipment modification work records)
- Technical Support
  - Nonclassified informational records on the operation of the plant
  - Comment sheets and letters related to the operation of the facility and considered to be useful at a future date
  - Classified records related directly to the building processes
  - Classified working documents
  - Plant drawings
  - Process data

- Sample result sheets
- Campaign reports

- Radiological Control
  - Contamination surveys
  - Radiation surveys
  - Airborne radiological surveys
  - CAM surveys
  - Instrumentation calibration
  - Records of RWPs.

In addition, groups such as Safety, QA, and Nuclear Material Management maintain records of audits, appraisals, processes, and individual group activities. Copies of these records are obtained by contacting the appropriate manager.

10.4.4.2 Occurrence Reporting System. Occurrence reporting is in accordance with DOE Order 0232.1, *Occurrence Reporting and Processing of Operations Information.* These requirements are implemented by *Reporting Occurrences and Processing Operations Information*, HNF-PRO-060 and by the PFP in *Occurrence Reporting*, FSP-PFP-5-8, Section 1.4. An occurrence is any event or condition that could have an adverse effect on safety, health, QA, safeguards and security, operations, or the environment. Occurrences are broadly classified into three categories of decreasing significance: emergency, unusual, and off-normal. For the PFP, FSP-PFP-5-8, Section 1.4 provides guidance for occurrence classification.

For emergency occurrences, the procedures defined in *Emergency Preparedness Program*, HNF-PRO-424, are invoked and implemented for the PFP in HNF-IP-0263-PFP, *Building Emergency Plan for Plutonium Finishing Plant Complex (BEP-PFP)* and in Section 10.5 below.

The contractor has established an Occurrence Notification Center (ONC) to assist facilities in notification and to provide centralized infrastructure support to the Hanford Site occurrence reporting program. This support includes hardware and software maintenance, training, occurrence report tracking and distribution, and input of occurrence reports onto the national DOE Occurrence Reporting and Processing System (ORPS). The PFP Building Emergency Director (BED) assumes responsibilities for making necessary reports, taking necessary actions to stabilize the facility/operation to a safe condition, preserving conditions for subsequent investigation, and initiating an investigation of the event following notification. The BED is to be trained and knowledgeable of applicable procedures. The PFP Building Emergency Plan (BEP) also reflects these guidelines and provides checklists for the BED, including initial notification and reporting, sources for assistance, event stabilization and/or emergency response procedures, and preserving conditions to facilitate accident investigations. The Hanford

Patrol Operations Center (POC) is also a source of assistance to the BED in an emergency.

For occurrences that involve the release of hazardous materials in reportable quantities, the BED notifies the Contractor Environmental Reports representative, who makes notification to offsite regulators with the assistance of the ONC (see Section 10.4.4.3 for details).

Preparing and filing of the occurrence Notification Report, update reports, and final report is the responsibility of the occurrence investigator. The final report is submitted only when the significance, nature, and extent of the event have been analyzed, the causes of the event or condition (including root cause) have been assigned, corrective actions have been identified, and lessons learned have been identified.

10.4.4.3 Environmental Reporting System. Reports and records required by federal, state, and local regulations are delineated in *Environmental Notification and Reporting*, HNF-PRO-453. These reports are primarily made by the Contractor Environmental Reports organization based upon information provided by the PFP.

10.4.4.4 QA Records Systems. See Chapter 12.0 of this document for discussion of specific recordkeeping and control systems.

10.4.4.5 Authorization Basis. The authorization basis of the facility is defined as those aspects of the facility design basis and operational requirements relied upon by DOE to authorize operation. These aspects are considered to be important to the safety of facility operations. The authorization basis for the PFP is provided by HNF-SD-CP-SAR-021, *Plutonium Finishing Plant Safety Analysis Report*, and WHC-SD-CP-OSR-010, *Operational Safety Requirements* (see FSP-PFP-5-8, Section 2.23 Appendix A for details of the authorization basis). Other safety analyses [i.e., hazard classification documents, technical safety requirements (TSRs), DOE-issued safety evaluation reports (SERs), and facility specific commitments made in order to comply with DOE orders or policies] supplement these documents (DOE Order 5480.21). Details of the FSAR revision process are provided in FSP-PFP-5-8, Section 2.34, *Final Safety Analysis Report Revisions*.

10.4.4.5.1 PFP Plant Manager. The PFP Plant Manager is responsible for ensuring the currency, accuracy, and completeness of the PFP FSAR.

10.4.4.5.2 Plutonium Finishing Plant Technical Support Manager. The PFP Technical Support Manager is responsible for designating the PFP FSAR representative, providing design engineering services for plant modifications that will impact the FSAR, and ensuring that FSAR update schedules and resources are available.

10.4.4.5.3 PFP FSAR Representative. The primary functions of the PFP FSAR Representative is to conduct an annual update of the FSAR as provided by DOE, initiating and approving ECNs resulting from annual review of FSAR or from an USQ, and act as FSAR document coordinator.

10.4.4.5.4 Cognizant Engineer. The cognizant engineer is to ensure that a particular system is accurately and adequately described in the FSAR.

10.4.5. Chemical Management Programs

The following discusses the development and implementation of chemical management programs at the PFP. These programs are described as they apply to the Hanford Site (Section 10.4.5.1), Fluor Hanford projects (Section 10.4.5.2), and the specific programs implemented at PFP (Section 10.4.5.3).

10.4.5.1. Hanford Site Chemical Management Program. The DOE and the Site contractors developed a chemical management program and requirements document for implementation on the Hanford Site. The purpose of the *Chemical Management Program Requirements* (CMP) (CMPR 1999) document is to establish common requirements to control onsite chemical (excluding waste and radioactive materials) management activities within the applicable regulatory requirements. The goal of the program and requirements is to protect Site personnel, the public, and the environment from chemical hazards.

The Site contractors (e.g., BHI, FDH, HEHF, PNNL) concurred with the requirements contained in the CMP with respect to the acquisition, tracking, storage, use, transportation, and final disposition of chemicals. This includes, as a minimum, hazardous chemicals as defined within the OSHA Hazard Communication Standard (29 CFR 1910.1200 and their Appendices A and B).

10.4.5.2. Fluor Hanford Chemical Management Program. The Fluor Daniel Hanford chemical management program and requirements are contained in HNF-PRO-2258, *Chemical Management*. The objective of HNF-PRO-2258, is to establish a chemical management program (excluding waste and radioactive materials), as required by the Integrated Environment, Safety and Health Management System Plan (ISMS), for implementation by the Fluor Hanford projects. The requirements contained in HNF-PRO-2258 can be applied using a 'graded approach' based on the complexity of the chemical management operations and the nature and severity of the chemical hazards. The PFP Chemical Management Program (PFP CMP) is based on the requirements contained in HNF-PRO-2258, *Chemical Management*.

10.4.5.3. PFP Chemical Management Programs. The PFP primarily relies on the following hierarchy of controls to mitigate or minimize hazardous chemical releases or exposures:

- Engineered controls
- Administrative controls
- Personnel protective equipment

The programs currently implemented at the PFP include the PFP Chemical Management Program, a compilation of facility specific procedures which meet the requirements of HNF-PRO-2258, the Hazardous Material Management Plan, EPCRA 312 and 313, and the Chemical Hygiene Plan. These are described in the following subsections.

10.4.5.3.1. PFP Chemical Management Program. In accordance with HNF-PRO-2258, the PFP CMP applies to all chemical operations associated with the acquisition, storage, use, transportation, and final disposition of chemicals, including management of newly generated waste. The implementation of the PFP CMP will minimize the use of and personnel exposure to hazardous chemicals.

As required in HNF-PRO-2258, a single individual at the PFP has been identified to create plans and programs to ensure the PFP CMP requirements are adhered to, and commit to minimizing waste generation and releases to the environment. Additionally, the PFP CMP is to be incorporated into the PFP ES&H management system.

Based on the results of the chemical hazards analyses performed at the PFP, the following four items, within HNF-PRO-2258, were identified as critical program elements necessary to ensure safe use and storage of hazardous chemicals at the PFP (HNF-6492, *Summary of Chemical Hazards Assessments and Chemical Management Programs at the Plutonium Finishing Plant*, Ullah 2000).

Operations –

- Chemical management operations are within the authorization envelope.
- A documented process for the identification, evaluation, and control of chemicals whose characteristics might have changed over time.
- New MSDS shall be forwarded and readily available to support hazardous chemical management.
- Interfaces between facilities and organizations are defined and documented.
- Chemical information is available and incorporated in emergency response and environmental procedures.
- Appropriate training will be provided to personnel using or handling chemicals.
- The PFP will generate rules and guidelines regarding the safe management of hazardous chemicals.

Acquisition – Acquisition of chemicals will be documented and must address the following:

- Need for chemical
- Nonhazardous or less hazardous substitutes or alternatives
- Amount required
- Suitability for storage facilities
- Final disposition plans
- Stability/shelf life
- Required documentation (e.g., MSDS)
- Input of chemical information in CMS tracking system
- Use of available excess chemicals in lieu of new chemical purchases

Storage – Storage of hazardous chemicals should consider the following:

- Proper safe storage at the proper facilities (e.g., flammable cabinets, segregation of reactive/incompatible chemicals)
- Inventory of the chemical be maintained current and include location and quantity, use, custodian, and hazards associated with the chemical in the CMS tracking system
- Control and documentation of chemical use in the CMS tracking system
- Periodic physical confirmation of inventory
- Documented maintenance and inspection program to ensure storage facility integrity

Use – Prior to using chemicals the following should be performed:

- Hazards analysis
- Controls (i.e., engineered barriers, administrative controls and PPEs)
- Tracking of newly created hazardous chemicals, if not immediately used, in the CMS tracking system
- Ensure the use is covered by a procedure or MSDS as appropriate

10.4.5.3.2. PFP Hazardous Material Management Plan. Hazardous chemicals or materials are addressed in FSP-PFP-5-8, Volume 1, Section 7.1, "Hazardous Material Management Plan EPCRA 312 and 313". The PFP HMMP is applicable to all organizations within the PFP that maintain or use hazardous chemicals (newly acquired, stored, or "hold-up"). The purpose of the PFP HMMP is to require hazardous chemical physical inventories, provide guidance on proper storage and segregation requirements, identify "hold-up" chemical management requirements, and hazardous chemical management reviews and reporting requirements.

The PFP HMMP applies to new hazardous chemicals as well as "hold-up" chemicals. "Hold-up" chemicals have been referred to in previous studies as legacy chemicals. For the purposes of this report "hold-up" chemicals are defined as material presently identified, which may or may not be fully characterized, in tanks, pipes, cylinders, process equipment or other vessels which is in solid, liquid or gaseous form. These are typically residual materials from previous production runs. The PFP HMMP is used in conjunction with HNF-PRO-2258; therefore, the following discussion focuses primarily on the management of "hold-up" chemicals or legacy chemicals. Previous analyses have determined that these hazardous chemicals represent the greatest potential chemical hazard at the PFP.

The concern regarding hold-up chemicals is primarily related to chemical incompatibility issues. That is, although extensive efforts have been undertaken to locate, identify, and characterize these chemicals, the potential exists for adverse chemical reactions due to inadvertent mixing.

Based on the results of the chemical hazards analyses performed at the PFP, the following items, within the PFP HMMP, are critical to ensure safe handling and storage of hazardous chemicals at the PFP (Ullah 2000).

1. **Facility Chemical Inventories** –

   - All OSHA reportable chemicals/hazardous materials are identified in the computerized chemical inventory control system
   - Data from the PFP vessel inventory (chemicals/materials identified during the FVA and hazards analyses) are included in the inventory control system
   - The inventory control system is maintained current

2. **Controlled Storage Locations** –

   - Storage areas are clearly marked

- Storage cabinets are clearly identified with respect the types of chemicals permitted for storage in the cabinet (e.g., corrosives, flammable/combustible)
- Storage cabinets and storage locations are segregated to prevent inadvertent mixing or adverse chemical reactions
- Quantities of chemicals outside of designated storage locations are limited to a one-day supply

3. **Training** -

- All employees using, handling, or storing hazardous chemicals receive Generator Hazards training prior to performing any activity
- All employees receive facility and hazardous material emergency response training

4. **Identification, Evaluation and Control** -

- All containerized chemical products are identified and entered in the inventory control system including,
  - potentially reactive chemicals
  - hold-up chemicals
- All chemicals are evaluated at time of purchase to identify,
  - hazards
  - shelf life
  - storage requirements and location
  - potential for chemical substitutes and source reduction
- All chemicals identified during the FVA and subsequent hazards analyses are evaluated to determine,
  - remediation techniques and schedule remediation activities
- All containerized chemicals are controlled by,
  - chemicals are stored in designated storage areas
  - storage areas are inspected for proper labeling, housekeeping, container integrity, leaks, or discoloration, etc.
- Hold-up chemicals are controlled by a task team responsible for,
  - mitigation
  - sampling
  - draining, flushing, and removal of lines and vessels containing hold-up chemicals

10.4.5.3.3. PFP Chemical Hygiene Program. Three chemical laboratories operate at the PFP: the analytical laboratory, the standards laboratory and PPSL. The analytical laboratory and standards laboratory operate using plant operating procedures. PPSL develops and troubleshoots plant processes. This laboratory also conducts significant work for others. Significant test activities in the PPSL are controlled using test plans. Although, generally small scale chemical activities up to the pilot scale can be conducted in the PPSL.

The *PFP Chemical Hygiene Plan*, ZAP-000-010 is an administrative procedure that currently addresses laboratory operations. The Plan includes a discussion on hazard communication and general rules for laboratory activities, including procurement and storage of chemicals, housekeeping and

maintenance, laboratory inspections, signs and labels, and record keeping. The Plan identifies chemicals typically used in the laboratories based on health effects and physical hazards (e.g., flammability). The Plan addresses employee protection including medical consultation, exposure monitoring, PPEs, and training and reading materials. The Plan also describes accident and spill prevention and response actions should a spill or accident occur.

The purpose of the PFP Chemical Hygiene Program (CHP) is to ensure that laboratory workers are not exposed to chemical hazards exceeding regulatory requirements during laboratory operations. Furthermore, the PFP CHP ensures that laboratory activities are evaluated and are controlled such that confinement barriers will not be challenged and personnel exposures are minimized, i.e. skin contact is avoided, ventilation systems are provided, and if identified in the MSDS or during pre-task planning appropriate PPEs are available. Because all of the laboratories exist within the PFP confinement building (Building 234-5Z), the programs specified in Sections 10.4.5.3.1 and 10.4.5.3.2 are applicable.

Based on the results of the chemical hazards analyses performed at the PFP, the following items, within the PFPCHP, are critical to ensure safe handling, storage, and use of hazardous chemicals in the PFP laboratories (Ullah 2000).

1. **Informing laboratory employees of:**

    - The contents of 29 CFR 1910.1450, *Occupational Exposure To Hazardous Chemicals In Laboratories* (OSHA 1990)
    - The location and availability of the chemical hygiene plan
    - The permissible exposure limits for OSHA regulated substances or recommended exposure limits for other hazardous chemicals where there is no applicable OSHA standard
    - Signs and symptoms associated with exposures to hazardous chemicals used in the laboratory
    - The location and availability of known reference material on the hazards, safe handling, storage and disposal of hazardous chemicals found in the laboratory including, but not limited to, Material Safety Data Sheets

2. **Training laboratory employees on:**

    - Methods and observations that may be used to detect the presence or release of a hazardous chemical
    - The physical and health hazards of chemicals in the work area
    - The measures employees can take to protect themselves from these hazards
    - The applicable requirements of the chemical hygiene plan

3. **Emergency Response Planning**

    - PFP emergency response planning incorporates the potential hazards associated with PFP's laboratory chemical inventory and potential adverse chemical reactions.

4. Test Plans

- Test plans are prepared when a laboratory activity is not subject to an approved plant operating procedure or is not a routine laboratory activity
- Test plans include a description of the specific activities evaluated; identify planned reactions, chemical reactants to be used, and their byproducts; describe potential hazards and consequences (including physical hazards) associated with the test including consideration of process upsets and equipment failures; describe the engineering barriers, and administrative controls and personal protective equipment that will be required
- Test plans are reviewed and approved by knowledgeable, independent chemical safety personnel

10.5 SCOPE OF EMERGENCY PREPAREDNESS

This section addresses the emergency planning for the Hanford Site as a whole, and the implications for the emergency preparedness program at the PFP. Two DOE documents that must be implemented are *Hanford Emergency Response Plan*, DOE-RL-94-02, and *Emergency Plan Implementing Procedures*, DOE-0223. Appendix 1-2.B of DOE-0223 is devoted to "Recognizing and Classifying Emergencies" at the Plutonium Finishing Plant. This appendix describes the initiating conditions, emergency action level, and event classification for identified PFP facility emergencies, natural emergencies, and security contingencies.

Three PFP specific procedures that are applicable are: *Building Emergency Plan for Plutonium Finishing Plant Complex*, HNF-IP-0263-PFP; *Authorization Listing of the Building Emergency Organization for PFP*, FSP-PFP-0760; and PFP Casualty Response Procedures (ZCRs). The details of the PFP emergency preparedness program are discussed in Section 10.6, Emergency Preparedness Planning.

10.5.1 Operational Emergency Classes

An accident is classified according to the severity of the emergency action level. Emergency action levels are observable criteria, such as instrument readings, equipment status indicators, analytical results, security events, natural events, and discernible events that are used to determine the extent of an operational emergency.

10.5.2 Operational Event Classes

The emergency classes covered in emergency planning for the PFP are alert, site-area emergency, and general emergency. Unusual occurrences and off-normal events are nonemergency incidents of less consequence, which may require assistance from the facility emergency response organization, as well as from organizations outside of the affected site. The emergency response procedures allow for escalation or termination when new data pertaining to the nature and magnitude of the incident are obtained.

These nonemergency categories and emergency classes are described in DOE-RL-94-02, *Hanford Emergency Response Plan*, in *Emergency Preparedness Program*, HNF-PRO-424, in addition to being posted in the emergency response centers. Definitions of the five event classifications are as follows:

1. Off-normal event--a nonemergency event that indicates degradation of, or adversely affects safety, security, environmental or health protection performance, or operation of a facility

2. Unusual occurrence--a nonemergency event that has significant impact, or potential for impact, on safety, environment, health, security, or operation of a facility

3. Alert--an event that is in progress or has already occurred, that involves a substantial reduction (actual or potential) in the level of facility safety

4. Site-area emergency--an event that is in progress or has already occurred, that involves a significant reduction (actual or likely) of facility safety, or failure of facility safety functions needed for protection of onsite personnel and the public

5. General emergency--an event that is in progress or has already occurred, that involves a catastrophic reduction (actual or imminent) of facility safety, or failure of safety functions with the potential for loss of containment or confinement integrity and/or releases exceeding protective action guideline exposure levels offsite.

10.5.3 Emergency Planning Zones

The PFP emergency planning includes identification of emergency planning zones, which are defined on the basis of the consequence analyses for the accident scenarios found in the hazard analyses for each facility. The following 200 Area zones are listed in DOE-RL-94-02:

- Plume exposure zone--the area within a 16-km (10-mi) radius for 200 Area facilities

- Ingestion exposure zone--the area within a 80-km (50-mi) radius of the Washington Nuclear Plant 2.

For an emergency limited to an onsite area, a graded approach is used to determine the required emergency response actions. For example, an event affecting only a few staff members would be handled primarily by building management and cognizant safety and medical personnel. The Emergency Operations Center (EOC) is activated when an emergency is declared. When an alert or higher classification of emergency is declared, all emergency centers are activated. Offsite emergency response activities are based on scenario-specific determinations made by responders to an emergency. Emergencies are classified in accordance with facility-specific recognition and classification procedures.

10.6 EMERGENCY PREPAREDNESS PLANNING

This section summarizes the PFP emergency preparedness planning, including activation of emergency organizations, assessment actions, notification processes, emergency facilities and equipment, protective actions, training and exercises, and recovery actions.

Emergency plans ensure that appropriate actions are taken to minimize the consequences of accidents. Emergency plans alleviate the consequences of an accident by using predetermined accident consequences in the planning, using facility conditions to determine emergency action levels, predesignating responsibilities and procedures that must be carried out in response to an emergency, and determining equipment and resources that must be available to respond to an emergency. These plans are already established for the 200 Area, and were used in planning the mitigation of the specific postulated accidents developed in Chapter 9.0.

Emergency response actions for building personnel are described in the BEP and Casualty Response Procedures for the PFP. The Hanford Site Emergency Preparedness organization, management responsibilities, and communication interfaces with the DOE-RL, EOC, and outside emergency response organizations (as well as the communication interfaces between the DOE-RL and outside agencies), are identified in the DOE-RL-94-02. This document applies to all Hanford employees and facilities. Emergency routes, access points, and assembly points for the PFP are also provided in the BEP.

As provided in HNF-IP-0263-PFP, the BED provides initial notification of an emergency to the Patrol Operations Center (POC) and the Occurrence Notification Center (ONC) on 911. The ONC then notifies DOE Headquarters and other offsite agencies. If the event is an emergency, the BED notifies the Hanford POC and ONC. The ONC provides offsite notifications and response recommendations to the offsite local, tribal, state, and federal agencies.

10.6.1 Emergency Response Organization

The Emergency Preparedness Program, including identification of the individual responsibilities within the PFP organization, is described in the BEP-PFP, HNF-IP-0263-PFP. The DOE Hanford Site Emergency Preparedness Program is described in DOE-RL-94-02. The Hanford Emergency Preparedness Program contains organizational elements necessary to ensure that the DOE fulfills its responsibilities for emergency planning, preparedness, and readiness assurance activities, and that the emergency response activities of the DOE onsite contractors are integrated with relevant local, tribal, state, and federal agency activities.

The objective of the Emergency Preparedness organization is to effectively respond to any event, whether it is an unusual occurrence affecting and requiring notification of onsite personnel only, or an emergency affecting and requiring offsite notification. The performance requirements for the Emergency Preparedness Program and its supporting plans emphasize that the program and plans be easy to understand and implement, so that they may be executed smoothly regardless of the timing (e.g., normal day shift, swing shift, back shift or holiday), experience of the emergency staff and workers

(i.e., personnel assigned as primary responders versus staff available at the time), and environmental conditions (e.g., snow, ice, high wind).

The DOE-RL manager has the overall responsibility and authority to establish, develop, and maintain an effective, integrated Emergency Preparedness Program consistent with the scope of operations, potential emergencies, and requirements in those facilities and operations under the jurisdiction of the DOE-RL. The Hanford Site management and operations contractor is assigned the responsibility for developing and implementing an Emergency Preparedness Program for the facilities it operates for the DOE, in accordance with DOE orders and DOE-RL-94-02.

The emergency preparedness plans for the PFP and the supporting DOE-RL plans follow the requirements of DOE Order 0151.1, *Comprehensive Emergency Management System*. The BEP-PFP is intended to meet all applicable requirements for BEPs, and the State of Washington requirements for hazardous and dangerous waste contingency plans.

10.6.1.1 Plutonium Finishing Plant Emergency Preparedness Organization. The PFP staff are assigned to emergency response duties on the basis of the similarity of their normal daily responsibilities to the emergency response duties, and their demonstrated ability to properly analyze data, assess situations, and make decisions under high stress conditions. The BED is responsible for assessing and categorizing an event, and if the event is categorized as an emergency, classifying the event and initiating appropriate protective actions for the welfare and safety of facility occupants and affected areas. The BED communicates with emergency staff and directs subsequent actions at the event site. Personnel are responsible for identifying health and safety issues, as well as recommending actions. Staff responsible for communication establish liaison with the DOE-RL EOC and others. Staff familiar with the facility and operations gather information directly related to the facility and event site necessary for public dissemination. A small cadre of staff assists in maintaining vital operations, planning for corrective actions (i.e., control or termination of the energy source, conditions, or situation that led to the event), and providing necessary logistical support to cope with the event (e.g., obtaining staff with specialized skills, additional protective equipment, heavy equipment). Additional specialized technical support is available by calling 911.

10.6.1.2 Incident Command Post. The Incident Command Post (ICP) provides a graduated response mechanism for unusual conditions and emergencies on the Hanford Site. An ICP shall be established when it is determined that an incident has occurred or is underway which requires a structured emergency response. The ICP shall be established in a safe location near the incident scene.

In its most basic form, the ICP may be staffed in its entirety by facility or process personnel as deemed necessary by the BED or Building Warden (BW). In these instances, the BED or BW coordinates emergency response efforts at the scene to include oversight of mitigation efforts, use of appropriate personal protective equipment, local protective actions, and relevant notifications. Examples of when ICP implementation may be carried out at this level are during small releases of known substances when

mitigation can be accomplished by trained on scene personnel, minor first aid cases, non-injury contaminations, and non-emergency plant responses.

Incidents that require the response of emergency personnel beyond the incident scene are reported to the POC via 911 and automated alarm system, where applicable. This level of response requires the designation of an Incident Commander (IC). The senior responding Hanford Fire Department officer for events involving fire, medical, hazardous materials, or rescue shall be the IC. The Hanford Patrol Shift Commander will act in the capacity of the IC during security incidents.

For events that require establishment of an ICP, organizations supporting the ICP co-locate with the IC and retain responsibility for managing their technical operations and personnel. The IC is responsible for the health and safety of all personnel at the event scene (i.e., the impacted area under his/her direct control) and for the overall management strategy associated with the incident to ensure that all functional areas are appropriately staffed and working cohesively towards mitigation of the incident.

10.6.1.3 Hanford Fire Department. The Hanford Fire Department Operations Division is the emergency response element of the department and is responsible for actions to confine and control the full range of potential fire emergencies to include radiological, structural, and wildland fire emergencies within the Hanford Site boundaries.

The Hanford Fire Department is the designated incident command agency for control of all hazardous materials incidents on the site and, as such, controls the fire, hazardous materials and/or personnel rescue response activities associated with an emergency.

The Hanford Fire Department also monitors facility fire alarm systems and coordinates and provides emergency medical services on the Hanford Site.

10.6.1.4 Hanford Patrol. The Hanford Patrol monitors alarm systems and provides security services including coordination of the movement of emergency personnel through security gates, evacuation assistance, and barricade establishment where needed. Additional law enforcement is available through agreements with local and Federal agencies at the request of RL. The Hanford Patrol is the designated incident command agency for security emergencies.

Additionally, the POC, a 24-hour operational facility, is responsible for emergency functions which include:

- acting as the single point-of-contact to initiate emergency response by
  - notifying the BED/BW (when not on the premises)
  - requesting response from the Hanford Fire Department
  - notifying appropriate on-call personnel
  - activating or requesting activation of appropriate alarm signals;

    NOTE: PNNL uses 375-2400 as the single point-of-contact

- activating the ONC conference call upon notification of a declared emergency and implementing onsite protective actions by activating warning sirens and crash alarm telephone systems; and

- receiving emergency response telephone calls during offsite shipments of RL-owned hazardous materials.

During a security event, the Hanford Patrol establishes a Tactical Operations Center (TOC), which serves as the ICP and directs response and control of the security event through direction from the RL-EOC. The TOC is established at a location that provides communications, protection of the team from event activities, and the capability to monitor the activities associated with the event.

Functions performed at the TOC include:

- directing Hanford Patrol forces at the event scene;
- coordinating Hanford Patrol resources;
- communicating with the RL-EOC for event status and direction; and
- hostage negotiation activities.

10.6.1.5 DOE-RL Emergency Operations Center. The DOE-RL Emergency Operations Center (RL-EOC) is an emergency response facility maintained by DOE-RL for the purpose of providing an area where personnel may convene during emergency conditions to provide essential response functions. These functions include public information, offsite protective action recommendations, field monitoring and sampling, hazard assessment, oversight of onsite mitigative activities, and oversight of onsite protective actions.

The RL-EOC shall be activated and operational within one hour upon declaration of an Alert level or higher emergency.

The RL-EOC may also be fully or partially activated in the following situations.

- As directed by the RL Manager, Deputy Manager, or Assistant Managers when events occur that are not classified as an Alert level or higher emergency but where action to provide monitoring or assistance to the event scene or other agencies, is requested. Such events may include:

  - Hanford Site emergency conditions that potentially involve significant onsite or offsite consequences

  - RL-declared security events (RL takes control of the emergency until relieved of law enforcement responsibilities by the Federal Bureau of Investigation)

  - natural disasters (i.e., earthquake, tornado) that could or does result in significant onsite or offsite public or environmental impact

  - requests from other government agencies for support of regional emergencies

  - threats or acts of terrorism, or when a national emergency is declared by the President of the United States or the United States Congress.

- As directed by the RAP team leader to support a RAP response.

- In response to non-DOE emergencies that affect the Hanford Site.

- In response to TEP events involving the offsite shipment of RL-owned hazardous materials.

The RL-EOC is made up of several organizations which are responsible for implementing defined emergency response tasks. These organizational areas are defined in the following subsections.

Detailed procedures for the activation, staffing, and operation of the RL-EOC are contained in DOE-0223, *U.S. Department of Energy, Richland Operations Office Emergency Plan Implementing Procedures* (DOE 1992a).

10.6.1.5.1 Policy Team. The primary functions of the Policy Team are the oversight of onsite activities, approval and communication of offsite protective action recommendations, approval of reclassification recommendations, approval and communication of RL requests for Federal assets, oversight of public information activities, and coordination with offsite agencies.

The Policy Team is staffed by the RL Emergency Manager, Public Information Director, Emergency Preparedness Advisor, Offsite Interface Coordinator, DOE-HQ Liaison, and the responding State and County representatives.

During RL-declared security events, RL is responsible for all decisions that address mitigation of the security event. This involves direction and control of Hanford Site security and patrol forces, and coordination of facility response. However, the Federal Bureau of Investigation (FBI) may exercise the option to take command of security events involving the violation of the Atomic Energy Act of 1954 or other Federal statutes. Associated response by site contractor personnel for personnel and operational safety rests with the IC and the BED.

The RL Manager is the RL Emergency Manager. In the absence of the RL Manager, the RL Deputy Manager acts as RL Emergency Manager. The RL Emergency Manager is responsible for oversight operations of the RL-EOC and for ensuring implementation of the responsibilities of RL as Lead Federal Agency (LFA). In consultation with the RL-EOC staff, the RL Emergency Manager approves emergency reclassification and termination, offsite PARs, and notifications.

Once operational, general functions of the Policy Team include:

- overviewing onsite response and mitigation actions, and providing assistance to the event contractor as needed;

- providing offsite notifications and PARs to state, local, and Federal agencies, and continuous updates to the state/counties about conditions;

- notifying the cognizant DOE-HQ Program Senior Official and the DOE-HQ Emergency Management Team if facility operations were shut down as a part of the protective action response;
- providing direction and control, as appropriate in an RL-declared security event (security declaration takes precedence in combined security/safety events);
- reclassifying or terminating the emergency;
- directing the activities of the Joint Information Center (JIC) in providing timely and accurate release of information to the public and media, including approval of all RL news releases;
- requesting additional Federal assets as needed;
- providing liaisons to offsite emergency centers and responding Federal assets;
- providing a representative to DOE-HQ as requested; and
- designating a recovery organization.

10.6.1.5.2 Joint Information Center. The primary function of the JIC is the dissemination of accurate and timely information to the public and employees about RL activities during declared emergencies. The JIC is staffed by RL, contractor, State, and County communication professionals responsible for coordinating the release of information to the public and media.

One or more Newswriter(s) reside next to the Policy Team area in order to obtain the most current information for the development of draft press releases. Once developed, the Newswriter(s) ensures that the releases are reviewed for technical accuracy and security sensitivities prior to approval by the RL Public Information Director. Upon approval, the press releases are sent to the JIC for dissemination.

The JIC provides a single location where RL and site contractors can coordinate the release of information with other Federal agencies, state, and local jurisdictions. The JIC operates under the direction of the RL Public Information Director and is managed and staffed by RL and site contractor personnel. Provisions shall be made at the JIC for representatives from the states of Washington and Oregon, plume EPZ counties, and other Federal agencies who may be involved in the emergency response.

The functions performed at the JIC include:

- preparing and coordinating information released to the public and media;
- answering questions of the public and media; and
- rumor control.

10.6.1.5.3 Site Management Team. The primary functions of the SMT are to provide support to the ICP by providing additional resources not easily obtained by the IC; tracking the status of onsite protective actions; developing and directing implementation of additional onsite protective

actions away from the event scene (i.e., the area not under the direct control of the IC) as required; and providing communications support. The SMT is also responsible for hazards assessment activities, developing additional offsite protective action recommendations, record keeping, and overall operation of the center. The SMT is made up of four support organizations that are responsible for implementing defined emergency response tasks. These organizations are defined below.

10.6.1.5.3.1 Executive Team and Support Staff. The Site Emergency Director is responsible for the coordination of all SMT activities. In this role, the Site Emergency Director is responsible for the activities of the Event Support Coordinator, EOC Operations Manager, and the Unified Dose Assessment Center (UDAC) Manager. Since RL has an operational function over Hanford security forces, the Security Director is responsible for the activities of the Security Operations Coordinator. The Security Director will receive information from and provide direction to the security forces. The Security Director will communicate planned actions of security forces to the Site Emergency Director and Safety Oversight Director to ensure all safety and security issues are addressed and coordinated. The Site Emergency Director, in conjunction with the Security Director and Safety Oversight Director, is responsible for periodically providing status information to the RL Emergency Manager on the Policy Team. The Contractor Representative and SMT Emergency Preparedness Advisor provide support to the Site Emergency Director.

10.6.1.5.3.2 Security and Event Support. As part of the SMT staff, the Security Operations Coordinator's primary functions are security operations, which include interface with local law enforcement agencies, coordination with the FBI, and oversight of onsite patrol activities. In this role, the Security Operation Coordinator reports directly to the Security Director.

The Event Support Coordinator is responsible for event support activities to include site support services, technical support, communications with the event scene, and coordination with the Emergency Decontamination Facility. In this role, the Event Support Coordinator reports directly to the Site Emergency Director.

10.6.1.5.3.3 Unified Dose Assessment Center. As part of the SMT, the primary UDAC functions are monitoring and evaluating existing emergency conditions in order to develop additional protective action recommendations. The UDAC is responsible for field team activities to include plume tracking, monitoring, and sampling.

Representatives from the states of Washington and Oregon participate in the development of recommendations and provide direction for offsite environmental monitoring. The UDAC is operated by site contractor personnel with knowledge in the technical areas of meteorology, toxicology, industrial hygiene, and health physics. The UDAC Manager is responsible for all UDAC activities. In this role, the UDAC Manager reports directly to the Site Emergency Director.

Specific UDAC responsibilities include:

- acquiring necessary data and measurements to evaluate personnel radiation doses and chemical exposures resulting from the event;

- assessing the potential for onsite and offsite consequences of a release of radioactive or nonradioactive materials based on meteorological conditions, source term, location and dispersal of the hazardous material;

- assisting the event contractor or other Hanford Site contractors in onsite hazard assessment or development of onsite protective actions;

- analyzing the consequences associated with evacuating versus remaining in a take cover situation for onsite personnel and recommending appropriate additional protective actions if necessary;

- developing offsite PARs in coordination with representatives from the states of Washington and Oregon; and

- coordinating and directing emergency environmental monitoring teams that are not assigned to the event facility. This may include state field teams performing offsite monitoring if requested by the states.

10.6.1.6 Outside Agencies. The DOE-RL and Contractor respond to all emergencies within the Hanford Site boundary (DOE Order 0151.1). The DOE-RL and its contractors have established agreements to coordinate responses to emergencies. The coordination agreements for the emergency responses of both onsite and offsite organizations are described in this section. The Hanford contractors' familiarity with Hanford facilities allows them to assist in emergency events with a minimum of direction.

10.6.1.6.1 Memorandums of Understanding. Notification and response for an event with a potential offsite impact or one that may require additional support from offsite agencies are prescribed by MOUs. Initial offsite notifications are made by the BED through the ONC. The EOC team has the responsibility for further offsite communications or requests.

Several MOUs are in place involving offsite agencies surrounding the Hanford Site. The DOE-RL, Benton County, Franklin County, Grant County, and the states of Washington and Oregon have MOUs that describe the planning, communication, and response to Hanford Site emergencies that may have offsite consequences. An MOU among the DOE-RL, the the Energy Northwest, Benton and Franklin counties, and the Thirteenth Coast Guard District is in place to ensure the safety of the Columbia River during an emergency at the Hanford Site and to provide guidelines for river evacuation. Another MOU between the DOE-RL and Energy Northwest provides for mutual assistance in the use of facilities and equipment for personnel decontamination, first aid, evacuation reassembly areas, respiratory protective equipment, protective clothing, vehicles (including the use of ambulances), radiological surveying equipment, resources for river evacuation, and radiological assistance. The DOE-RL also has an agreement with the Washington Area National Weather Service that defines the mutual responsibilities for providing meteorological information in an emergency situation. The Federal Aviation Administration (FAA) has agreed to establish flight restrictions surrounding the Hanford Site during emergencies, as requested by the DOE-RL.

MOUs are also in place between Hanford emergency and security personnel and surrounding site agencies. Mutual aid agreements for support of the HFD have been established with the Richland, Kennewick, and Pasco Fire Departments; Benton County Fire Districts 1, 2, and 4; Franklin County Fire District 3; and Walla Walla Fire District 5. The Hanford Patrol, the physical security agency for the Hanford Site, has several MOUs established with area law enforcement agencies to provide additional backup capabilities.

10.6.1.6.2 Medical Support. The HEHF provides professional medical support for the entire Hanford Site. Doctors and nurses who are trained to work with personnel contaminated with a radioactive source or exposed to a hazardous material are available for emergency assistance during normal duty hours. Hospital services are provided by Kadlec Medical Center in Richland, with backup service at Kennewick General Hospital and Our Lady of Lourdes Health Center in Pasco. Ambulance service with qualified emergency medical technicians and paramedics as attendants is provided 24 h/day by the HFD.

An exposure evaluator, also available 24 h/day for consultation and assessing radiation doses, is notified whenever there is an inhalation, ingestion, or injection of a radioactive or hazardous substance.

An RCT, with the appropriate radiation monitoring instruments, accompanies any patient contaminated with radioactivity to the hospital and provides continued monitoring for the patient and hospital premises as needed.

Severely contaminated injured patients are treated in the Emergency Decontamination Facility (EDF) (also referred to as the 748 Building), which provides for both isolation and decontamination. The EDF is located immediately north of Kadlec Medical Center in Richland. The only exception is if the injury is so severe that immediate medical attention in a hospital is necessary. The HEHF directs activation of the EDF and uses personnel from Kadlec Medical Center or other organizations as necessary. Additional details of the EDF are provided in Section 10.6.4.1.2.

10.6.2 Assessment Actions

The UDAC provides onsite and offsite dose consequence projections (see Section 10.6.1.5.3.3).

10.6.3 Notification

Notification of an emergency may be initiated by a staff person who becomes aware of a condition that may affect occupants or operations (see Section 10.4). When the automatic or manual actuation of a building alarm (such as fire) is the alerting mechanism, the alarm is automatically relayed to the POC. If an alarm is not the initiating action, a staff person calls PAX 222, 911 or 373-3800 and provides their name, and the nature and exact location of the emergency. Staff in the building, area, or on the Hanford Site in general are notified about the emergency by one or more of the following emergency warning systems.

- Building public address system. A public address system (referred to as the PAX system) is used for incidents that affect only the PFP complex.

- Hanford Site standard emergency alarm signals. These signals sound different alarms (gongs, sirens, bells, etc.) depending on the emergency situation. Specific emergency alarms for the PFP are listed in the BEP.

- Crash alarm telephone system. This telephone system is used to disseminate emergency messages and is normally activated by the POC, which has been notified by a BED that an emergency exists. Dialing a single number connects the initiator to a set of predetermined telephones across the site. The location of crash alarm telephones that serve the PFP are provided in the BEP. Persons receiving the crash alarm telephone messages notify the BED and forward instructions to other personnel in the area who do not have crash alarm telephones, by standard telephone, radios, or word-of-mouth.

10.6.3.1 Public Information. The public information plan provides instructions for the implementation, operation, and activities of the DOE JIC during emergency situations at the Hanford Site. The plan states that each event will be handled on a case-by-case basis to determine which provisions of the plan will be implemented. The JIC is always activated in the event of an alert or higher classification of emergency.

The DOE and Hanford contractors are directed to make prompt and accurate information available to the public by DOE-0223 (DOE-RL 1997). Audiences served by the JIC are the media; local community; onsite employees and emergency workers; elected federal, state, and local officials; DOE Headquarters; federal, state, and local agencies; and special interest groups.

10.6.3.2 Records. The record-keeping process for emergency preparedness includes taping telephone conversations with emergency response centers and collecting written records generated during the emergency. Much of the communication within and among emergency centers occurs via written emergency messages that can be stored for future reference.

10.6.4 Emergency Facilities and Equipment

The PFP is responsible for maintaining facility emergency equipment and ensuring that it is complete and in working order. All emergency kits are inventoried and/or calibrated, and all items removed for testing or maintenance are simultaneously replaced. Stored emergency kits are maintained in a complete and working condition. Contractor emergency management staff are responsible for maintaining the communications equipment in the DOE-RL EOC.

10.6.4.1 Emergency Facilities. The following emergency facilities and resources are available to the PFP.

10.6.4.1.1 Medical. As described in Section 10.6.1.4.2, professional medical help is available to provide emergency assistance for the entire Hanford Site at any time.

A Health Care Center staffed by trained medical personnel is located in the 200 West Area and is available for response to other areas. Injured or contaminated persons can be treated by the nurse during normal day shift hours Monday through Friday, and transported offsite to the hospital or emergency decontamination if necessary. Medical assistance is also available 24 h/day from the 200 E Health Care Center.

10.6.4.1.2 Radiation and Contamination Assessment. Two facilities, the EDF (748 Building) and the Invivo Radioassay and Research Facility (747A Building), are available for evaluating the radiation exposure of contaminated individuals. Both facilities are staffed by PNNL, HEHF, and Kadlec personnel and are located adjacent to the Kadlec Medical Center.

747A Building (Invivo Radioassay and Research Facility; Whole Body Counter). This facility is available for performing whole body and lung counts, as well as routine whole body counts. The PNNL Radiation Control staff assigned to the 747A Building can perform portable whole-body radiation counting near the event scene, or offsite if an event warrants such support. Special bioassay and external dose measurement can also be arranged for by the PNNL's Hanford exposure evaluator. Since this facility is part of the Federal Radiological Monitoring and Assessment Program, a substantial inventory of emergency supplies and equipment is stored in a mobile trailer near the whole-body counter. This equipment includes radiation detection/measurement instrumentation and protective clothing kits. The equipment is available for use in emergencies occurring on the Hanford Site.

748 Building (Emergency Decontamination Facility). This facility provides radiosurgery for highly contaminated individuals, as well as providing whole body counting and wound counting. The facility is equipped with emergency decontamination utilities (showers, etc.) and shielded bays to prevent contamination of staff personnel from contaminated patients.

10.6.4.1.3 Federal Emergency Response Assets. The DOE-RL EOC may also request activation of the appropriate DOE Federal Emergency Response Assets to assist in monitoring and assessment for radiological emergencies. These assets include the Aerial Measuring System, the Atmospheric Release Advisory Capability, the Federal Radiological Monitoring and Assessment Center, and the Radiological Emergency Assistance Center.

10.6.4.2 Emergency Equipment. Emergency equipment is used primarily to protect emergency response personnel and to mitigate an accident or incident consequences. The emergency equipment includes protective clothing, respiratory protection equipment, equipment for cleanup or control of hazardous chemical spills, first-aid kits, firefighting equipment, and emergency response team identifiers (e.g., hard hats, arm bands, vests). Lists of facility-specific equipment and its location, including fixed and portable emergency equipment, are provided in the BEP and emergency response guides (WHC-IP-1045-PFP). A portable whole-body counter located in the 200 East Area is also available for use, at the event site or offsite, as needed.

10.6.4.2.1 Hazardous Materials Response Vehicles. In addition to facility-specific equipment, the 200 Area Fire Department has a hazardous materials response vehicle and a crew of trained hazardous materials responders available at all times. The vehicle is equipped with the supplies

necessary to detect, contain, and mitigate or neutralize hazardous materials. The unit is able to respond to the following nine classes of hazardous materials: (1) explosives; (2) gases; (3) flammable liquids; (4) flammable solids, spontaneously combustible materials, and materials that are dangerous when wet; (5) oxidizers and organic peroxides; (6) poisonous and etiologic (infectious) materials; (7) radioactive mixed waste materials; (8) corrosives; and (9) miscellaneous hazardous materials.

10.6.4.2.3 Richland Operations Office Emergency Operations Center. The DOE-RL EOC is equipped with telephones, radios, telefax machines, emergency plans, maps, status boards, etc.

10.6.4.2.4 Other Emergency Control Equipment and Supplies. Several sources of equipment and supplies are available on the Hanford Site for use in controlling and mitigating the consequences of an emergency situation. A large variety of light and heavy equipment and supplies that could be diverted from routine to emergency use, if needed, are maintained at the Hanford Site.

Through a mutual-aid agreement, WPPSS has agreed to provide emergency facilities and equipment for personnel decontamination, first aid, evacuation reassembly, and respiratory protection, as well as protective clothing, vehicles, and survey instruments. The WPPSS has also agreed to provide information on radiological conditions, meteorological data, and other necessary environmental data.

Radiological monitoring teams can gain access to the east and north sides of the Columbia River with a boat made available by PNNL. Arrangements are in place for aerial surveillance and monitoring through the UDAC. The radiological monitoring teams, the Hanford Patrol, and the HFD have radio-equipped vehicles in use on a daily basis that may be used in the event of an emergency.

10.6.4.3 Communications Equipment. The telephone systems are the primary source of communication, with radios serving as backup. Telephone communication can take place via the commercial telephone system and dedicated telephone lines. Several radio systems and frequencies are available for emergency communication. The Safety Net is a dedicated radio frequency for communication between emergency centers and field teams.

10.6.4.3.1 Plutonium Finishing Plant. Emergency communication equipment consists of the following:

- Building public address system for events that affect only the PFP complex
- Hanford Site standard emergency alarm signals (described in DOE-RL-94-02)
- Crash alarm telephones to disseminate emergency messages (dialing a single number connects the initiator to a predetermined number of telephones)
- Two-way radios and cellular phones.

10.6.4.3.2 Not Used

10.6.4.3.3 Richland Operations Office Emergency Operations Center. The following is a list of the emergency communication routes available to the DOE-RL EOC:

- A telephone system installed with sufficient instruments to contact onsite and offsite groups, DOE headquarters, and federal agencies
- A conferencing bridge to provide communications between the incident command past and the DOE-RL EOC
- A base radio system located in the DOE-RL EOC Security Room, with frequencies for the Hanford Patrol, Hanford Tactical, Hanford Fire, Hanford Safety (the dedicated Safety Net emergency frequency), the Benton County EOC, Franklin County, Grant County, Benton County Law Enforcement Primary, the Law Enforcement Radio Network, WPPSS, and the Coast Guard
- A dedicated communication system for notifying and communicating with the WPPSS, Benton and Franklin counties, and the Washington State EOC (a facsimile transmission of the notification form is sent to verify verbal information concerning the event)
- A secure phone located in the DOE-RL EOC
- Cellular phones.

10.6.4.3.4 Miscellaneous Communication Information. The Hanford Site ONC, the POC, and DOE-RL EOC can communicate 24 h/day by radio, telephone, and telefax with emergency dispatch centers in Benton and Franklin counties, WPPSS, the sheriffs of Benton and Franklin counties, the Washington State Patrol, the state of Washington ECC, the management and duty officers of DOE-RL, and onsite support response organizations. The National Warning Service Circuit, located in the POC, can be used as a backup notification channel to the state and counties in the event that contact cannot be made by telephone. Descriptions of the communications capabilities for the state and local emergency centers are given in the state and local emergency plans.

10.6.5 Protective Actions

Protective actions are taken during an emergency to prevent or minimize actual or projected exposure to releases of hazardous radioactive or nonradioactive materials. Specific actions are typically sheltering or evacuation, or the use of time, distance, and, shielding to reduce exposure to hazardous materials by emergency workers and the public.

The BED uses facility emergency action levels to classify the event as an operational, security, or natural emergency. The event is classified by the BED according to the event recognition and classification procedure that is based on the emergency classification criteria discussed in Section 10.5.2. The BED either evacuates the facility or directs the facility to take cover, and contacts the POC for all additional protective actions that are kept on the POC checklists specific to each area.

Predetermined emergency planning zones are also used in response actions. Specific requirements regarding protective actions listed in DOE Order 0151.1 are addressed as follows:

- Offsite recommendations are made through the DOE-RL EOC to the appropriate state, tribal, and local authorities
- Workers evacuated from the site undergo radiological and hazardous material surveys and decontamination as necessary (see Section 10.6.1.4.2)
- Field teams equipped with instruments capable of detecting radiological or hazardous materials are deployed to determine the area actually affected by an operational emergency
- The emergency response team uses specific procedures to account for all facility personnel within 30 min; BEP describes procedures, assembly areas, transportation methods, and evacuation routes
- During response activities, control of emergency worker exposures to hazardous materials is guided by radiological and nonradiological criteria in DOE-RL Emergency Plan 4.0 of DOE-0223 (DOE-RL 1993); systems already in place for monitoring exposures and maintaining records are used
- Radiological and hazardous material decontamination of equipment evacuated from the site is performed as necessary.

10.6.6 Training and Exercises

10.6.6.1 Training. Emergency response training is conducted at all levels (i.e., the facility, area, DOE-RL EOC). Specialized individual training programs are provided for Hanford Site contractors, the DOE-RL staff, and non-DOE emergency personnel. Training includes initial training and retraining, as appropriate. In addition, personnel perform periodic exercises and drills. The PFP training program is contained in FSP-PFP-1121.

10.6.6.2 Drills and Exercises. HNF-PRO-424, *Emergency Preparedness Program*, requires all Hanford Site exercises to be developed and conducted in accordance with DOE orders. All exercise scenarios are reviewed by the Contractor exercise project officer, DOE-RL Emergency Preparedness, facility representatives, Contractor Safety, and Contractor Safeguards and Security. If appropriate, scenarios are also reviewed by the Contractor Environmental Program, Contractor Radiological Engineering, the Hanford Patrol, the HFD, HEHF Industrial Safety, an HEHF medical representative, appropriate site contractor representatives, and PNNL.

The extent, type and frequency of PFP drills are the responsibility of the plant manager, who is responsible for coordinating these drills with affected organizations, including nearby facilities, the HFD, Hanford Patrol, etc.

10.6.6.2.1 Drills. Drills are supervised instruction periods aimed at either training or testing skills in a particular function or operation.

Hanford Site emergency personnel participate in periodic subsystem drills and exercises in addition to an annual exercise. Drills are conducted at the PFP at least annually to maintain proficiency in emergency response for credible emergencies. These drills may include scenarios and response needs for fire, evacuation, sheltering, security, loss of utility, contamination spread, and hazardous material containment.

10.6.6.2.2 Hanford Sitewide Exercises. DOE orders establish guidelines for the planning and conduct of major sitewide emergency exercises. An exercise is conducted annually to test the integrated capabilities, as well as a major portion of the basic elements in the emergency plans and procedures for DOE-RL and the Hanford management and operations contractors. These exercises include offsite participation by counties and states.

10.6.6.2.3 Emergency Drill and Exercise Critiques and Follow-Up. Oral critiques, with all players at each location, are conducted immediately following the exercise. The evaluators of the event note all comments and consider them for input into the formal critique of the event. In addition, all evaluators provide immediate feedback to the participants relative to accomplishment of the exercise objectives.

Evaluators complete the evaluation forms provided in the exercise manual for their area of responsibility. The project officer compiles the evaluations into a final critique after review by the exercise director, exercise committee, evaluators, and action item responders. An exercise closeout meeting is held as needed to resolve any remaining issues pertaining to the final critique. The project officer forwards the final critique, with corrective action plans, to the DOE-RL within six weeks from the date the exercise was conducted. All corrective action items are incorporated into a tracking system.

10.6.7 Recovery and Reentry

Actions to be taken after an emergency situation has been stabilized are specified in DOE-0223, DOE-RL-94-02, and HNF-PRO-424. Actions generally fall into the categories of emergency event termination, reentry, and recovery.

10.6.7.1 Emergency Event Termination. The emergency can be officially terminated and closed out when the event has been stabilized and protective actions have been implemented. Termination and closeout is the responsibility of the highest activated agency, and occurs after all applicable criteria have been met and concurrence between the event contractor and the DOE-RL has been obtained. The applicable criteria for closeout are found on the closeout checklist and include the following:

- The event scene is in a controlled and stable condition
- Release of hazardous material is controlled to less than emergency action levels (i.e., radiation levels, airborne radioactivity, and hazardous materials concentrations are determined to be stable or decreasing, and below alert-level criteria)
- Fire, flooding, or similar emergency conditions are controlled or have ceased

- Damage to facilities and process-related systems and equipment are stabilized or corrected
- Contaminated and injured individuals have been properly treated, or transferred to a hospital or suitable treatment facility
- Security of the affected facilities is controlled.

All relevant onsite entities, as well as the DOE and relevant state, county, and offsite agencies, are notified of an event's termination.

10.6.7.2 Reentry. Reentry is the act of reentering an evacuated area to perform emergency activities, or to assess facility damage to determine if the emergency can be terminated and the recovery activities that are required. Reentry can be performed at any time before termination of the emergency and during recovery activities.

The DOE-RL EOC emergency manager approves reentry to an event area, except when time-urgent actions are required to save a life, minimize injuries, or prevent or minimize damage. When time-urgent actions are required, reentry may be authorized by the event commander or the Emergency Response organization.

Reentry investigations are performed by reentry teams. Objectives and specifications for members of the reentry teams (including at least one RCT or industrial hygienist, depending on the nature of the event) are established. The Site Emergency Director is responsible for ensuring that the event commander (or designee) provides a pre-entry briefing to the reentry teams. Work is conducted in accordance with the process described in Section 10.4.3. Hazardous material work is conducted in accordance with established industrial hygiene requirements. The reentry team is debriefed after exiting.

10.6.7.3 Recovery. A recovery organization is formed to plan and implement the activities necessary to return the affected facility and surrounding areas to normal upon termination of the emergency event. The recovery organization also supports the offsite recovery efforts of federal, state, and local agencies.

The recovery organization is composed of at least two teams; support and onsite recovery. The recovery support team provides oversight for the onsite recovery effort, and provides information and assistance to offsite agencies. The onsite recovery team is responsible for developing and implementing the onsite recovery plan. This team includes engineering, operations, support services, safety, and planning experts. For a nuclear facility emergency, members are assigned to the Washington State Fixed Nuclear Facility Reentry and Recovery Task Force, which is responsible for coordinating offsite recovery in its jurisdictional area.

Upon completion of the initial reentry team assessment and evaluation activities, the Site Emergency Director is responsible for implementing recovery actions in compliance with normal site requirements and procedures. This includes an investigation in accordance with DOE-RL Order 0225.1, *Accident Investigations*.

10.7 DECONTAMINATION AND DECOMMISSIONING

Activities required to accomplish decontamination and decommissioning (D&D) of facilities are described in Section 10.7.1. Previous experience with D&D activities is presented in Section 10.7.2.

10.7.1 Decontamination and Decommissioning Activities

DOE Order 6430.1A *General Design Criteria*, requires that facilities where radioactive materials are used to be designed to simplify ultimate facility decommissioning and disposal or reuse. The D&D activities are an integral part of the overall scope of the management of DOE-owned, contractor-operated facilities.

The disposition of a facility is conducted to meet all applicable laws, DOE orders, codes, and standards. The approach consists of five phases and encompasses all project activities, from post-operational characterization through project final reporting. The five phases include the following.

1. Post-Operational Characterization--thorough chemical, physical, and radiological characterization of the project facilities

2. Environmental Review Process--a series of planning, evaluation, public comment, and decision-making steps required by the National Environmental Policy Act (NEPA); the Resource Conservation and Recovery Act (RCRA); and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)

3. Engineering--preparation of detailed technical, administrative, cost, and schedule information

4. Decommissioning Operations

5. Post-Decommissioning--conduct of final radiation and hazardous chemical surveys, and preparation of project completion records.

The D&D activities are responsive to CERCLA and other environmental requirements and involve the following activities: preliminary assessment, site investigation, remedial investigation, feasibility study, and site remediation.

With the conclusion of the operating mission at the PFP, the facility will be deactivated to meet regulatory requirements and turned over to the Hanford Site Environmental Remediation Contractor for surveillance and maintenance to maintain the facilities in a safe condition until D&D activities are initiated. Plans for both deactivation and D&D will be prepared before any activities are initiated.

10.7.2 Decommissioning Experience

The D&D activities involving both in-plant and onsite plutonium-contaminated facilities have been conducted at the Hanford Site for the past 25 yr.

Such activities have been conducted in the PFP on specific gloveboxes and other areas of the plant as facility missions have changed, and gloveboxes and equipment have been upgraded and/or replaced. In addition to TCO of miscellaneous gloveboxes, ducting, and piping, the 232 Building has undergone TCO and HVAC isolation. Project B-634, "Improved Plutonium Nitrate Handling Facility," involves the D&D of the 242-Z Building. Portions of unused piping and duct work are being removed to reduce radiation levels and to reduce overall risk. Such efforts are managed by Nuclear Material Stabilization Operations. Earlier in-plant experience includes the decommissioning of the rubber glove line, the Recuplex plutonium facility, the Division of Military Applications plutonium fabrication facilities, replacement of hoods 27 and HC-30, portions of the 232-Z Building, and portions of the Radioactive Acid Digestion Test Unit facility.

Onsite D&D experience is also rather extensive and includes the decommissioning of the P-11 plutonium-contaminated Critical Testing Facility, portions of the 231-Z Building, the 233-S Plutonium Concentration Facility, and the 201-C Strontium Semiworks.

10.8 PFP CONDUCT OF OPERATIONS IMPLEMENTATION

Criteria for the development of DOE compliant conduct of operations program at the PFP is provided by DOE Order 5480.19, *Conduct of Operations Requirements for DOE Facilities*. The conduct of operations program at PFP is developed and implemented primarily through the administrative procedures contained in FSP-PFP-0821, *PFP Conduct of Operations*. The program described in this manual meets the requirements of DOE Order 5480.19 and covers the following topics in detail:

- Operations Organization and Administration
- Shift Routines and Operating Practices
- Control Area Activities
- Communications
- Control of On-Shift Training
- Control of Equipment and System Status
- Lockouts and Tagouts
- Independent Verification
- Logkeeping
- Operations Turnover
- Operational Aspects of Facility Chemistry and Unique Processes
- Required Reading
- Timely Orders to Operators
- Operator Aid Postings
- Plutonium Operations Tickle File
- Control of Locked Equipment
- Housekeeping
- Keys, Locks and Combination Control

Specific chapters/sections of other PFP procedures/manuals further implement some of the requirements of DOE Order 5480.19, including the following:

- FSP-PFP-5-8, *Plutonium Finishing Plant Administration*
- FSP-PFP-0848, *PFP Facility Engineering Directives*

- FSP-PFP-0887, *PPSL Required Reading*
- FSP-PFP-1121, *Plutonium Finishing Plant Training Administration*

The specific procedure, chapter, and section that implements each part of the 18 chapters of the DOE Order are defined in the *Conduct of Operations Applicability Summary*, Memo 15000-98-026 dated August 24, 1998 (FDH 1998).

FINAL SAFETY ANALYSIS REPORT

CHAPTER 11.0

OPERATIONAL SAFETY REQUIREMENTS

FEBRUARY 2001

This page intentionally left blank.

PREFACE

In accordance with the letters of approval of the Operational Safety Requirements (OSRs) from DOE-HQ (see Note 1) and DOE-RL (see Note 2), the OSRs presented in WHC-SD-CP-OSR-010, are approved for implementation at the PFP. The requirements contained in WHC-SD-CP- OSR-010 are in compliance with and implemented in accordance with DOE 5480.22.

As with Technical Safety Requirements (TSRs), the OSRs are consistent with: (a) the current plant configuration and mission, and (b) the accident analyses presented in Chapter 9.0.

NOTE 1: DOE-HQ Memorandum, Donald F. Knuth, Acting Deputy Assisstant Secretary for Facility Transition and Technical Support to Manager Richland Operations Office, May 20, 1994. "Approval of Plutonium Finishing Plant Operational Safety Requirements"

Note 2: DOE-RL Letter 94-OPB-54, J. E. Mecca, Director Operations and Transition Division, to President, Westinghouse Hanford Company, May 23, 1994. "Approval of Operational Safety Requirements for the Plutonium Finishing Plant".

12.0 QUALITY ASSURANCE

12.1 POLICY

B&W Hanford Company (BWHC) under a Project Hanford Management Contract (PHMC) operates the Plutonium Finishing Plant (PFP). BWHC's PFP Quality Assurance (QA) organization is committed to excellence in its work and delivering to the customer the highest quality products and services available. BWHC will continue to seek to comprehend and comply with the customer's requirements and expectations, while maintaining cost effective performance of services and activities.

Directors and Managers at PFP take full ownership of the PFP Quality Assurance Program, are responsible for its implementation, ensure quality objectives are established, measured and met, and ensure work is conducted in a disciplined and cost effective manner.

Employees are responsible to achieve quality through thorough analysis, detailed planning and adherence to procedures and work controls. Post-job feedback is used to achieve continuous improvement and high quality in work performance at PFP.

12.2 INTRODUCTION

BWHC subcontract #8023764-9-K002, Clause 55, with the PHMC Prime Contractor requires BWHC to implement the *Project Hanford Quality Assurance Program Description* (QAPD), HNF-MP-599. Nonreactor nuclear facilities such as PFP are subject to the requirements of Title 10, *Code of Federal Regulations*, Part 830.120, *Quality Assurance Requirements* (10CFR830.120). As required by 10CFR830.120, the PHMC prime contractor has an approved Quality Assurance Program Description (QAPD) and submitted to the U. S. Department of Energy (DOE) Richland Operations an implementation plan (IP), HNF-SP-1228 that is subject to enforcement under 10CFR820, *Procedural Rules for DOE Nuclear Activities*. BWHC has developed and promulgated the *Facility Stabilization Project Quality Assurance Program Plan* (QAPP), FSP-MP-004, to describe and implement Quality Assurance requirements for all facility stabilization and advanced reactor projects subject to BWHC control at Hanford. The quality assurance program for PFP satisfies the requirements identified in the *PFP Standard Requirements Identification Document*, HNF-SD-MP-SRID-003, HNF-MP-599, the IP approved for use at Hanford, 10CFR830.120, and the BWHC QAPP, FSP-MP-004. The QAPP for the PFP is tailored to the needs and activities of BWHC at PFP. Since this QAPP is an administrative tool, it is promulgated in the *PFP Administrative Manual*, FSP-PFP-5-8, Section 15.1.

12.3 PROGRAM

The PFP QAPP, FSP-PFP-5-8, Section 15.1, fully describes the responsibilities, functions, requirements, and structure needed to accomplish BWHC's tasks of maintaining a safe facility and stabilizing wastes at PFP. This plan references higher tier documents, such as HNF-MP-599, where needed, rather than restate requirements or information contained therein. In like fashion, this chapter of the PFP facility Final Safety Analysis Report

references the FSP-PFP-5-8, Section 15.1 procedure (QAPP) rather than restate the information contained or referenced therein.

1.0 INTRODUCTION

1.1 PURPOSE AND SCOPE

This addendum to the Plutonium Finishing Plant (PFP) Final Safety Analysis Report (FSAR) (FDH 1999) provides the basis for authorization for testing of the Laboratory Prototype Calciner. Testing of the calciner involves processing of plutonium-bearing solutions to produce a dry plutonium oxide product. This FSAR addendum is necessary to permit processing of reactive plutonium-bearing solutions in the calciner to a stable dry form. Solution processing for testing of the laboratory calciner is not specifically addressed in the current PFP FSAR.

The scope of this addendum includes the operations, equipment and controls necessary for safely converting plutonium-bearing solutions to a stable dry material for long term storage. The addendum covers operations involving loadout of solutions from Glovebox HC-227S, interim storage of solutions, transfer of solutions to Glovebox 188-1, processing of solutions in Glovebox 188-1, and transfer of calcined material from the product receiver vessel to ½ L slip-lid cans inside Glovebox 188-1. Although the addendum discusses sampling and packaging of the calcined product and transfer of the product to storage, these operations are included for completeness and are not specifically covered by this addendum. Information is provided in this addendum on the process chemistry, the equipment and operations used to process the solutions, the potential hazards involved in the operations and the appropriate controls to minimize the hazards. The addendum also defines the appropriate safety classification for the equipment used in the process. It is noted that operation of the calciner equipment occurs essentially as a batch process and, therefore, is of an intermittent nature. The accident analysis provided in this addendum does not consider the intermittent operation of the calciner when evaluating the annual likelihood of the postulated events.

This addendum complies with the requirements for activity based safety basis documents as defined in the criteria document for the 1999 FSAR update (BWHC 1999a).

1.2 BACKGROUND

The end of the "cold war" and resultant reductions in nuclear weapons production requirements left many U.S. Department of Energy (DOE) processing plants with large inventories of plutonium and uranium in various forms which are not suitable for long term storage. In 1995, the DOE issued its plan for dispositioning the excess inventories throughout the DOE complex. The plan included a requirement to stabilize the plutonium nitrate solutions stored at the PFP.

The excess inventory of plutonium at the PFP includes about 4,800 L of solutions from various sources. The solutions are corrosive and container leakage is a potential hazard over long periods of time. The compositions of these solutions vary in plutonium concentration, acid concentration and impurities depending on the source of the solution. These solutions need to be processed to convert the plutonium to a stable, dry form suitable for long-term storage and to

transfer the corrosive solutions resulting from the processing operations to waste tanks for disposal.

In anticipation of the requirements of the DOE plan for disposition of excess inventories, PFP initiated development of a vertical direct denitration calciner process to thermally stabilize the plutonium nitrate solutions at PFP by conversion to plutonium oxide powder. The conversion is accomplished by heating to (1) boil off the liquids, (2) decompose the nitrate anion, leaving only an oxide compound, and (3) improving the hygroscopic properties and particle size of the oxide crystals as they reach appropriately high temperatures. The calciner uses the direct denitration process to avoid introducing additional chemicals into the calciner. To determine the adequacy of the equipment and process design, a prototype calciner was installed in the Plutonium Process Support Laboratory (PPSL) at the PFP. The prototype was used to evaluate the calciner design for safe and reliable use for application to the design of the future production calciner. The prototype calciner unit and the process rates were full scale designs for direct transfer of the test results to the future calciner production process and equipment.

The Laboratory Prototype Calciner began testing with plutonium nitrate solutions in September, 1995. The basic testing performance of the calciner process equipment was generally favorable, resulting in relatively few equipment and process design modifications. The successful prototype calciner test program resulted in the design and initiation of construction of a production calciner. However, prior to initiation of operations using the new production calciner, solution stabilization operations using the Laboratory Prototype Calciner will continue for additional evaluation of the equipment and process design to validate the production calciner design and process parameters. Details of testing for the calciner are contained in the calciner test plan (BWHC 1999b). This addendum provides the authorization basis for testing of the Laboratory Prototype Calciner.

1.3 PLANNED OPERATIONS UNDER THIS FSAR ADDENDUM

This addendum covers plutonium-bearing solution stabilization operations using the Laboratory Prototype Calciner in the PPSL portion of Building 234-5Z at the PFP and related support operations. The principal operations involve load-out, transfer, interim storage, and processing of plutonium nitrate solutions. The operations also involve sampling, seal-out, packaging and transfer to storage of the plutonium oxide product which are included in this addendum for completeness but are not a part of the authorization basis provided by the addendum. A description of the feed solutions to be processed and the process chemistry for solution stabilization are provided in Sections 2.1 and 2.2, respectively. The equipment used in the stabilization operations and a description of the process are provided in Sections 2.3 and 2.4, respectively.

This FSAR addendum primarily covers the solution stabilization equipment and operations performed in Building 234-5Z of the PFP as follows:

- Load-out of plutonium-bearing solutions from Glovebox HC-227S in Room 227.

- Transferring solutions for processing in Glovebox 188-1 in Room 188 of the PPSL or for interim storage in appropriate locations.

- Processing the solutions through the prototype vertical denitration calciner and collecting the dry plutonium oxide product in the product receiver vessel.

- Transfer of material from the product receiver vessel to ½ L slip-lid cans in Glovebox 188-1.

The above activities support the test objectives identified in the calciner test plan (BWHC 1999b). The objectives are specified in the plan are:

- To demonstrate satisfactory direct denitration conversion of plutonium-bearing solutions to stable solids in a vertical calciner and ancillary systems.

- To demonstrate the adequacy of performance of the essential components of a vertical calciner and support systems for direct denitration processing of plutonium-bearing solutions and to determine deficiencies for possible remediation.

In addition, the addendum includes discussion of various activities associated with calciner operations for completeness. However, these activities are not included as a part of this addendum for purposes other than information. These activities include:

- Sampling, testing and bag-out of the product.

- Final canning of the product and transfer to storage.

- Transfer of spent scrub solutions to the waste storage tanks.

Additionally, some activities associated with the performance of solution stabilization operations (e.g., blending and sampling of solutions in Glovebox HC-227S and storage of the plutonium oxide product) are already addressed within the PFP FSAR (FDH 1999) and have been previously authorized. These activities are included, as appropriate, to provide for clarity and completeness.

This page intentionally left blank.

2.0 SYSTEM DESCRIPTION

The PFP currently contains a large quantity of residual plutonium-bearing solutions that remain from prior production operations at the PFP as well as from other Hanford facility operations, e.g., PUREX. These solutions are reactive and are not suitable for long term storage. Therefore, the solutions are to be stabilized by conversion to a dry product which facilitates safe, long-term storage until final disposition of the material is determined. The solution stabilization process using the Laboratory Prototype Calciner and related equipment is designed to safely load-out solutions, transfer solutions, provide interim storage of solutions, if needed, process the solutions to a stable, dry product form, and test, package and transfer the product to storage.

The following sections provide information on the feed materials to be stabilized, the process chemistry involved in the calciner operations, the equipment used in the stabilization process and a description of the process operations. The information in these sections is primarily based on various reports discussing the design and performance of the Laboratory Prototype Calciner (WHC 1996, BWHC 1997, and FDH 1998a).

2.1 PROCESS FEED MATERIALS

The feed material for the Laboratory Prototype Calciner is limited to plutonium nitrate solutions. Other solutions, e.g., concentrated filtrate solutions and flush solutions, are not currently allowed to be processed since they have not been evaluated for hazards or accident potential. The plutonium nitrate solutions are normally limited to 2.5 L in a single 3 L polybottle per transfer container and must have a nitric acid concentration greater than 4 M to limit the hydrogen production rate during transfers and interim storage of the solution prior to processing. This, along with other controls, e.g., vent clips on transfer containers, reduces the potential for a hydrogen deflagration during transfers or upon opening of transfer containers, polyethylene bag-out bags, or the solution polybottles.

The plutonium nitrate solution is limited to a concentration of 450 g-Pu/L of solution. This limit is established for criticality control purposes and to limit the hydrogen generation rate in transfer containers. The isotopic distribution of the plutonium in the feed solution is limited to $< 10\%$ ^{240}Pu content to limit the potential doses resulting from a seismic event. The feed solution is limited to 1% organic content with no visible, separable phase of organic material permitted in the feed solution. This limits the potential for a deflagration due to organic decomposition in the calciner. In addition, feed solution must not contain any significant amount of sodium, potassium, calcium or similar materials which could melt and form plugs of material inside the calciner bed and impact agitation and product removal through the product drop tube.

Solutions not meeting the above requirements are not permitted to be stabilized in the Laboratory Prototype Calciner.

2.2 PROCESS CHEMISTRY

The objective of the plutonium-bearing solution stabilization program using the Laboratory Prototype Calciner process is to convert the plutonium in plutonium nitrate solutions to plutonium oxide. The acidic offgases produced by the conversion process are treated in the scrubber prior to being released to the atmosphere. The process technology is described in the following sections. A flow diagram for the process is shown in Figure 1.

2.2.1 Plutonium Oxidation

The plutonium nitrate, $Pu(NO_3)_4$, in a solution of nitric acid, HNO_3, at a concentration of 4.0 M or greater, is decomposed to plutonium oxide when heated in excess oxygen/air in the calciner, which has been heated to a temperature of 1000 °C. A residence time of approximately 4 hours in the calciner assists in heating the product for a sufficient length of time to obtain the desired product which meets loss-on-ignition (LOI) requirements (BWHC 1998) and produces a product that meets the long-term storage criteria in DOE-STD-3013 (DOE 1996).

The decomposition of the plutonium nitrate to plutonium oxide follows a reaction similar to:

$$Pu(NO_3)_4 + \text{heat} \longrightarrow PuO_2\downarrow + 0.6NO\uparrow + 3.4NO_2\uparrow + 1.6O_2\uparrow$$

The nitric acid in the feed thermally decomposes to water, as steam, and oxides of nitrogen (NO_x). The offgases produced from the reaction are a mixture of the NO_x compounds with nitric acid vapor and steam.

2.2.2 Offgas Treatment

The NO_x compounds, nitric acid vapor and steam discharged from the vertical calciner are drawn through the offgas treatment scrubber using the 26-in.-Hg vacuum system. The offgas scrubber uses a fritted glass disk that disperses the gas into small bubbles in a sodium hydroxide solution. This dispersion increases the reaction area in the scrubber solution and reduces NO_x and nitric acid vapor emissions.

The neutralization of the NO_x compounds and nitric acid vapor follows reactions:

1) $2NO_2 + H_2O \longrightarrow HNO_3 + HNO_2$

2) $HNO_3 + NaOH \longrightarrow NaNO_3 + H_2O$

3) $HNO_2 + NaOH \longrightarrow NaNO_2 + H_2O$

4) $3HNO_2 \longrightarrow HNO_3 + 2NO + H_2O$

5) $2NO + O_2 \longrightarrow 2NO_2$

The NO_x compounds and nitric acid vapor are converted to mostly sodium nitrate, per reaction 2, in the liquid phase. The reaction consumes a portion of the sodium hydroxide (NaOH) and lowers the pH, or sodium hydroxide concentration, as sodium salts of nitrate/nitrite and water are formed.

2.2.3 Offgas Scrubber pH

The reactions shown above consume sodium hydroxide which reduces the pH of the scrubber solution. The hydroxide ion is forced to form water to maintain a chemical balance in the system. Gases and accumulated liquid exit the scrubber and separate in the spent scrub solution tanks (also called phase disengaging tanks). The scrubber tank volume and pH is adjusted by continuously adding fresh 30% sodium hydroxide solution. The sodium hydroxide addition maintains the scrubber at a pH of approximately 14.1 at 1.0 – 1.5 M NaOH. Lower pH values (below 13.5) result in NO_x emissions to the vacuum system lines and, hence, the vacuum pump seal water which causes low pH discharges to the Low Level Waste Treatment Facility in Building 243-Z.

2.3 DESIGN DESCRIPTION

The process of stabilizing plutonium-bearing solutions in the Laboratory Prototype Calciner is accomplished using primarily the following equipment in Building 234-5Z of the PFP:

1. Glovebox HC-227S and solution transfer bottles --- solutions are blended and sampled in this glovebox, located in Room 227 of Building 234-5Z, and are loaded into transfer bottles (polybottles) for transfer to the calciner glovebox.

2. Transfer containers --- these containers are used to safely transport polybottles of solutions between Glovebox HC-227S and Glovebox 188-1 for processing in the calciner.

3. Glovebox 188-1 --- this glovebox, located in the Plutonium Process Support Laboratory (PPSL), contains the vertical denitration calciner and related support systems/equipment required for the stabilization process.

The following sections provide design details for this equipment and for related support systems/equipment. Where appropriate, reference is made to chapters or sections of the PFP FSAR (FDH 1999) where adequate descriptive information already exists rather than duplicating the information.

2.3.1 Glovebox HC-227S and Solution Transfer Bottles

This glovebox is located in Room 227 of Building 234-5Z, as shown in Figure 2, and is used to blend various solutions and to sample the resultant plutonium-bearing solutions to ensure they meet the requirements for stabilization operations in the Prototype Laboratory Calciner. Acceptable solutions are loaded into transfer bottles (polybottles) which are then placed in transfer containers (described in Section 2.3.2) for transport to Glovebox 188-1 in the PPSL.

Glovebox HC-227S is described in Chapter 5 of the PFP FSAR (FDH 1999). A front view of the glovebox is shown in Figure 3. Use of the glovebox for processing and downloading solutions for stabilization in the calciner has not required any change in the design or operation of the glovebox as described in the FSAR.

The solution transfer polybottles are fabricated from polyethylene and have a nominal capacity of 3 L. The fill volume of the bottles is normally limited to 2.5 L so that 2 bottles will fill the calciner feed tank without leaving any excess solution in the bottles. The polybottles have dimensions of approximately 4.6 in. in diameter by 17.75 in. in length. Polybottles are closed with a plastic screw cap having a small vent hole which prevents pressurization and limits the buildup of hydrogen within the bottle. The polybottles are bagged out of Glovebox HC-227S, placed in a second bag and then placed in transfer containers for transport to the PPSL for processing in the calciner. The bags are closed in a manner which prevents pressurization and limits hydrogen buildup.

2.3.2 Transfer Containers

Filled polybottles bagged out from Glovebox HC-227S are placed in either a Product Receiver (PR) can storage container or an Isolated Transport Container (ITC) for transfer to the PPSL. A PR can container is essentially a standard, DOT 17H, 55-gal. drum constructed of 16 gauge stainless steel. A schematic including the PR container (identified as "drum") is shown in Figure 4. A supporting framework, located in the bottom of the container, holds the solution transfer bottle in place during container transport. The container closure consists of a gasket and lid which are held in place by a locking ring. The locking ring is a split ring design which is closed by tightening of a bolt. A vent clip is placed between the lid and body of the PR Container to prevent pressurization and limit the buildup of hydrogen in the container due to radiolysis. The PR Container is mounted on an I-beam skid which is welded to the bottom of the container. The I-beam skid allows a pallet jack to be used to transport the container around the facility.

The second type of container used to transfer bottles of solution is the ITC. The ITC is constructed of plastic with a snap type closure lid which is not designed to seal tightly. This prevents container pressurization and limits the buildup of hydrogen in the container due to radiolysis. The ITC is approximately 12-in. in diameter at the bottom, 16-in. in diameter at the top and 20-in. in height. The ITC is transported around the facility by being hand carried.

2.3.3 Glovebox 188-1 and Process Equipment and Support Systems

This glovebox is located in Room 188 of Building 234-5Z as shown in Figure 5. Also shown on Figure 5 are other rooms related to stabilization operations in Room 188. Room 188 and Glovebox 188-1 contain most of the equipment and systems necessary to support plutonium-bearing solution stabilization operations using the vertical calciner process. Section 2.3.3.1 provides a description of the glovebox and Section 2.3.3.2 provides a description of the process equipment and support systems.

2.3.3.1 Glovebox 188-1

A schematic of Glovebox 188-1 is shown in Figure 6. The glovebox is constructed of stainless steel with numerous viewing windows, glove ports, bag-out ports and sphincter seal ports. The viewing windows are generally wire-reinforced glass except for the large rectangular window in front of the calciner equipment which is a fire-resistant plastic. The glovebox measures approximately 8 ft. in length, 3 ft-8 in. in depth and 6 ft-11 in. in height and rests on a structural framework which provides a base to elevate the glovebox approximately 2 ft off the floor. The glovebox structure and supports are seismically qualified to withstand a 0.2-g seismic event to ensure that it will not topple from the seismic motion. However, the equipment inside the glovebox is not seismically qualified.

The glovebox is divided into an upper and lower section by an intermediate floor approximately 2 ft above the floor of the glovebox. The lower section is termed "the basement" with the intermediate level being "the main floor."

At one end of the glovebox, there are two extensions. The upper extension is open to the main part of the glovebox and is approximately 3 ft wide by 3 ft deep by 2 ft-9 in. high. The floor of the upper extension extends about 3 ft into the main part of the glovebox to provide a partial third level which is identified as "the attic." The lower glovebox extension, identified as "the basement annex", measures approximately 3 ft wide by 3 ft deep by 3 ft high. The intermediate level floor ends at the lower extension section and is open to the extension. The floor level of the main part of the glovebox extends into the lower extension to provide the floor for the extension. A criticality drain is provided in the "basement" of the glovebox to limit the potential for accumulation of water and resultant criticality.

The glovebox is designated as a safety significant item (see Table 6), as are all operational gloveboxes, because of its personnel protection function. The PFP safety equipment list (FDH 1998b) provides the definition of the glovebox safety boundary.

2.3.3.2 Process Equipment and Support Systems

A process flow diagram for the Laboratory Prototype Calciner and a simplified piping and instrumentation diagram are shown in Figures 1 and 7, respectively. The principal items of equipment required for the calciner process are:

- Feed Tank and Feed Pump

- Calciner
- Caustic Scrubber
- Spent Scrub Solution Tanks
- Vacuum Trap.

Systems required to support operation of the calciner equipment consist of the following:

- Process air system
- 26-in.-Hg vacuum system
- Caustic supply system
- Chilled water system
- Fire protection system
- Electrical power
- Emergency shutdown systems
- Ventilation systems
- Radiation protection.

The equipment and systems listed above are described in the following sections. Instrumentation and controls required for operation of the calciner process equipment and support systems are discussed together with the related equipment or system.

2.3.3.2.1 Feed Tank and Feed Pump. The feed tank provides a reservoir for the plutonium-bearing solutions to be processed through the calciner. Feed solution is poured from polybottles into the top of the tank after removal of the tank closure lid. The feed tank is constructed of glass and is approximately 6-in. in diameter by 12-in. in length. The tank volume is 5.2 L with an operating capacity of 5 L. The tank is supported by metal legs attached to the bottom flange of the tank and bolted to the glovebox intermediate level floor. The feed line from the tank is ¼-in. Teflon™ tubing and contains an isolation valve to provide positive feed shutoff.

The feed pump draws solution from the feed tank and pumps it through ¼-in Teflon™ tubing to the liquid feed injector on the calciner. The feed pump is a diaphragm-operated metering pump that injects feed to the calciner in discrete pulses. There are two control knobs on the pump for controlling both frequency and volume of the pulses. The maximum flowrate for the pump is approximately 15 L/hr with the normal flowrate set at about 4 L/hr. The maximum pressure is about 100 psi with the normal operating pressure about 60 psi.

2.3.3.2.2 Calciner. The calciner receives plutonium nitrate feed solution and converts it to plutonium oxide through the application of heat. A cross-sectional view of the calciner showing the major components is contained in Figure 8. The main components of the calciner are constructed of 310 stainless steel. The body of the calciner is schedule 10 pipe and consists of two sections: the lower section is the calciner chamber; the upper section is the filter chamber. The overall calciner is approximately 6-in. in diameter by 21-in. in length. The calciner chamber is approximately 9-in. long and the filter chamber is about 12-in. in length. The calciner is supported by steel legs which are connected to the ½-in. thick lower flange assembly and bolted to the glovebox intermediate floor.

The calciner chamber is constructed with a dome extending into the chamber from the base into which a heater is inserted. Thermowell assemblies are provided in the baseplate and dome to monitor and control calciner temperatures. A schematic of the dome and baseplate assembly is shown in Figure 9. Feed solution is injected along with process air from the bottom into a bed of plutonium oxide which is maintained in the annulus formed between the dome and outer wall of the calciner chamber. A motor-driven agitator continually stirs the material bed in the annulus and, as the bed increases in height due to addition of feed solution, plutonium oxide powder from the top of the bed falls through the product drop tube into a collection vessel. The product drop tube fits into a cutout formed in the dome. The outside of the calciner chamber is heated by a series of tubular heaters mounted to the inside of thermal insulation. The insulation/heater assembly is supported by the lower ½ in. thick flange base assembly of the calciner chamber.

The filter chamber contains three filters which prevent the plutonium oxide powder in the calciner chamber from being carried along with the off-gases to the scrubber tank. The filter chamber is not heated but is insulated. The agitator shaft enters the calciner through the top plate of the filter chamber which also contains the connections for the off-gas vacuum lines, back-pulse air for cleaning the filters, and a vacuum sensor. The top plate also contains the calciner pressure relief device.

The main components of the calciner are as follows:

- Liquid feed injector
- Product drop tube and receiver vessel
- Agitator
- Off-gas filters
- Heaters
- Insulation

Liquid Feed Injector – The liquid feed injector is fabricated from 310 stainless steel and consists of a ¼-in. liquid feed tube concentrically housed inside a ½-in. air supply line. A schematic of the injector is shown in Figure 10. The feed solution and air are injected at the bottom of the calciner into a hot bed of approximately 4 kg (approximately 1 L) of plutonium oxide powder. The plutonium nitrate feed solution is converted into plutonium oxide and gradually dries and rises to the top of the bed before being expelled out of the product drop tube. This ensures that the plutonium oxide has sufficient residence time in the calciner to pass the loss-on-ignition test performed on the product. The agitator continually stirs the plutonium oxide bed over the injection port to ensure that the incoming solution reacts with hot material and that a hole does not develop in the bed which would allow the solution to flush directly into the calciner. This would result in inadequate residence time in the calciner since the plutonium oxide product would then end up on top of the bed and be quickly swept out of the product tube. The combination of pressurized feed solution injection, air injection and agitator rotation, all occurring through the plutonium oxide bed in the base of the calciner, results in generation of a significant amount of plutonium oxide dust in the calciner airspace.

The air supply around the feed tube serves to insulate the liquid feed from the hot baseplate as well as to provide some cooling. This prevents the feed solution from boiling inside the feed tube which could lead to excessive corrosion or possibly precipitative blockage of the feed tube. The feed line system is fitted with an air nozzle at the calciner baseplate surface. The injection nozzle is engineered so that air delivery rates above 1 cfm will produce supersonic air velocity at the plate surface. This breaks the feed liquid into a fine mist, which is carried by the air up into the material bed. This atomization prevents the feed solution from pooling and potentially corroding the baseplate. The feed tube has been designed to be replaceable. However, the air injector nozzle is not readily replaceable.

Air is normally supplied at a rate of 40 scfh at approximately 65 psi and the liquid feed is supplied at a rate of 1 ml/sec at a pressure of 60 psi. Upon loss of air pressure, there is a potential for liquid to be forced by the feed pump back up the air line and into the process air system. Therefore, an interlock is installed to shut down the feed pump and to prevent startup of the pump when the air pressure is below about 60 psi. In addition, a check valve in the air supply line prevents solution from backing up into the air line should the feed port in the calciner base become plugged.

The feed port location is such that the agitator blades wipe directly across the orifice roughly 4 times per second. This is designed to continually bring new material in contact with the feed solution. It also helps prevent tube blockage, scale buildup, and pooling of solution.

During normal operation, positive liquid feed flow prevents powder from the material bed from being packed down the tube by the action of the agitator. A cleanout rod has been provided should the feed tube become plugged. It is designed to fit flush with the top of the calciner baseplate to prevent powder from being packed down the tube by action of the agitator when the feed pump is not running.

Compression fittings are used throughout the system to connect the feed tube, feed supply line, cleanout rod and air supply line.

Product Drop Tube and Receiver Vessel – The overflow collection port is a slot cut out of one side of the dome in the bottom of the calciner chamber. The slot contains a chamber which holds a 1-in. stainless steel product drop tube that is inset into the dome to permit excess bed material to drop into a collection vessel. The tube is calibrated and is adjusted vertically through a compression fitting with a Teflon ferrule to set the depth of the plutonium oxide bed in the calciner chamber. The drop tube extends well below the base of the calciner and is adjusted externally during calciner operation. The base of the drop tube is connected to a ball valve mounted on the top plate of the product receiver vessel. This valve allows material collection to be suspended while the receiver vessel is replaced. The receiver vessel is constructed of heat-resistant glass which allows visual observation that product is falling from the calciner and of the level of product within the vessel. The receiver vessel has a nominal operating volume of 500 ml with a maximum capacity of 850 ml. The vessel is approximately 6 in. in height by 3.5 in. in diameter with a wall thickness of about 3/16 in. and a rounded bottom. A tray is located beneath the receiver vessel to collect any material that may spill from the tube or vessel.

The receiver vessel is periodically removed from the drop tube assembly and emptied into a 1 lb, stainless steel, lead-lined, slip-lid can for bag-out from the glovebox. The slip-lid can has a nominal capacity of 0.5 L and a maximum capacity of 0.55 L. There is a limit of approximately 1000 g of plutonium oxide in the slip-lid can due to a 3 W heat loading limit for the PVC plastic bags used for bag-out.

Agitator – The agitator is designed to provide continual mixing of the bed material in the calciner and to drive processed plutonium oxide powder to the product drop tube. A schematic of the agitator is shown in Figure 11. The rotation of the agitator continuously moves hot bed material over the feed injection port to vaporize the incoming feed. The rate of rotation can be varied between 0 and 120 rpm and is set at a nominal rate of 60 rpm. Adjustment of the rotation rate is accomplished using a stop watch and varying the speed of the drive motor.

The agitator assembly consists of a drive motor, drive shaft, pipe cap and four agitator blades. The drive motor is a ¼ hp, variable speed, dc electric motor which is torque-limited to 50 in.-lb to prevent damage to the agitator or vessel should the assembly jam. The drive motor transfers power to the agitator through a chain and sprocket assembly with a one-to-one gear ratio. The drive gear is linked to the agitator shaft with a slide coupling. The assembly is enclosed in a guard housing. The chain drive prevents heat from being conducted from the agitator shaft to the motor and permits the motor to be located away from the area of high convective heat flow from the calciner. A thermocouple is used to monitor the temperature of the motor.

The agitator shaft is constructed of 1-in.-diameter 310 stainless steel. A 5-in.-diameter pipe cap is welded to the lower end of the shaft with a conical cap welded on top of the pipe cap to reinforce the shaft-to-pipe-cap connection. The agitator blades consist of ¼-in. plate welded to the pipe cap. The agitator blades continuously rotate through the bed material.

The top plate of the calciner is a 1-in. thick, stainless steel plate which contains various fittings for operation of the calciner and a sleeve to hold the graphite shaft alignment bushing for the agitator. The primary function of the bushing and sleeve is to align and center the agitator shaft. It also supports the weight of the agitator assembly, serves as a gas seal to preserve the vacuum in the calciner and acts as a thrust bearing. A second graphite shaft bearing is located in the lower portion of the filter plate which is below the calciner top plate. This bearing distributes the forces exerted by the agitator over a wider area.

Off-gas Filters – There are three off-gas filters in the filter chamber of the calciner which are supported by a 2-in. thick stainless steel filter plate near the top of the calciner. The filter plate has been machined to mate with the filter seals. The 1-in. thick top plate of the calciner maintains compression on a flexitallic gasket on top of the filters and provides the connections for the vacuum lines to draw off the gases from calciner operation. The top plate also contains the filter blow-back assembly which periodically cleans the filters.

The off-gases from the calciner process must be removed without allowing plutonium oxide powder to escape. To accomplish this, calciner offgases are drawn off under vacuum through a set of 1 micron, high-temperature, sintered, silicon carbide particle filters. These

filters ensure a high efficiency of radionuclide separation from the waste gases, while minimizing contamination of the gaseous and liquid effluents.

The filter chamber section of the calciner is designed principally to house the offgas filters. The height of the filter section was determined by the length of filters required to handle full flow with 25 % additional capacity. The three ceramic filters together have a capacity of about 20 cfm. The filter chamber is equipped with a pressure relief weight designed to lift at a pressure of approximately 2 psi. Should the filters become plugged and a positive pressure buildup in the calciner, the pressure relief weight would lift and allow the off-gases to escape into the glovebox. The gases would then be swept out with the glovebox E-4 ventilation system flow. Breakage of a filter would allow plutonium oxide particulate to be carried out of the calciner and to the scrubber. This would be noticeable by a dramatic change of color in the solution in the scrubber. Either of these conditions, plugged or broken filters, would be noticed by a change in the differential pressure gauge between the calciner and the filter vacuum line or by a change in the vacuum gauge on the calciner. Similarly, should the liquid feed rate overwhelm the filter/vacuum system, the gauges would indicate a change in the operating conditions.

With the high gas flow, moist air, and large amounts of lofted powder, it is crucial to provide a means of clearing the filters while the calciner is in operation. Compressed air is blown back through the filter elements to remove accumulated plutonium oxide powder on the element surface. The filter blowback system sends a pulse of compressed air sequentially to each filter. The pulse is directed through a venturi port, causing a small shock wave to dislodge any accumulated material from the filter surface. The blowbacks are controlled by a 2-stage electronic timing system in the instrument panel. The blowbacks are not uniformly timed and are not always in the same pattern but occur approximately once every 1-2 minutes in each filter.

Heaters – Heat is supplied to the calciner from two heater units, each with its own power supply. The first is a single 1100 W canister heater located inside the dome of the calciner chamber. The second is a 6000 W set of 14 separate tubular heater elements around the outside of the calciner chamber. All heaters are internal resistance heaters that radiate heat to the calciner walls. The outside elements are mounted through the two half sections of insulation surrounding the chamber. One element may be non-functional in each half section of insulation. However, replacement is required when either half has two or more non-functional elements.

Power for the heater units is supplied from phase-angle controlled, silicon-controlled rectifier (SCR) current sources. The power supplies are operated from a programmable temperature controller. The temperature controller monitors the temperature on the outside of the calciner at a point near the center of the jacket heating elements. At full temperature, the heating elements are designed to operate about 250 °C above the temperature of the vessel wall; this is the temperature drop across the air space between the furnace and the vessel.

During startup, the temperature controller varies the amount of current the power sources supply to the furnaces to maintain a set ramp-up rate, typically between 5 °C and 10 °C per minute, to prevent excessive thermal stress on the calciner. Once at full operating temperature, the controller modulates the power to maintain its setpoint temperature. The controller also

provides a programmable interlock to the solution feed pump to prevent the feed pump from operating whenever the calciner vessel temperature is below 700 °C. This prevents flooding of the calciner with liquid feed and subsequent paste formation in the powder bed due to the introduction of liquid at low temperatures.

To preclude excessively high calciner temperatures, an interlock is provided by a programmable temperature alarm relay which receives input from a thermocouple probe. This probe senses temperature on the calciner vessel wall and automatically shuts off power to the heaters and provides a local over-temperature alarm should the vessel temperature exceed 1100 °C.

Insulation – The calciner assembly and offgas tubing are thoroughly insulated to ensure efficient operation of the calcination process and to prevent overheating of the glovebox. The calciner chamber is insulated with a 4-in. thick layer of high-efficiency sintered glass fibers. The insulation is made in two blocks that are banded together at assembly. This insulation restricts heat flow very well, but is very absorbent and must be kept dry for criticality prevention. The calciner chamber heaters are attached to the inside of each half of insulation with the individual heater ends protruding through the insulation. The filter chamber is insulated by a multi-layered stainless steel foil "mirror" insulation jacket. The jacket is a series of 17 reflective concentric sheets of metal each separated by 1/8 inch of air. The chambers formed by the concentric sheets are not sealed but have openings small enough at the top and large enough at the bottom to prevent liquid accumulation inside. The filter chamber insulation is made in two halves that hinge together.

2.3.3.2.3 Caustic Scrubber. A schematic of the caustic scrubber is shown in Figure 12. The scrubber receives off-gases from the calciner, cools and condenses the vapors, neutralizes the acidic offgases, and reacts NO_x vapors to form soluble salts. Sodium hydroxide solution is used to neutralize the acids and react the NO_x vapors.

The primary components of the scrubber are fabricated from heat-resistant glass and stainless steel. The glass scrubber tank is approximately 6-in. in diameter by 44-in. in height. The total capacity of the scrubber is approximately 21 L with an operational volume of about 16 L of caustic solution. The scrubber tank is provided with stainless steel top and bottom flanges and a stainless steel service ring with connections for filler and caustic solution. The scrubber is supported on legs mounted on the lower flange and bolted to the glovebox intermediate floor.

The offgas from the calciner is brought to the scrubber under vacuum through an insulated ¾-in. stainless-steel pipe. The offgas is brought into the scrubber through a 1-in. glass inlet tube which extends from the top of the scrubber to the base of the internal cooling coil where the gases enter a quartz gas dispersion chamber. At the top of the gas dispersion chamber is a fritted glass diffuser disk designed to disperse the offgas into small bubbles. This facilitates efficient conduction of the heat from the offgas and neutralization of the acids.

The hot offgas from the calciner heats the caustic solution in the scrubber. To efficiently cool, condense, and react the offgas, the caustic solution in the scrubber is cooled by an internal

heat exchanger that consists of a cooling coil made of ½-in. stainless steel tubing. The cooling coil is suspended down the center of the scrubber and the coils are closely spaced to form a long cylinder within the scrubber. Cooling water in the coil recirculates through a chiller located in Room 187 to provide the necessary cooling for the scrubber. The offgas inlet tube runs down the center of the cooling coil. The tightly stacked cooling coils provide a chimney effect where the incoming gas bubbles rise to create a current that circulates around the coils in the caustic solution. Once the bubbles reach the top, the gas, along with any excess liquid is drawn down the exhaust tube.

The proper concentration of the caustic solution is maintained by continuous pumping of caustic solution from the caustic supply drum located external to the process glovebox. The makeup caustic solution has a concentration of approximately 30% NaOH.

2.3.3.2.4 Spent Scrub Solution Tanks. There are two identical spent scrub solution tanks (also termed phase disengaging tanks) in the calciner process which receive the offgas and excess liquid from the caustic scrubber. A schematic of a spent scrub solution tank is shown in Figure 13. The units separate the calciner offgas from liquids which are comprised of condensed vapor and the caustic makeup solution injected into the scrubber. Only one of the two tanks is used at a time.

The spent scrub solution tanks are each fabricated from a 48-in. long piece of 6-in.-diameter, heat-resistant glass pipe and have PVC end flanges, neoprene gaskets, and stainless steel fittings and tubing. They are mounted horizontally in the basement section of the glovebox. Liquid and gas come from the scrubber to the tanks through ¾-in. stainless steel tubing and valves. The total capacity of each tank is approximately 22 L with an operating capacity of 19-L. The large volume allows for the liquids to settle calmly at the tank bottom while the gas exits continuously at the top of the tank. The gas then passes through a vacuum trap to ensure that there are no entrained liquids entering the process vacuum system.

When full, the active tank is valved out and the standby tank is valved in. A liquid sample is taken from the filled tank to check for radiological materials and caustic concentration. A sample valve is provided on the tank along with a vent line and valve to permit sampling and draining of the solutions in the tank. Once the liquid in the tank is verified to meet release criteria and appropriate approvals obtained, it is discharged to Building 241-Z, Tank D-8, for disposal.

2.3.3.2.5 Vacuum Trap. The offgas from the spent scrub solution tanks flows to a vacuum trap before entering the 26-in.-Hg vacuum system in the plant. The trap ensures that liquids do not enter the plant vacuum system. Liquids in the vacuum trap drain back to the spent scrub solution tanks. If a significant amount of liquid enters the trap, a polyethylene float will rise to plug the flow and shut off the vacuum. This would stop the vacuum source to the calciner offgas system and result in pressurization of the calciner which would be vented through the relief weight device to the glovebox.

The vacuum trap is fabricated from stainless steel plate, perforated plate, and a 6-in.-long piece of 3-in.-diameter, heat-resistant, glass pipe. The glass pipe contains the float which shuts

off the vacuum. The glass pipe has steel plates on each end which contain the inlet and outlet connections.

2.3.3.2.6 Process Air System. The plant process air system supplies air at approximately 65 psig for use by the calciner process. The plant air system is described in Chapters 5 and 6 of the PFP FSAR (FDH 1999). Process air from the plant air system is used in the calciner process to provide cooling air to the feed injector nozzle and to assist in aerosolizing the feed solution from the injector. The air system also provides the back pulse air required to clean the calciner off-gas filters.

A rotameter is located on the air line to the feed injector to indicate air flowrate. The rotameter contains an integral needle valve to allow adjustment of the air supply to ensure that an adequate vacuum is maintained in the calciner. When the needle valve is fully open, the air supply rate is approximately 40 scfh which is the normal setpoint. Too much air could overwhelm the calciner vacuum system and pressurize the calciner which would release material out of the relief cap into the glovebox. A solenoid valve is located upstream of the rotameter which is used to isolate the air supply to the feed nozzle. During process startup, the valve is energized to open (fails closed) to supply air to the nozzle. The valve is interlocked with both the manual and seismic shutdown systems to close when the switches are actuated. Closure of the valve prevents potential pressurization of the calciner, due to air flow from the accumulator tank in the filter back-pulse air line, during a seismic event and release of significant airborne material. This valve is not seismically qualified. A check valve is provided in the air line near the feed injector to ensure that feed solution does not enter the air system should the air pressure drop below the feed pressure which is approximately 60 psig.

A manual isolation valve is located on the air supply line outside of the glovebox to shut down the air supply when the calciner process is not operating. In addition, two solenoid valves are located on the air supply line outside of the glovebox which automatically isolate the supply line during a seismic event. The valves are seismically qualified and the calciner manual shutdown system and the PFP ventilation seismic shutdown system automatically deenergize the solenoids, resulting in closure of the valves. This prevents the compressed air from potentially pressurizing the calciner and releasing significant quantities of airborne material.

An air filter-trap assembly is located on the air line outside of the glovebox to remove oil which may be in the supplied air. Oil in the air to the calciner could react in the calciner and result in an overpressure condition. The filter-trap assembly is equipped with a drain line and valve which is maintained open to continuously drain any accumulated oil to a collection vessel.

A pressure sensor is located on the air supply line outside of the glovebox to monitor the supply pressure. The sensor is interlocked with the solution feed pump to prevent operation of the pump if the air pressure is less than 60 psig.

Filter back-pulse air is provided by the plant air system through an accumulator tank. The tank supplies air to three solenoid valves providing air to the three off-gas filters. A controller periodically energizes each of the solenoids to open the valves, one at a time, to provide a short burst of air to clean the off-gas filters. The valves are not opened in any

particular sequence but each is opened once every 1 to 2 minutes. A solenoid valve is located downstream of the accumulator tank which is used to isolate the air supply to the off-gas filters. During process startup, the valve is energized to open (fails closed) to supply air to the three solenoid valves providing back-pulse air to the off-gas filters. The solenoid isolation valve and the three sequencing solenoid valves are interlocked with both the manual and seismic shutdown systems to close when the switches are actuated. The valves are closed during a seismic event to prevent injecting air into the calciner. Air injected into the calciner could potentially result in a pressurization and release of airborne material. Closure of these valves is required, even though the two solenoid valves on the incoming process air line are also closed, since the accumulator contains a reservoir of air which could continue to pressurize the calciner even after the incoming air line is isolated. These valves are not seismically qualified.

Two check valves, in series, are located on the inlet line to the accumulator tank for the offgas filter back-pulse air supply. The valves, together with the solenoid valve on the air supply line to the feed nozzle, prevent backflow of air from the accumulator to the feed nozzle which could pressurize the calciner and release airborne material during a seismic event. The check valves are not seismically qualified.

2.3.3.2.7 26-in.-Hg Vacuum System. The plant 26-in.-Hg vacuum system provides the vacuum requirements for the calciner process. The plant has several vacuum systems which are described in detail in the PFP FSAR (FDH 1999). The 26-in.-Hg vacuum system is connected to the vacuum trap which in turn is connected to the calciner process equipment. The vacuum trap prevents liquids from the calciner process from entering the vacuum lines.

A vacuum controller, located outside the glovebox, adjusts the vacuum level according to a control signal received from the calciner vessel. The controller is set to maintain a vacuum in the calciner of approximately 8-in.-Hg. A solenoid valve, located in the vacuum control line from the calciner, closes each time the solenoid valves on the filter back-pulse lines open to prevent significant contamination from being drawn into the control line. Vacuum gauges are provided on both the calciner vessel and the vacuum trap inlet to monitor performance of the system.

2.3.3.2.8 Caustic Supply System. The caustic supply system supplies makeup solution to the off-gas scrubber to maintain the proper concentration of caustic. The main components of the system are a caustic supply drum, caustic pump and a check valve.

The caustic supply drum is a 55 gal. plastic drum which contains 30% NaOH solution. The caustic pump draws solution from the drum and pumps it through metal tubing to the scrubber tank at a constant rate. The pump is a diaphragm-operated metering pump essentially the same as the solution feed pump to the calciner. It has an adjustable capacity between 0 and 15 L/hr at a maximum pressure of approximately 100 psig. The pump injects the caustic solution into the scrubber in discrete pulses. The frequency and volume of the pulses are both adjustable.

The caustic supply line is draped with plastic for personnel protection should the line develop a leak. A check valve is installed in the supply line to prevent backflow of contaminated

solution from the scrubber to the caustic drum or to the room through a leak. A manual isolation valve is also located on the caustic supply line.

2.3.3.2.9 Chilled Water System. The chilled water system provides cooling water to the cooling coil in the scrubbers. The cooling water maintains the temperature of the scrubber solution at levels which ensure condensation of the water vapor in the offgas and proper reaction of the calciner off-gases.

The cooling water is supplied from a commercial chiller unit in Room 187 which is adjacent to the calciner room. The water capacity of the system is approximately 5 gal. The circulating water pump is an integral part of the chiller unit. All major components required to supply the chilled water are located in the chiller unit. The chilled water is supplied to the scrubber through ½ in. stainless steel tubing. Isolation valves for the cooling water supply and return lines are located external to the calciner glovebox.

2.3.3.2.10 Fire Protection System. The fire protection system for Room 188 of the PPSL consists of sprinkler system which is described in the PFP FSAR (FDH 1999) and has not been altered by the installation of the Laboratory Prototype Calciner. There is no automatic or manually actuated fire protection system for the glovebox containing the calciner equipment. A temperature sensor is provided in the glovebox which actuates a high temperature warning light on the process control panel if the temperature exceeds 50 °C. A dry chemical fire extinguisher is available for fire protection. The extinguisher is equipped with a bayonet for ease of puncturing glovebox gloves in the event of a glovebox fire.

2.3.3.2.11 Electrical Power. The plant electrical power system, described in the PFP FSAR (FDH 1999), provides power at the required voltage and current for operation of the calciner electrical equipment. There are no special requirements for calciner operation other than the silicon-controlled rectifiers and related controllers for the calciner heaters. There are two emergency shutdown systems associated with electrically operated equipment in the calciner system which are described in the next section.

2.3.3.2.12 Emergency Shutdown Systems. There are two emergency shutdown systems for equipment in the calciner process. These systems are in addition to the interlocks and controls provided for individual calciner equipment which are discussed in previous sections along with the applicable equipment.

Manual Shutdown System: One emergency shutdown system is manually actuated at the calciner process control panel. It is used to quickly shut down the process equipment when an operational upset has occurred. Actuation of the manual shutdown switch automatically cuts off electrical power to the calciner heaters, agitator, filter back-pulse air solenoid valves, feed pump and the caustic pump.

Seismic Shutdown System: The second emergency shutdown system is automatically actuated by interconnection with the existing plant ventilation seismic shutdown system which is described in the PFP FSAR (FDH 1999). This is intended to terminate the calciner process to prevent the potential generation of significant quantities of airborne plutonium oxide due to

pressurization of the calciner from seismically initiated equipment failure. The system automatically deenergizes the following components:

- calciner heaters including dome heater
- process air supply solenoids to close valves A thru G shown in Figure 7
- agitator motor
- feed pump motor

Figure 15 shows the control logic for the calciner interconnection with the PFP ventilation seismic shutdown system. The figure also identifies the safety class electrical components of the control system. Figure 16 shows the safety class valves associated with the calciner air supply shutdown portion of the seismic shutdown system. The electrical components shown in Figure 15 and the solenoid operated valves shown in Figure 16 are the only safety class components associated with the seismic shutdown for the Laboratory Prototype Calciner.

In addition to the equipment deenergized by the seismic shutdown system, two check valves, valves H and I on Figure 7, are provided in the inlet line to the accumulator for the offgas filter back-pulse air supply. These valves prevent backflow of air from the accumulator to the calciner feed nozzle after the seismic shutdown system has terminated calciner operations. The check valves are redundant to the solenoid isolation valve, valve C on Figure 7, on the air supply line to the feed nozzle.

2.3.3.2.13 Ventilation Systems. The Building 234-5Z ventilation supply system provides air to Room 188. The E-3 Exhaust System draws air from the room through HEPA filters and exhausts it to the atmosphere through the 291-Z-1 Stack. The E-4 Exhaust System draws air from Room 188 into Glovebox 188-1 through glovebox inlet HEPA filters. The air passes through the glovebox and exits through a non-testable HEPA filter into the E-4 system. The air then passes through additional HEPA filters and is exhausted through the 291-Z-1 Stack.

The ventilation supply and exhaust systems for Building 234-5Z maintain the calciner room at a negative pressure relative to the nonradiological areas of the building. The glovebox is maintained at a negative pressure relative to the room which is indicated by a differential pressure gauge. The relative pressure differentials ensure that air flows from clean areas to progressively more contaminated areas. The ventilation supply system and the E-3 and E-4 exhaust systems are described in detail in the PFP FSAR (FDH 1999).

2.3.3.2.14 Radiation Protection. Radiation protection for personnel involved in calciner operations primarily consists of personal dosimetry, a fixed head air sampler and a continuous airborne radiation monitor (CAM) in Room 188. Personal dosimetry, the air sampler and the CAM are as described in the PFP FSAR (FDH 1999) and require no special provisions due to operation of the calciner.

2.4 PROCESS DESCRIPTION

The process for stabilization of plutonium-bearing (plutonium nitrate) solutions, using the Laboratory Prototype Calciner consists of two principal operations:

- Solution transfer to Room 188.
- Solution processing in Glovebox 188-1.

These operations are discussed in the following sections. In addition, product sampling, testing, packaging and transfer to storage are discussed for completeness.

2.4.1 Solution Transfer to Room 188

Solutions to be processed in the laboratory calciner primarily originate from two areas as follows:

- Solutions transferred from Glovebox HC-227S in Room 227.
- Solutions transferred from the PR container storage area, Room 236.

2.4.1.1 Solutions Transferred from Glovebox HC-227S in Room 227

The tanks in Glovebox HC-227S contain solutions to be stabilized in the Laboratory Prototype Calciner. The solutions are blended and sampled to ensure they meet the requirements for processing identified in Section 2.1. Acceptable solutions are loaded into 3 L polybottles which are normally filled to a maximum of 2.5 L so that two bottles can be completely emptied into the calciner feed tank. To prevent pressurization and limit the buildup of hydrogen in the polybottle, a vent hole is provided in the closure cap.

The polybottles are bagged out of the glovebox in a plastic bag, either polyvinylchloride or polyethylene, which is then closed with a "horsetail." A "horsetail" closure is accomplished by twisting the end of the bag and placing tape around the twisted section to maintain closure. The taped section is then cut to separate the bagged item from the bag-out port. The exposed end of the twisted section is then taped. This closure method is intended to prevent pressurization of the bag due to radiolytic generation of gases. The bag and contained bottle is then placed in a second plastic bag which is also "horse-tailed" for closure. The "horse-tailed" end of the second bag is usually folded in half and taped again. The bag-out bag and the overpack bag may be heat sealed on one end and "horse-tailed" on the other end or they may be "horse-tailed" on both ends.

The plastic-bag-enclosed polybottles may be placed in either of two different containers, an Isolated Transport Container (ITC) or a PR container, for transfer from Room 227. In the case of the ITC, bagged polybottles are simply placed in the ITC and the lid snapped in place. The lid is loose fitting and does not require any special provisions to prevent pressurization or

hydrogen buildup due to radiolysis. The bagged bottle leans against the side of the ITC since it is too long to completely lay on its side. Once placed in the ITC, it is hand carried to Room 188 in the PPSL for processing the solution through the calciner in Glovebox 188-1. Alternatively, it may be taken to Room 179 of the PPSL for temporary storage in Gloveboxes 10 or 12. Respiratory protection is not required during transfer of solutions in ITCs or for receipt of solutions in either Room 179 or 188. Temporary storage in Gloveboxes 10 or 12 consists of bagging in the bagged polybottles or loading them in through an airlock. Respiratory protection is required during bag-in and bag-out operations. Once inside the glovebox, the plastic bags around the polybottles are removed and disposed of. When the calciner operations personnel are ready to process the solutions, the polybottles are again bagged-out of one of the gloveboxes in Room 179, overpacked in a second bag and transferred to Room 188. The transfer may be done by hand carrying the bagged bottles or by again placing them in an ITC. It is noted that there is no temporary storage pad in either Room 179 or Room 188 for the ITC. Therefore, the polybottles must be loaded into the gloveboxes from the ITCs without any interim storage.

When a PR container (see Figure 4) is used for solution transfers, the bagged polybottle is placed in a positioning rack inside the container. The rack keeps the bottle upright during container movement or storage. A vent clip and gasket are placed on the container rim and the lid is placed on the container. The lid is secured by a bolted lock ring. A pallet jack is then used to transport the container to Room 236, the PR Container Storage Area, for interim storage. Although not the normal mode of operation, a PR container may occasionally be transferred by pallet jack directly from Room 227 to the hallway outside of Room 188 with the subsequent operations as described in Section 2.4.1.2.

2.4.1.2 Solutions Transferred from the PR Container Storage Area, Room 236

When the solutions in Room 236 are to be processed in the calciner, the container is retrieved from the room in accordance with appropriate transfer documentation. Since Room 236 may contain hundreds of drums, it is important that the correct container be identified since some drums are unvented and could pose a hazard when opened due to pressurization or the presence of hydrogen. Only vented drums are permitted to be transported to Room 188. When the correct container has been identified, it is transported using a pallet jack to the hallway outside of Room 188. The container is then slid across the floor of Room 188 to a position near the glovebox where it is opened and unloaded. Care is taken when sliding the container across the floor so as not to disturb fixed contamination that exists on the floor. Workers use respiratory protection while moving the container into Room 188 and during subsequent opening and unloading. There is no limit on the number of containers that may be brought into Room 188 but space in the room essentially limits the number of containers to three.

2.4.2 Solution Processing in Room 188, Glovebox 188-1

As mentioned in Section 2.4.1, solutions may be received in ITCs or in PR containers. Prior to opening the ITCs or PR containers, they are moved into Room 188. This is typically done when laboratory personnel enter the room to initiate startup of the calciner process. Since respiratory protection is required for opening the ITCs or PR containers and loading the solutions

into the glovebox, it is also worn when the ITCs or PR containers are moved into the room. This conserves time between the movement of the ITCs and PR containers and subsequent opening. However, respiratory protection is not required just for the movement of the ITCs or PR containers. The respiratory protection also provides protection for personnel from the very unlikely event of airborne contamination caused by sliding PR containers across the floor which has fixed contamination.

When receiving material, appropriate documentation is examined to ensure that the proper material is being received. In addition, in the case of PR containers, the presence of a vent clip is verified to ensure that the container is not pressurized and that there is no potential for flammable quantities of hydrogen in the container. Even though a vent clip is present, PR containers are grounded and spark-resistant tools are used as added protection against ignition of flammable quantities of hydrogen.

The containers are opened and a Radiological Control Technician (RCT) checks the container for dose rate and loose contamination. The bagged polybottle is then retrieved and placed on its side in the glovebox airlock for transfer to the glovebox processing area. The glovebox ventilation system maintains the airlock at negative pressure relative to the room atmosphere. The outer airlock door is closed, the inner door is opened, and the bagged polybottle is withdrawn from the airlock into the main part of the glovebox. Both bags are cut open and the polybottle is removed. The opposite ends of the bags are cut off so the bags are not considered a container for criticality purposes. The lid is removed from the feed tank and the cap is removed from the polybottle. The contents of the polybottle are poured into the tank. The feed tank lid simply rests on top of the tank and is replaced after the solution is poured in the tank.

The empty polybottle is then bagged out of the glovebox, overpacked in another bag, and placed in the PR container or ITC for reuse. The empty bags are bagged out periodically and transferred as waste. Following the same process, another bottle of feed solution may be loaded into the glovebox for addition to the feed tank or to be stored in the glovebox for later addition to the tank. Due to criticality considerations, only one bottle of any solution, empty or full, may be in the glovebox at any time. Therefore, before adding additional bottles of solution for processing or before adding flushing solution at the end of the process run, any bottle previously placed in the glovebox must be removed.

Once the feed tank has been filled and bag-out operations completed, an RCT checks the room for airborne contamination. If the contamination levels are acceptable, respiratory protection equipment may be removed. To initiate processing operations in the calciner, the agitator and heaters are turned on. The agitator speed is set at approximately 60 rpm by adjusting the motor speed and using a stop watch. The vacuum is then turned on along with the pressurized air supply. The vacuum is started before the air supply to prevent pressurizing the calciner which would raise the relief cap and potentially spread plutonium oxide powder into the glovebox. The vacuum and air supply are then adjusted, as necessary, to obtain the proper vacuum and airflow in the calciner. The air supply to the calciner feed injector nozzle is set, using a needle valve, at approximately 40 scfh as indicated by the rotameter in the air line. The

vacuum is adjusted such that there is about an 80-in.-w.g. vacuum in the calciner. The offgas filter back-pulse air system is then started.

The heater controller is set to increase the temperature of the calciner at a rate of 5 °C to 10 °C a minute to avoid excessive stresses on the calciner components. During the heatup period, the caustic feed pump for the scrubber is started. This must be done before initiation of pumping of feed solution to the calciner.

After the calciner has reached operating temperature, approximately 1000 °C, the feed nozzle cleanout rod is lowered, the isolation valve on the feed line near the feed tank is opened and the feed pump is started. The differential pressure across the calciner filters and the calciner vacuum gauge are observed to indicate that solution is being fed to the calciner. The isolation valve on the product drop tube is opened to allow excess plutonium oxide product in the calciner to fall into the collection jar.

During steady state operation, the feed tank level and elapsed time are monitored to determine the solution feed rate and the feed pump is adjusted accordingly to maintain the desired feed flowrate, normally about 4 L/hr. Feed solution and process air enter the calciner through the feed injector nozzle. The air cools the nozzle to prevent the solution from boiling in the nozzle, which could result in plugging, and the air assists in aerosolizing the liquid feed. As the feed solution enters the hot bed of plutonium oxide in the calciner, it quickly evaporates and is converted from plutonium nitrate to plutonium oxide. The resultant offgases are drawn off by vacuum through the three filters at the top of the calciner and flow to the scrubber. Due to the dusty atmosphere in the calciner, the filters tend to clog. Therefore, the filter back-pulse system periodically, approximately once per minute, injects air through the filters to blow the dust off.

While injecting feed solution into the calciner, the agitator continually sweeps hot bed material over the nozzle to ensure that the feed contacts hot material and to prevent the pressurized feed from creating a hole in the bed. In addition to sweeping material over the feed nozzle, the agitator sweeps the bed material by the product drop tube. As the level of the bed increases due to the oxidized plutonium from the feed solution, the level rises higher than the drop tube and some of the material falls through the tube to the product collection vessel. When the collection vessel contains approximately ½ L of plutonium oxide product, it is removed and emptied into ½ L, lead-lined, slip-lid cans. Only two ½ L cans of product, in addition to a full product collection vessel, are permitted in the glovebox at one time due to criticality prevention requirements.

The off-gases from the calciner flow to the scrubber where the vapors and gases are neutralized and reacted to limit the emission of NO_x compounds. Caustic solution is continually added to the scrubber to maintain the proper pH level. Due to the condensing vapors and caustic addition, the level of the solution in the scrubber rises. The solution overflows into the scrubber outlet line to one of the two spent scrub solution tanks along with the gases from the scrubber which are drawn through the scrubber by the vacuum system. The scrubber solution is visually monitored for color changes which would occur if a calciner filter broke and allowed significant quantities of plutonium oxide dust to be drawn from the calciner to the scrubber. Should a significant change in color occur, the calciner operations are terminated. This can be

accomplished through an orderly shutdown of the operating equipment or by actuating the emergency shutdown switch which automatically shuts off most of the operating equipment.

The gases and liquid from the scrubber flow to one of the two spent scrub solution tanks until that tank is full. The tank is then isolated and the second tank is placed in service. A sample is taken of the liquid in the full tank to determine if it is acceptable for transfer to the waste collection tanks in Building 241-Z. If the sample is acceptable, appropriate approvals for the transfer are obtained and the spent scrub solution is drained to Tank D-8 for disposal to the Hanford tank farms.

The gases from the spent scrub solution tanks flow to a vacuum trap and then through the plant 26-in.-Hg vacuum system. The vacuum system then discharges the gases through the plant ventilation exhaust system. If liquids are drawn from the spent scrub solution tanks into the vapor trap, a float will block off the vacuum line to prevent the liquid from entering the vacuum system. This will result in loss of vacuum to the calciner equipment and pressurization of the calciner vessel. The process operations would be manually terminated if this situation occurred.

2.4.3 Product Sampling, Testing, Packaging and Transfer to Storage

Product sampling, testing, packaging and transfer to storage are not specifically included in this addendum as part of the calciner process. The following discussion is provided for information and completeness.

As mentioned previously, the plutonium oxide product overflows from the calciner into a product collection vessel. This is then emptied into ½ L slip-lid cans for eventual transfer out of the glovebox for long term storage in the Building 2736-Z vaults. Prior to transfer and storage, the plutonium oxide product is tested to ensure that it meets vault storage requirements (BWHC 1998) and DOE requirements for long-term storage (DOE 1996). The plutonium oxide in the slip-lid can is thoroughly mixed by hand. A small sample, approximately 10-20 g, is taken from the can and placed in a sample vial. The vial is bagged out of the glovebox, overpacked with a second bag and placed in an ice cream carton. The carton is transferred to the Analytical Laboratory for loss-on-ignition (LOI) testing to verify that the product meets the storage requirements (BWHC 1998). The laboratory also tests the plutonium oxide density to verify that it is a maximum of 5.5 g-Pu/cm^3 as required by the criticality analysis.

If the plutonium oxide sample meets the LOI requirement for storage of material, the lid is placed on the can and taped closed. The slip-lid can is bagged-out of the glovebox and the bag is closed by heat-sealing. A horsetail is not required since there is no significant potential for pressurization of the bag or hydrogen generation. In addition, a horse-tailed bag would not fit in the storage container. It is noted that there is a limit of about 1000 g of plutonium oxide in the slip-lid can due to a 3 W heat loading limit for the PVC plastic bags used for bag-out. Scales are provided in the glovebox basement level to weigh the cans before and after filling.

The bagged-out slip-lid can is inserted in an overpack can (a large tomato can) which is crimp-sealed for closure. The tomato can is then taken to the hallway outside of Room 188

where it is overpacked in a 7-in. can. The can is appropriately labeled and transferred to the Building 2736-Z storage vaults. Transfer operations are as discussed in the PFP FSAR (FDH 1999).

3.0 HAZARD ANALYSIS

A hazards analysis was performed to identify and evaluate hazards associated with the stabilization of Plutonium nitrate solutions using the PFP Laboratory Prototype Calciner. This chapter summarizes the methodology and the results of the hazard analysis performed. The techniques used in identifying the hazards associated with the operation of the calciner were a Preliminary Hazards Analysis (PHA) and a Hazards and Operability Analysis (HAZOP). A complete discussion of the Hazards Analysis and the hazards tables resulting from the work is presented in Appendix A.

The scope of the PHA and HAZOP included the range of activities involved in the transport of plutonium nitrate solutions in a PR Container or Isolated Transport Container (ITC) to Room 188, processing the solutions in the calciner and then to the transport of the over-packed cans of plutonium oxide product to the vaults for long term storage.

3.1 METHODOLOGY

The hazards analysis was performed using two distinct techniques with differing data collection forms. The PHA and HAZOP are similar but focus on different aspects of the calciner system and operations. A PHA was used to identify the hazards associated with the movement of the plutonium nitrate solutions to Room 188 and into Glovebox 188-1 and the removal of the plutonium oxide product from Glovebox 188-1 and transfer to storage vaults. A HAZOP was selected as the method to identify the hazardous conditions associated with the operation of the Laboratory Prototype Calciner to process the plutonium nitrate solution into plutonium oxide.

The activities associated with the movement of the Pu nitrate solutions into Glovebox 188-1 and the removal of the Pu oxide over-packed can from Glovebox 188-1 into vault 190 were evaluated via a PHA. The PHA is a form-driven exploratory method for identifying hazards and candidates for controls. The PHA process is a systematic approach whereby a system, process, or activity are divided into basic elements and the hazards associated with the system, process operations, or activities are identified. Then potential causes of the hazards are determined, potential consequences of the hazards are evaluated, and possible or existing engineered and administrative safety features are identified. A detailed discussion of the PHA technique can be found in *Guidelines for Hazard Evaluation Procedures* (AIChE 1992).

The PHA was developed using a table to guide and record the results of the hazard identification and evaluation process. The PHA form is shown in Table A-1 of Appendix A. The purpose and contents of each column in the PHA table are described in detail in Appendix A.

The calciner process is amenable to the HAZOP method because the calciner is a system in which specific points or nodes can be identified where process parameters such as temperature, pressure, and flow can be examined for variations that can lead to hazardous conditions. The purpose of a HAZOP study is to carefully review a process or operation in a systematic way to determine whether deviation from prescribed procedures or parameters can

lead to undesirable consequences. A HAZOP leader guides a team through the design using a fixed set of guide words. These guide words are applied at specific points or nodes in the design and are combined with specific process parameters to identify potential deviations from the intended operation. For example, the guide word "No" combined with the process parameter "Flow" results in the deviation "No Flow."

The HAZOP findings are documented on a HAZOP Form which is shown in Table A-2 of Appendix A. A more detailed description of the HAZOP and PHA techniques are provided in Appendix A.

For both the PHA and the HAZOP, the engineered safety features and controls specific to the processing of plutonium nitrates were not credited in assigning the consequence rankings. This was to allow determination of whether Safety Significant or Safety Class equipment or controls were warranted.

The mitigative effects of features previously designated at the plant as Safety Significant or Safety Class were credited in assigning the consequence rankings in the tables. For example, the Building 234-5Z Safety Class structure and E-3 ventilation system were credited with protecting onsite workers and the offsite public outside the PFP from accidents that breach glovebox confinement. The effects of energetic events on the glovebox structure, however, were assessed to determine if the hazardous event can compromise the Safety Significant confinement function provided by the glovebox structure and ventilation system.

The selection of accidents for quantitative analysis was performed using a binning process as recommended by DOE-STD-3009-94 (DOE 1994a) and HNF-PRO-704 (HNF 1997).

All accidents are binned according to the potential accidents identified in the PHA and HAZOP tables (Appendix A, Tables A-5 and A-6). The binning is based on grouping similar accidents that challenged similar barriers. The potential accidents were grouped into 15 bins which are summarized in Table 1. Matching characteristics for the specific hazards to these respective bins was completed using the same ID as in the PHA and HAZOP tables. The results of the binning are presented in Table 2.

A generalized summary of the bins (labeled accident groups in Tables 1 and 2) includes:

Group A1 – Process Upset – No Worker Impacts. Events in this group are production upset events which do not result in the release of radiological material or in a significant increase in worker exposure, but the occurrence of the events degrades the normal operation of the Laboratory Prototype Calciner and possibly decreases product output.

Group A2 – Process Upset – Worker ALARA concerns. Process upsets of a more serious nature than those of Group A1 are characterized by a release of radiological material within the glovebox and a resultant increase in worker exposure. Dealing with the upset often results in additional dose to facility workers, especially in the cleanup or repair process where additional worker doses are incurred.

Group B – Radiological Release Inside Glovebox. Events considered in this group take credit for the mitigative containment of the glovebox. The principal control is the maintenance of a negative pressure differential between the glovebox and the surrounding room. Release of radiological material to the glovebox , while not a danger by worker inhalation, does increase sources of direct radiation and, in a similar manner as Group A2, results in additional worker exposure as a result of recovery operations.

Group C – Radiological Release From Glovebox. The potential for a release of plutonium or other contamination from the glovebox during an event exists whenever there is a loss of confinement such as a damaged or torn glove or failure of the ventilation system, but can also occur during bag-out operations and airlock transfers.

Group D1 – Deflagration in Glovebox. Several sources of flammable gas and potential sources of ignition which could lead to a deflagration in the glovebox were identified by the PHA and HAZOP processes. These events from Tables A-5 and A-6 of Appendix A are assigned to this accident group.

Group D2 – Deflagration Outside of Glovebox. A flammable gas deflagration in a PR container due to the presence of radiolytically-generated hydrogen was identified by the PHA as a potential event resulting from the transfer of solutions for processing in the Laboratory Prototype Calciner.

Group E – Criticality. Relatively large masses of plutonium are handled during prototype laboratory calciner operations. Placing a large mass of plutonium in a glovebox or having sufficient material in a non-safe geometry could result in an accidental nuclear criticality. Controls to prevent criticality typically include administratively controlled mass and spacing limits, hardware that physically separates plutonium containers, limited quantities of water in the gloveboxes, controlled water addition by fire protection systems, and limits on the size and number of containers in gloveboxes. Events identified in the PHA and HAZOP as having the potential to result in a criticality are assigned to this group. However, the analysis of hazardous conditions presenting criticality concerns is performed as part of a Criticality Safety Evaluation Report (CSER) for the Laboratory Prototype Calciner and, therefore, these hazards are not evaluated further in this addendum. The results of the CSER are incorporated into a Criticality Prevention Specification for implementation within the facility which provides adequate protection from criticality hazards.

Group F1 – Fire in Glovebox. The PHA identified several causes of a glovebox fire, including electrical motor burnout, incompatible chemical reactions, or combustible materials coming into contact with hot furnace surfaces.

Group F2 – Fire Outside of Glovebox. This accident group is similar to Group D2 because the flammable material and ignition source are the same. However, the postulated reaction, fire versus a deflagration, is much less energetic and results in different consequences.

Group G – Industrial Hazards. The hazards in this group are the same ones faced by workers in standard industrial activities, such as falls, burns, shocks, and including to some degree, exposure to chemical hazards.

Group H – Release to Vacuum System. The hazards in this group include lowered efficiency NO_x, as well as possible equipment damage from corrosion caused by processing chemical carryover, and possible contamination of the vacuum system.

Group I – Toxic Chemical Release Inside Facility. Several strong acids and bases used in significant quantities in the laboratory prototype calciner have the potential for spills and pressurized leaks. Reactions of incompatible chemicals are possible. The calciner has a collection system for the off gas products of the calciner which can be a source of toxic release.

Group J – Radiological Release Inside Facility. This category is similar to Group C above. In Group J, the hazards are those from radionuclides headed for the glovebox , or coming from it to a vault, in which the container is contaminated or containment is lost. A dropped container would be an example.

Group K – Inadequate Stabilization of Product. The PHA identified numerous process upsets and failures that could result in inadequately stabilized plutonium oxide. If this condition was not detected before the oxide was packaged, the container could rupture in storage due to internal pressurization.

Group NPH – Natural Phenomena Initiator. Group NPH includes events resulting from natural forces such as earthquakes, rain, snow, flooding, high winds, and fires.

After binning, the accidents were further sorted according to the magnitude of their consequences. The accident sorting criteria used was based entirely on qualitative consequence ranking. Each failure or hazardous condition identified by the PHA and HAZOP was assigned a consequence as defined below.

Consequence Rank

S0 No effect outside the glovebox confinement systems; negligible safety concerns for the facility worker.

S1 Potential industrial injury, low radiological or chemical exposure dose consequences to the facility worker.

S1* Potential severe harm or potential death from industrial injury, radiological dose, or chemical exposure to facility worker. Hazardous conditions sufficient to cause severe harm or death to facility workers are typically associated with events which may result in significant pressurization of or damage to the glovebox structure with potential release of radiological material. Therefore, events with sufficient energy to impact the glovebox in a manner which may cause a release of radiological material are assigned an S1* consequence rank. This is a

conservative approach since such events will not necessarily result in harm or death to facility workers.

S2 Potential significant radiological dose consequences or chemical exposure to onsite workers located outside the facility.

S3 Potential significant radiological dose consequences or chemical exposure to the offsite population.

3.2 HAZARD ANALYSIS RESULTS

The PHA and HAZOP tables in Appendix A identify 42 S0 events, 89 S1 events, 34 S1* events, and 9 S2 events.

The results of binning by groups and sorting by the consequence rankings from above are presented in tabular form in Table 2. For each group, all S1* and S2 events are sorted out and collected into a subgroup for evaluation as accidents as shown in Table 2. All S1 events in each group are collected into a second subgroup for evaluation as abnormal operations. Finally, all S0 events in each group are collected into a third subgroup identifying events with negligible consequences. Categorizing hazardous events as either "abnormal operations" or "accidents" is consistent with the NRC Regulatory Guide 3.39 format of the PFP FSAR. In this way, every hazard was binned into one of the accident groups and sorted by its consequence ranking. As noted in the following discussion of each group, in some cases only S1 or S0 events exist for some groups.

3.2.1 Accident Selection

Selection of accidents for quantitative analysis is the final sort that began with the grouping and sorting process described above. For each accident group with an S1* or S2 consequence, a representative accident is chosen for further quantitative analysis. This representative accident bounds the consequences of similar accidents in the accident group it represents. Similar accidents challenge analogous barriers. Analogous barriers reflect the same design philosophy for prevention and mitigation as the representative accident, even though the similar accidents may be in different locations. If there is only one accident of a given type, it is analyzed as a unique representative accident. If several accidents are similar in the bin, one or more can be combined to form the representative accident, or several representative accidents can be chosen for further analysis.

The accident scenario is then fully developed for the chosen representative accident and then refined consequences compared to the hazards it represents. The safety classification implications and control requirements that the representative accident determines are required are then generalized to be required for all the hazards in the group.

From the Laboratory Prototype Calciner accident groupings, discussed below, four groups were selected as requiring accident analysis scenario development. The representative accidents were chosen from the following four groups.

- Fire in the Glovebox (Group F1)
- Deflagration in the Glovebox (Group D1)
- Deflagration outside the Glovebox (Group D2)
- Seismic Event (Group NPH, Natural Phenomenon Hazards)

The rationale for choosing the representative accidents is discussed below along with the rationale for not developing scenarios from the remaining groups. The rationale for choosing and rejecting is also contained in the comments and justification column of Table 2. In Table 2, selected representative accidents and abnormal occurrences are highlighted by using bold and all capitalized print.

Group A1 – Process Upset – No Worker Impacts. All entries in this group have a consequence ranking of S0. Because they result in no effect outside of the glovebox confinement system and negligible safety concerns to facility workers, hazards with S0 consequences are not evaluated further.

Group A2 – Process Upset – Worker ALARA concerns. Only events with a consequence category of S1, abnormal occurrences, are contained in this group, so the group is forwarded to the Abnormal Occurrence Selection section, Section 3.2.2. Consequences from these events involve increased worker exposure from radiation or chemical hazards because of activities needed to recover from the occurrence.

Group B – Radiological Release Inside Glovebox. All entries in this group have a consequence ranking of S1 with the exception of one S0 negligible safety concern so the group is forwarded to the Abnormal Occurrence Selection section, Section 3.2.2.

Group C – Radiological Release From Glovebox. Both events with a consequence category of S1, abnormal occurrences, and S0, negligible safety concerns, are contained in this group so the group is forwarded to the Abnormal Occurrence Selection section, Section 3.2.2.

Group D1 – Deflagration in Glovebox. The PHA identified several causes of a deflagration in the glovebox. From these, three accidents , 04.01 deflagration of hydrogen in a bag or bottle, 08.03.17 deflagration in the calciner due to organic feed, and 08.03.18 deflagration in the calciner due to oil from feed air supply, were chosen to be representative accidents. Event 04.01 was chosen because it involves one of the largest amounts of dispersible material, the 2.5 L of solution in a polybottle, and one of the largest energy sources, hydrogen deflagration, for dispersion. Events 08.03.17 and 08.03.18 were chosen because they are similar to each other and involve a large amount of dispersible material, the plutonium oxide in the calciner, with a large energy source for dispersion.

Group D2 – Deflagration Outside of Glovebox. There was only one accident in this group, 03.01/1 deflagration in the PR container that ejects the lid. It was selected as a representative accident because of its potential for severe injury to facility workers.

Group E – Criticality. The PHA and HAZOP identified several hazardous events for the Laboratory Prototype Calciner operations that could potentially lead to a criticality. Events identified in the PHA and HAZOP as having potential to result in a criticality are assigned to this group. However, the analysis of hazardous conditions presenting criticality concerns is performed as part of a Criticality Safety Evaluation Report (CSER) for the Laboratory Prototype Calciner and, therefore, these hazards are not evaluated further in this addendum. The results of the CSER are incorporated in a Criticality Prevention Specification for implementation within the facility which provides adequate protection from criticality hazards.

Group F1 – Fire in Glovebox. The PHA and HAZOP identified several causes of a glovebox fire, including electrical motor burnout, incompatible chemical reactions, or combustible materials coming into contact with hot furnace surfaces. Only S1* consequence events were identified in this grouping so a representative accident was identified. Two events in this group 06.01 and 08.13.07 are the same event, a fire involving combustibles in the glovebox, that were identified by the two different hazard analysis methods. Event 06.01 was identified in the PHA while 08.13.07 was identified by the HAZOP process. This event, (both 06.01 and 08.13.07) was chosen to be a representative accident from the others in the group because it involved the greatest amount of fuel and would create the greatest dispersal mechanism for this type of event.

Group F2 – Fire Outside of Glovebox. There is only one accident in this group, 03.02/2, a hydrogen burn of a polybottle and the bag around it. This accident is bounded by the deflagration event 03.01/1 in Group D2 where it is the representative accident for a deflagration outside of a glovebox.

Group G – Industrial Hazards. Occupational hazards are not evaluated further as the associated risk is not uniquely related to plutonium processing operations.

Group H – Release to Vacuum System. All entries in this group have a consequence ranking of S0. Because they result in no effect outside of the glovebox confinement system and negligible safety concerns to facility workers, hazards with S0 consequences are not evaluated further.

Group I – Toxic Chemical Release Inside Facility. Chapter 9, Section 9.2.8 of the PFP FSAR analyzes toxic chemical releases. The consequences of accidents in Group I are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in Section 9.2.8 of the PFP FSAR.

Group J – Radiological Release Inside Facility. Chapter 9, Sections 9.1.1 and 9.1.3 of the PFP FSAR analyzes abnormal operations involving radioactive liquid and powder spills. The consequences of abnormal occurrences in Group J are not unique to the laboratory prototype

calciner operations and are considered to be adequately addressed by the analyses in Sections 9.1.1 and 9.1.3 of the PFP FSAR.

Group K – Inadequate Stabilization of Product. Chapter 9, Section 9.1.3 of the PFP FSAR analyzes radioactive powder spills. The consequences of abnormal occurrences in Group K are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in Section 9.1.3 of the PFP FSAR.

Group NPH – Natural Phenomena Initiator. Event 08.16.00/02 was chosen as the representative accident because of all of the accidents in Group NPH, it involves the largest amount of dispersible material combined with the least mitigation to exposed onsite workers outside of the facility to radiological consequences.

3.2.2 Abnormal Occurrence Selection

The six groups (A2, B, C, G, I, and J) where abnormal occurrence events were identified are contained in Table 2. There were no abnormal occurrence events identified in any of the other groups. From the six groups, no unique representative abnormal events associated with calciner operations were identified. The rationale for not developing scenarios for any of the abnormal events is discussed below and also in the comments and justification column of Table 2.

Group A2 – Process Upset – Worker ALARA concerns. Only events with a consequence category of S1, abnormal occurrences, are contained in this group. Consequences from these events involve increased worker exposure from radiation or chemical hazards because of activities needed to recover from the occurrence. No representative abnormal occurrence was selected from this group and hazards are not evaluated further because the associated risk is covered in various abnormal operations evaluated in the PFP FSAR and is not uniquely related to operation of the prototype laboratory calciner operation.

Group B – Radiological Release Inside Glovebox. All entries in this group have a consequence ranking of S1 with the exception of one S0 negligible safety concern. Chapter 9, Sections 9.1.1 and 9.1.3 of the PFP FSAR, analyze abnormal operations involving radioactive liquid and powder spills. Chapter 9, Section 9.1.2, analyzes pressurized liquid releases. Chapter 9, Section 9.2.8, analyzes toxic chemical releases. The consequences of abnormal occurrences in Group B are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in Sections 9.1.1, 9.1.2, 9.1.3, and 9.2.8 of the PFP FSAR.

Group C – Radiological Release From Glovebox. Both events with a consequence category of S1, abnormal occurrences, and S0, negligible safety concerns, are contained in this group. Chapter 9, Section 9.1.9 of the PFP FSAR analyzes a glovebox glove breach. Chapter 9, Sections 9.1.1 and 9.1.3 of the PFP FSAR analyzes abnormal operations involving radioactive liquid and powder spills. The consequences of abnormal occurrences in Group C are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in Sections 9.1.9, 9.1.1, and 9.1.3 of the PFP FSAR.

Group G – Industrial Hazards. Industrial hazards are not evaluated further as the associated risk is covered by various occupational health and safety programs existing within the facility.

Group I – Toxic Chemical Release Inside Facility. Chapter 9, Section 9.2.8 of the PFP FSAR, analyzes toxic chemical releases. The consequences of abnormal occurrences in Group I are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in Section 9.2.8 of the PFP FSAR.

Group J – Radiological Release Inside Facility. Chapter 9, Sections 9.1.1 and 9.1.3 of the PFP FSAR analyzes abnormal operations involving radioactive liquid and powder spills. The consequences of abnormal occurrences in Group J are considered to be adequately addressed by the analysis in the PFP FSAR.

3.2.3 Evaluation of Impacts on Existing FSAR Accidents

The previous sections discussed the new accidents and abnormal occurrences (Section 3.2.2) associated directly with Laboratory Prototype Calciner operations which were identified through the PHA/HAZOP process. In addition, an evaluation is required to determine if the initiation of calciner operations has any impacts on the accidents and abnormal events analyzed previously in the PFP FSAR (FDH 1999). In order to examine the incremental doses that may accrue from operation of the Laboratory Prototype Calciner to the existing abnormal operations and accidents analyzed in the PFP FSAR, each abnormal operation and accident analyzed in the FSAR has been evaluated for impacts assuming operation of the calciner. This evaluation is documented in Table 3 for abnormal operations and Table 4 for accidents. As can be seen from the tables, effects on the accidents and abnormal operations currently analyzed in the FSAR are not expected from operation of the calciner, except for the case of the Seismic Event. For the seismic accident analysis, calciner operations result in an increased release from the laboratories portion of the PFP facility. The effect of the calciner on the seismic event analyzed in the FSAR is evaluated in Section 4.2.5.

4.0 ACCIDENT ANALYSIS

Accident analyses documented in Safety Analysis Reports (SAR) demonstrate that facility design and operation incorporate adequate features to protect the public, onsite workers, and the environment from the consequences of credible accident scenarios. The design incorporates appropriate engineered safety barriers and administrative controls for postulated hazards to prevent the occurrence of accidents or to mitigate the resulting consequences to acceptable levels. Bounding accidents, whether requiring mitigation or not to maintain acceptable consequences, are referred to as design basis accidents (DBAs). These accidents are the most severe circumstances for which facility features must comply with functional goals to prevent unacceptable consequences to the public, facility and onsite workers, and the environment. DBAs are analyzed for the Laboratory Prototype Calciner in this chapter and compared to the Risk Evaluation Guidelines presented in Figure 9-34 of the PFP FSAR (FDH 1999).

4.1 ABNORMAL OCCURRENCES

Abnormal occurrences associated with operation of the Laboratory Prototype Calciner are discussed and evaluated in Section 3.2.2. There were six groups in Table 2 (A2, B, C, G, I, and J) where abnormal occurrence events, defined as those events with S1 hazards, were identified out of the total of 15 accident groups. There were no abnormal occurrence events identified in any of the other groups. From the six groups, there were no unique representative abnormal events associated with calciner operations. As discussed in Section 3.2.2, all of the abnormal occurrences identified in Table 2 have been shown to be adequately addressed by existing analyses in the PFP FSAR (FDH 1999).

4.2 ACCIDENTS FOR THE LABORATORY PROTOTYPE CALCINER

To demonstrate that the facility design and operation incorporate adequate safety controls, the accident analysis fully develops and evaluates the representative accidents identified in the hazards analysis.

4.2.1 Hydrogen Deflagration in Room 188 from Opening Drum

Plutonium nitrate solutions generate hydrogen, oxygen, and NO_x due to radiolysis. As discussed in Chapter 2.0, the plutonium nitrate solutions are brought to Room 188 in 3 L polybottles that have been placed in PR containers, which are DOT 17H, 55 gal drums, or Isolated Transport Containers (ITC), which are plastic pails with snap-closed lids. Radiolytically generated hydrogen in the polybottle vents through a hole in the bottle cap into the air space of the PR container or ITC. This section evaluates the potential for a flammable buildup of hydrogen in the PR container and ITC and the potential for a hydrogen deflagration caused by a mechanical or static spark during opening.

4.2.1.1 Scenario

Three liter polybottles are used to transfer the solutions from Glovebox HC-227S to Glovebox 188-1. The bottles, filled in Glovebox HC-227S with 2.5 L of solution, have a double-bag overwrap. The bottle is bagged-out of the glovebox, and the second bag is then put in place. The bottles are transported to Glovebox 188-1 in either PR containers or in ITCs which are only large enough to contain one polybottle. Temporary storage of these containers between departure from Glovebox HC-227S and arrival at Glovebox 188-1 is usually necessary.

Temporary storage of PR containers with polybottles is in Room 236. If the storage is prolonged, free hydrogen, generated by radiolytic decomposition of the solutions, first accumulates in the polybottles, moves by venting or diffusion to the plastic bags, and finally vents and diffuses into the PR container. If the concentration of hydrogen in any space reaches the lower flammability limit (LFL), ignition of the gas is possible. A deflagration in the PR container would present a serious hazard to facility workers close to the container from the ejected lid. The analysis in Appendix B calculates the radiolytic generation rate of hydrogen from a polybottle containing 2.5 L of plutonium nitrate solution and calculates the time to reach flammable levels in the PR container (55 gal drum), assuming no leakage or diffusion of hydrogen from the container. The calculations in Appendix B indicate that the time to reach a 1 vol% hydrogen concentration in the container atmosphere (25% of the 4 vol% LFL) could be as low as 22.6 days for a 4 M solution of nitric acid, or 55.3 days for an 8 M solution, when no leakage path through the container lid seal is available. Using 25% of the LFL for hydrogen as the limit for accumulation in a container applies the standard safety factor considered acceptable for the presence of hydrogen.

The analysis in Appendix C calculates the potential hydrogen concentration in drums containing 2.5 L of plutonium nitrate solution that vent through minute holes in the drum lid gasket or are vented through holes created by clips placed between the drum and drum lid. The analysis in Appendix C shows that flammable concentrations are not possible in vented drums. An administrative control has been determined to be necessary to ensure only drums containing vent clips (or equivalent) are opened in Room 188, to ensure the safety of workers opening the drum. The consequence and probability analyses provided in this section evaluate the potential of hydrogen deflagrations due to the inadvertent opening of non-vented drums in Room 188.

Temporary storage of a polybottle in an ITC is accomplished by transfer to Room 179 where the polybottle is removed and temporarily stored in a glovebox. After placement of the polybottle in a glovebox, the double-bag overwrap is removed. When the polybottle is to be transferred to Room 188 for solution processing in the calciner, the polybottle is bagged out of the Room 179 glovebox, overwrapped in a second bag and transferred to Room 188. The transfer is accomplished either by hand carrying the bagged polybottle or by placing it in an ITC. The process steps for temporary storage of a polybottle transferred in an ITC limits the amount of time that a polybottle is in the ITC and, consequently, the amount of hydrogen that may accumulate in the ITC. Similarly, the amount of hydrogen in the bag-out and overwrap bags would be limited due to the relatively short time that the polybottle is in the bag. If, for some reason, this method of storage of the polybottle out of the ITC is not possible, storage in the ITC does not present the same hazard of hydrogen buildup as it does in the PR container. The reason

is that the ITCs have snap-closed lids that are loose fitting and, therefore, not leak tight. The analysis of Appendix C, showing flammable concentrations are not possible in vented PR containers, is also applicable to the ITCs.

If it is postulated that leakage is not possible from the bags, a flammable mixture could be present in the bags surrounding the polybottle and in the bottle itself. This would present a hazardous condition for the movement of the bagged polybottle from the PR container or ITC into Glovebox 188-1, and for the unbagging and opening of the bottle in the glovebox. The PR container or ITC would be opened in Room 188, and the polybottle would be hand carried to the Glovebox 188-1 airlock for transfer into the glovebox. Analysis of the overpressure caused by the deflagration of hydrogen in the bags is presented in Section 4.2.2 and, therefore, is not further developed in this section.

4.2.1.2 Mitigation

Mitigation is provided at each level of confinement by providing a leak path for escape of the hydrogen. A vent hole in the polybottle lid allows passage of hydrogen generated from the solution in the bottle, to vent to the surrounding bag. The inner bag is closed by twisting the end of the bag and taping the twisted section, creating a "horsetail," and then taping over the exposed end of the twisted section. For the outer bag, the "horsetail" may be folded in half and taped. Tape is wrapped around the horsetail to keep it in place. Creases and crevices in the horsetailed plastic provides passages for the hydrogen to escape from one bag into the other and then out into the drum free space. A vent clip placed on the lip of the drum opening before placing the drum lid on, leaves gaps in the drum lid seal for hydrogen to escape from the drum. Calculations in Appendix C demonstrate that hydrogen concentrations in the drum will not approach the LFL for any length of storage time as long as there is a vent clip in place.

Administrative procedures are instituted that prohibit opening of any drum that does not have a vent clip installed between the lid and the drum lip, or holes drilled in the drum lid. Administrative procedures are also in place that prohibit movement of the bagged bottles if there is any indication, such as inflated bags, of gas buildup in the bagged polybottles.

For defense in depth, workers opening the drums and handling the polybottles are dressed in protective clothing and use respiratory protection. In addition, non sparking tools are used, and the drum is grounded to prevent any sparks which could ignite any hydrogen present in the drum.

4.2.1.3 Probability

Using the most conservative leak rate from measurements performed on four unvented and four vented drums, the calculations in Appendix C show that both weapons grade and "worst case" fuels grade plutonium nitrate in 4 M nitric acid stored in vented PR can drums will not reach a flammable hydrogen concentration. A hydrogen burn during the opening of a vented drum is therefore not considered to be credible. A hydrogen deflagration requires the inadvertent opening of a non-vented drum, meaning the wrong drum would have to be selected from the temporary storage location. Given the labeling of the drums and worker training, the likelihood

of selecting the wrong drum is judged to be in the range of one per hundred drums transported. Given the independent check of the drum identification and paperwork and the visual check for a vent clip before opening the drum in Room 188, it is judged that only one in 100 incorrectly selected drums would be opened and not sent back to storage. Because of the use of bonding, grounding, and spark-proof tools, it is judged that the frequency of a hydrogen deflagration can be lowered by another order of magnitude. The combination of faults gives the following accident probability, on a per drum basis:

$$\text{Probability of hydrogen burn per drum} = (1 \times 10^{-2})(1 \times 10^{-2})(0.1) = 1 \times 10^{-5}/\text{drum}$$

Assuming 100 drums are transported and opened per year the annual probability is 1×10^{-3}. The accident is in the Unlikely frequency range (1×10^{-2}/yr to 1×10^{-4}/yr).

4.2.1.4 Consequence Analysis

Quantitative calculations are not provided because the accident requires failure of operators and lab workers to follow administrative controls. Qualitatively, should an unvented drum containing hydrogen be opened and ignited, the potential airborne release of plutonium nitrate solution is considered to be adequately represented by the radioisotope-bearing pressurized liquid container accident analyzed in Section 9.1.2 of the PFP FSAR (FDH 1999). Tests have been performed on 55 gal drums that show that ignited hydrogen will not turn the drums into shrapnel. The lid and bottom of the drum are weaker than the cylindrical portion of the drum, as hoop stresses greater than the tensile strength of the steel are required to fail the cylindrical portion of the drum. The lid is ejected or the bottom fails in the burn causing the drum to be propelled upward (DOE 1993). Severe worker injuries and damage to equipment in the room can occur in the drum deflagration. Significant damage, however, to the Building 234-5Z confinement system would not be expected due to size of the building and the distance of the accident site from the E-3 and E-4 filters and fans. The consequences outside the plant from radiological material released within the room would be negligible due to filtration provided by the facility ventilation system HEPA filters.

4.2.1.5 Conclusions

Severe worker injuries are possible should hydrogen be ignited in a PR container or ITC. The radiological consequences of a deflagration are expected to be negligible outside the plant. Calculations provided in Appendix C show that the concentration of hydrogen in vented PR containers and ITCs used to transport 3 L polybottles of plutonium nitrate solution will be below flammable limits, no matter how long the container or ITC has been in storage. To ensure only PR containers with safe levels of hydrogen are opened in Room 188, vent clips are administratively required to be installed on the PR containers used to transport and temporarily store 3 L polybottles of plutonium nitrate solution. Independent verification of PR container identity and the presence of the vent clip are required before opening in Room 188. Vent clips are not required for ITCs since the lids are loose fitting and not sealed.

4.2.2 Hydrogen Deflagration in Glovebox 188-1 from Opening Bagged Polybottle

As discussed previously, the 3 L polybottles of plutonium nitrate solution are double bagged before being placed into the PR container (55 gal drum) or ITC for transport to Room 188. In Room 188, the double bagged polybottle is removed from the PR container or ITC, hand carried to Glovebox 188-1 and loaded into the glovebox through an airlock. Free hydrogen, due to radiolytic decomposition of the solutions, may be present in these bagged polybottles. If a flammable concentration of hydrogen develops, it can be ignited by mechanical friction or static spark during transfer of a bagged bottle to the glovebox or during the opening of the bag or bottle inside the glovebox.

4.2.2.1 Scenario

From the analysis of Appendix B, an equilibrium hydrogen concentration of 5.1×10^{-6} moles H_2/cm^3, generated by radiolytic decomposition of plutonium nitrate solution and assuming diffusion but no leakage from the bagged polybottle, is initially present in the bags and polybottle. The volume of the bag and the headspace of the polybottle (assuming 2.5 L of plutonium nitrate solution) is estimated in Appendix B to be 6.8×10^3 cm^3. The equilibrium quantity of H_2 in the bag and bottle is thus 3.5×10^{-2} moles of hydrogen.

The polybottle overwrap bags are cut open using scissors. As the bags open, a flammable mixture of hydrogen and air may be released. Because of its low ignition energy, nominally small heat producing sources (e.g., friction and static generation) can result in the ignition of hydrogen.

4.2.2.2 Mitigation

Assuming that there is no leakage from the bagged polybottle, and that there is a flammable mixture in the bags, the first line of defense for the worker transporting the bagged bottle from the PR container or ITC to the glovebox is the protective clothing, including respiratory protection, that is worn. The multi-layered clothing would protect the worker from flame and dispersed chemicals, and the respiratory protection from inhalation of vapor or particulate. Mitigation from release from the facility is provided by the ventilation exhaust systems, which consist of the E-4 exhaust system for Glovebox 188-1 and the E-3 exhaust system for Room 188. The E-4 exhaust system will sweep and dilute any hydrogen released from a bag or bottle during opening in the glovebox. Room CAMs are available for alerting workers to airborne contamination. A bayonet-equipped fire extinguisher is available for extinguishing small fires in the glovebox should a hydrogen burn also ignite combustibles. In addition, magnesium oxide may be placed in the glovebox for use in extinguishing fires.

4.2.2.3 Probability

The assumption for this accident scenario is that there is no leakage from the bags. For this to happen, the horsetail would have to be twisted so tightly and taped so completely that hydrogen could not leak out. The method of plastic bagging of waste with a horsetail closure, specifically because of its breathing capability, has been successfully used at Hanford and around

the DOE complex for many years. Reasons for the success can be seen in the hydrogen generation and leakage calculations presented in Appendix C. In Appendix C the hydrogen concentration in non-vented drums is calculated based on measured leak rates. Using the slowest experimentally measured leak, an equivalent leak path hole area of 2.29×10^{-4} cm^2 was calculated. An equilibrium (long time) concentration of hydrogen for these conditions was just barely into the flammable range. However, it was concluded that vented drums or other vented containers would have openings at least 10 times larger than those estimated, and flammable hydrogen concentrations would not be possible. It is very unlikely that the twisted neck of a plastic bag could be made tight enough to close the creases and crevices down to leak path areas less than the equivalent leak path area determined in Appendix C. A hydrogen deflagration, resulting from the buildup of hydrogen in a bagged bottle with subsequent ignition, requires that the bag be extra tightly twisted and abnormally taped to prevent hydrogen escape. Given the effort required to do this and worker training in correct handling and packaging, a seal like this is conservatively judged to be in the range of one in 100 polybottles bagged and sealed.

If a bag is sealed leaktight, some amount of time is required for hydrogen to build up to a flammable concentration. Normal operations move the freshly filled polybottle in a PR container from Glovebox HC-227S to Room 236 for temporary storage, then to Room 188 and into Glovebox 188-1. Filled polybottles in ITCs are usually transferred directly to Glovebox 188-1 but may be placed in temporary storage as discussed in Section 4.2.1.1. From calculations in Appendix B where the 47.5 L volume of an ITC reaches 25% of the lower flammability limit in 5 days, the concentration in the bag could reach the same condition in less than 2 days. For 100% of the LFL, the time would be closer to 6 to 8 days. Overnight delays may occur occasionally, but longer delays during regular operations would be infrequent. A mechanical friction or static spark must also be present to ignite the flammable mixture. Opening of the bag is accomplished by cutting the bag with scissors. Given these conditions, it is estimated that only one in 100 sealed bags would both have a flammable mixture and be exposed to a source of ignition. This combination of faults gives the following accident probability, on a per bagged polybottle basis:

$$\text{Probability of hydrogen burn per bag} = (1 \times 10^{-2})(1 \times 10^{-2}) = 1 \times 10^{-4}/\text{bag}$$

In Section 4.2.1.3, it was assumed that 100 polybottles are transported and opened per year. The annual point estimate probability is therefore 1×10^{-2}. The burning of flammable gas released from bagged 3 L polybottles is an unlikely event, defined in Table 9-49 of the PFP FSAR (FDH 1999) as having an annual probability in the range of 1×10^{-2} to 1×10^{-4}.

4.2.2.4 Consequence Analysis

If it is assumed that hydrogen does not leak from the bagged polybottle as the bag is opened, a flammable mixture of hydrogen and air will be released. If the hydrogen does not burn as it exits the opened bag, it will, given its high diffusivity, rapidly mix with the glovebox atmosphere. Glovebox 188-1, with dimensions of 96 in. by 83 in. by 44 in., with two additional spaces of 37 in. by 38 in. by 36 in. and 37 in. by 30 in. by 36 in., has a volume of 7,230 L. To

account for the calciner and associated equipment in the glovebox, the glovebox air volume is reduced by a factor of 10%. Subtracting the 723 L volume of the calciner portion of the glovebox yields a volume of 6,507 L. Applying the ideal gas law, this volume can contain 290 moles of gas. If the 3.5×10^{-2} moles of hydrogen released from the bag were to mix uniformly within the volume of the glovebox, the resultant concentration would be 0.01%, which is significantly below the lower flammability limit of 4%. Accordingly, the hydrogen would not burn but would be swept from the glovebox via the E-4 exhaust system and further diluted.

As the hydrogen is released from the bag and mixes with the glovebox atmosphere, localized concentrations within the flammability range will exist for a short period of time. Assuming that all of the hydrogen is released as a puff and is ignited before mixing below the lower flammability limit, the instantaneous energy release would be:

$$Q = (240 \text{ kJ/g-mole})(3.5 \times 10^{-2} \text{ moles}) = 8.4 \text{ kJ}$$

where:

Q = heat generated, kJ
kJ/g-mole = heat of combustion of hydrogen

Conservatively assuming 100% of the heat from the hydrogen burn is transferred to the air in the glovebox, the increase in temperature can be calculated by:

$$\Delta T = Q/mC_P$$

where:

ΔT = change in temperature, K
Q = heat generated, kJ
m = mass of air in glovebox, kg
C_p = specific heat of air, kJ/kg-K

The mass of air in Glovebox 188-1 is equal to the volume of air multiplied by its density:

$$m = (\text{volume})(\text{density}) = (6.51 \text{ m}^3)(1.16 \text{ kg/m}^3) = 7.55 \text{ kg}$$

Note that the pressure inside the glovebox is approximately -0.3 psig (14.4 psia) due to three successive pressure drops between (1) the atmosphere and the building non-radiation zone, (2) the building non-radiation zone and radiation zone, and (3) the building radiation zone and the glovebox interior. The glovebox air density used in this analysis is not corrected for the lower pressure because the calculations for glovebox temperature increase due to the hydrogen

burn and the resulting pressure change are not sensitive to the slight difference in air density due to the slight negative pressure in the glovebox.

Solving for ΔT yields a temperature increase of:

$$\Delta T = 8.4 \text{ kJ}/(7.55 \text{ kg})(1.007 \text{ kJ/kg-K}) = 1.10 \text{ K}$$

Applying the ideal gas law, the pressure in the glovebox given a temperature rise of 1.10 K is calculated as follows:

$$(P_{final}/P_{initial}) = (T_{final}/T_{initial})$$

$$P_{final} = (14.7 \text{ psia})(300 \text{ K} + 1.1 \text{ K})/(300 \text{ K}) = 14.75 \text{ psia}$$

The increase in pressure is therefore 0.05 psig.

A pressure increase of 0.05 psi is not expected to damage the glovebox containment boundary. Walden (1980) suggests gloves fail at an overpressure of 0.6 psig. A pressure increase of 0.4 psig could breach the glovebox via failed bag-in/bag-out ports. The increased pressure could result in a short-lived air flow and pressure increase through the E-4 exhaust system. Increased flow through the HEPA filters increases the pressure drop across the filters and, if large enough, could lead to filter failure. Data obtained from the Tank 241-Z-361 Justification for Continued Operation (JCO) (BWHC 1999c) indicates that filters can typically withstand pressure drops up to 0.36 psi (10 in. w.g.) before failure would be expected. The JCO for Tank 241-Z-361 also indicates that the typical pressure drop across HEPA filters at rated flow is a maximum of 1.3 in. w.g. The pressure rise of 0.05 psi in the glovebox due to the deflagration is equivalent to 1.4 in. w.g. Combining the maximum operational pressure drop of 1.3 in. w.g. with the 1.4 in. w.g. pressure increase from the deflagration yields a maximum pressure drop across the E-4 exhaust system filters of 2.7 in. w.g. Consequently, the pressure increase caused by the deflagration is not expected to adversely impact the E-4 exhaust filters. If the filters were significantly impacted by the deflagration, pressure monitoring instrumentation for the filters would indicate either high pressure, if the filters were plugged, or low pressure, if the filters breached. In addition, periodic filter integrity testing would eventually indicate degraded filters. The air flow increase through the E-4 filters would have no appreciable impact on stack emissions since the increased flow would occur for such a short time.

Although a pressure increase of 0.05 psig can be conservatively calculated, such an increase would not be realized for three principal reasons. First, 100% of the hydrogen contained in a sudden release would not burn as assumed. A stoichiometric mixture of 3.5×10^{-2} moles of hydrogen and air has a volume of 0.5 L, which would fill approximately 0.01% of the glovebox. Accordingly, the hydrogen would burn as an unconfined cloud, the efficiency of which can be significantly less than 100%. As stated in *Evaluation of Unconfined*

Vapor Cloud Explosion Hazards (Pugh 1987), when small unconfined vapor clouds are ignited, the vapors usually burn without pressure effects and with a low flame speed. Second, 100% of the heat from the hydrogen burn would not be transferred to the air as assumed above, i.e., the system is not adiabatic. Third, Glovebox 188-1 is not a sealed vessel. Qualitatively considering these factors, it is concluded that the release and subsequent ignition of hydrogen from a bag will not breach Glovebox 188-1 since there would be little or no pressure increase. This conclusion is consistent with operating experience at PFP and throughout the DOE complex.

The analyzed scenario does not result in breach of the glovebox. Any quantity of plutonium potentially suspended inside Glovebox 188-1 by burning hydrogen remains confined to the glovebox will be drawn through the E-4 exhaust system and filtered by a least two stages of HEPA filters before discharge to the environment.

If the deflagration occurred in Room 188, outside of the glovebox, the volume of the room is much larger than the glovebox and the pressure increase would be correspondently less, and bounded by the analysis of the glovebox. The dispersal of the nitrate solution by the accident outside of the glovebox is bounded by the analysis of the radioisotope-bearing pressurized liquid container in Section 9.1.2 of the PFP FSAR (FDH 1999) where 5 L of nitrate solution is released.

4.2.2.5 Conclusions

The release and ignition of hydrogen from a bagged 3 L polybottle is an unlikely event. If the deflagration occurred in the glovebox, the small pressure increase, if any, due to the burning hydrogen would not be sufficient to breach the glovebox. Occurrence of the accident outside of the glovebox in a larger volume would not have greater consequences. Accordingly, from a pressurization event perspective, the hydrogen does not pose a risk to workers, the public, or the environment.

If the accident occurred outside of the glovebox, the dispersal of the nitrate solution by the accident is bounded by the analysis of the radioisotope-bearing pressurized liquid container in Section 9.1.2 of the PFP FSAR (FDH 1999).

4.2.3 Flammable Gas Deflagration in the Laboratory Prototype Calciner

The aqueous solutions processed by the Laboratory Prototype Calciner contain small concentrations of entrained organic solvent residuals from processing. It is possible that the immiscible organic material in the feed solution may coalesce and separate out from solution in the feed tank and be injected as a slug into the prototype calciner. It is also possible that oil, overflowing from traps in the calciner air supply line, could be introduced through the feed nozzle into the calciner. Because the prototype calciner operates at very high temperatures (approximately 1000 °C), the injection of a slug of organic (TBP or compressor oil) may result in a flammable gas deflagration inside the calciner.

4.2.3.1 Scenario

The hazard analysis documented in Appendix A recognized the possibility that organic material could be injected into the calciner and result in a deflagration.

The most likely organic material to be pumped into the calciner is a mixture of TBP and its degradation products di-butyl phosphate (DBP) and mono-butyl phosphate (MBP). At temperatures below the auto-ignition point, the TBP and its decomposition products are likely to break down into butene, water vapor, and pyrophosphoric acid vapor (or acid decomposition products), based on experimental data reported in WHC (1994). Flammable hydrocarbons lighter than butene are also possible. For the purposes of this analysis, it is conservatively assumed that a stoichiometric mixture of butene and air develops in the calciner and is then ignited.

It is further assumed in this scenario that a total of approximately 50 ml of concentrated TBP is in the feed (in a separable phase). This quantity corresponds to 1% of a full 5 L feed tank. This material is assumed to be fed into the calciner at a rate of 1 ml/s until the supply of TBP is exhausted. This means that after the initial deflagration in the calciner, deflagrations could continue for the next 49 seconds. Variations in the rate at which material is fed to the calciner would alter the frequency and, potentially, the magnitude of a given deflagration or series of deflagrations. However, the results of this analysis are not sensitive to feed rate variations.

The calciner fails because of the initial deflagration (see Section 4.2.3.4). The flames jetting from the failed calciner in the subsequent deflagrations are assumed to generate sufficient heat to fail one of the fire-resistant plastic windows or window seals in Glovebox 188-1, creating a pathway for contamination to reach the room. This assumption is based on a calculated flame temperature of 3500 °C (see Section 4.2.3.4) due to the butene deflagration. If the flame were to impinge on the window, the heat is sufficient to damage or weaken the window and create a release pathway.

Although it is possible for flammable gases to be generated inside the calciner and to pass into the calciner offgas system, deflagrations inside the scrubber or phase separator tank are bounded by the calciner deflagration case analyzed here. Although the energy release and pressures produced in those tanks could be similar to the calciner case, the scrubber and phase separator tanks contain negligible radiological material in comparison to the calciner (e.g., 4 kg PuO_2).

4.2.3.2 Mitigation

Mitigation for this scenario is provided by minimizing the quantity and concentration of organic material that may be introduced into the calciner. As discussed earlier in Section 4.2.3, two potential sources of organic material potentially could be introduced into the calciner: concentrated TBP in the plutonium nitrate feed solution or air compressor lubrication oil.

Organic material in excess of 1% concentration in the plutonium nitrate feed solution is not permitted to be introduced into the calciner. Chapter 5.0 states that the feed solution is limited to 1% organic content with no visible, separable phase. This requirement has been shown to be effective in prior calciner operations and needs to be retained for future operations.

Additionally, to prevent the injection of compressor lubrication oil into the calciner, it is necessary to ensure that the compressed air oil trap is operational and continuously drained.

4.2.3.3 Probability

As discussed previously, two potential sources of organic material potentially could be introduced into the calciner: TBP in the plutonium nitrate feed solution or air compressor lubrication oil.

Organic material in excess of 1% concentration in the plutonium nitrate feed solution is not permitted to be introduced into the calciner. As stated in Section 2.1, the feed solution is limited to 1% organic content with no visible, separable phase of organic material. It is considered unlikely that a concentrated slug of TBP (or other organic material) would be injected into the calciner. This probability is based on: (1) the requirement to sample for organic content, (2) the requirement to confirm that no separable layer exists, (3) visual inspection of the aqueous feed prior to calciner operations, and (4) the prior operational history of calciner operations.

Feed preparation procedures require steps to sample for the presence and concentration of organic. Feed found to be excess of 1% organic content is rejected from the process. In addition, the feed is analyzed to determine if a separable layer either exists, or is likely to exist after sampling. If the feed contains (or is likely to contain) a separable phase, it is not processed in the calciner.

Prior to the start of the calciner operation, the operator inspects the feed for a separable layer. It is recognized that if the feed container does contain a separable layer of only 50 ml (1% of 5 L), it may not be easily spotted by the operator. Based on the dimensions of the feed container, this layer would only be approximately 1/16-in.-deep. Prior operational history of the calciner processing more than 60 L of solutions, primarily plutonium nitrate, and using similar inspection procedures supports the unlikely frequency since deflagrations have not been experienced, although small pressurizations of the calciner have occurred from process upsets.

Collectively, based on the discussion presented here, the probability of introducing a slug of TBP (or other organic material) into the calciner is estimated to be unlikely.

Similarly, it is considered unlikely that air compressor lubrication oil would be injected into the calciner. WHC (1996) also recognized and eliminated this hazard by modifying the filter trap drain lines so that they are left permanently open.

Therefore, in order for compressor lubrication oil to be injected into the calciner, a number of failures would be required. Currently, the drain on the air line trap is kept open, with air line condensate/oil draining into an open 3 or 5 gal container. The line between the trap and

open drain container would have to fully plug and remain plugged for an extended period to allow the trap to fill. Overflow of the trap with oil would then be required. In order for the trap to overfill, numerous operator surveillance activities would need to be missed (i.e., not recognizing a plugged drain line or material buildup in the trap).

The scenario analyzed is this section is estimated to have an annual probability that falls in the unlikely range (i.e., 10^{-4} to 10^{-2}).

4.2.3.4 Consequence Analysis

For this accident analysis, it is conservatively assumed that a stoichiometric mixture of flammable gas and air develops in the calciner and is ignited. As discussed in Section 4.2.3.1, the most likely material to be pumped into the calciner is a mixture of TBP and its degradation products DBP and MBP. The TBP and TBP decomposition products are expected to break down into butene, water vapor, and pyrophosphoric acid vapor (or acid decomposition products). For the purposes of this analysis, the volume of the calciner vapor space taken up by water and acid vapor (or acid decomposition products) is conservatively ignored. The vapor space gas mixture is assumed to be composed only of air and butene gas, with the oxygen from the air and the butene in stoichiometric proportion. The air for the combustion reaction is supplied by the atomizing injector.

The internal volume of the calciner, excluding the volume of the internal dome heater and the volume of the ceramic filters has been estimated to be 7.7 L. Assuming a PuO_2 mass of 4 kg at its maximum estimated bulk density of 5.67 kg/L (Hillesland 1997), the maximum freeboard volume in the calciner vessel is 7.0 L. Variations in the density of the PuO_2 (creating slightly more or less freeboard volume) do not have a significant effect on the pressures that are generated in the calciner.

If it is assumed that the flammable mixture in the freeboard volume is at the normal offgas operating temperature of 626 °C (see Figure 14) at the time of ignition and at atmospheric pressure, the total quantity of butene and air in the calciner at the time of ignition, per the ideal gas law, is 0.095 g-mol. The balanced equation for the reaction of butene in air is as follows:

$$C_4H_8 + 6O_2 + 22.6N_2 \rightarrow 4CO_2 + 4H_2O_{(vapor)} + 22.6N_2$$

The ratio of N_2 to O_2 in the above equation reflects the ratio of N_2 to O_2 in atmospheric air. Based on the above equation, of the 0.095 total moles of gas initially in the calciner, 3.21×10^{-3} moles are butene molecules to ensure a stoichiometric mix. The mole fraction of butene in the calciner air is 3.50×10^{-2} (3.50%). Similarly scaling the remaining reactant and product species coefficients for the total number of moles of gas initially in the calciner gives the following balanced equation:

$$3.21 \times 10^{-3}\ C_4H_8 + 1.9 \times 10^{-2}\ O_2 + 0.073\ N_2 \Rightarrow$$

$$1.28 \times 10^{-2}\ CO_2 + 1.28 \times 10^{-2}\ H_2O_{(vapor)} + 0.073\ N_2$$

The heat of combustion for butene is 19,496 BTU/lb (Section 22 of Perry [1950]), or 2537 kJ/g-mol. The total heat released in the deflagration is therefore 8.14 kJ ([2537 kJ/g-mol][3.21 x 10^{-3} g-mol]) or 7.71 BTU.

To calculate the pressure that is generated inside the calciner, the ideal gas law is used. In order to accurately determine the pressure created by the combustion products of the deflagration inside the calciner, it is first necessary to determine the temperature that is created inside the calciner. To do this, the following equation is used:

$$Q = mc_v\Delta T \qquad (1)$$

where:

Q = energy created by reaction, 8.14 kJ (1,945 cal)
m = mass of product, g (see following equation for values)
c_v = specific heat of product, cal/g-°C (assumes constant volume reaction)
ΔT = temperature difference, °C

Tailoring this equation to the combustion products of the reaction analyzed here and solving for ΔT gives:

$$\Delta T = Q/(m_{CO2}c_{v(CO2)} + m_{H2O}c_{v(H2O)} + m_{N2}c_{v(N2)}) \qquad (2)$$

where:

Q = 1,945 cal
m_{CO2} = 0.528 g
m_{H2O} = 0.216 g
m_{N2} = 2.04 g
$c_{v(CO2)}$ = 0.260 cal/g-°C
$c_{v(H2O)}$ = 0.480 cal/g-°C
$c_{v(N2)}$ = 0.219 cal/g-°C

The c_v values shown here were calculated using an iterative procedure to account for the wide temperature range associated with this reaction. Using a polynomial expansion method similar to that found in Chapter 6 of Lindeburg (1994) and a final iterative temperature of 1,997 °C (2270 K), the listed specific heats are developed.

Solving equation (2) gives a ΔT of 2,830 °C. Calculating a final temperature of the reaction gives 3,456 °C ($\Delta T + T_i$ = 2,830 °C + 626 °C). To determine the final pressure in the calciner, the ideal gas law is used. Input parameters include the calculated final temperature (3,456 °C), the interior freeboard volume of the calciner (7.0 L), and the total number of moles of combustion products in the calciner (0.099 g-mol). The final pressure is calculated to be 63 psi.

The calciner is constructed of stainless steel pipe. The pipe will have reduced strength at the extreme operating temperature of the calciner (up to 1000 °C) and would likely rupture due to the pressure generated as a result of the deflagration. Calculations performed in Appendix E show that the calciner would fail at a pressure of approximately 24 psi. It is clear that rupture of the calciner would be expected as a result of a deflagration of butene vapors.

The production of shrapnel fragments that could penetrate the glovebox structure, however, is not anticipated, due to the ductility of the metal at high temperatures. The shape and design of the agitator prevent it from being ejected out of the top of the calciner. The product collection jar, however, is likely to rupture in the accident. Pressure relief will occur through the product drop tube on the bottom of the calciner because of the broken product collection jar, through the calciner pressure relief port, and through any openings that might develop in the calciner shell. Plutonium dioxide powder will be expelled out of these relief paths into the glovebox air. It is assumed in the scenario that the calciner fails such that flames and hot gases are directed toward the fire-resistant window in Glovebox 188-1.

The hot offgases generated from the calciner deflagration expanding through the calciner relief paths will cause a pressure increase in the Glovebox 188-1 air. The gas flow from the calciner will be limited to sonic velocity through the calciner relief paths.

For this analysis, the pressure increase in the glovebox is calculated using equation (2) that has been modified using the specific heat (c_v) for air and the mass of air present initially in the glovebox. The c_v for air is taken to be 0.171 cal/g-°C and the mass of air initially present is calculated using the ideal gas law. Section 4.2.2.4 states that the available expansion volume in the glovebox is 6,570 L. If the initial temperature of the glovebox air is 300 K, the number of moles of air present in the glovebox is 267 g-mol (7,743 g).

If the heat generated in the calciner deflagration is transferred to the glovebox air, equation (2) can be solved for ΔT:

$$\Delta T = Q/(m_{air}c_{v(air)}) \qquad (3)$$

Substituting the values stated previously gives a ΔT of only 2.4 K. This means that the final temperature of the glovebox air is 302.4 K.

Substituting this temperature value into the ideal gas law gives a final pressure of 14.8 psi in the glovebox. This is an increase of only 0.1 psi over the initial pressure. Based on the

discussion provided in Section 4.2.2.4, the confinement capability of the glovebox structure is not expected to be compromised as a result of this overpressure. In addition, as also discussed in Section 4.2.2.4, the E-4 exhaust system filters are not expected to be affected by this small of an overpressure.

A breach of the glovebox, however, is postulated in this scenario. Because the flames and heat from each deflagration are assumed to be directed toward one of the fire-resistant plastic windows, it is assumed that the confinement capability of that plastic window is compromised by melting, burning a hole through it or damaging the window seal. This provides a release path to Room 188.

Following the initial deflagration, it is postulated that TBP continues to be injected into the calciner at a flow rate 1 ml/s. The glovebox ventilation exhaust system (E-4) is assumed to continue to operate. This provides a source of air for subsequent deflagrations. Therefore, deflagrations are assumed to continue for the next 49 seconds until the remaining TBP is exhausted. As the deflagrations are occurring, process air continues to flow into the calciner. The air violently disturbs (i.e., sparges) the bed of plutonium oxide powder creating airborne material and spreading contamination to the glovebox and the room.

The fire is not expected to spread outside of Glovebox 188-1. If other combustibles are present in the glovebox, it is possible that they could catch fire and contribute to the release. Besides the plastic window that is assumed to fail in this scenario, the remainder of the glovebox is made of steel and glass (see Section 2.3.3.1).

It is conservatively assumed in this scenario that the equivalent of 4 kg of PuO_2 is subject to release. This value is equivalent to a full bed of material. Using 4 kg is intended to cover the amount of Pu that is vented in the initial deflagration, the amount spilled from the broken product collection container, and amount created from the subsequent process air sparging and deflagrations. Two off-normal events that occurred during prior operation of the calciner demonstrate that large releases are possible. In one of the off-normal events (i.e., pressurization of the calciner), it was estimated that 50 to 60 g of material was released in a period of 15 to 30 s. Section 4.2.5.1 provides additional discussion of these events.

All of this material is conservatively assumed to be available for release (i.e., airborne release fraction [ARF] = 1). This value seems reasonable given that the process air continues to be injected into the calciner during and after the assumed deflagrations. The respirable fraction for this release is estimated to be 3%, based on Figure 9-28 in the PFP FSAR (FDH 1999). The figure is based on data for plutonium fluoride which is assumed to also be representative of plutonium oxide. Applying the ARF x RF (1 x 0.03) to the 4 kg of material assumed to be released gives a respirable quantity of 120 g (4,000 g x 0.03).

For the purposes of this analysis, it is conservatively assumed that the all of the plutonium aerosol generated is exhausted via the E-3 exhaust system servicing Room 188. The E-3 exhaust system has only a single stage of HEPA filtration whereas the E-4 exhaust system (which exhausts Glovebox 188-1) has two stages. While it is likely that some portion of the plutonium aerosols would be exhausted through the E-4 exhaust system that services the glovebox, there is

no justifiable basis for determining the aerosol split that may be realized through the ventilation exhaust systems. Therefore, if it is assumed that the entire quantity of plutonium aerosol is vented through the one stage of HEPA filtration in the E-3 exhaust system, the calculation of released quantity will be conservative. The minimum acceptable collection efficiency, as indicated by testing, is 99.95%. Applying this value to the 120 g of plutonium released via the E-3 exhaust pathway, results in the discharge of 0.06 g from the 291-Z-1 Stack, all of which is respirable.

The doses due to the release of 0.06 g of plutonium can be calculated by using the methodology from Section 9.3.6 of the PFP FSAR (FDH 1999) as follows:

$$D(rem) = Q(g) \cdot \chi/Q'(s/m^3) \cdot R(m^3/s) \cdot C(rem/g)$$

where:

D = Dose, rem

Q = Quantity of plutonium released, 0.06 g

χ/Q = Atmospheric dispersion coefficient for elevated release, 1.62×10^{-5} s/m^3 for onsite receptor and 5.73×10^{-6} s/m^3 for offsite receptor from Tables 9-39 and 9-40, respectively, of the PFP FSAR (FDH 1999)

R = Breathing rate, 3.3×10^{-4} m^3/s

C = Gram plutonium to dose conversion factor for Class Y, >10% ^{240}Pu, 90th percentile; 1.7×10^{8} rem/g (EDE) and 2.7×10^{9} rem/g (Bone Surface) from Tables 9-46 and 9-47, respectively, of the PFP FSAR (FDH 1999)

Therefore, the EDE doses are:

- onsite = 5.5×10^{-2} rem
- offsite = 1.9×10^{-2} rem

The bone surface doses are:

- onsite = 0.87 rem
- offsite = 0.31 rem

4.2.3.5 Conclusions

The results of the preceding analysis show that the consequences of a bounding calciner deflagration are below the risk acceptance guidelines (Table 9-49 of the PFP FSAR [FDH 1999]) for an unlikely event. The reason the doses remain so small is the functioning of the E-3 exhaust system HEPA filters during and after the calciner deflagration event.

4.2.4 Glovebox 188-1 Fire

Section 4.2.3 analyzed the impacts of a deflagration occurring inside the calciner and, potentially, impacting the confinement capability of Glovebox 188-1. The fire analysis in this section evaluates the potential for a significant fire to occur in the glovebox due to combustible materials coming into contact with the hot process equipment.

4.2.4.1 Scenario

The hazards identification team determined that a glovebox fire could be initiated in one of the following ways:

- Pump or motor burnout
- An accumulation of flammable waste materials is placed next to a hot surface.

There is one pump and one motor within the glovebox. The pump transfers feed from the feed tank into the calciner. The agitator drive motor drives the agitator. Neither the pump nor the motor is near the area where waste is normally accumulated. The feed pump is at the bottom of the glovebox beneath the floor of the operating area. The agitator drive motor is up high in the glovebox, well above the operating deck.

The waste in the glovebox is comprised primarily of plastic bags, ice cream cartons and polybottles. The feed solution is transferred to Glovebox 188-1 in polybottles within plastic bags. The waste is kept at the far right hand side of the glovebox near the bag-out port. This location is well away from the pump and the agitator motor. There are two fire-resistant plastic windows in the glovebox. The windows are situated above the floor of the operating area. The bottom of the windows are near the center of the calciner. The top of the windows are near the top of the glovebox. The agitator drive motor is not near the plastic windows. Therefore, motor burnout would not start the plastic windows on fire as they are too far away and the motor is small.

A pump or motor burnout could create a small, short duration fire. However, as is discussed above, this fire would not likely involve combustible materials and, therefore, would not be expected to be large enough to disperse radioactive material or cause operator injury.

A fire could conceivably start if combustible material was brought in contact with hot surfaces. Hot surfaces include the calciner, the calciner off-gas piping and the product piping and collection jar. In general, the hot surfaces are either well insulated or located near the top of the glovebox far from the normal location of waste accumulation. The calciner is insulated to prevent heat loss and operator injury. The insulation extends from the base of the calciner, 4 in. above the glovebox operating area floor, upward to just above the calciner off-gas outlet nozzle. The insulation temperature remains below 50 °C (WHC 1996). There is also insulation around the feed and product tubes between the base of the calciner and the operating floor.

The off-gas lines can become quite hot. The off-gas temperature is around 330 °C (FDH 1998a). The off-gas lines are in the upper half of the glovebox, in the vicinity of the plastic

panel. The plastic panel also contains a few gloves with additional ports for other gloves. The off-gas piping extends above the insulation and is cooled by radiation and convection to the glovebox air. The pipes are ¾-in. tubing. One of the off-gas tubes comes out of the calciner towards the panel. The tube is then routed parallel to the panel, about 6 in. away, for about 8 in. It then travels back toward the center of the glovebox. Except for this short run, the hot off-gas tubes are at the center of the glovebox about 22 in. from the panel and gloves. Operation of the calciner during testing showed that the plastic panel and gloves are unaffected by the heat from the off-gas tubes. Waste accumulations are on the operating deck far from the off-gas tubing. It is possible that a hole could be melted in a glovebox glove if the operator inadvertently touches an off-gas tube or if the gloves are left inside the glovebox near the portion of the off-gas tubing that passes close to the glovebox. This location is recognized by the operators as being hot and care is taken to keep the gloves away.

The product line can also become hot. The product line drops down below the calciner into the lower portion of the glovebox. There are no plastic panels or waste at this location; however, there are gloveports in the glass windows at this location. Gloves could touch the hot tube or collection jar. Both are located about 18 in. from the side of the glovebox and are small. Care is taken to keep the gloves away from this location. This location is recognized by the operators as being hot and care is taken to keep the gloves away.

Lastly, the gap between the calciner base and the glovebox operating floor can get hot. The heat comes from radiation through the calciner base and convection of the hot dome air (heated by the internal dome heater) down into the gap. The gap is 4 in. tall and 16 in. in diameter. The feed tube, product tube, and dome heater are inside of a 5 in. diameter circular area near the centerline of the calciner. The calciner is supported by 4, ½ in. posts on an 8 in. diameter circle. The posts are within a base tray that is square in shape having sides 16 in. long. The sides of the base are made of 1 in. by 1 in. angle iron. As a result, the actual gap is only 3 in. wide. If waste should get into this gap, close to the heat sources near the center of the calciner, it could be ignited. The fire would likely be small, as it is not expected that much waste can get to this location. The area contains feed tubing, scrubber tubing and waste tubing. The plastic windows are about 18 in. above the floor and about 16 in. from the center of the calciner. The separation distance prevents propagation to the windows. It is possible that a glove or other combustible, such as window seals, could burn but the fire would not propagate.

As a result, under normal operational conditions there would be no fire due to contact of gloves, plastic windows or waste with hot surfaces. It is possible, however, for a hole to be burned in a glove and it is possible for small fires to occur. It is also possible that debris from maintenance could be inadvertently left near a hot surface. It is believed that this fire, if it occurs and is not extinguished, would remain small, as large accumulations of debris would almost certainly be removed following maintenance.

Even if a fire should start, there is a dry chemical, bayonet-equipped, portable fire extinguisher external to the glovebox. The bayonet can be pushed through any number of gloved, glovebox ports to fight fires inside the glovebox. There is also a wet pipe sprinkler system in the room.

All except two of the glovebox windows are made of wire-reinforced glass, not plastic. Because of this, ignition of combustibles leading to a fire that can directly or indirectly result in the dispersal of radioactive material outside the glovebox is not considered to be credible.

Even though a fire in the glovebox during normal operations is not considered credible, it is possible for a seismic event to result in a fire within this glovebox. The analysis of a seismically initiated fire in Glovebox 188-1 is included in Section 4.2.5.

4.2.5 Glovebox 188-1 Seismic Event

This section presents unmitigated and mitigated Design Basis Earthquake (DBE) accident analyses for the Laboratory Prototype Calciner. The purpose of these analyses is to quantify the incremental risk associated with calciner operations relative to analyses contained in Chapter 9 of the PFP FSAR (FDH 1999).

The calciner is housed in Glovebox 188-1 of the Plutonium Process Support Laboratory (PPSL). The PPSL encompasses Rooms 179 through 191 and Rooms 201 and 202 of Building 234-5Z. The structural response of Building 234-5Z to the DBE is discussed in Chapter 9, Section 9.2.4.1.1 of the PFP FSAR. Seismic analyses and evaluations have concluded that Building 234-5Z can resist DBE motions without collapse. However, internal structures (e.g., gloveboxes), systems (e.g., ventilation), and components (e.g., motors) can be damaged.

Chapter 9, Section 9.2.4.2.1I of the PFP FSAR states that gloveboxes in the PPSL are not seismically qualified and assumes that powders and solutions contained therein are spilled. Glovebox 188-1 has been upgraded and is qualified to withstand seismic events to prevent a criticality as a result of the seismic event and for personnel protection from a falling glovebox. Although the glovebox will not topple, glovebox windows, equipment within the glovebox, and supporting services are not qualified and may or may not fail during a seismic event.

Section 4.2.5.1 presents an unmitigated DBE accident analysis where no controls are credited with shutting down the calciner. The unmitigated consequences are shown to exceed radiological risk acceptance guidelines such that a control is warranted. Section 4.2.5.2 presents the mitigated DBE accident analysis that assumes that an interconnection to the PFP ventilation seismic shutdown system deenergizes calciner equipment and systems to prevent pressurization of the calciner and generation of airborne material. Section 4.2.5.3 analyzes the same event as Section 4.2.5.2 but further postulates a seismic induced fire. The mitigated consequences are shown to meet most of the radiological risk acceptance guidelines.

4.2.5.1 Unmitigated Seismic Event

To identify credible DBE scenarios, an event tree was developed that postulated the success or failure of calciner systems and components (Appendix F). The systems and components selected for inclusion in the event tree were those whose failure could directly and significantly contribute to the release of plutonium. The event tree identified thirty unique sequences initiated by a seismic event, nine of which were judged to result in large releases.

Large releases were determined to result primarily from event sequences leading to a pressurized calciner due to continuing feed injection along with the process air supply to the calciner. This information combined with the hazards analysis binning and accident selection (Section 3.2.1) led to selection of the unmitigated scenario presented here. Although the HAZOP recorded an S2 consequence (onsite receptor), the subsequent analysis found possible offsite receptor consequences. The individual frequencies (or annual probabilities) of the nine event sequences resulting in large consequences ranged from 1.5×10^{-5}/y to 9×10^{-7}/y. Summing the nine event sequences yields a frequency of 2.7×10^{-5}/y. Consequently, a seismic event potentially leading to large releases is considered credible and has been analyzed for potential consequences and comparison with the applicable risk acceptance guidelines.

The main function of the event tree for the unmitigated seismic analysis was to determine the credibility of a postulated large release from the calciner process equipment and, if credible, to determine the set of conditions leading to the largest consequence. The probability values used in the event tree were based on qualitative engineering judgement without any attempt to perform field evaluations of the various component and system designs to determine their ability to withstand a seismic event. Consequently, for risk acceptability comparisons for the unmitigated seismic event analysis, all component and system failures were assumed to occur with a probability of 1 rather than the estimated value in the event tree. Therefore, for risk acceptability purposes, the accident dose consequences are evaluated against the guidelines at the annual seismic event probability of 1×10^{-4}. This is conservative since larger doses are acceptable at lower probability values, which would be the case if components were determined to fail at probabilities less than 1.

The specific scenario selected to quantify the unmitigated consequences of a DBE assumes that the 26-in.-Hg vacuum system servicing the calciner fails. The calciner is assumed to continue operating and feed to the calciner is assumed to continue. Given loss of vacuum and continuation of feed, the calciner will pressurize to the point that the pressure relief cap actuates. Detailed scenario development and dose calculations are presented in Appendix F. The entire 4.0 kg of plutonium contained in the calciner and 2.25 kg of plutonium in the liquid feed is conservatively assumed to be ejected from the calciner. Figure 9-28 of the PFP FSAR (FDH 1999) provides data for respirable fraction (RF) for plutonium fluorides that yields a value of 0.03. Although the data in the figure is for plutonium fluoride, it is assumed that it is also applicable to plutonium oxide. Applying the 0.03 RF to the plutonium oxide and an airborne release fraction (ARF) of unity, the respirable release is calculated to be 188 g ($6{,}250 \text{ g} \times 0.03 = 187.5 \text{ g}$).

In Appendix F, the onsite and offsite doses were calculated for both the "no ventilation" and the "ventilation" cases. In the "no ventilation" case, both the ventilation supply and exhaust fans are assumed to shut down during the earthquake. Although the ventilation system is non-operational, airborne radiological material can escape to the environment via open doors due to wind effects. Chapter 9, Section 9.2.4.7.1 calculates that 38% of the airborne material is released. The release for the unmitigated scenario is, therefore, 71 g. From Appendix F, the corresponding onsite and offsite doses are 1040 rem EDE and 22 rem EDE, respectively. These doses exceed the radiological risk acceptance guidelines shown in Table 9-49 of the PFP FSAR (FDH 1999) for an event with an annual probability of 1×10^{-4}.

In the "ventilation" case, the E-3 and E-4 exhaust fans are assumed to continue to operate but the associated ventilation system HEPA filters are assumed to fail. Chapter 9, Section 9.2.4.7.2 calculates that, as a result of settling within the facility, 84% of the airborne material is released to the environment. The release for the unmitigated scenario is therefore 158 grams. The corresponding onsite and offsite doses calculated in Appendix F are 79 rem EDE and 28 rem EDE, respectively.

Based on the large doses potentially resulting from an unmitigated seismic event, a mitigative feature was selected and is discussed in the following section, Section 4.2.5.2.

4.2.5.2 Mitigated Seismic Event

The previous section demonstrated the need for a mitigative feature to prevent unacceptable consequences resulting from a seismic event. The mitigative feature selected, as discussed in the following paragraphs, is to interconnect various calciner process equipment and systems to the existing PFP ventilation seismic shutdown system. This interconnection deenergizes various components and, thereby, prevents pressurization of the calciner and potential release of significant quantities of airborne material. This section analyzes a seismic event involving the calciner process equipment incorporating the mitigation afforded by the interconnection to the seismic shutdown system.

The mitigative feature selected involves the principal operating equipment for the calciner having been interconnected to the PFP ventilation seismic shutdown system. This interconnection results in deenergizing the following components:

- calciner heaters including the dome heater
- process air supply solenoids to close valves A through G shown in Figure 7.
- agitator motor
- feed pump motor

Deenergizing the above equipment prevents the potential pressurization of the calciner and generation of significant airborne material by shutting off the air supply to the calciner feed nozzle and to the offgas filters and by shutting off the calciner feed solution. Shutting off the agitator limits the potential for sweeping material out of the calciner bed. Shutting off the heaters reduces the potential for boiling of solutions released into the glovebox and potential ignition of flammable materials.

In addition to the components deenergized by the seismic shutdown system, two check valves (designated as valves H and I on Figure 7) are provided in the inlet air line to the accumulator supplying air for the offgas filter back-pulse operation. These valves prevent backflow of air from the accumulator to the feed nozzle which could result in pressurization of the calciner and generation of airborne material. The check valves are redundant to the solenoid valve (valve C on Figure 7) on the air supply line to the feed nozzle which is deengerized to close by the seismic shutdown system.

Incorporation of the interconnection to the PFP ventilation seismic shutdown system, when factored into the accident analysis for a seismic event, results in offsite dose consequences below the Risk Acceptance Guidelines (RAG) and onsite dose consequences for the accumulator depressurization case that are slightly above the RAG, as demonstrated in the remainder of this section and and in Section 4.2.5.3. Descriptions of the components interlocked with the seismic shutdown system and the related design requirements are provided in Chapter 2.0. The related controls and safety designation are provided in Chapter 5.0.

4.2.5.2.1 Scenario. It is assumed that the calciner is operating at its normal, maximum operating temperature (e.g., a calciner wall temperature of 1000 °C) at the time of the DBE. Similar to the unmitigated analysis, it is assumed that the DBE results in a loss of calciner vacuum. The interconnection to the PFP ventilation system seismic shutdown system is assumed to function as designed, thereby shutting down the heaters, agitator motor, and feed pump, and closing the solenoid valves on the incoming air supply header which provides air for the feed nozzle and for filter back-pulse operation.

Closing the air supply solenoid valves prevents continuous pressurization of the calciner given a loss of vacuum. However, it is assumed that the solenoid and check valves (Figure 7, valves C, H and I), between the air accumulator (nominally pressurized to 70 psig) and the feed nozzle fail such that air flows through the calciner bed as the accumulator depressurizes. This airflow through the bed results in the suspension of plutonium oxide. Also, assuming failure of solenoid valves D, E, F and G (Figure 7), air from the accumulator could also flow to the calciner filters, which would dislodge any accumulated material. Given loss of vacuum, depressurization of the accumulator will pressurize the calciner to the point that the pressure relief cap lifts, thereby releasing plutonium suspended within the calciner into the glovebox.

After the air accumulator depressurizes, it is assumed that the calciner, feed tank, and product receiver vessel structurally fail in a manner that releases their contents into the glovebox as described below.

Calciner Failure. The calciner contains 4 kg of plutonium as an oxide powder. Because the calciner metal parts are at high temperatures, it can be postulated that the calciner body or flange bolts fail due to the additional stress caused by the DBE. If the calciner body would fail, it is likely that failure would result in the release of some of the plutonium oxide powder. However, it is conservatively assumed that all of the powder is released.

The seismic event could cause failure of the calciner chamber heater/insulation sections. These half-sections could become detached from the calciner body, thereby exposing the heating elements at an initial temperature as high as 1250 °C and the body which could be at 1000 °C. Another possibility is failure of the upper insulation sections. This would expose the upper part of the calciner body which is at a lower temperature than the chamber region.

If the calciner fails and exposes hot surfaces and hot powder, heat would be lost by radiation, conduction, and convection to the glovebox walls, decks, ceiling, air, and any liquids that come into contact with the hot surfaces. The calciner body and inner chamber (with dome) are cylindrical and would be expected to retain partial cylindrical shape. Some of the calciner

flanges could be expected to remain attached in their design configuration. These features limit the metal contact surface available for heat transfer to the feed liquid. Therefore, only a fraction of the calciner heat stored in the metal mass could transfer heat to the feed liquid.

The plutonium oxide powder released from the calciner would land on the intermediate level of the glovebox and some could fall to the floor of the glovebox through openings in the intermediate level deck. Some of the powder could be entrained in the glovebox air as it falls to the floor of the glovebox. The convective air currents driven by the hot segments and pieces from the failed calciner would tend to suspend plutonium oxide powder. In addition, hot oxide powder could loft some surface material due to thermally driven air currents. If hot powder were to contact plutonium-bearing feed liquid, it could cause boiling of the liquid and consequent release of plutonium. Some of the plutonium oxide powder that is postulated to boil the liquid might be resuspended by puffs of vapor.

Product Receiver Vessel. The product receiver vessel can hold 0.750 kg of plutonium as an oxide powder. The vessel is constructed of glass and is assumed to fail, releasing all of its contents. The plutonium oxide powder in the receiver vessel cools after exiting the calciner, and thus is not at the maximum temperature of the calciner. As was the case with the calciner powder, the falling receiver vessel powder can become airborne. The powder could also come into contact with feed liquid causing boiling of the liquid.

Liquid Feed Tank. The liquid feed tank holds 5 L of feed solution containing 2.25 kg of plutonium assuming a plutonium concentration of 450 g/L. The tank is constructed of glass and is assumed to fail releasing all of its contents. Solutions from the failed liquid feed tank could fall to the glovebox intermediate level floor and spread out. If the floor were perfectly flat and perfectly level, the depth of the liquid would be approximately 0.1 cm. The intermediate level deck ends before it reaches one of the glovebox walls. Also, there is one opening in the intermediate level deck under the calciner and another a short distance away. Thus, the liquid might drain to the floor of the glovebox. If the intermediate deck is not level, the liquid may simply drain to the lowest spot on that deck. If the intermediate level is uneven, some liquid might form one or more pools.

Some liquid could flow adjacent to hot pieces of the failed calciner (e.g. metal, heaters, insulation) or hot plutonium oxide powder. Some portion of the solution, therefore, could vigorously boil or flash to steam, causing an additional aerosol generation and release to the glovebox air.

4.2.5.2.2 Mitigation. Mitigation is provided by the interconnection to the PFP ventilation seismic shutdown system that terminates calciner process equipment and system operations during a seismic event. The interconnection to the seismic shutdown system and the actions accomplished upon detection of a seismic event are discussed in Section 4.2.5.2.

4.2.5.2.3 Probability. The annual probability of the 0.2g DBE is given in the PFP FSAR (FDH 1999) as $1x10^{-4}$. The events in the scenario postulated above are assumed to occur with a conditional probability of one (1) given the occurrence of the earthquake.

4.2.5.2.4 Consequence Analysis. The accident scenario assumes that 4.75 kg of plutonium as an oxide powder and 2.25 kg of plutonium as plutonium nitrate solution is released into the glovebox. Physical forces acting to suspend this material include free falling through air, boiling, aerodynamic entrainment, and evaporation. The movement and distribution of the plutonium oxide powder and plutonium nitrate materials within the glovebox cannot be accurately predicted. However, the distribution impacts the quantity of material released into the facility due to the potential for the liquid contacting hot surfaces and boiling. To quantify the onsite and offsite doses, the following assumptions are made:

1. The accumulator, at a pressure of 70 psig, depressurizes by airflow through the feed nozzle into the calciner bed that contains 4000 g Pu.

2. The steady-state concentration of respirable Pu in the calciner head space due to normal operations is 2.2 g. This value is derived in Appendix I.

3. A total of approximately 4.75 kg of plutonium as an oxide powder is released from the calciner and product receiver vessel, a fraction of which becomes airborne while falling. The term "approximately" is used as 2.2 g Pu are present in the calciner head space per assumption 2.

4. 5 L of liquid containing 2.25 kg of plutonium is released from the feed liquid tank, a fraction of which becomes airborne while falling.

5. Half of the feed liquid is assumed to absorb the heat stored in half of the plutonium oxide powder (2.375 kg) and one-fourth of the heat stored in the major metal calciner segments.

6. The other half of the feed liquid is assumed to fall, splatter, and come to rest in a benign location and evaporate.

7. The other half of the powder (i.e., that not contributing to heating of the liquid) is subject to entrainment by thermally-generated air currents.

The assumptions above are judged to form a reasonable and conservative basis for consequence analyses for a seismic event. The quantity of respirable airborne plutonium is calculated in the following subsections. The glovebox panels and HEPA exhaust filters are not seismically qualified, so all releases into Glovebox 188-1 are assumed to be available for release from Building 234-5Z.

4.2.5.2.4.1 Analysis of Releases from Glovebox 188-1 into the Facility.

Airborne Release from Accumulator Depressurization. The accumulator tank has a volume of 2.3 L and is normally pressurized to 70 psig during calciner operation. Based on tests conducted with the laboratory prototype calciner, the accumulator depressurizes in 15 seconds. As the accumulator depressurizes, air flows through the feed nozzle (at an initial velocity of 21 m/s) and into the bed thereby suspending plutonium oxide. The release due to accumulator air passing through the bed is 9 g Pu as an oxide powder. In addition, it is assumed that the calciner headspace contains 2.2 g Pu resulting from normal operation for a total release of 11.2 g Pu. The derivation of these values is presented in Appendix I. Appendix I also presents an evaluation of airflow through the ceramic filters versus through the feed nozzle and concludes that the feed nozzle release is larger.

Airborne Release From Falling Plutonium Oxide Powder. Falling powder is made airborne due to the shearing forces imparted during freefall. The applicable release fraction is based on data for free-fall spills of fine uranium oxide powders from a height of 1 meter (DOE 1994b, Section 4.4.3.1.2). This data is applicable since plutonium oxide and uranium oxide have similar bulk densities and particle size distributions. The airborne release fraction (ARF) of 8×10^{-5} multiplied by the respirable fraction (RF) of 0.5 gives a respirable release fraction of 4×10^{-5}. Use of this value is conservative as the powder has less than one meter to fall. Thus, the respirable release due to falling powder is:

$$M_f = 4750 \text{ g} \times (4 \times 10^{-5}) = 0.190 \text{ g}$$

Airborne Release From Falling Plutonium Nitrate. Falling solutions are made airborne due to shearing forces imparted during freefall and impact. The applicable release fraction is based on data for free-fall spills of uranyl nitrate hexahydrate (UNH) from a height of 3 meters (DOE 1994b, Section 3.2.3.1, Table 3-6). The UNH data are stated to apply to any solution containing heavy metal salts where the liquid alone has a density in excess of ~1.2 g/cm^3 (considered a "concentrated heavy metal solution"). The ARF (1×10^{-5}) multiplied by the RF (1.0) gives a respirable release fraction of 1×10^{-5}. Use of this value is conservative as the distance from the feed tank to the intermediate level is much less than a meter, and the distance from the intermediate to basement levels is less than one meter. Thus, the respirable release due to falling plutonium nitrate is:

$$M_s = 2250 \text{ g} \times (1 \times 10^{-5}) = 0.023 \text{ g}$$

Airborne Release from Boiling Plutonium Nitrate. As stated in assumption 3 above, half of the feed liquid is assumed to absorb the heat stored in half of the powder (i.e., 2375 g) and one-fourth of the heat stored in major calciner metal segments. Detailed calculations are presented below.

Heat Content of Plutonium Oxide Powder. It is assumed that half of the feed liquid (2.5 L) is heated by 2375 g of hot plutonium oxide powder. Heat transfer from the powder to the steel glovebox metal floor is conservatively neglected. The heat available in the powder to boil the solution (Qp) is given by:

$$Qp = Mp \times Cp \times (T_{ip} - T_{bl})$$

where:

Mp = mass of available plutonium oxide powder, g
Cp = average specific heat of powder over the temperature range, cal/g-°C
T_{ip} = initial temperature of the powder, °C
T_{bl} = boiling temperature of solution, °C

It is assumed that the initial temperature of the oxide powder is 1000 °C. This is conservative as the powder in the receiver vessel will be at a significantly lower temperature. The *Chemistry of Actinide Elements* (Katz 1986), Table 7.70, "Thermodynamic properties of plutonium dioxide," provides the following correlation for the specific heat that covers the temperature range of interest, 100-1000 °C.

$$Cp\ (J/K\ mole) = 92.80 + (8.702 \times 10^{-4}) \times T - (20.648 \times 10^{5})/T^{2}$$

where:

T = temperature in K and the temperature range is 192-1400 K

This correlation was used to obtain the oxide specific heat in cal/g-°C using the following data:

Gram molecular weight of PuO_2 = 271.1 (assuming the material is 89.95 % ^{239}Pu, 9% ^{240}Pu, 1% ^{241}Pu, 0.05% ^{242}Pu) and 4.184 J/cal.

The correlation shows that the specific heat changes by about 6% in the range of 300-1000 °C. Therefore, an average specific heat of 0.08 cal/g-°C (value at 600 °C) for the oxide powder was chosen. The boiling temperature of a 4 M nitric acid solution is a few degrees above 100 °C. However, 100 °C was used and is conservative because the hot materials deposit less energy with increasing boiling point. A change of +/- 10 °C in the boiling point results in a change of the amount vaporized by less than 3%. The available heat in the powder is:

$$Qp = 2375\ g \times 0.08\ cal/g\text{-}°C \times (1000 - 100)\ °C$$

$$Qp = 1.71 \times 10^5 \text{ cal}$$

Heat Content of the Failed Calciner. It is assumed that the feed tank liquid comes into contact with some segments of the failed calciner. It is further assumed that one-fourth of the heat stored in the calciner metal (stainless steel) mass heats some of the liquid. The metal parts assumed to obtain the mass include the lower flanges, body, and inner chamber for a total of 26 kg (see Appendix G). The metal parts are conservatively assumed to be at 1000 °C although some of the metal could be substantially cooler. An average stainless steel specific heat of 0.14 cal/g-°C (ORNL 1975) yields the total heat stored in the metal as:

$$Qc = Mc \times Cp \times (T_{ip} - T_{bl})$$

$$Qc = 26{,}000 \text{ g} \times 0.14 \text{ cal/g-°C} \times (1000 - 100) \text{ °C}$$

$$Qc = 3.28 \times 10^6 \text{ cal}$$

Of this total heat, one-fourth, or 8.2×10^5 cal, is assumed to be available to boil liquid. Thus, the total heat available (Q_t)is:

$$Q_t = Qp + 0.25 \times Qc = (1.71 + 8.2) \times 10^5 = 9.9 \times 10^5 \text{ cal}$$

Volume of Boiled Plutonium Nitrate. It is again conservatively assumed that this heat is transferred to an ideal amount of liquid. The total heat required to vaporize the feed liquid (H_t) is:

$$H_t = \text{sensible heat} + \text{heat of vaporization}$$

$$H_t = C_l \times (T_{bl} - T_{il}) + H_v$$

where:

C_l = specific heat of liquid, cal/g-°C
T_{bl} = boiling temperature of liquid, °C
T_{il} = initial temperature of liquid, °C
H_v = heat of vaporization (value for water used)

The initial temperature of feed liquid is 70 °F (21 °C). The specific heat of 4 M nitric acid is obtained from Figure 3-12 of *Plutonium Reclamation Facility Engineering*

Technical Reference (RHO 1980) as 0.78 cal/g-°C. The latent heat of vaporization of water is 539 cal/g. The total heat to vaporize (H_t) is:

$$H_t = 0.78 \text{ cal/g-°C} \times (100 - 21) \text{ °C} + 539 \text{ cal/g} = 600 \text{ cal/g}$$

The mass of liquid boiled (M_{lb}) is:

$$M_{lb} = Q_t / H_t = 9.9 \times 10^5 \text{ cal}/600 \text{ cal/g} = 1650 \text{ g}$$

The mass of plutonium (M_p) available for release from boiling is:

$$M_p = \text{Volume of liquid boiled} \times \text{plutonium concentration}$$

$$= [M_{lb} \text{ (g)} / \text{Density (g/L)}] \times [\text{Pu (g/L)}]$$

The specific gravity of the solution is given in equation 3.16 of RHO (1980) as follows:

$$\text{Spg (at 25 °C)} = 1 + (0.031)(\underline{M}\ HNO_3) + (0.00146)(\text{g-Pu/L})$$

where:

$\underline{M}$ = molarity of the solution, 4
maximum concentration = 450 g-Pu/L

The specific gravity at 100 °C is approximately that at 25 °C.

$$SpG = 1.78$$

$$\text{Density (g/L)} = 1000 \times SpG$$

The mass of plutonium available for release from boiling is then:

$$Mp = [1650 \text{ (g)} / 1780 \text{ (g/L)}] \times 450 \text{ (g/L)} = 417 \text{ g}$$

DOE (1994b), Section 3.2.1.2, Heating of Pools, provides measurements of airborne plutonium during heating of pools to 90% evaporation of plutonium nitrate solution.

Table 3-2 of DOE (1994b) provides four data points at hot plate temperatures of 200 to 220 °F. The highest ARF is 1.8×10^{-3}, with a bounding value of 2×10^{-3} recommended. The recommended RF is 1. Thus, the respirable plutonium release from evaporation is:

$$Mp = ARF \times RF \times 417\ g$$

$$= (2 \times 10^{-3}) \times 417 = 0.84\ g$$

Airborne Release from Aerodynamic Entrainment of Plutonium Oxide. It is assumed that the other one-half of the plutonium oxide powder, i.e., that not associated with liquid boiling, is deposited as a bed.

DOE (1994b), Section 4.4.1, Table 4-10, "Thermal Stress [of chemically non-reactive powders]," presents the ARFs for a series of tests in which powder beds at varying temperatures where exposed to varying air velocities. The largest ARF given in Table 4-10 is 5.6×10^{-3} (ambient temperature and 1.17 m/s velocity). Other values are an order of magnitude or more lower. DOE (1994b) recommends use of the 6×10^{-3} value as the bounding ARF and a conservative RF of 1×10^{-2}. Thus, the respirable release is:

$$Wd = 2375\ g \times ARF \times RF$$

$$Wd = 2375\ g \times (6 \times 10^{-3}) \times (1 \times 10^{-2}) = 0.143\ g$$

The release is calculated as described above for entrainment of plutonium oxide in the next subsection.

Entrainment of Plutonium Oxide During Liquid Boiling. A fraction of the 2375 g of powder assumed to transfer heat to the plutonium nitrate solution could also become suspended by bubbles sparging through the wet powder. It is difficult to select a model for this phenomenon as the physical orientation of the two phases is uncertain. Conceivably, the two phases could be uniformly mixed, or could be adjacent to each other with interaction only occurring along one edge. It is assumed that the lofting of plutonium oxide powder as it interacts with the liquid can be approximated applying data on lofting of powder from a hot bed. The release is calculated as described above for entrainment of plutonium oxide. Therefore, the respirable release is 0.143 g.

Airborne Release from Evaporation. The 2.5 L of plutonium nitrate not involved in boiling is subject to evaporation which would occur slowly relative to the other processes described herein. DOE (1994b), Section 3.2.1.1, Heating of Shallow Pools, provides measurements of airborne plutonium during drying of shallow pools of concentrated plutonium nitrate solution. Table 3-1 of DOE (1994b) provides six data points at three air velocities and

four temperatures. The measured ARF for 50 °C and 1 m/s is 1.3×10^{-7}. The recommended RF is 1. Thus, the respirable release from evaporation is:

$$Qe = ARF \times RF \times 2.5\ L \times 450\ g\text{-}Pu/L$$

$$Qe = (1.3 \times 10^{-7}) \times (1.0) \times (2.5) \times (450) = 1.5 \times 10^{-4}\ g$$

This value is insignificant relative to the other release mechanisms.

Total Seismic Induced Release into the Facility. Summing the contribution from the above described mechanisms, the total seismic induced release is 12.54 g. Plutonium oxide releases are distinguished from nitrate releases because the dose conversion factors differ due to differences in Lung Clearance Class Y (indicating "years") and Lung Clearance Class W (indicating "weeks").

	Pu (g) as Oxide (Y)	Pu (g) as Nitrate (W)
Release from Accumulator Depressurization (9 g plus 2.2 g from "normal" head space loading)	11.2	
Release from falling plutonium oxide powder	0.19	
Release from falling plutonium nitrate		0.023
Release from boiling plutonium nitrate		0.84
Entrainment of plutonium oxide during boiling	0.143	
Aerodynamic entrainment of plutonium oxide	0.143	
Subtotals	11.676	0.863
Total	12.539 g	

As shown above, the majority of the release (i.e., 9 grams or 72%) is associated with depressurization of the accumulator. This release results from the assumed failure of non-safety class solenoid and check valves (Figure 7, valves C, H and I), prior to the assumed structural failure of the calciner assembly. Although they are not seismically qualified, the solenoid and check valves could function as designed, thereby preventing the 9 g Pu release. The same logic is true for solenoid valves D, E, F and G, thereby preventing a release due to air injected through the calciner filters. Alternatively, the check valves could fail open after the assumed structural failure of the calciner assembly, in which case air from the pressurized accumulator could be vented without suspending plutonium.

A failure modes and effects analysis of the calciner has been performed (BWHC 1999d). It was found that the likelihood of back flows from the accumulator through non-safety class solenoid and check valves is beyond extremely unlikely. Accordingly, the following section presents mitigated seismic event dose consequences assuming the valves fail as described in the

scenario, and assuming the valves function as intended. If the two check valves and the solenoid valve function as intended, the total release is 3.54 g Pu. This value includes the 2.2 g Pu normally present in the calciner headspace.

4.2.5.2.4.2 Dose Consequences of Release from Facilities due to Seismic Event.

The releases from Glovebox 188-1 due to the seismic event are categorized according to Lung Clearance Class (W or Y) and ^{240}Pu content (greater than or less than 10% ^{240}Pu). Appendix H, Seismic Event Dose Calculations, provides additional details of the analysis process and the dose calculations for just the laboratory calciner.

Plutonium nitrate solutions to be fed to the calciner originate primarily from weapons grade material. It is assumed, for this analysis, that all plutonium material associated with the calciner in Glovebox 188-1 has a ^{240}Pu isotopic content of less than 10%. Feed containing greater than 10% ^{240}Pu is blended to ensure that it has less than 10% ^{240}Pu content.

As discussed in Chapter 9, Section 9.2.4.7 of the PFP FSAR (FDH 1999), there are two release scenarios, i.e., "no ventilation" case and "ventilation" case. In the "no ventilation" case, the facility ventilation system is assumed to fail or to be shut down as a result of the earthquake. Material is released from the facility through open egress paths due to wind effects on the building. In the "ventilation" case, the E-3 and E-4 exhaust system is assumed to continue running, but with failed HEPA filters such that material is released through the 291-Z-1 Stack unfiltered. The FSAR analysis accounts for gravitational settling within the facility. Since material is drawn out of the facility faster in the "ventilation" case, a lower percentage of the material released from the laboratory calciner glovebox settles out before release in the "ventilation" case than in the "no ventilation" case. The elevated release in the "ventilation" case results in much higher dispersion than that in the "no ventilation" cases.

"No Ventilation" Case. For the "no ventilation" case, 38% of the material released into the laboratories is released from the facility as shown in Chapter 9, Section 9.2.4.7.1 of the PFP FSAR. The remaining 62% of the respirable plutonium material released into the laboratories settles out due to gravity. The releases from the laboratory calciner glovebox is shown in Appendix H to be about 4.765 g (Table H-1) assuming accumulator depressurization and about 1.345 g (Table H-3) assuming the valves function as intended.

The details of the analyses summarized in this section for the laboratory calciner releases only are found in Appendix H. Table H-1 provides the doses assuming accumulator depressurization. The doses are as follows:

	Onsite	Offsite
EDE	21.33 rem	0.45 rem
Organ	256 rem	5.46 rem

The offsite consequences meet the RAGs. The onsite consequences meet the EDE but exceed the organ RAGs of 25 rem and 250 rem, respectively.

Table H-3 provides the doses assuming the valves (Figure 7, valves C, D, E, F, G, H and I), function as designed. The doses are as follows:

Onsite		Offsite	
EDE	6.35 rem	EDE	0.13 rem
Organ	85.28 rem	Organ	1.81 rem

These consequences meet both the onsite and offsite RAGs.

"Ventilation" Case. In the "ventilation" case, gravitational settling within the facility is calculated in the FSAR to reduce the releases from the facilities by 16%. Thus, 84% of the material released inside the building escapes unfiltered through the exhaust stack. The total facility release from the laboratory calciner only is shown in Appendix H to be about 10.5 g (Table H-2) assuming accumulator depressurization and about 3.0 g (Table H-4) if the check valves function.

The details of the analyses summarized in this section are found in Appendix H. Table H-2 provides the doses assuming accumulator depressurization. The doses are as follows:

Onsite		Offsite	
EDE	1.61 rem	EDE	0.57 rem
Organ	19.38 rem	Organ	6.85 rem

These consequences meet both the onsite and offsite RAGs.

Table H-4 provides the doses assuming the valves (Figure 7, valves C, D, E, F, G, H and I), function as designed. The doses are as follows:

Onsite		Offsite	
EDE	0.48 rem	EDE	0.17 rem
Organ	6.45 rem	Organ	2.28 rem

These consequences meet both the onsite and offsite RAGs.

4.2.5.2.5 Conclusions - Mitigated Seismic Event. A conservative analysis has been performed to quantify the incremental risk associated with calciner operations in Glovebox 188-1 only

relative to seismic analyses contained in Chapter 9 of the PFP FSAR (FDH 1999). The effect of the seismic event on the calciner system and Glovebox 188-1 increases the doses significantly. If the two check valves and the solenoid valve are assumed to fail such that the air accumulator tank is vented through the calciner bed, the onsite consequences exceed the RAGs for an event with an annual probability of 1×10^{-4} (i.e., the probability of the DBE). However, the probability of the failure of the check valves alone coincident with a DBE is much lower than 1×10^{-4} and is judged to be "beyond extremely unlikely." A probabilistic failure analysis was performed of the solenoid and check valves (BWHC 1999d) and concludes that flow to the calciner via the air nozzle or filters during the seismic event is beyond extremely unlikely. If the valves function as designed, both the onsite and offsite consequences are within the RAGs for an event with an annual probability of 1×10^{-4}.

4.2.5.3 Mitigated Seismic Event with Fire

The scenario for a mitigated seismic event with a fire is the same as that described in Section 4.2.5.2, Mitigated Seismic Event, except that combustion of two plastic panels, half of the gloves, and materials that are typically found in the glovebox have been added. It is assumed that the interconnection to the PFP ventilation seismic shutdown system functions as described in Section 4.2.5.2. All of the assumptions, release mechanisms, and results in Section 4.2.5.2 are used herein. Section 4.2.4, Glovebox 188-1 Fire, provides additional information on a postulated fire in the glovebox due to an initiating event other than a seismic event.

4.2.5.3.1 Scenario. If hot plutonium oxide powder were to be released from the calciner, it could settle on combustible material and cause ignition. The ensuing fire would cause some of the powder that had settled on the combustible material to become airborne.

Good housekeeping practice requires that extraneous material in Glovebox 188-1 be removed on a regular basis. The material that is expected to be inside the glovebox include bags remaining from bagging-in containers, ice-cream cartons used for material transfer in through the sphincter port, and polybottles. A procedure requires all these containers to be converted to non-containers after their contents are unloaded inside the glovebox. Thus, bags are flattened and rolled up, cartons are flattened, and polybottles are cut into pieces. The non-containers are routinely removed by bagging-out of the glovebox. There are no procedural limits for Glovebox 188-1 on the amount of bags, ice cream cartons, and other typical process materials.

The operating procedures allow work to be performed using the gloves while the calciner system is in operation. Therefore, it can be postulated that some of the released hot powder lands on some gloves resulting in glove fire(s). It is further postulated that the burning gloves in the plastic panels (windows) could cause ignition of the plastic panels. Because the calciner is assumed to fail and its resulting configuration cannot be predicted, it could be postulated that the gloves and the panels are ignited by some part of the hot calciner coming into close proximity or direct contact with these components.

The calcining process creates powder and is not perfectly sealed. Thus, it can be postulated that there is some surface contamination, although small, on all inside surfaces of the

glovebox including the gloves and the plastic panels. If any of these ignite, some of the surface contamination can become airborne within the glovebox.

In developing a conservative scenario for the seismic event with a fire inside the glovebox, it was necessary to select a reasonable amount of material that could be assumed to ignite as a result of the earthquake. The feed and scrubber solutions are assumed to spill away from the fire. This assumption is conservative because a fire could be extinguished by the liquid. A corollary of this assumption is that there is also no transfer of heat from the fire to liquids in the glovebox. No credit is taken for operation of the room or glovebox fire protection features.

4.2.5.3.2 Mitigation. As discussed in Section 4.2.5.2 for the seismic event without fire scenario, mitigation is provided by operation of the seismic shutdown system that deenergizes calciner systems and equipment. However, there is no specific mitigation for the fire initiated by the seismic event. In addition, no credit has been taken for liquid, either in the feed or scrubber systems, to eliminate or mitigate a fire or for fire suppression systems in Room 188.

4.2.5.3.3 Probability. The annual probability of the DBE is given as 1×10^{-4}. The probability of a fire occurring as a result of the seismic event is assumed to be 1. Thus, the annual probability of the DBE with a fire is 1×10^{-4}.

4.2.5.3.4 Consequence Analysis. The scenario postulates a seismic event in which the calciner fails and releases all of its hot plutonium oxide powder. Some of the powder becomes airborne, lands on combustible material, and ignites it. Ignition of the gloves is assumed to occur. The resulting glove fires and/or radiation from or contact with hot calciner surfaces is postulated to cause ignition of the plastic panels. The gloves and panels are assumed to have surface contamination of small amounts of plutonium oxide powders. Some of this material will be released because of the fires.

4.2.5.3.4.1 Analysis of Releases from Glovebox 188-1 into Facility due to Fire.

Release from Combustion of Trash. It is assumed that the hot plutonium oxide powder released from the calciner bed contaminates the trash. Section 5.2 of DOE (1994b) provides values of ARF and RF for packaged waste and unconfined cellulose waste. The experiment for the unconfined waste used 10 g samples of tissue, paper or cloth in a pan with air forced upward through the pan at 0.06 to 1.04 m/s. The quantity of uranium in the waste being burned was about 0.1 to 2 g on samples of plastic and paper weighing 10 g. Thus, the highest ratio of contamination to combustible was 0.2. It is judged that larger quantities of plutonium on the waste will act more as a heated powder bed than contaminated waste. The bounding ARF was determined to be 1×10^{-2} and the RF was determined to be 1.0. The ARF multiplied by the RF for burning contaminated waste is therefore 1×10^{-2}.

It is assumed that there is 200 g of combustible waste present in the glovebox. This is equal to about 10 to 20 bags. This waste is assumed to be contaminated by 50 g of plutonium powder released from the calciner as a result of its failure. This ratio of 0.25 g of powder per gram of combustible is slightly greater than the tests referenced above. The mass of plutonium released from burning this material (W_b) is:

$$W_b = ARF \times RF \times 50\ g = 0.5\ g$$

Release of Surface Contamination due to Combustion of Gloves. It is assumed that, of the 38 gloves in the glovebox, the 19 that are closest to the calciner (i.e., within 3 ft) are ignited as a result of the calciner failure. All of these are on 8 in. gloveports. Eight gloves are on each of the two plastic panels. It is assumed that these gloves have a small amount of plutonium oxide powder as a result of routine calciner operation. The amount of this material is addressed in *An Estimate of Airborne Release of Plutonium from Babcock and Wilcox Plant as a Result of Severe Wind Hazard and Earthquake* (PNL 1978). For nuclear fuel cycle facilities in use for some period of time, the quantity of radioactive materials routinely found on contaminated surfaces can range from that which can only be removed by harsh, corrosive techniques to that which is readily visible to the unaided eye. A value of 0.7 g PuO_2 per ft^2 has been reported as just visible. This amount will be used as a bounding value for this evaluation. This approach is conservative because the operating time for the calciner in this glovebox could be an order of magnitude shorter than the time on which the above data are based.

The surface area of a single glove mounted in an 8 in. glove port is approximately 3.7 ft^2. The total surface area of 19 gloves is approximately 70 ft^2.

The surface contamination (W_g) is:

$$W_g = 70\ ft^2 \times 0.7\ g/ft^2 = 49\ g$$

DOE (1994b), Section 5.2.1.4 provides values for releases of surface contamination for uncontained polychloroprene (elastomer, rubber). Table 5-3 from that reference includes values for depleted uranium oxide (DUO) powder as ARF = 3.7×10^{-3} and RF = 0.16. Thus, the release from the gloves (W_g) is:

$$W_g = 49\ g \times (3.7 \times 10^{-3}) \times 0.16 = 0.029\ g$$

Release of Surface Contamination due to Combustion of Panels. It is assumed that either the ignition of the gloves or the radiant heat from the burning material leads to ignition of both the polymethylmethacrylate (PMMA) panels. The other glovebox panels are constructed of wire-reinforced glass. It is assumed that the PMMA panels have a small amount of plutonium oxide powder as a result of routine calciner operation. The value of 0.7 g/ft^2 of PuO_2 reported in DOE (1994b) is used as a bounding value for this evaluation.

The surface area of a single panel (~5 ft x 4 ft) is approximately 20 ft^2. The surface contamination (W_p) is:

$$W_p = 2 \times 20\ ft^2 \times 0.7\ g/ft^2 = 28\ g$$

DOE (1994b), Section 5.2.1.4 provides values for releases of surface contamination for PMMA. Table 5-4 from that reference includes values for a thick layer of DUO powder as ARF = 3.6×10^{-2} and RF = 0.84. Thus, the release from the two panels (W_p) is:

$$W_p = 28\ g \times (3.6 \times 10^{-2}) \times 0.84 = 0.85\ g$$

Summary of releases from Glovebox 188-1 due to the Seismic-Induced Fire. All of the mechanisms addressed above are listed below. The releases due to the fire are all from plutonium oxide powder .

	Pu (g) as Oxide (Y)	Pu (g) as Nitrate (W)
Combustion of trash	0.50	0
Combustion of 19 gloves	0.029	0
Combustion of 2 plastic panels	0.85	0
Total	1.379	

4.2.5.3.4.2 Doses for Additional Release from Glovebox 188-1 due to Fire.

The additional releases due only to the seismic-induced fire are calculated below for the "ventilation" and the "no ventilation" cases.

"No Ventilation" Case. For the "no ventilation" case, 38% of the material released into the laboratories is released from the facility. The remaining 62% of the respirable plutonium material released into the laboratories settles out due to gravity. The additional release from the building due to the fire is:

$$(1.379\ g) \times (0.38) = 0.524\ g$$

The details of the analyses summarized in this section are found in Appendix H, Sections 5.0 and 5.1.

From Appendix H, Section 5.1, the doses due only to the fire are as shown below:

Onsite		Offsite	
EDE	2.29 rem	EDE	0.05 rem
Organ	26.23 rem	Organ	0.56 rem

Table H-5 provides the doses that are the sum of those from seismic event and the fire for the laboratory calciner releases only assuming the accumulator depressurizes. The doses are as follows:

Onsite		Offsite	
EDE	23.62 rem	EDE	0.50 rem
Organ	282 rem	Organ	6.02 rem

The offsite consequences meet the RAGs. The onsite consequences meet the EDE and exceed the organ RAGs of 25 rem and 250 rem, respectively.

Table H-6 provides the doses assuming the valves function as intended. The doses are as follows:

Onsite		Offsite	
EDE	8.64 rem	EDE	0.18 rem
Organ	112 rem	Organ	2.37 rem

The onsite and offsite consequences meet the RAGs.

"Ventilation" Case. In the "ventilation" case, gravitational settling within the facility is calculated in the FSAR to reduce the releases from the facilities by 16%. Thus, 84% of the material released inside the building escapes unfiltered through the exhaust stack. Thus, the additional release from the facility due to the seismic-induced fire is:

$$(1.379\ g) \times (0.84) = 1.158\ g$$

The details of the analyses summarized in this section are found in Appendix H, Section 5.2. The increase in doses due to the fire are shown below:

Onsite		Offsite	
EDE	0.17 rem	EDE	0.06 rem
Organ	1.98 rem	Organ	0.70 rem

Table H-7 provides the doses which are the sum of those from seismic event and the fire for the laboratory calciner releases only assuming the accumulator depressurizes. The doses are as follows:

Onsite		Offsite	
EDE	1.78 rem	EDE	0.63 rem
Organ	21.36 rem	Organ	7.55 rem

The onsite and offsite consequences meet the RAGs.

Table H-8 provides the doses assuming the valves function as intended. The doses are as follows:

Onsite		Offsite	
EDE	0.65 rem	EDE	0.23 rem
Organ	8.43 rem	Organ	2.98 rem

The onsite and offsite consequences meet the RAGs.

4.2.5.3.5 Conclusions - Mitigated Seismic Event with Glovebox 188-1 Fire. A conservative analysis has been performed to quantify the incremental risk associated with calciner operations in Glovebox 188-1 only relative to the seismic analyses contained in Chapter 9 of the PFP FSAR (FDH 1999). The postulated fire in Glovebox 188-1 due to a seismic event increases the dose a small amount relative to those calculated in Section 4.2.5.2 for a seismic event without a fire.

If the two check valves and the solenoid valve are assumed to fail such that the air accumulator tank is vented through the calciner bed, the onsite organ consequences exceed the RAGs for an event with an annual probability of 1×10^{-4} (i.e., the probability of the DBE). However, the probability of the failure of the check valves coincident with a DBE is much lower

than 1×10^{-4} and is judged to be "beyond extremely unlikely" (BWHC 1999d). If the check valves function as designed, both the onsite and offsite consequences are within the RAGs for an event with an annual probability of 1×10^{-4} with the exception of the onsite organ dose, "no ventilation" case. Although organ doses have been calculated in this addendum for consistency with the PFP FSAR, current risk evaluation guidelines, as established HNF-PRO-704, *Hazard and Accident Analysis Process* (HNF 1997), are based on EDE only.

This page intentionally left blank.

5.0 EQUIPMENT SAFETY CLASSIFICATION AND OPERATIONAL CONTROLS

Chapters 3.0 and 4.0 identified potential hazards and accidents associated with the operation of the Laboratory Prototype Calciner. The hazard and accident analysis identify the engineered features and operational controls that provide for the prevention and mitigation of the potential consequences for each of these hazardous events and accidents. The safety classification for selected engineered features and operational controls are summarized in this chapter. Section 5.1 and Table 6 provide the safety classification for structures, systems, and components (SSC) relied upon to perform a safety function during calciner operations. Section 5.2 specifies the operational controls for the calciner which are intended to assure the availability of equipment and systems relied upon for the prevention and mitigation of abnormal events and accidents. In addition, the operational controls specify various limits and requirements to ensure that the analytical assumptions used in the accident analyses are implemented.

5.1 EQUIPMENT SAFETY CLASSIFICATION

As part of the hazard and accident analysis process, engineered features have been identified that provide for the prevention or mitigation of hazardous events. The proposed engineered features have been evaluated with respect to the criteria for safety classification specified in HNF-PRO-704, *Hazard and Accident Analysis Process* (HNF 1997). For accidents in which significant consequences to facility workers, on-site non-facility workers, or the public could potentially occur, the evaluation identified the engineered features and the associated safety functions being relied upon to prevent or mitigate the accident. Based upon the safety function being performed and the accident consequences, Safety Significant or Safety Class designations are assigned to the engineered features using a conservative application of the criteria provided in Table 5 of HNF-PRO-704. The resulting SSC safety designations for calciner operations are provided in Table 6 and are discussed below.

The E-3 and E-4 ventilation exhaust system HEPA filters and connecting ductwork are specifically credited in the accident analyses presented in Chapter 4, Section 4.2. The HEPA filters are credited with filtering airborne plutonium particulates with an efficiency of 99.95%. The E-3 and E-4 exhaust system HEPA filters and ductwork have been previously designated as Safety Class equipment in the PFP FSAR (FDH 1999).

The interconnection of calciner equipment to the PFP ventilation system seismic shutdown system represents a new Safety Class SSC specific to calciner operations. This interconnection is credited in Chapter 4, Section 4.2.5, with reducing the consequences of a DBE to below the risk acceptance guidelines by reducing the quantity of airborne plutonium. The PFP ventilation system seismic shutdown system has been previously designated as Safety Class equipment in the PFP FSAR (FDH 1999).

Glovebox 188-1 is equipped with a criticality drain. This drain is specifically identified in Appendix A as an engineered safety feature that functions to prevent a potential criticality. Glovebox criticality design features (including the Glovebox 188-1 criticality drain) have been previously designated as Safety Class equipment in the PFP FSAR (FDH 1999). The functional

requirement of criticality design features is to prevent criticality by maintaining a critically safe configuration.

The Glovebox 188-1 structure, including gloves, bag-out ports, sphincter seals, and pie plates) provides primary confinement and is implicitly credited in all glovebox "breach of confinement" events analyzed in the hazards and accident analyses presented in Chapters 3 and 4, respectively. Plutonium gloveboxes and hoods have been previously designated as Safety Significant equipment in the PFP FSAR (FDH 1999). The functional requirement of glovebox structures is to prevent or mitigate radiation exposure to facility workers by minimizing contamination spread. Definition of the glovebox safety boundary is provided in the PFP safety equipment list (FDH 1998b).

The continuous air monitor (CAM) located in Room 188 is specifically identified in Appendix A as an engineered safety feature that functions to protect facility workers. Room CAMs have been previously designated as Safety Significant equipment in the PFP FSAR (FDH 1999). The functional requirement for CAMs is to mitigate worker exposure to radioactive release by monitoring work areas and alerting facility workers to airborne radioactive concentrations exceeding limits. The PFP safety equipment list (FDH 1998b) further identifies room air samplers as being Safety Significant equipment.

5.2 OPERATIONAL CONTROLS

The controls outlined in this section are those which have been determined to be necessary for the safe operation of the calciner process. The controls have been developed from the hazards analysis and the accident analysis discussed in Chapters 3.0 and 4.0. The controls for the calciner are primarily associated with equipment and operations intended to prevent or mitigate events potentially posing worker safety issues.

5.2.1 Operational Safety Requirements

The controls specified in this section are in addition to those provided by the existing PFP operational safety requirements (OSR) (BWHC 1999e). Accordingly, adequate safety assurance for operation of the Laboratory Prototype Calciner requires implementing the existing operational safety requirements as well as the new controls specified in this section. The applicability of each existing OSR is provided in Table 7.

Note that criticality safety is implemented through application of the PFP criticality safety program. Criticality prevention requirements are specified in the criticality safety evaluation reports for the calciner and the associated PFP criticality prevention specifications.

The OSRs required as a result of Laboratory Prototype Calciner operations are as follows:

1. Prior to initiation of any calciner operations, the automatic seismic shutdown system shall be verified to be operable to limit the potential release due to a seismic event. This control limits the quantity of material that may be released following a seismic event. Surveillance requirements and frequencies for the seismic shutdown system related to the calciner process system are shown in Table 11.

2. The isotopic distribution of the plutonium in the calciner feed solution shall contain less than 10% ^{240}Pu in order to limit the potential doses as analyzed for the seismic accident. This control limits the consequences in the accident analysis by limiting the total quantity of the higher dose rate isotopes of plutonium allowed in the glovebox.

3. The maximum inventory in Glovebox 188-1 shall not exceed 7000 g of plutonium to meet the analysis assumption for material at risk in a seismic event.

These controls minimize the consequences presented in Section 4.2.5, Glovebox 188-1 Seismic Event. The controls are presented in tabular format in Table 8.

5.2.2 Additional Controls for the Laboratory Prototype Calciner

The controls in this section address equipment and define controls necessary to implement key assumptions upon which the safety analysis is based. In addition, in some cases, the controls outline specific actions required by operators under certain conditions of inoperability of equipment. These controls are not OSR level controls but are implemented by incorporation in operational specification documents, procedures and test plans. The controls are presented in tabular format in Tables 9 and 10 and are discussed below.

5.2.2.1 Operational Controls

1. Feed solutions for processing in the calciner shall be transported in polybottles in vented PR can containers (vent clip or drilled hole) or ITCs. Unvented containers shall not be accepted by the laboratory. The vents in the container preclude the accumulation of hydrogen or flammable gases that could be released or burned during the opening of the transfer container. The lids for ITCs are sufficiently loose so as not to require special venting mechanisms. (Note: these vents do not preclude hydrogen buildup in bag-out bags or polybottles.) Inadvertent burns of flammable gasses are included in the discussion of accidents in Sections 4.2.1, 4.2.2, and 4.2.3.

2. A Radiation Protection Program shall be in place to protect workers from exposure to ionizing radiation. A key element of worker protection for the calciner process is the requirement for the use of respiratory protection while unloading PR containers and ITCs in Room 188, while loading solution bottles into Glovebox 188-1, and while bagging out various materials from Glovebox 188-1 (includes use of bag ports or airlock). This prevents significant worker uptake if a release of material occurs. Worker hazards are included in the discussion of abnormal occurrences in Section 4.1.

3. Another key element of the Radiation Protection Program is the requirement that Glovebox 188-1 be verified to be at negative pressure relative to the room prior to initiation of any operations in order to prevent release of glovebox contamination to the room and personnel contamination.

4. Prior to calciner operation, proper ventilation flow in Glovebox 188-1 shall be verified in order to ensure adequate heat removal from the glovebox. This requirement assures maintaining the integrity of the process equipment in the glovebox as well as the integrity of the confinement function of the glovebox.

5. The calciner over-temperature protection system shall be operable prior to initiation of operations to prevent overheating and potential failure. The calciner operates at elevated temperatures and the vessel is postulated to be a potential fire source in the accident scenario in Section 4.2.4. The over-temperature limit prevents calciner failure which could initiate a fire scenario.

6. The CAM in Room 188 shall be verified to be operable prior to initiation of operations in order to ensure that operators are alerted to contamination releases into the room. All the accident scenarios in Chapter 4.0 include the possibility of release of contamination into the room occupied by the operators. Proper operation of the CAM alerts the operator that, in addition to the upset condition, some contamination has escaped from the glovebox.

7. A Fire Protection Program shall be in place to minimize the potential for and magnitude of any possible fires. For the calciner operations, these measures shall include housekeeping to limit combustible loading in the glovebox, operability of the glovebox temperature monitoring system to prevent excessively high temperatures and availability of a dry chemical, bayonet-equipped, portable fire extinguisher for fire protection.

8. The compressed air oil trap on the process air line in Room 188 shall be operational and continuously drained during calciner operation in order to prevent the injection of any oil from air compressor operation into the calciner with a resultant organic burn. A flammable gas deflagration is evaluated in Section 4.2.3.

9. Controls shall be implemented to prevent the introduction of incompatible chemicals in the feed tank or chemicals into the calciner that could cause a fire or deflagration. Introduction of organic into the calciner and the potential for flammable gas has been evaluated (Section 4.2.3) to consider the potential for incompatibility issues that could arise with the calciner. Introduction of new chemicals must be evaluated to ensure that the process remains within the analyzed bounds.

10. An Industrial Hygiene Program shall be in place to provide appropriate controls for worker protection from chemical hazards. Controls for calciner operations shall be implemented to ensure safe use and transfer of caustic solution (e.g. protective covering around caustic transfer line and valves) to minimize the chemical hazards to workers. Worker protection is discussed in Section 4.1 of the accident analysis.

5.2.2.2 Controls Required to Implement Key Analytical Assumptions

1. Transfer and receipt of feed solutions shall be limited to polybottles containing a maximum of 2.5 L of solution in a 3 L bottle to limit the hydrogen generation rate during transfers. The deflagration scenarios discussed in Sections 4.2.1, 4.2.2, and 4.2.3 assume certain quantities of hydrogen gas that could be present in the containers. Larger containers or larger headspaces could invalidate the conclusions of that analysis.

2. Plutonium nitrate feed solutions shall contain a maximum of 450 g-Pu/L for criticality control purposes, to limit hydrogen generation, and to remain within the bounds of the dose consequence analysis. The consequence analysis for the accident scenarios in Chapter 4.0 assumed this concentration of plutonium.

3. Plutonium nitrate feed solutions shall have a nitric acid concentration greater than 4 M to limit the hydrogen generation rate during container transfers and interim storage, if necessary. Hydrogen generation rates assumed in the deflagration scenarios, Sections 4.2.1, 4.2.2, and 4.2.3 are based on a nitric acid concentration of 4 M or greater. A lower concentration would result in larger hydrogen generation rates and higher concentrations in the containers evaluated.

4. Feed solutions shall be limited to plutonium nitrate. Other materials have not been evaluated for processing in the calciner and, therefore, are not supported by the accident analysis presented in this document.

5. Feed solutions shall be tested for a visible, separable layer of organic. Solutions with a visible, separable organic layer shall not be processed through the calciner in order to limit the potential for a significant organic burn in the calciner. In addition, the calciner feed solution shall be limited to 1% organic in order to limit the potential for an organic burn in the calciner. Organic burns inside the calciner are discussed in Section 4.2.3.

This page intentionally left blank.

6.0 SUMMARY AND CONCLUSIONS

As a result of the termination of plutonium production operations at Hanford, the PFP has significant quantities of unprocessed plutonium-bearing solutions in storage. These solutions are considered unsuitable for long-term storage and must be stabilized by conversion to plutonium oxide powder to meet storage requirements (BWHC 1998) for the PFP vaults and the DOE criteria (DOE 1996) for long term storage. Stabilization of the plutonium-bearing solutions is accomplished using a direct denitration process in a vertical calciner. The calciner, designated the Laboratory Prototype Calciner, and support systems/equipment are located in Glovebox 188-1 in Room 188 in the PPSL.

The prototype calciner is not specifically included in the PFP FSAR (FDH 1999) for solution stabilization operations, although general operations and process tests are included for the PPSL. Therefore, this addendum to the FSAR has been prepared to provide the authorization basis for DOE-RL approval of plutonium-bearing solution stabilization operations using the Laboratory Prototype Calciner. The scope of activities for which the authorization basis is developed is described in Chapter 1.0 in this addendum.

This FSAR addendum provides background information in Chapter 1.0 supporting the need for stabilization of plutonium-bearing solutions. Descriptions of the process chemistry, equipment and systems, and the process for stabilization operations are provided in Chapter 2.0. Chapter 3.0 provides a discussion of the Hazard and Operability (HAZOP) Analysis performed for the stabilization process and equipment. The chapter also presents a summary of the HAZOP results and the representative abnormal events and accidents derived from the HAZOP. The significant accidents identified through the HAZOP process are analyzed in Chapter 4.0 which demonstrates the acceptability of the stabilization operations through comparison with risk guidelines. During the performance of the HAZOP and accident analysis, candidate controls and safety equipment were developed to prevent or mitigate identified hazards. The controls and safety equipment developed during the hazard and accident analyses were evaluated and then consolidated in Chapter 5.0. The controls and equipment specified in Chapter 5.0 are in addition to those in the existing PFP FSAR (FDH 1999) and in the OSR document (BWHC 1999e).

Most of the hazards and accidents associated with operation of the Laboratory Prototype Calciner do not result in an on-site impact to non-facility workers, or an off-site impact to the public, but do have the potential to impact operations personnel. The principal exception to this is a seismic event which has the potential to pose a significant risk both on-site and off-site. This risk is caused by the potential loss of various calciner process and facility confinement features which could result in on-site and off-site radiological doses. As a result of the seismic accident analysis, certain calciner process equipment has been connected to the PFP ventilation system seismic shutdown switch. This ensures that calciner processing operations are terminated as a result of a seismic event which will mitigate the potential release of radiological materials from the PFP facility.

Based on the results of the hazard and accident analysis, this addendum demonstrates that calciner operations can be performed safely under all credible accident and abnormal event scenarios. Appropriate safety equipment and controls are in place to prevent or mitigate

accidents and abnormal events such that the risk to facility workers, non-facility on-site personnel and the off-site public is acceptable. The equipment and process described in this addendum along with the controls and safety items can be safely used for stabilization of plutonium-bearing feed solutions meeting the requirements defined herein.

NPH	Natural Phenomena Hazard (Seismic Event)

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection. (15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
A1.	PROCESS UPSET – NO WORKER IMPACTS				
		Accidents			
		There are no accidents (S2 or S1* events) identified for Group A1.			
		Abnormal Occurrences			
		There are no abnormal occurrences (S1 events) identified for Group A1.			
		Negligible Safety Concerns			
	08.01.08/1	Feed concentration too high	Requires changeout and cleanup	S0	Events in this group are production upset events and do not result in release of radiological material or significant increase in worker exposure. Because they result in negligible safety concerns to facility workers, hazards with S0 consequences are not evaluated further.
	08.02.01/2	Inadequate pump output causes nozzle plug	Yields low product from calciner	S0	
	08.02.01/3	Plugged calciner feed nozzle	Yields low product output	S0	
	08.02.02/1	Small pump stroke	Yields low product output	S0	
	08.02.04/1	Pump overheating and failure	Yields low product output	S0	
	08.03.00/2	Inadequate pump output	Yields low product output	S0	
	08.03.04	Feed supply valve shut off	Causes damage to pump	S0	
	08.04.08	Low vacuum	Degrades scrubber function	S0	
	08.04.16	Calciner motor drive overspeeds	Yields low product output	S0	
	08.05.04	Excess air to nozzle	Yields low product output	S0	
	08.05.09	Low vacuum	Degrades scrubber function	S0	
	08.06.01/1	High scrubber caustic flow	Prematurely fills tanks	S0	
	08.06.03	Scrubber temperature too low	Degrades scrubber function	S0	
	08.06.06/2	Inadequate vacuum	Allows calciner to pressurize	S0	
	08.06.09	High caustic flow rate	Results in high consumption	S0	
	08.07.07	Incompatible chemical reaction in scrubber	Requires cleanup	S0	
	08.07.08	Low vacuum	Degrades scrubber function	S0	
	08.07.10	Scrubber solution pH too low	D-8 tank pH affected	S0	
	08.07.11	Scrubber solution pH too high	Degrades scrubber function	S0	
	08.07.14/1	No sparging of spent scrubber solution	Degrades scrubber function	S0	
	08.11.00	Caustic flow to high	Degrades scrubber function	S0	
	08.12.00	Leak in chiller	Causes water spill in cell	S0	
	08.12.01	Leak in chiller	Yields elevated NO_X in vacuum system	S0	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
	08.13.00	Glovebox air flow is low	Inadequate air change	S0	
	08.13.01	Glovebox air flow is low	Inadequate air change	S0	
	08.13.13	Spills in glovebox	Cleanup required	S0	
	08.14.01	Excess air flow in glovebox	Potential containment damage	S0	
	08.14.02/1	Excess air flow in glovebox	Potential containment damage	S0	
	08.16.03	Loss of facility electrical power	Hazards of blackout at night	S0	
	16.00	Isolated Transport Container dropped or PR container dropped	Leak of solution through polybottle vent hole	S0	
A2.	PROCESS UPSET – WORKER ALARA CONCERN INCREASED WORKER EXPOSURE FROM RADIATION OR CHEMICAL DOSE				
		Accidents There are no accidents (S2 or S1* events) identified for Group A2.			
		Abnormal Occurrences			
	04.00/1	Damage to or cut of glove	Worker dose from cleanup	S1	ALARA concerns in recovering from the events
	05.01/1	Feed pumped to calciner before temperature reached	Worker dose from cleanup	S1	
	09.00/1	Solids buildup in nozzle	Worker dose from cleanup	S1	
	09.00/2	Pressurization of calciner due to solids buildup	Worker dose from cleanup	S1	
	08.01.02	Pump damage due to feed tank not refilled	Worker dose from cleanup	S1	
	08.02.01/1	Nozzle overheating & pump damage due to closed valve	Worker dose from cleanup	S1	
	08.02.02/2	Pump damage due to nozzle plugging	Worker dose from cleanup	S1	
	08.03.16	Back flow into air supply	Worker dose from cleanup	S1	
	05.01/2	Overflow of feed solution into collection jar	Worker dose from cleanup	S1	
	08.03.05	Feed pump stroke set to high	Worker dose from cleanup	S1	
	08.03.07/2	Back flow of feed due to air supply loss	Worker dose from cleanup	S1	
	08.03.07/3	Back flow of feed due to air supply loss	Worker dose from cleanup	S1	
	08.03.08/1	Plugging of calciner feed	Worker dose from cleanup	S1	
	08.03.08/2	Plugging of calciner feed	Worker dose from cleanup	S1	
	08.03.13	Back flow of feed due to air supply loss	Worker dose from cleanup	S1	
	08.04.00	Lack of powder bed causes plugging of calciner	Worker dose from cleanup	S1	
	08.04.13/2	Heater failure causes nozzle plugging	Worker dose from cleanup	S1	
	08.04.14/1	Low calciner temperature allows flooding	Worker dose from cleanup	S1	
	08.04.14/3	Low calciner temperature allows flooding	Worker dose from cleanup	S1	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection. (15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
	08.04.15/1	Plugging of injector due to agitator motor failure	Worker dose from cleanup	S1	
	08.04.15/2	Plugging of injector due to excess feed in bed	Worker dose from cleanup	S1	
	08.04.17	Feed into cool calciner results same as 08.04.14	Worker dose from cleanup	S1	
	08.05.01	Calciner pressurization due to lack or loss of vacuum	Worker dose from cleanup	S1	
	08.07.02	Spill of scrubber solution into glovebox	Worker dose from cleanup	S1	
	08.07.05/2	Calciner filter failure lets Pu into scrubber	Worker dose from cleanup	S1	
	08.07.12/1	Calciner filter failure lets Pu into scrubber	Worker dose from cleanup	S1	
	08.07.13/1	Flooding of calciner	Worker dose from cleanup	S1	
	08.13.21	Accumulation of radioactive material in glovebox	Worker dose from cleanup	S1	
	14.00/2	Contamination spread by unsealed drum	Worker dose from cleanup	S1	
	08.11.01	Contamination of fresh caustic supply due to siphoning	Worker dose from cleanup	S1	
		Negligible Safety Concerns			Accidents with S0 consequences do not require further analysis
	08.01.04	Phase separation of feed solution	Worker dose from cleanup	S0	
	08.01.05a	Phase separation of feed solution	Worker dose from cleanup	S0	
	08.01.06	Incompatible chemical reaction in feed tank	Worker dose from cleanup	S0	
	08.03.02	Feed line plugged	Worker dose from cleanup	S0	
	08.03.03	Feed pump failure	Worker dose from cleanup	S0	
	08.03.06	Nozzle plugging	Worker dose from cleanup	S0	
	08.03.07/1	Nozzle plugging	Worker dose from cleanup	S0	
	08.03.09	Low air flow to calciner	Worker dose from cleanup	S0	
	08.03.10	High air flow to calciner	Worker dose from cleanup	S0	
	08.03.12	Feed pump stroke set too high	Worker dose from cleanup	S0	
	08.03.14	Excessive air pressure to nozzle	Worker dose from cleanup	S0	
	08.03.15	Low operating temperature for nozzle	Worker dose from cleanup	S0	
	08.04.13/1	Low temperature in calciner	Worker dose from cleanup	S0	
	08.05.02	Leak in offgas line to scrubber	Worker dose from cleanup	S0	
	08.05.06	Low temperature in calciner	Worker dose from cleanup	S0	
	08.06.01/2	Excessive caustic feed to scrubber	Worker dose from cleanup	S0	
	08.07.00	High level of caustic in scrubber	Worker dose from cleanup	S0	
	08.07.03	Low level of caustic in scrubber	Worker dose from cleanup	S0	
	08.15.04	High temperature in product collection jar	Worker dose from cleanup	S0	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection.
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
B.	RADIOLOGICAL RELEASE INSIDE GLOVEBOX INCREASED WORKER EXPOSURE FROM RADIATION OR CHEMICAL DOSES				
		Accidents There are no accidents (S2 or S1* events) identified for Group B.			
		Abnormal Occurrences			
	04.00/2	Solution spilled inside glovebox	Releases Pu into glovebox	S1	Chapter 9, Sections 9.1.1 and 9.1.3 of the PFP FSAR analyzes Abnormal Operations involving radioactive liquid and powder spills. Chapter 9, Section 9.1.2 analyzes pressurized liquid releases. Chapter 9, Section 9.2.8 analyzes toxic chemical releases. The consequences of abnormal occurrences in Group B are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in the PFP FSAR.
	04.03	Incompatible chemical added to feed tank	Releases Pu into glovebox	S1	
	05.00	Pressurized calciner	Releases Pu into glovebox	S1	
	08.01.03	Overfilled feed tank spills on floor	Releases Pu into glovebox	S1	
	08.03.00/1	Nozzle plug pressurizes calciner	Releases Pu into glovebox	S1	
	08.03.01	Feed line break releases Pu into glovebox	Releases Pu into glovebox	S1	
	08.04.03	Plugged ceramic filters pressurizes calciner	Releases Pu into glovebox	S1	
	08.04.07	Loss of vacuum causes pressure relief cap to lift	Releases Pu into glovebox	S1	
	08.04.09	Pressure relief cap in place during cooldown	Releases Pu into glovebox	S1	
	08.04.18	Failed calciner	Releases Pu into glovebox	S1	
	08.05.00	Plugged ceramic filter pressurizes calciner	Releases Pu into glovebox	S1	
	08.06.02/1	Blocked flow to scrubber tank	Releases Pu into glovebox	S1	
	08.06.02/2	Backpressure to calciner by blockage in scrubber	Releases Pu into glovebox	S1	
	08.06.06/1	Overpressure in scrubber	Releases Pu into glovebox	S1	
	08.10.00	Plugged calciner filters	Releases Pu into glovebox	S1	
	08.15.00	Spill during transfer from collection jar to slip lid can	Releases Pu into glovebox	S1	
	08.15.02	Product collection jar breaks	Releases Pu into glovebox	S1	
	08.01.00	Feed tank failure	Release of solution into glovebox	S1	
	08.01.01	Feed tank failure	Release of solution into glovebox	S1	
	08.02.03/2	Oversupply from feed pump pressurizes calciner	Releases Pu into glovebox	S1	
	08.04.04	Overpressure in calciner	Releases Pu into glovebox	S1	
	08.04.06	Overpressure in calciner	Releases Pu into glovebox	S1	
	08.01.07b/1	Reaction in feed tank	Produces NOx	S1	
	08.13.11/2	Feed pump seal fails allowing spray leak	Release of solution into glovebox	S1	
	08.15.01	Drop of slip lid can	Releases Pu into glovebox	S1	
	09.01/3	Incompatible chemical reaction in feed tank	Release of solution into glovebox	S1	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
	10.00	Spill during transfer from collection jar	Releases Pu into Glovebox	S1	
		Negligible Safety Concerns			
	08.01.07a	Reaction of water and solution	Releases aerosols to glovebox	S0	Accidents with S0 consequences do not require further analysis.
	08.03.11	Feed line leak releases solution into glovebox	Release of solution into glovebox	S0	
	08.04.02/1	Product overflow tube set too high	No product collected in jar	S0	
	08.04.02/2	Plugging of product overflow tube	No product collected in jar	S0	
	08.04.11/1	Excessive temperature in calciner	Release of gases to vacuum system	S0	
	08.04.11/2	Excessive temperature in calciner	Increase vaporization in scrubber	S0	
	08.05.05	Excessive feed into calciner	Increases offgases	S0	
	08.05.07	Leak in offgas line	Release of gases to glovebox	S0	
	08.05.08	Excessive offgas temperature	Increased vaporization in scrubber	S0	
	08.05.11	Inadequate vacuum	Pressure rise in calciner	S0	
	08.06.00	Scrubber vessel leak	Release of caustic to glovebox	S0	
	08.07.01/1	Leaking spent scrubber tank	Spill of solution to glovebox	S0	
	08.07.01/2	Spent scrubber tank sample valve left open	Spill of solution to glovebox	S0	
	08.07.06/1	Wrong spent scrubber tank valved in	Release of gases to glovebox	S0	
	08.07.06/2	Leak in scrubber tank	Release of gases to glovebox	S0	
	08.09.01	Loss of vacuum	Release of gases to glovebox	S0	
	08.13.05	Pressure release from calciner	Release of gases to glovebox	S0	
	08.13.06	Chemical reactions in glovebox tanks	Release of gases to glovebox	S0	
	08.13.14	Spill of Pu solution, or caustic	Release of solution into glovebox	S0	
	08.14.04	Glovebox exhaust filter failure	Elevated release to E-4 system	S0	
	08.15.03	Collection jar misaligned	Allowing air into calciner	S0	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection.
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
C.	RADIOLOGICAL RELEASE FROM GLOVEBOX				
		Accidents			
	01.03	Glove pulled off or torn during drum movement	Release of Pu to room	S1*	Chapter 9, Section 9.1.9 of the PFP FSAR analyzes a glovebox glove breach. Chapter 9, Sections 9.1.1 and 9.1.3 of the PFP FSAR analyzes radioactive liquid and powder spills. The consequences of accidents in Group C are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in the PFP FSAR.
	02.01	Glove pulled off or torn during caustic supply change out	Release of Pu to room	S1*	
	03.03	Loss of glovebox confinement due to open airlock	Release of Pu to room	S1*	
	03.05	Glove torn during polybottle load in	Release of Pu to room	S1*	
	08.04.10/1	Calciner overheating fails calciner	Release of Pu to room	S1*	
	08.04.10/2	Calciner overheating fails calciner	Release of Pu to room	S1*	
	08.13.04	Pressurized air leak in glovebox causes air flow out	Loss of confinement	S1*	
	09.01/1	Incompatible chemical reaction in feed tank	Release of solution to room	S1*	
	09.03/1	Breach of glovebox confinement boundary	Release of Pu to room	S1*	
	09.03/2	Breach of glovebox confinement boundary	Release of Pu to room	S1*	
	11.00	Breach of glovebox confinement boundary	Release of Pu to room	S1*	
	13.00	Breach of glovebox confinement boundary	Loss of confinement	S1*	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
	08.13.02	Ventilation imbalance allows reverse flow in glovebox	Contamination spread	S1	
		Negligible Safety Concerns			
	08.13.03	Pressure rise in glovebox	Negligible consequence because glovebox still more negative than room	S0	
	08.13.12	Loss of glovebox ventilation	Glovebox temperature increase	S0	
D1.	**DEFLAGRATION INSIDE OF GLOVEBOX**				
		Accidents			
	04.01	**DEFLAGRATION OF HYDROGEN IN BAG OR BOTTLE**	**RELEASE OF PU INTO GLOVEBOX WITH POTENTIAL RELEASE INTO THE ROOM**	**S1***	**EVENT 04.01 CHOSEN TO BE A REPRESENTATIVE ACCIDENT BECAUSE IT INVOLVES ONE OF THE LARGEST AMOUNTS OF DISPERSIBLE MATERIAL, THE 2.5 L OF SOLUTION IN A POLYBOTTLE, AND ONE OF THE LARGEST ENERGY SOURCES, HYDROGEN DEFLAGRATION, FOR DISPERSION.**
	04.02	Reaction in feed tank with potential burning of gases	Release of Pu into glovebox	S1*	
	08.03.17	**DEFLAGRATION IN CALCINER DUE TO ORGANIC IN FEED**	**RELEASE OF PU INTO GLOVEBOX WITH POTENTIAL RELEASE INTO THE ROOM**	**S1***	**EVENTS 08.03.17 AND 08.03.18 CHOSEN TO BE REPRESENTATIVE ACCIDENTS BECAUSE THEY ARE SIMILAR TO EACH OTHER AND INVOLVE A LARGE AMOUNT OF DISPERSIBLE MATERIAL, THE PLUTONIUM OXIDE IN THE CALCINER, WITH A LARGE ENERGY SOURCE FOR DISPERSION.**
	08.03.18	**DEFLAGRATION IN CALCINER DUE TO OIL FROM FEED AIR SUPPLY**	**RELEASE OF PU INTO GLOVEBOX WITH POTENTIAL RELEASE INTO THE ROOM**	**S1***	
	08.04.05	Deflagration in calciner due to organic in feed	Release of Pu into glovebox with potential release into the room	S1*	Event 08.04.05 is essentially the same as 08.03.17 and is bounded by that analysis.
	08.13.09	Deflagration in calciner due to organic in feed	Release of Pu into glovebox with potential release into the room	S1*	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
	08.13.16	Deflagration in calciner due to organic in feed	Release of Pu into glovebox with potential release into the room	S1*	
		Abnormal Occurrences There are no abnormal occurrences (S1 events) identified for Group D1.			
	08.01.07b/2	**Negligible Safety Concerns** Reaction in feed tank with potential burning of gases	No release expected	S0	
D2.	**DEFLAGRATION OUTISDE OF GLOVEBOX**				
	03.01/1	**Accidents** **DEFLAGRATION IN DRUM EJECTS LID**	**POTENTIAL SEVERE INJURY TO WORKER**	**S1***	**EVENT 03.01/1 CHOSEN TO BE A REPRESENTATIVE ACCIDENT BECAUSE OF THE POTENTIAL FOR SEVERE INJURY TO FACILITY WORKERS**
		Abnormal Occurrences There are no abnormal occurrences (S1 events) identified for Group D2.			
		Negligible Safety Concerns There are no negligible safety concerns (S0 events) identified for Group D2			

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection. (15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
E.	CRITICALITY				
		Accidents			
	06.00	Multiple polybottles in glovebox	Potential CPS violation	S1*	Controls to prevent criticality are contained in the CSER and the CPS for the plutonium handling operations associated with the Laboratory Prototype Calciner operations.
	08.01.05B	Phase separation of Pu due to incorrect solution Ph	Potential CPS violation	S1*	
	08.01.05C	Phase separation of Pu due to incorrect solution Ph	Potential CPS violation	S1*	
	08.01.08/2	High Pu concentration in feed tank	Potential CPS violation	S1*	
	08.04.14/2	Low temperature causes calciner to flood with Pu nitrate	Potential CPS violation	S1*	
	08.04.14/4	Low temperature causes calciner to flood	Potential CPS violation	S1*	
	08.07.04	Filter failure causes PuO_2 buildup in spent scrub solution tank	Potential CPS violation	S1*	
	08.12.02/2	Insufficient cooling in scrubber	Potential CPS violation	S1*	
	8.13.20	Buildup of Pu oxide sludge in glovebox from spills	Potential CPS violation	S1*	
	08.13.22	Activation of room fire suppression system	Potential CPS violation	S1*	
	08.16.00/03	Seismic event pools Pu & solution in glovebox corner	Potential CPS violation	S1*	
	09.01/4	Incompatible chemical reaction in feed tank	Potential CPS violation	S1*	
	16.01	CPS mass violation during canister transport	Potential CPS violation	S1*	
		Abnormal Occurrences			
		There are no abnormal occurrences (S1 events) identified for Group E.			
		Negligible Safety Concerns			
	08.07.05/1	Ceramic filter failure results in possible transfer of Pu to Tank D8	Potential CPS violation	S0	Accidents with S0 consequences do not require further analysis
	08.07.13/2	Flooding of calciner damages ceramic filters	Potential CPS violation	S0	
	08.07.14/2	Inaccurate sample results in possible transfer of Pu to Tank D8	Potential CPS violation	S0	
	08.07.15	Inaccurate sample results in possible transfer of Pu to Tank D8	Potential CPS violation	S0	
	08.08.00	Ceramic filter failure results in possible transfer of Pu to Tank D8	Potential CPS violation	S0	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
F1.	FIRE IN GLOVEBOX				
		Accidents			
	06.01	FIRE INVOVLING WASTE BAGS, ICE CREAM CARTONS, AND OTHER FLAMMABLE WASTE	RELEASE OF PU INTO GLOVEBOX WITH POTENTIAL RELEASE INTO THE ROOM	S1*	EVENTS 06.01 IDENTIFIED IN THE PHA AND 08.13.08 FROM THE HAZOP WERE CHOSEN TO BE REPRESENTATIVE ACCIDENTS BECAUSE OF ALL OF THE ACCIDENTS IN GROUP F1, THEY ARE SIMILAR TO EACH OTHER AND INVOLVE THE GREATEST AMOUNT OF COMBUSTIBLE WASTE.
	08.02.04/2	Electric motor burnout	Potential loss of confinement	S1*	
	08.13.08	FIRE INVOLVING COMBUSTIBLES	LOSS OF CONFINEMENT	S1*	
	09.01/2	Incompatible chemical reaction	Potential fire in feed tank	S1*	
		Abnormal Occurrences			
	08.13.10	Overheated calciner	Potential fire of combustibles	S1	
	08.13.15	Glovebox fire	Potential fire of combustibles	S1	
		Negligible Safety Concerns			
		There are no negligible safety concerns (S0 events) identified for Group F1.			
F2.	FIRE OUTSIDE OF GLOVEBOX				
		Accidents			
	03.02/2	Hydrogen burn of bag and bottle	Potential release of Pu into Room 188	S1*	Event 03.02/2 is bounded by the deflagration event in Group D2.
	08.13.07	Fire involving combustibles in room	Potential release of Pu into Room 188	S1*	
		Abnormal Occurrences			
		There are no abnormal occurrences (S1 events) identified for Group F2.			

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection.
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
G.	**INDUSTRIAL HAZARDS**				
		Accidents			
		There are no accidents (S2 or S1* events) identified for Group G.			
		Abnormal Occurrences			
	01.0	Industrial hazards to facility worker	Hazards to worker	S1	Occupational hazards are not evaluated further as the associated risk is not uniquely related to plutonium processing operations.
	08.13.11/1	Electrical shock to facility worker	Hazards to worker	S1	
	08.15.05	Facility worker burned by hot calciner product	Hazards to worker	S1	
		Negligible Safety Concerns			
		There are no negligible safety concerns (S0 events) identified for Group G.			
H.	**RELEASE TO VACUUM SYSTEM**				
		Accidents			
		There are no accidents (S2 or S1* events) identified for Group H.			
		Abnormal Occurrences			
		There are no abnormal occurrences (S1 events) identified for Group H.			
		Negligible Safety Concerns			
	08.05.03/1	Broken offgas line	Inadequate scrubbing of offgas	S0	Because they result in negligible safety concerns to facility workers, hazards with S0 consequences are not evaluated further.
	08.05.03/2	Relief cap off of calciner	Inadequate scrubbing of offgas	S0	
	08.05.10	Excessive evaporation of caustic	Degrades scrubber function	S0	
	08.06.04/1	Loss of chiller	Reduced scrubbing of offgas	S0	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection.
(15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
	08.06.04/2	Loss of chiller	Reduced scrubbing of offgas	S0	
	08.06.05	Plant vacuum system upset	Loss of vacuum	S0	
	08.06.07	Low caustic level	Release of NO_X from vacuum system to facility stack	S0	
	08.06.08	Acid put in caustic scrubber	Vigorous reaction with heat generation in scrubber	S0	
	08.07.09	Scrubber pH low	NO_X release	S0	
	08.09.00	Liquid accumulation in vacuum system	Degrades scrubber function	S0	
	08.09.02	Vacuum system leaks	Degrades scrubber function	S0	
	08.11.05	Scrubber pH low	Degrades scrubber function	S0	
	08.12.03/1	Insufficient cooling in scrubber	Degrades scrubber function	S0	
	08.12.03/2	Insufficient cooling in scrubber	Degrades scrubber function	S0	
	08.12.04	Insufficient cooling in scrubber	Degrades scrubber function	S0	
I.	**TOXIC CHEMICAL RELEASE INSIDE FACILITY**				
		Accidents			
	01.04a	Caustic spill in glovebox	Release of caustic	S1*	Chapter 9, Section 9.2.8 analyses toxic chemical releases. The consequences of abnormal occurrences in Group I are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in Section 9.2.8 of the PFP FSAR.
	01.04b	Caustic spray leak	Release of caustic	S1*	
	02.00	Caustic drum leak	Worker chemical burn	S1*	
	03.01/2	NO_X release	Hazard to worker	S1*	
	08.11.03/1	Caustic spill	Release of caustic	S1*	
	08.11.03/2	Caustic spill	Release of caustic	S1*	
	08.11.04	Caustic spray leak	Release of caustic	S1*	
	09.02	Acid bottle dropped	Worker chemical burn	S1*	
		Abnormal Occurrences			
	02.02	Caustic drum leak	Worker chemical burn	S1	
		Negligible Safety Concerns			
	08.12.05	Loss of scrubber refrigeration fluid	Exposure to refrigerant	S0	

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection.

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
		Accidents			
	01.02	PR container or ITC tips and releases solution	Potential release of Pu solution into room	S1*	Chapter 9, Section 9.1.1 and 9.1.3 of the PFP FSAR, analyzes abnormal operations involving radioactive liquid and powder spills. The consequences of accidents in Group J are considered to be adequately addressed by the analyses in the PFP FSAR.
	13.01	Release due to dropped slip lid can	Release of Pu into room	S1*	
		Abnormal Occurrences			
	01.01	Chipped floor paint uncovers contamination	Worker inhalation of airborne contamination	S1	Chapter 9, Section 9.1.1 and 9.1.3 of the PFP FSAR, analyzes abnormal operations involving radioactive liquid and powder spills. The consequences of abnormal occurrences in Group J are considered to be adequately addressed by the analyses in the PFP FSAR.
	03.00/1	Particulate released when PR container opened	Worker exposure to radiological material	S1	
	03.00/2	Particulate released when PR container opened	Worker exposure to radiological material	S1	
	03.02/1	Bottle dropped or bag torn during handling	Worker inhalation of airborne contamination	S1	
	03.04	Bag rupture during loading into airlock	Contamination of worker	S1	
	07.00	Bag rupture during handling	Spread of contamination	S1	
	11.01	Sample vial dropped after bagout	Spread of contamination	S1	
	14.00/1	Inadequately sealed container allows release	Spread of contamination	S1	
	15.00	Second overpack applied in hallway	Contamination spread during transport of PR container	S1	
		Negligible Safety Concerns			
		There are no negligible safety concerns (S0 events) identified for Group J.

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
		Accidents			
	08.02.03/1	Excessive feed flow causes inadequate mixing of feed to calciner	Yields inadequate stabilization of product that may pressurize final storage container	S1*	Chapter 9, Section 9.1.3 of the PFP FSAR, analyzes radioactive powder spills. The consequences of abnormal occurrences in Group K are not unique to the laboratory prototype calciner operations and are considered to be adequately addressed by the analyses in the PFP FSAR.
	08.04.01	Low calciner bed	Yields inadequate stabilization of product that may pressurize final storage container	S1*	
	08.04.12/1	Low heat in calciner	Yields inadequate stabilization of product that may pressurize final storage container	S1*	
	08.04.12/2	Low heat in calciner	Yields inadequate stabilization of product that may pressurize final storage container	S1*	
	11.02	Rupture of container in storage	Release of Pu	S1*	
		Abnormal Occurrences			
		There are no abnormal occurrences (S1 events) identified for Group K.			
		Negligible Safety Concerns			
		There are no negligible safety concerns (S0 events) identified for Group K.			

Table 2. Binning, Sorting, and Representative Abnormal Event and Accident Selection. (15 Sheets)

Accident Group	Event ID	Hazards Description	Consequence Description	Consequence Category	Comments and Justification for Selection of Representative Accidents and Abnormal Occurrences
		Accidents			
	08.16.00/01	Seismic event with potential continuous operation of calciner with loss of vacuum causing continuous release of plutonium through calciner relief port	Release of Pu to room through failed glovebox, windows, seals, and penetrations	S2	
	08.16.00/02	**SEISMIC EVENT WITH POTENTIAL CONTINUOUS OPERATION OF CALCINER WITH LOSS OF VACUUM CAUSING CONTINUOUS RELEASE OF PLUTONIUM THROUGH CALCINER RELIEF PORT AND ALSO FAILURE OF E-3 AND E-4 HEPA FILTERS**	**RELEASE OF PU TO ENVIRONMENT**	**S2**	**EVENT 08.16.00/02 CHOSEN AS THE REPRESENTATIVE ACCIDENT BECAUSE OF ALL OF THE ACCIDENTS IN GROUP NPH, IT INVOLVES THE LARGEST AMOUNT OF DISPERSABLE MATERIAL COMBINED WITH THE LEAST MITIGATION TO EXPOSE ONSITE WORKERS OUTSIDE OF THE FACILITY TO RADIOLOGICAL CONSEQUENCES.**
	08.16.00/04	Seismic event with potential toppling of glovebox and failure of E-3 and E-4 HEPA filters	Release of Pu to environment	S2	
	08.16.00/05	Seismic event with failure of Swagelok fitting allowing product collection jar to drop and break releasing plutonium oxide and failure of E-3 and E-4 HEPA filters	Release of Pu to environment	S2	
	08.16.00/06	Seismic event with puncture or toppling of 55 gallon drum of caustic from falling debris	Release of caustic to environment	S1*	
	08.16.00/07	Seismic event with spray leak of caustic from failed fitting or line	Release of caustic to environment	S1*	
		Abnormal Occurrences			
		None			

Table 3. Effect of the Laboratory Prototype Calciner Operations on Prior PFP Abnormal Occurrences. (3 Sheets)

PFP FSAR Section	PFP Abnormal Operations	Effect on Current Analysis Posed by Calciner Operations	Comments
9.1.1	Radioisotope-Bearing Liquid Spills	**No effect.** Analysis generically covers spills of plutonium nitrate solution within the facility. The analysis adequately covers potential spills of plutonium materials in the load in/load out of Glovebox HC-188-1.	The spill scenario is applicable to the Lab Prototype Calciner . The scenario analyzed is a bounding 10-L of plutonium nitrate from a height of 3 m. Analysis credits building ventilation system and a single stage of HEPA filtration with mitigating the release to the atmosphere.
9.1.2	Radioisotope-Bearing Pressurized Liquid Container	**No effect.** Analysis adequately bounds pressurized releases that could occur from the 3 liter containers to be used to support calcine operations in Glovebox HC-188-1.	Analysis postulates that 5 L of solution are ejected upon depressurization when opening container; splatter release fraction is for 3 m fall. E-3 ventilation system and single stage HEPA filter is credited with limiting release to the atmosphere.
9.1.3	Radioisotope-Bearing Powder Spills	**No effect.** Analysis covers PuO_2 spills outside of gloveboxes. Analysis adequately covers potential spills of powder inside or outside the product handling glovebox.	1 kg powder spill is assumed to occur from height of 3 m, releasing 1.2 g. E-4 and E-3 ventilation systems and single stage HEPA filtration credited with limiting release to atmosphere.
9.1.4	Radioisotope-Bearing Pressurized Powder Container	**No effect.** Analysis covers, generically, pressurized powder releases from cans in gloveboxes, vaults or rooms. Improper calciner operation has the potential to produce insufficiently stabilized PuO_2, with potential canister rupture during handling or NDA testing in the 2736-ZB Building or potential canister rupture in the storage vaults in the 2736-Z Building. Ruptured canister releases are considered to be adequately represented by the pressurized powder release evaluated in Section 9.1.4.	Analysis is based on historical facility airborne contamination levels measured following off- normal events. Single stage HEPA filter is credited with limiting release to the atmosphere.
9.1.5 9.1.5A 9.1.5B	Stack Release Resulting from Filter Changes Dropped Filter , Filter Room 309 and 310 Filter Room 26, 236-Z Building	**No effect.** Second stage filter source term is insignificantly effected by laboratory prototype calciner operations. Changes to analysis not required.	Analysis assumes filter is dropped containing twice the contamination levels ever measured on the secondary filters.

Table 3. Effect of the Laboratory Prototype Calciner Operations on Prior PFP Abnormal Occurrences. (3 Sheets)

PFP FSAR Section	PFP Abnormal Operations	Effect on Current Analysis Posed by Calciner Operations	Comments
9.1.6	Overpressure of Remote Mechanical C Line Pressure Vessel	**No effect.** The RMC Line pressure vessel is no longer used. Accident no longer relevant.	
9.1.7A	Excessive Building Pressurization--234-5Z	**No significant effect.** Analysis presents qualitative argument that the consequences of building pressurization would be low because the structure remains intact and multiple failures would have to occur for a significant quantity of radiological material to be released from Zone 4 areas into Zone 3 areas.	Potential source term added by calciner operations is small in comparison to the total source term in the plant.
9.1.7B	Excessive Pressurization of 236-Z Building	**No effect.** Calciner operations not relevant to 236-Z.	
9.1.7C	Excessive Building Pressurization 2736-ZB Building	**No effect.** The analysis concludes that the building pressurization does not result in a significant release to the environment because the building has no significant levels of contamination and the building structure is not compromised by the overpressure.	
9.1.7D	Excessive Building Pressurization 2736-Z Building	**No effect.** The analysis concludes that building pressurization would not cause the storage packages to rupture or the vault structure to be compromised. The analysis concludes there is no loose radiological material stored in the vaults. Storage of material processed in the laboratory prototype calciner presents no new hazards to the storage vaults.	
9.1.7E	Excessive Building Pressurization, 241-Z Building	**No effect.** Calciner operations not relevant to 241-Z.	
9.1.7F	Building Depressurization--All Plutonium Finishing Plant Operations	**No effect.** The analysis in Section 9.1.7F concludes that depressurization of Building 234-5Z will not result in structural failures. The analysis also concludes that the RMC line pressure will remain more negative than room pressure should the building depressurize due to dry air supply regulating valve. Based on the conclusions of the analysis in Section 9.1.7F, the laboratory prototype calciner will not contribute to an environmental release.	Any contamination spread from the calciner glovebox (Glovebox HC-188-1) to the room would pass through the E-3 HEPA filters before discharge to the atmosphere.

Table 3. Effect of the Laboratory Prototype Calciner Operations on Prior PFP Abnormal Occurrences. (3 Sheets)

PFP FSAR Section	PFP Abnormal Operations	Effect on Current Analysis Posed by Calciner Operations	Comments
9.1.8	Loss of Ventilation	**No significant effect.** An air flow reversal from the exhaust stack is concluded to only result in minor contamination spread from Zone 4 to Zone 3 areas. The plutonium inventory in Glovebox HC-188-1 is small compared to total inventory in all the gloveboxes in the plant.	
9.1.9	Glovebox Glove Breach	**No effect.** Glovebox glove breach analysis is representative of potential glove breach accident in HC-188-1.	

Table 4. Effect of the Laboratory Prototype Calciner Operations on Prior PFP Accident Analysis. (2 sheets)

PFP FSAR Section	PFP Accident Analysis	Effect on Current Analysis Posed by Calciner Operations	Comments
9.2.1A	Product Concentrator	**No effect.** The Product Concentrator is not currently in use at PFP.	
9.2.1B	Filtrate Evaporator	**No effect.** The Filtrate Evaporator is not currently in use at PFP.	
9.2.1C	Deflagration in Gloveboxes MT-5/HC-21C	**No effect.** There is no impact on the Glovebox MT-5/HC-21C deflagration analysis due to calciner operations in Glovebox 188-1. They are totally independent operations.	
9.2.1D	Laboratory Waste Concentrator	**No effect.** The Laboratory Waste Concentrator is not currently in use at PFP.	
9.2.1E	Explosion, Hydrogen in Fluorinator	**No effect.** The Fluorinator is not currently in use at PFP.	
9.2.1F	Flammable Gas Explosion	**No effect.** The risk associated with flammable gases in PFP is determined to be acceptable in Section 9.2.1F based on the implementation of specific controls on gas cylinder purchase, storage and use. Compressed flammable gases are not used in calciner operations.	
9.2.1G	Explosion, Slag and Crucible System Deentrainer	**No effect.** The slag and crucible process is not currently in use at PFP.	
9.2.2A	Remote Mechanical C Line Fire	**No effect.** Glovebox HC-188-1 is not located in the same area as the RMC line.	
9.2.2B	Roof Fire, 234-5Z	**No effect.** Laboratory Prototype Calciner operations do not affect the likelihood or consequences of a roof fire at PFP.	
9.2.2C	Glovebox MT-5/HC-21C Fire	**No effect.** Laboratory Prototype Calciner operations do not affect the likelihood or consequences of a fire in these gloveboxes.	
9.2.2D	Waste Drum Events	**No effect.** Calciner operations not relevant to waste drum accidents.	

Table 4. Effect of the Laboratory Prototype Calciner Operations on Prior PFP Accident Analysis. (2 sheets)

PFP FSAR Section	PFP Accident Analysis	Effect on Current Analysis Posed by Calciner Operations	Comments
9.2.3	Criticality	**No effect.** Although glovebox HC-188-1 will handle greater than a critical mass of Pu at any given time, the glovebox design features and controls from the CSERs minimize the likelihood of criticalities in the glovebox. In the unlikely event a criticality occurs in Glovebox HC-188-1, the criticality analysis in Section 9.2.3 is adequately representative. No changes are required to Section 9.2.3 as a result of calciner operations.	
9.2.4	Seismic Event	**Additional source term potential.** The radiological inventory in Glovebox HC-188-1 adds to the potential source term in the seismic event due to the potential for calciner pressurization and vessel upsets.	The seismic analysis in Chapter 4 presents an analysis on the increase in dose due to a seismic event considering the effects from calciner operations.
9.2.5	Strong Wind	**No effect.** The 234-5Z Building is shown in the analysis to survive the design basis wind. No releases from the laboratory prototype calciner area is postulated. Calciner operations do not affect the Strong Wind accident analysis.	
9.2.6	Hydrogen Fluoride – Induced Plutonium Release	**No effect.** The fluorinator is not currently in use at PFP.	
9.2.7	Aircraft Accident	**No effect.** Aircraft impacts into the PFP facility are shown in the analysis to be incredible given flight restrictions prohibiting helicopter operation in proximity to the PFP.	
9.2.8	Toxic Chemical Release	**No effect.** The postulated accident in Section 9.2.8 (failure of the 7000 gal outside HNO_3 storage tank) bounds potential NO_x or nitric acid vapor releases through the plant vacuum system caused by calciner or scrubber upsets within Glovebox HC-188-1. The accident in Section 9.2.8 also bounds potential accidents involving the nitric acid or NaOH supplies to the calciner process.	

Table 5. High Temperature Airborne Release Fractions for Thermally Stressed Material.

Material	Air flow rate, m/s	ARF
PuO_2	0.1	5.3E-6
	1.17	2.5E-4
Air-dried Pu $(NO_3)_4$	0.01	6E-5
	0.05	1.5E-3
	0.1	1.9E-4

ARF = Airborne Release Fraction

Table 6. Laboratory Prototype Calciner Equipment Safety Designations

System, Structure, Component (SSC)	Support Systems	Functional Requirements	Criteria from HNF-PRO-704
SAFETY CLASS SSCs			
E-3 and E-4 Ventilation Exhaust System HEPA Filters and Ductwork	See HN F-SD-CP-SDD-005	Filters radionuclide particulate released from Glovebox 188-1 to E-3 or E-4 ventilation exhaust system before discharge to the environment. The filters were previously evaluated as being Safety Class in the PFP FSAR.	1
Calciner Equipment Interconnection to PFP Ventilation Seismic Shutdown System	PFP ventilation seismic shutdown system (see HNF-SD-CP-SDD-004)	The connection to the seismic shutdown system is designed to rapidly terminate calciner operations by deenergizing the following components: • calciner heaters including dome heater • process air supply solenoids to close valves A and B shown in Figure 7.[1] • agitator motor • feed pump motor Deenergizing these components places the calciner process in a safe shutdown mode. Failure to shut down could lead to a continuous release of radiological materials that could result in unacceptable on-site or off-site doses. In addition to the seismic shutdown system deenergizing the above components, two check valves (identified as valves H and I in Figure 7) are provided in the air supply line to the accumulator to prevent backflow of air from the accumulator to the feed nozzle which could pressurize the calciner.	1
Process Air Supply Solenoid Operated Isolation Valves (Valves A & B on Figure 7)	Interconnection to PFP ventilation seismic shutdown system	The connection to the seismic shutdown system isolates the air supply from the calciner process equipment by deenergizing the two solenoids resulting in closure of the valves. This prevents a continuous release of radiological materials due to pressurization of the calciner.	4
Criticality Drain (see HNF-SD-CP-SDD-008)	None	The drain limits the amount of plutonium-bearing solution that can accumulate which prevents a potential criticality.	4
SAFETY SIGNIFICANT SSCs			
Glovebox Structure	None	The glovebox structure (including gloves, bag-out ports, sphincter seals and pie plates) provides the primary confinement for material that may be airborne inside the glovebox and, therefore, protects the worker from potential uptake. (Refer to PFP SEL [FDH 1998b] for definition of glovebox safety boundary)	11
Room 188 CAM and Fixed Head Air Sampler (HNF-SD-CP-SDD-011)	Backup power system	The Room CAM alerts operators to the presence of contaminants in the room that may have been released from the glovebox. The fixed head air sampler provides a permanent record of the levels of airborne contamination in the room.	11

Note : Valves C through G shown in Figure 7 are also deenergized by the seismic shutdown system to isolate the air accumulator tank discharge line which could continue to supply air to the calciner until the air tank is empty. However, only valves A and B are designated safety class since the additional material potentially released from accumulator tank air injection has been determined to be acceptable. In addition, two check valves (identified as valves H and I in Figure 7) are provided in the air supply line to the accumulator to prevent backflow of air from the accumulator to the feed nozzle which could pressurize the calciner. These valves are also not designated as safety class since the additional material potentially released has been determined to be acceptable.

Table 7. Applicability of Existing PFP Operational Safety Requirements to the Laboratory Prototype Calciner Operations. (3 sheets)

OSR Number *	OSR	Applicable to Addendum	Impacted By Addendum	Comments
LCO 3.1.1.1	The 26-Inch Process Vacuum Liquid Detection Interlock System shall be operable whenever the 26-Inch Process Vacuum System is operating	Yes	No	Although the 26-Inch Process Vacuum System does provide ventilation of the calciner offgas system, calciner operations do involve liquids that could potentially be drawn into the vacuum system.
LCO 3.1.1.2	Glovebox Criticality Drains shall be operable (unobstructed) in the following locations: 234-5Z Gloveboxes: HC-4 HC-9B HC-227T HC-6 HC-227S HC-7 HA-23S Pu Process Support Laboratories Gloveboxes: 188-1 179-10 179-12 Analytical Laboratory Glovebox: 522 (Room 152) 236-Z Gloveboxes: MT-5 1st Floor East Cell Access MT-6 1st Floor West Cell Access 4th Floor column 2nd Floor East Cell Access 5th Floor column 2nd Floor West Cell Access 6th Floor column	Yes	No	Glovebox 188-1 houses the Laboratory Prototype Calciner. This requirement is independent of whether or not calciner operations are conducted.
LCO 3.1.1.3	The following criticality safety features shall be in place: • Glovebox Sump Discs in gloveboxes HC-7, HC-9B • Glovebox Floor Filler Plates in glovebox HC-6 • Raschig Rings in Room 166 Sump.	No	No	Calciner operations do not utilize the specified gloveboxes or sump.
LCO 3.1.2	The Criticality Alarm System (CAS) shall be operable.	Yes	No	Calciner operations involve kg quantities of fissile material. Criticality identified as a potential accident.
LCO 3.2.1.1	Before release to the environment, ventilation exhaust from Zone 4 areas shall pass through two operable HEPA filter stages.	Yes	No	Calciner accident analyses do credit the E-4 ventilation system with reducing doses.
LCO 3.2.1.2	Before release to the environment, ventilation exhaust from Zone 3 areas shall pass through one operable HEPA filter stage.	Yes	No	Calciner accident analyses credit the E-3 system with providing one stage of HEPA filtration.

Table 7. Applicability of Existing PFP Operational Safety Requirements to the Laboratory Prototype Calciner Operations. (3 sheets)

OSR Number *	OSR	Applicable to Addendum	Impacted By Addendum	Comments
LCO 3.2.2	The alpha continuous air monitors (CAMs) for the 291-Z-1, 296-Z-3, 296-Z-14, 295-Z-5, and 296-Z-6 stacks shall be operable.	Yes	No	Exhaust air from the rooms and gloveboxes used in support of calciner operations is released from stack 291-Z-1.
LCO 3.2.3	The accelerometer activated 234-5Z supply ventilation system seismic shutdown shall be operable and set to shut down building supply and dry air process fans (supply fans) and the GB 188-1 Calciner in the event of a greater than 0.07 g seismic event.	Yes	Yes	Glovebox 188-1 contributes to the seismic analysis dose consequences for the plant. Select calciner systems are interconnected with the ventilation system seismic shutdown system. This LCO will require modification to reflect this new safety function.
LCO 3.3.1	The dispersible plutonium inventory within PFP shall not exceed the following limits: • 234-5Z Building excluding Analytical Laboratory, Plutonium Process Support Laboratory, and Standards Laboratory: 274,310 g • 236-Z Building excluding canyon and seismically qualified access gloveboxes: 33,400 g • 2736-ZB Repackaging Glovebox: 20,000 g • Analytical Laboratory, Plutonium Process Support Laboratories, and Standards Laboratory: combined total of 12,450 g of which not more than 5,250 may be greater than 10% ^{240}Pu.	Yes	Yes	Dispersible inventory in gloveboxes used in support of calciner operations must be included in Building 234-5Z total. Glovebox 188-1 analysis has been based on 7000 grams and below 10% material.
AC 5.2	Contractor Responsibility	Yes	No	Generic requirement applicable to all PFP operations
AC 5.3	Compliance	Yes	No	Calciner operations must be conducted in compliance with applicable OSRs
AC 5.4	Operational Safety Requirement Violations	Yes	No	Generic requirement applicable to all operations with associated OSRs
AC 5.5	Occurrence Reporting	Yes	No	Generic requirement for all PFP operations. Calciner operations may result in events and conditions which may involve safety, health, quality, safeguards, security, or environmental implications.
AC 5.6	Revisions to the Operational Safety Requirements	Yes	No	Generic requirement applicable to all OSR revisions
AC 5.7	Operational Safety Requirement Basis Control	Yes	No	Generic requirement applicable to all OSR bases
AC 5.8	Minimum Operations Shift Compliment	Yes	No	Generic requirement for PFP main facility and other process areas.
AC 5.9	Procedures	Yes	No	Generic requirement for all PFP operations.

Table 7. Applicability of Existing PFP Operational Safety Requirements to the Laboratory Prototype Calciner Operations. (3 sheets)

OSR Number *	OSR	Applicable to Addendum	Impacted By Addendum	Comments
AC 5.10	Facility Change Control	Yes	No	Generic requirement for all facility equipment, design features, engineering configuration, and operation documentation.
AC 5.11	Unreviewed Safety Questions	Yes	No	Generic requirement for all nuclear facilities.
AC 5.12	Personnel Qualifications and Training	Yes	No	Generic requirement to qualify and certify personnel performing or supporting PFP operations
AC 5.13	Facility Reviews and Audits	Yes	No	Generic facility requirement
AC 5.14	Audit Records Requirements	Yes	No	Generic facility requirement
AC 5.15	Nuclear Criticality Safety	Yes	No	Calciner operations involve kg quantities of fissile material. Criticality identified as a potential accident.
AC 5.16	Radiation Protection	Yes	No	Calciner operations involve kg quantities of radioactive material.
AC 5.17	Effluent Monitoring and Sampling	Yes	No	Generic facility requirement
AC 5.18	MODE Changes	Yes	No	Generic facility requirement
AC 5.19	OSR Interfaces with Other Facilities	No	No	Calciner operations do not include material transfers to interfacing facilities.
AC 5.20	Fire Protection	Yes	No	Calciner accident analyses credit minimization of combustible loading and fire protection equipment.
AC 5.21	Flammable Gas Inventory	No	No	Calciner operations do not use flammable gas cylinders (e.g., propane, acetylene).
AC 5.22	Plutonium Inventory	Yes	Yes	Total dispersible inventories of plutonium contained in gloveboxes operated in support of calciner operations must not exceed the values listed in Table 5.22.1 and Table 5.22.2 of WHC-SD-CP-OSR-010. . Glovebox 188-1 analysis has been based on 7000 grams and below 10% material.
AC 5.23	OSR Compliance Program	Yes	No	Generic requirement applicable to OSRs.

*The OSR numbering scheme is based on the format of WHC-SD-CP-OSR-010. The document sections are as follows: 1.0 Use and Application, 2.0 Safety Limits (no safety limits have been identified for PFP), 3.0 Limiting Conditions for Operations, 4.0 Surveillance Requirements (these are integral with the LCOs presented in Section 3.0), 5.0 Administrative Controls.

Table 8. Operational Safety Requirements

CONDITION	REQUIREMENT	SAFETY FUNCTION
1. Mitigation of seismic event releases.	Prior to calciner operations, the interconnection to the PFP ventilation seismic shutdown system shall be verified to be operable.	This control deenergizes calciner process equipment to limit the quantity of material that may be released as a result of a seismic event which is analyzed in Section 4.2.5.
2. Isotopic distribution of plutonium in feed solution.	Limited to <10% ^{240}Pu content.	Limiting the quantity of higher dose rate isotopes allowed in the glovebox minimizes the consequences in the seismic accident analysis in Section 4.2.5.
3. Glovebox inventory control.	≤ 7000 g of plutonium	Limiting the maximum inventory allowed in the glovebox minimizes the consequences in the seismic accident analysis in Section 4.2.5.

Table 9. Operational Controls for the Laboratory Prototype Calciner
(3 sheets)

CONDITION	REQUIREMENT	SAFETY FUNCTION
1. Accumulation of flammable gas in feed solution transport containers.	Transportation of Pu feed solution shall be in polybottles in vented PR can containers or ITCs. Unvented containers shall not be accepted by the laboratory for use in calciner operations.	The vents in the container and the lids on the ITCs preclude accumulation of flammable gas that could be released or burned during opening of the transfer container. Refer to Section 4.2.1, Hydrogen Deflagration in Room 188 from Opening Drum (PR Container), for a discussion of this scenario and its consequences.
2. Worker exposure to ionizing radiation.	A Radiation Protection program shall be established, implemented and maintained. A key element of the program in Calciner Operations is the use of respiratory protection when unloading PR containers and ITCs in Room 188, when loading solution bottles into Glovebox 188-1, and when bagging out material from Glovebox 188-1	The radiation protection program protects workers from exposure to ionizing radiation through training, dosimetry, shielding, posting, contamination controls and other elements. The hazards analysis notes in numerous entries that a potential exists for worker uptake if a release of material occurs.
3. Confinement of Plutonium in Glovebox 188-1.	The glovebox shall be verified to be at negative pressure relative to the room prior to initiation of any operations at the calciner.	All airflow is to be towards the more contaminated area and away from the worker occupied area to prevent worker contamination or uptake. The hazards analysis notes in numerous entries that a potential exists for worker uptake if a release of material occurs.
4. Excessive heating of Glovebox 188-1 from process operations.	Proper ventilation airflow for heat removal shall be verified prior to operation of the calciner.	Removal of glovebox heat load with the ventilation airflow prevents damage to the process equipment in the glovebox as well as protects as the integrity of the confinement function of the glovebox. Note that glovebox high temperature indication alerts operators of excessive temperature. Refer to Section 4.2.4, Glovebox 188-1 Fire, for additional information on one of the hazards of inadequate heat removal from the glovebox (fire).
5. Calciner over-temperature protection	The calciner over-temperature protection system shall be operable while the calciner is operating.	The over-temperature protection system notifies operators that calciner temperatures are high and automatically shuts power off to the heaters. This prevents calciner failure and potential fire.

Table 9. Operational Controls for the Laboratory Prototype Calciner
(3 sheets)

CONDITION	REQUIREMENT	SAFETY FUNCTION
6. Airborne room contamination monitoring.	A Continuous Air Monitor (CAM) in Room 188, with an audible alarm for alerting the operators, shall be verified to be operable prior to initiation of operation of the calciner.	Long term exposure to airborne plutonium contamination is prevented by the use of the room CAM. The CAM ensures that operators are alerted to contamination releases into the room. The hazards analysis notes in numerous entries that a potential exists for worker uptake if a release of material occurs.
7. Fire prevention and mitigation for calciner operations.	A fire protection program shall be established, implemented, and maintained. Key elements of the program as implemented for calciner operations shall include: minimizing combustible loadings in the glovebox, operability of the glovebox temperature monitoring system and availability of a dry chemical, bayonet-equipped, portable fire extinguisher.	The Fire Protection Program minimizes the potential for and magnitude of any possible fires. Protection of the facility and loss prevention are provided by the program. Refer to Section 4.2.4, Glovebox 188-1 Fire, for additional information on fire scenarios and possible combustible loadings in the glovebox.
8. Control of oil in compressed air supply.	The compressed air oil trap on the process airline in Room 188 shall be operational and continuously drained during calciner operation.	In order to prevent injection of oil from air compressor operation into the calciner with a resultant organic burn, it is necessary to remove oil from the air supply and to drain the oil from the trap. Refer to Section 4.2.3, Flammable Gas Deflagration in the Laboratory Prototype Calciner, for a representative accident scenario involving the injection and burn of organic material in the calciner.
9. Prevention of incompatible chemicals introduced to the feed tank or the calciner.	Controls shall be established addressing chemical compatibility for calciner operations. The controls as applied to calciner operation shall include: control of chemicals brought to and used in calciner operations, evaluation of any new chemicals proposed for calciner operations, and continuous awareness of chemicals in use, or stored in the calciner or feed tanks.	Incompatible chemicals can generate flammable gas, heat, and combustible reactants. To prevent a fire or deflagration in the calciner the use of chemicals must be controlled. Refer to Section 4.2.3, Flammable Gas Deflagration in the Laboratory Prototype Calciner, for a representative accident that could result from the reactions of incompatible chemicals.

Table 9. Operational Controls for the Laboratory Prototype Calciner
(3 sheets)

CONDITION	REQUIREMENT	SAFETY FUNCTION
10. Worker exposure to hazardous chemicals.	An Industrial Hygiene Program shall be established, implemented, and maintained to provide worker protection from chemical hazards.	The Industrial Hygiene program provides appropriate controls for worker protection from chemical hazards. The program provides training and procedures that ensure safe use and transfer of caustic solution used in calciner operations and minimize chemical hazards to workers. The hazards analysis notes in numerous entries that a potential exists for worker injury from the use and proximity of hazardous chemicals.

Table 10. Controls Required to Implement Key Analytical Assumptions

CONDITION	REQUIREMENT	SAFETY FUNCTION
1. Feed solution transfer polybottles.	≤ 3 L maximum capacity ≤ 2.5 L feed solution	This control limits the hydrogen generation rate during transfers to that assumed in the analysis. Larger containers or larger headspaces could invalidate the conclusions of analyses in Sections 4.2.1, 4.2.2, and 4.2.3.
2. Feed solution plutonium concentration	≤ 450 g-Pu/L.	For criticality control purposes, to limit hydrogen generation from radiolysis, and to remain within the bounds of the dose consequence analysis, material brought to the calciner for processing must be controlled. The dose consequences of each accident scenario in Section 4.2 are based on this limit.
3. Feed solution nitric acid concentration	> 4 M.	This control limits the hydrogen generation rate during container transfers and interim storage, if necessary. Lower nitric acid concentration could invalidate the conclusions of analyses in Sections 4.2.1, 4.2.2, and 4.2.3
4. Feed solution control	Feed solutions shall be limited to plutonium nitrate.	Other materials have not been evaluated for processing in the calciner and, therefore, are not supported by the accident analysis of Section 4.2.
5. Feed solution organic content	≤ 1 % organic content with no visible, separable layer of organic.	Limiting the organic concentration to 1% and no visible, separable layer of organic limits the potential for a significant organic burn in the calciner. The deflagration analysis in Section 4.2.3 provides additional information on the consequences of organic burns within the calciner.

Table 11. Required OSR Revisions to Incorporate Calciner Interconnection with PFP Ventilation Seismic Shutdown System.

Surveillance Requirement	Surveillance	Required Frequency	Surveillance Function
SR 3.2.3.1	Perform FUNCTIONAL TEST of the accelerometer activated seismic shutdown system.	Annually	Surveillance 3.2.3.1 ensures the accelerometer activated seismic shutdown system is tested annually to VERIFY functionality. The surveillance verifies that in response to an accelerometer signal indicating a 0.07-g earthquake, supply fans shut down as required, and when the calciner seismic shutdown is required to be operational, power to the Glovebox 188-1 calciner equipment is shut down. The annual frequency is based on the reliable nature of the components (relays, contacts, undervoltage coils) and their limited usage. The components are subjected more to the effects of aging than wear.
SR 3.2.3.2	CALIBRATE each accelerometer channel.	Annually	Surveillance 3.2.3.2 ensures a CALIBRATION of each accelerometer channel is conducted annually to VERIFY each channel is capable of responding properly to a 0.07-g earthquake.
SR 3.2.3.3	VERIFY both seismic shutdown system accelerometers are on line and in service.	Once within 24 hours prior to Glovebox 188-1 calciner startup AND Daily thereafter while the Glovebox 188-1 calciner is operating	Surveillance 3.2.3.3 ensures that a visual inspection of supply ventilation system seismic shutdown accelerometers has been performed to verify both accelerometers are on line and in service prior to initial startup of the Glovebox 188-1 calciner and once every 24 hours thereafter when the calciner is in operation. This surveillance frequency ensures that an accelerometer malfunction not detected by the seismic shutdown alarm system would be detected by plant personnel and calciner operations suspended within a time frame in which a DBE is considered to be an incredible event.

1.0 INTRODUCTION

A hazards analysis was performed to identify and evaluate hazards associated with the stabilization of plutonium nitrate solutions using the PFP Laboratory Prototype Calciner. This appendix describes the methodology and presents the results of the hazard analysis performed. The techniques used in identifying the hazards associated with the operation of the calciner were a Preliminary Hazards Analysis (PHA) and a Hazards and Operability Study (HAZOP).

The scope of the PHA and HAZOP included activities from the transport of the PR can drum into Room 188 to the transport of the over-packed product can into a storage vault.

2.0 HAZARD ANALYSIS

The methodology and results of the PFP Laboratory Prototype Calciner hazard analysis and evaluation are presented in this section. The hazard analysis is a structured, systematic examination of the calciner system, and pre- and post-processing activities of the plutonium nitrate solutions. The resulting identified hazards were then evaluated and placed into Accident Groups based on the initiating event and the resulting consequences of the hazard.

2.1 Hazard Identification Methodology

This section describes the methodologies used to identify and characterize hazards associated with the calciner pre- and post-processing activities and the calciner operations. Two techniques were used in identifying the hazards associated with the activities performed before and after the calciner and the operation of the calciner. These techniques are described in Sections 2.1.1 (PHA) and 2.1.2 (HAZOP).

2.1.1 Laboratory Prototype Calciner Hazard Identification Methodology

The activities associated with the movement of the plutonium nitrate solutions into Glovebox 188-1 and the removal of the over-packed can of plutonium oxide from Glovebox 188-1 for transfer to a storage vault were evaluated via a PHA. The PHA process is a systematic approach whereby a system, process, or activities are divided into basic elements and the hazards associated with elemental system, process operations, or activities are identified. Then potential causes of the hazards are determined, potential consequences of the hazards are evaluated, and possible or existing engineered and administrative safety features are identified.

A detailed discussion of the PHA technique can be found in *Guidelines for Hazard Evaluation Procedures* (AIChE 1992).

The PHA was developed using a table to guide and record the results of the hazard identification and evaluation process. The PHA form is provided in Table A-1. The purpose and contents of each column in the PHA table are described in detail in the following paragraphs.

Column 1, Item ID: Provides an alpha-numeric identifier for each postulated hazard in the table. The identifier is primarily used for cross referencing within the table.

Column 2, Acc Group: Provides an alpha-numeric identifier of the accident group the hazard has been assigned to.

Column 3, Activity Operation: Lists the activities or operations performed before and after the calciner operation. For general activity or operation, a description is listed in this column. Safety functions for the activity were identified, and failure of the safety functions was postulated to identify the hazards.

Column 4, Hazardous Event: Hardware failures or operational faults of concern are identified in this column. Hazards are identified by asking "what-if" type questions, such as, "what if the operation is not performed," "what if the operation is performed out of order," "what if the operation is performed too fast". Guide word deviations such as are used in HAZOP analysis (AIChE 1992) were also utilized to identify hazardous conditions. Guide words are process parameters such as pressure, temperature, flow, concentration, etc. Relevant deviations include "low/no," "high," "other than."

Column 5, Causes: Identifies the causes for the failures/hazardous conditions postulated in Column 3. Identifying causes is important to identifying potential preventative controls for significant hazards. In many cases, multiple hardware or operational faults are required to produce a hazardous event. This column identifies the sequence of hardware and operational faults required to produce the postulated hazardous event.

Column 6, Consequences: Describes the potential consequences that could result from the postulated hazards identified in Column 3. The focus of this column is to identify effects to the glovebox confinement system and to facility workers.

Column 7, Engineered Safety Features: Identifies the engineered safety features (hardware items) available to prevent or mitigate the consequences identified in Column 5. The engineered features in this column are candidates for designation as Safety Significant items for hazards that pose a significant threat to the health of facility workers.

Column 8, Administrative Safety Features: Identifies the administrative requirements that reduce the likelihood of the hazardous event identified in Column 3, or that help minimize the potential consequences of the hazardous event. The controls listed in this column are candidates for operational safety requirement (OSR) designation for hazardous events with the potential to significantly harm facility workers.

Column 9, Consequence Category: Used to capture a code designator for the level of consequence associated with a hazardous event. The consequence ranking is a "first cut," qualitative estimate of the safety severity of the consequences. An alphanumeric system has been used at the PFP to designate the severity of hazardous events. The system has the following "S" rankings characterizing safety consequences:

S0 No effect outside the facility confinement systems, and no safety concerns for the facility worker, the onsite worker, or members of the general public.

S1 Potential industrial injury, low radiological or chemical exposure dose consequences to the facility worker. An example of such a hazard would be an operator injury where glovebox gloves are penetrated by the can punch causing worker injury and possible skin/wound contamination.

S1* Potential severe harm or potential death from industrial injury, radiological dose or chemical exposure to the facility worker. Hazards of this severity level may warrant safety significant controls.

S2 Potentially significant radiological dose consequence or chemical exposure to the maximum onsite worker outside the facility, or discharge of hazardous material to the environment within the Hanford Site boundary. This is conservative as such events will not necessarily cause severe harm to facility workers.

S3 Potentially significant radiological dose consequence or chemical exposure to the offsite population, or discharges of hazardous material to the environment outside the Hanford Site boundary or to the groundwater.

Engineered safety features and controls specific to the processing of plutonium oxides are not credited in assigning the above consequence rankings. This is to allow determination of whether the controls warrant designations as safety significant or safety class.

The mitigative effects of features previously designated as safety significant or safety class are credited in assigning the consequence rankings. The effects of energetic events on the glovebox structure, however, are assessed to determine if the hazardous event can compromise the Safety Significant Confinement function provided by the glovebox structure and ventilation system. Similarly, the Building 234-5Z Safety Class Structure and E-3 and E-4 Ventilation Exhaust Systems are credited with protecting onsite workers and the offsite public outside the PFP from accidents that breach glovebox confinement.

Column 10, Frequency Category: Used to capture a code designator for the estimated frequency of occurrence of a hazardous event. The ranking is a "first cut," qualitative estimate of the frequency of the hazardous event. The following ranking system is used.

F0 Events categorized as "beyond extremely unlikely" with a frequency less than 1×10^{-6}/yr.

F1 Events not expected to occur within the lifetime of a typical facility, categorized as "extremely unlikely". The frequency range associated with this category is 1×10^{-6}/yr to less than 1×10^{-4}/yr.

F2 Events that could occur during the lifetime of the facility, but with low probability. Such events are categorized as "unlikely" and fall in the range of 1×10^{-4}/yr to less than 1×10^{-2}/yr.

F3 Events that are expected to occur one or more times during the lifetime of the facility, categorized as "anticipated" events. The frequency range associated with this category is equal to or greater than 1×10^{-2}/yr

The frequency estimate, like the consequence ranking, is assigned taking no credit for active engineered features. The frequency ranges shown above are based on the risk acceptance criteria for the onsite receptor from the PFP FSAR (FDH 1999).

Column 11, Remarks: Contains miscellaneous observations or clarifying comments for a given hazard. The comments column can be used to identify hazards that are adequately addressed in other documentation.

2.1.2 Laboratory Prototype Calciner Operations Hazard Identification

A Hazards and Operability Study (HAZOP) was selected as the method by which to identify the hazardous conditions associated with the operation of the calciner. A HAZOP is a systematic approach in which the basic elements of the system and the hazardous conditions of interest are identified, potential causes and effects are evaluated, and possible corrective and/or preventive measures are proposed. HAZOP findings are documented on a HAZOP Form, which is shown in Table A-2. Guide words and column headings in a HAZOP form are used to aid in ensuring completeness. The columns of the HAZOP Form contain the following data:

Column 1, Node ID: Alphanumeric identifier. Each hazardous condition is assigned a unique identification number which permits cross-referencing information contained in the HAZOP with the accident tables that are generated later in the hazard evaluation process.

Column 2, Acc Group: Provides an alpha-numeric identifier of the accident group the hazard has been assigned to.

Column 3, Node Description: Defines the system node that is being evaluated.

Column 4, Design Function: Contains a description of the operation(s) being performed in the operational area, or a description of the system functions in the case of a system being evaluated.

Column 5, Parameter Guide Word: Contains a description of the operation(s) being performed in the operational area, or a description of the system functions in the case of a system being evaluated.

Column 6, Cause: Lists the potential cause or causes of the hazardous event or failure.

Column 7, Consequence: Lists the potential consequences of the hazardous event.

Column 8, Engineered Safety Features : Lists existing hardware design features that could mitigate or prevent the event being considered.

Column 9, Administrative Safety Features: Lists administrative controls that could mitigate or prevent the event being considered.

Column 10, Cons Cat: Consequence Category contains a qualitative estimate of the result of the event, assuming that no controls, engineered or administrative, are present. However, naturally occurring phenomena that limit the consequences of an event are assumed to take place ("rules of the universe"). This consequence ranking is a "first cut," qualitative, consensus estimate of the safety severity of the consequences. The following "S" rankings are used to characterize the severity of the safety consequences:

S0 No effect outside the facility confinement systems, and no safety concerns for the facility worker, the onsite worker, or members of the general public.

S1 Potential industrial injury, low radiological or chemical exposure dose consequences to the facility worker; limited discharge of hazardous material to the environment outside the facility. An example of such a hazard would be an operator injury where glovebox gloves are penetrated by the can punch causing worker injury and possible skin/wound contamination.

S1* Potential severe harm or potential death from industrial injury, radiological dose or chemical exposure to the facility worker. Hazardous conditions sufficient to cause severe harm or death to facility workers are typically associated with events which may result in significant pressurization of or damage to the glovebox structure with potential release of radiological material. Therefore, events with sufficient energy to impact the glovebox in a manner which may cause a release of radiological material are assigned an S1* consequence rank. This is a conservative approach since such events will not necessarily result in harm to or death of facility workers.

S2 Potentially significant radiological dose consequence or chemical exposure to the maximum onsite worker outside the facility, or discharge of hazardous material to the environment within the Hanford Site boundary.

S3 Potentially significant radiological dose consequence or chemical exposure to the offsite population, or discharges of hazardous material to the environment outside the Hanford Site boundary or to the groundwater.

Column 11, Freq Cat: Frequency Category is a "first cut," qualitative, consensus estimate of the frequency of the hazardous condition (also referred to as "event"), assuming that no engineered or administrative safety features are present. The following "F" rankings are used to characterize the frequency of the hazardous condition:

F0 Events categorized as "beyond extremely unlikely" with a frequency less than 1×10^{-6}/year.

F1 Events not expected to occur within the lifetime of a typical facility, categorized as "extremely unlikely". The frequency range associated with this category is 1×10^{-6}/year to less than 1×10^{-4}/year.

F2 Events that could occur during the lifetime of the facility, but with low probability. Such events are categorized as "unlikely" and fall in the range of 1×10^{-4}/year to less than 1×10^{-2}/year.

F3 Events that are expected to occur one or more times during the lifetime of the facility, categorized as "anticipated" events. The frequency range associated with this category is equal to or greater than 1×10^{-2}/year.

Column 12, Remarks: Remarks contains information that the team judges to require documentation. This can include, but is not limited to, assumptions about facility operation or recommendations for changes in the planned design or operation.

The HAZOP table is structured to ensure a systematic and thorough review of potential hazards associated with the operation of the calciner.

2.2 Hazard Analysis Results

2.2.1 PHA Hazardous Condition Evaluation Results

A PHA was performed to identify the hazards associated with calciner operations, including the activities before and after the calciner operations which involve the movement of the plutonium nitrate solutions into Glovebox 188-1 and the removal of the plutonium oxide over-packed can from Glovebox 188-1 into a storage vault. The PHA was performed by a multi-disciplinary team comprised of PFP laboratory personnel with a detailed knowledge of the pre- and post-processing activities associated with the calciner operations, and safety analysis subject-matter experts. The work experience of each of the team members is provided in Section 2.2.3.

The PHA table in the analysis is specially structured to ensure a systematic and thorough review of potential hazards associated with the pre- and post-processing activities of the calciner.

The operational steps covered by the PHA were identified from applicable operating procedures, verbal descriptions provided by the cognizant engineer, and available design media. The groups of operations performed and evaluated in the PHA are:

1. Move PR can drum into Room 188
2. Move replacement drum of caustic into Room 188
3. Open plutonium nitrate drum
4. Remove bags from bottle and load solution into feed tank
5. Start up calciner system in the following sequence: (1) turn on vacuum, (2) turn on pressurized air, and (3) activate agitator and heaters
6. Bag-out empty bottle and waste
7. Load empty bottles back into drum from laboratory, move drum out of laboratory
8. Glovebox 188-1 Laboratory Prototype Calciner- Oxidize plutonium nitrate
9. Load flush solution into glovebox and flush calciner feed line
10. Transfer collection jar contents to slip-lid can
11. LOI sampling
12. Weigh can, tape lid on, and reweigh can
13. Bag-out filled slip-lid can
14. Canning of bagged slip-lid can into overpack (large tomato can)
15. Second overpack (7 in. can) applied in hallway
16. Transfer overpacked can to vault

"What if" questions were asked at each of the activities that are provided above. Hazardous Event, Causes, and Consequences were then identified for each activity and recorded in tabular format (Table A-1). The resulting hazards of this process are recorded in a PHA tabular format and is provided in Table A-5.

2.2.2 HAZOP Hazardous Condition Evaluation Results

The hazards associated with calcining the plutonium nitrate in the calciner were identified via the HAZOP technique. The HAZOP was conducted by a safety analysis expert facilitating a team of knowledgeable contributors with PFP and calciner system experience. That team consisted of safety analysts, accident analysts, and an engineer who has operated this calciner. The work experience of each of the team members is provided in Section 2.2.3.

A HAZOP was performed to identify the hazards associated with operation of the Production Vertical Denitration Calciner (VDC) system but the results were not issued. The results of the previous VDC HAZOP (node id, node description, design function parameter/guide word, cause, consequence) were used as a starting point for the identification of hazardous conditions for the operation of the laboratory calciner.

The calciner system was subdivided into 15 hardware nodes. These nodes are shown in Figure A-1. Each of the nodes were evaluated for relevant design parameters: pressure, temperature, flow rates, pH, composition, mixing, etc. The following guide words are examples of those that were used in determining parametric deviations to the above parameters: no, less, more, part of, as well as, reverse, and other than. All guide words are included in Table A-6. These deviations were applied to each parameter at each of the following nodes:

1. Feed Tank
2. Feed Pump
3. Calciner Injector Nozzle
4. Calciner Vessel
5. Off-gas line between calciner and scrubber
6. Scrubber
7. Spent Scrubber Solution Tank
8. Spent Scrub Solution Drain Line
9. Vacuum Trap
10. Filter Pulsing Supply Air
11. Sodium Hydroxide Feed Supply Line
12. Scrubber Chiller
13. Glovebox 188-1
14. E-4 Exhaust Duct at Outlet of glovebox
15. Product Collection Jars and Slip Lid Cans

"What if" questions were asked at each of the nodes for each of parametric deviations that were identified. Causes and consequences were then identified for each hazard and recorded. The results of this process are recorded in the HAZOP provided in Table A-6.

2.2.3 Laboratory Prototype Calciner PHA/HAZOP Participant Biographies

This section contains the professional biographies of the participants of the PFP Laboratory Prototype Calciner PHA/HAZOP conducted during February 2 – 5, 1999.

David J. Braun - Fluor Daniel Northwest Inc, Engineer, Safety Analysis and Risk Assessment PE

Mr. Braun has over 21 years experience at Hanford working primarily in Safety Analysis. His experience includes Probabilistic Risk Analysis of nuclear reactors, tank farm activities, and hazards identification and evaluation of various Hanford site operations and facilities. He was one of the lead engineers on the hazards identification and evaluation team for the current TWRS BIO and draft FSAR. He has facilitated numerous PHA and HAZOP studies for projects at the Hanford site. Mr. Braun has a Master of Science Degree in Mechanical Engineering from the University of California at Davis. He is a registered Professional Engineer in Mechanical Engineering (Washington State).

Jim Compton - B&W Hanford Company, Engineer

Mr. Compton is the cognizant engineer for the PFP laboratory prototype calciner. He has a Bachelor of Science degree in Chemical Engineering from the University of Kansas. He has worked in the Plutonium Process Support Laboratories for 22 years. He has worked with the design, installation, and testing of this calciner since 1994.

Brett Hall - Fluor Daniel Northwest Inc, Engineer, Safety, Analysis and Risk Assessment

B. S., Chemical Engineering, Process Engineer, FDNW Safety Analysis and Risk Assessment Group. Over nine years experience at Hanford. Eight years of experience in performing and documenting safety analyses for various Hanford facilities, including the TWRS tank farms and the Plutonium Finishing Plant (PFP). One year of experience in Tank Waste Characterization.

Don Porten - Fluor Daniel Northwest Inc, Engineer, Safety, Analysis and Risk Assessment

Mr. Porten is a Nuclear Engineer with 25 years of experience with the safety aspects of nuclear reactors and nuclear facilities in the Hanford area and in commercial power production. He has worked as a safety analysis engineer performing hazard and accident analysis for nuclear facility Safety Analysis Reports and Assessments. He performed hazard and accident analysis for the entire series of safety documents, (Hazard Classification, PSE, PSAR, FSAR) that accompanied WRAP 1 from conceptual design through construction to completion and startup. As a nuclear fuel management engineer, he prepared and used reactor simulation computer models for reload core design, operation, and safety margin evaluation of the Pallisades Nuclear Plant. He worked as a nuclear fuels testing engineer performing transient irradiation experiments of mixed oxide fuel elements which contributed to the safety basis for the Fast Flux Test Facility. Mr. Porten has Master of Science degree in Nuclear Engineering from the University of Washington in Seattle.

Martin Prisc - B&W Hanford Company, Engineer

Mr. Prisc has 30 years experience working at the Mound Facility in the process development and analytical sections. For over 15 years his experience includes involvement with Safety Analysis and Risk Assessments, USQ and FSAR documentation, and as a member of the Safety Overview Committee. Mr. Prisc has a Master of Science degree in Inorganic Chemistry from the University of Cincinnati located in Cincinnati, Ohio.

Jim Shapley - Fluor Daniel Northwest Inc, Engineer,

Mr. Shapley is a Senior Principal Engineer with Fluor Daniel Northwest. He received his B.S. Engineering Degree from the University of California in Los Angeles. He is a systems and project engineer with 30 years of experience in systems design, engineering and analysis. Currently he is the lead engineer responsible for preparation, review and approval of the annual updates and overall maintenance of the PFP SAR.

2.3 Accident Group Selection

The hazardous events identified by the PHA and HAZOP process are segregated into accident groups. This process of grouping the hazards is the starting point for the quantitative accident analysis process. The results of that type of analysis are compared to applicable regulations and requirements for systems, structures, and components. The comparison is made to determine the necessary safety class and safety significant components and to define Operational Safety Requirements (OSRs). The accident selection methodology is provided in Section 2.3.1 and the results of application of this process to the calciner are provided in Section 2.3.2.

2.3.1 Accident Selection Methodology

The selection of accidents that will subsequently be used for quantitative analysis was performed by a grouping process designed to comply with the requirements of Section 3.3.2.3.5 of DOE-STD-3009-94 (DOE 1994) and the requirements of HNF-PRO-704 (HNF 1997). DOE-STD-3009-94 suggests a matrix approach in which only "unacceptable accidents" (moderate to high consequences, and unlikely to anticipated frequency) should be identified. The initial accident screening criteria used in this process were based on qualitative consequence rankings that were developed in the PHA/HAZOP. Any accident appearing in the S2 or S3 consequence category was a potential candidate for quantitative analysis. Thus a broader spectrum of candidate accidents was considered for quantitative analysis than is required by DOE-STD-3009-94. This approach does not omit any accident that the standard would consider and provides for consideration of a broader spectrum of representative and unique accidents to furnish adequate technical justification for the choice of safety class equipment and OSRs.

The selection process is represented in the flowsheet of Figure A-2. All accidents developed in the HAZOP were classified by "Type" and placed into accident groups. The type classification of each accident relates to the initiating phenomena such as canister failures, fire, pressurization, etc. For each accident group with an S1*, S2, or S3 consequence, a representative accident was developed for further quantitative analysis. This representative accident bounds the consequences of similar accidents/hazards in the accident group it represents. Similar accidents/hazards challenge analogous barriers. Analogous barriers reflect the same design philosophy for prevention and mitigation as the representative accident, even though the similar accidents may be in different locations. If there is only one accident/hazard of a given type, it is analyzed as a unique representative accident. The "Category" of an accident was used to help identify initiating events that, for accidents of a common type, could result in significantly different challenges to the analogous barriers.

The results of the accident grouping process are presented in tabular format for each accident group. This information is provided in Table A-5 and Table A-6 under the column Acc. Group. Accidents that would not have effects of concern outside Glovebox 188 (S0 category consequences) are grouped together. Accidents that result in increased worker exposures (direct dose) or minor air contamination releases, but not above exposure limits (S1 category consequences) are grouped together. Accidents that could result in severe worker injury, or

radiological or toxicological exposure to facility workers above established exposure limits (S1* category consequences) are grouped together. (S1* accidents do not have significant consequences outside the facility confinement boundary). Accidents that could potentially have effects of concern to either the maximum onsite individual or the maximum offsite individual (S2 and S3 category consequences) are also grouped together.

2.3.2 Accident Selection Results

The accident groups that were chosen for consideration are provided in Table A-3. An appropriate representative (bounding) accident was chosen for each selected accident group. If a group contained a single accident, that accident was identified as unique and representative. The representative accidents were otherwise chosen as the accident having the highest consequence with the highest frequency ranking in a specific accident group.

Table A-4 contains a list of accidents that were derived from the hazardous conditions generated by the Laboratory Prototype Calciner PHA and HAZOP. The accidents were derived using the "Cause" and "Consequence" columns of the hazardous condition definition. The hazardous conditions were selected on the basis that there was impact on the facility worker (life threatening - S1*) and onsite worker (S2). These resulting accidents are sorted according to the accident groups provided in Table 3. A total of 10 of the 15 accident groups of Table A-3 had S1* and/or S2 defined accidents.

A representative accident was selected for each of the 10 accident groups. A representative accident having the highest consequence and frequency ranking was selected from the accidents in a particular accident group. The selected representative accident is at the top of the list of each accident group and its identifying number ends with an "R".

One event in Table A-4 falls in the consequence category of S2 and frequency category F2. The event is in Accident Group NPH: Release of plutonium to room through failed glovebox, windows, seals, and penetrations due to seismic event resulting in exposure to site personnel.

The other hazardous conditions listed in Table A-4 for Accident Groups C through K are in the Consequence Category S1* and Frequency Categories F1, F2, and F3. There are a total of 57 hazardous condition identifiers listed in Table A-4, which are represented by 42 accidents.

2.4 Abnormal Occurrences and Negligible Consequence Events

Within the 10 accident groups that have S1* and/or S2 consequence defined events, there are four groups that also have S1 and/or S0 consequence defined events. From Section 2.1.2, S1 events are defined as potential industrial injury, low radiological or chemical exposure consequences to the facility worker, and limited discharge of hazardous material to the

environment. Events with an S0 designation have no effect outside the facility and negligible safety concerns for the facility worker.

For each of the 10 groups, all S1* and S2 events are sorted out and collected into a subgroup for evaluation as accidents. All S1 events in each group are collected into a second subgroup for evaluation as abnormal operations. Finally, all S0 events in each group are collected into a third subgroup with the S0 negligible safety concerns.

Of the 15 accident groups of Table A-3, six of them (A2, B, C, G, I, and J) have events with a consequence category of S1, designating abnormal occurrences. There were no representative abnormal occurrence events identified in any of the groups. The rationale for not developing abnormal occurrences is presented in Section 3.2.2 in this addendum.

Table A-3. Accident Groupings

No.	Accident Group Title
A1	Process Upset - no worker impacts
A2	Process Upset - worker ALARA concern
B	Radiological Release Inside Glovebox
C	Radiological Release from Glovebox
D1	Deflagration in Glovebox
D2	Deflagration Outside of Glovebox
E	Criticality
F1	Fire Inside of Glovebox
F2	Fire Outside of Glovebox
G	Industrial Hazards - not resulting in severe worker injury
H	Release to Vacuum System
I	Toxic Chemical Release Inside Facility
J	Radiological Release Inside Facility
K	Inadequate Stabilization of Product
NPH	Natural Phenomena Initiator (Seismic Event)

Table A-4. Plutonium Finishing Plant Laboratory Prototype Calciner S1*, S2 Hazards by Accident Groups

Acc Group	Node /Item ID	General Hazardous Event Considered	Cons Cat	Freq Cat
Radiological Release From Glovebox				
C	01.03 02.01	Pull or tear glove off glovebox due to movement of bottle drum, or caustic drum too close to glovebox, resulting in worker contamination	S1*	F3
	03.05	Glove breach during transfer of bottle from airlock into glovebox due to airlock door, resulting in worker contamination	S1*	F3
	08.04.10/1 08.04.10/2	1. Structural failure of calciner (partially melts) with spill of hot plutonium oxide to floor of glovebox due to control failure of calciner heater power supply (full on) caused by controller or thermocouple failure, software set point, or human error... 2. Pressurization of glovebox due to heat released and flashed liquid, damage to glovebox and loss of confinement due to control failure of calciner heater power supply (full on) caused by controller or thermocouple failure, software set point or human error... 3. Plutonium oxide and nitric oxides released to room due to control failure of calciner heater power supply (full on) caused by controller or thermocouple failure software set point or human error... 4. Structural degradation of calciner due to control failure of calciner heater power supply (full on) caused by controller or thermocouple failure, software set point or human error... Resulting in to Room 188 and worker contamination	S1*	F2
	03.03	Loss of glovebox confinement due to inner & outer airlock doors open at same time (human error), resulting in Room 188 and worker contamination	S1*	F2
	08.13.04	Blown out gloves or glovebox seal/penetration failures due to plant pressurized air leak into glovebox (catastrophic line failure to calciner ceramic filters or air regulator failures), resulting in contamination spread to Room 188 and worker contamination	S1*	F2
	09.01/1	Blown out gloves due to pressurized air leak inside of Glovebox 188-1, results in contamination release to Room 188 and worker contamination	S1*	F2
	09.03/1	Breach of glovebox confinement due to bottle pushed all the way through sphincter port without bottle or carton trailing, resulting in contamination spread to Room 188 and worker inhalation	S1*	F2
	09.03/2	Breach of glovebox confinement boundary due to both airlock doors opened at the same time during load in/load out of item or waste, resulting in worker inhalation	S1*	F2
	11.00	Breach in glovebox confinement boundary due to port bag torn during bagout of LOI sample, resulting in worker inhalation	S1*	F2
	13.00	Breach in glovebox confinement boundary due to port bag torn during bagout of slip lid can, resulting in worker inhalation	S1*	F2

Table A-4. Plutonium Finishing Plant Laboratory Prototype Calciner S1*, S2 Hazards by Accident Groups

Acc Group	Node /Item ID	General Hazardous Event Considered	Cons Cat	Freq Cat
Deflagration Inside of Glovebox				
D1	08.04.05	Deflagration in calciner vessel due to injection of feed containing organics into calciner resulting from sampling errors causing pressurization of glovebox and release of radiological material to Room 188 air and worker inhalation	S1*	F3
	08.03.17 04.02	Acetone or other organic solution loaded into glovebox and poured into feed tank by mistake resulting in flammable gas burn in calciner, pressurization of glovebox, and release of radiological material from glovebox	S1*	F2
	08.03.18	Organic present in plant pressurized air supply resulting in flammable gas burn in calciner, pressurization of glovebox, and release of radiological material from glovebox	S1*	F2
	04.01	Ignition of hydrogen emission from bag or bottle when opened during loading of calciner feed tank of plutonium nitrate resulting in pressurization of glovebox and release of radiological material to room air	S1*	F2
	08.01.07b/2	Flammable gas production due to mixing of organic (methanol) with highly acidic HNO_3 in feed tank	S1*	F1
Deflagration Outside of Glovebox				
D2	03.01/1	Hydrogen release and potential burn due to opening of drum having hydrogen accumulation from radiolysis, resulting in worker injury	S1*	F2
Criticality				
E	08.12.02/2	Criticality in chiller due to chiller line leak in scrubber, resulting in ionizing radiation dose to worker	S1*	F1
	08.07.04	Buildup of plutonium oxide sludge in spent scrubber solution tank due to ceramic filter failure in calciner, resulting in ionizing radiation dose to worker	S1*	F1
	08.04.14/2 08.04.14/4	Flooding of calciner with plutonium nitrate due to incorrect settings on calciner heaters (component failures, human error) resulting in ionizing radiation dose to worker	S1*	F1
	06.00	Criticality violation due to excess plutonium nitrate bottles left in glovebox, resulting in ionizing radiation dose to worker	S1*	F1
	08.01.05b 08.01.05c	Criticality in feed tank due to polymerization/precipitation of plutonium (pH greater than 2), resulting in ionizing radiation dose to worker	S1*	F1
	08.01.08/2	Criticality in feed tank due to make up error of plutonium nitrate, resulting in ionizing radiation dose to worker	S1*	F1
	08.13.20	Buildup of plutonium oxide sludge on floor of glovebox due to spills during operation of calciner, resulting in a criticality	S1*	F1
	08.13.22	Potential criticality in glovebox 188-1 due to activation of room fire suppression system	S1*	F1
	16.01	Criticality during transport of canister to vault due to CPS mass violation	S1*	F1

Table A-4. Plutonium Finishing Plant Laboratory Prototype Calciner S1*, S2 Hazards by Accident Groups

Acc Group	Node /Item ID	General Hazardous Event Considered	Cons Cat	Freq Cat
Fire in Glovebox (Ignition of combustible materials present in Glovebox 188-1)				
F1	08.02.04/2	Fire in glovebox due to electric motor burnout from deadhead conditions or wiring failure, resulting in failure of glovebox and worker inhalation of contamination	S1*	F3
	06.01 08.13.07	Fire in glovebox due to accumulation of waste bags, ice cream cartons, and other flammable waste in proximity to hot surfaces of calciner or ignition due to electrical short, resulting in failure of glovebox and worker inhalation of contamination	S1*	F2
	09.01/2	Incompatible chemical reaction in feed pump tank due to methanol being added by mistake, resulting in a fire and glovebox failure	S1*	F2
Fire Outside of Glovebox (Ignition of flammable materials in Room 188)				
F2	03.02/2	Hydrogen release and burn due to bag breach during handling outside of glovebox, resulting in worker contamination	S1*	F1
Toxic Chemical Release Inside Facility				
I	01.04b	Spray leak into Room 188 and contact with worker due to contact of bottle drum with caustic drum or transfer line during transfer, resulting in worker exposure to caustic spray	S1*	F3
	08.11.03/1	Spray leak into Room 188 due to corrosion of caustic transfer line, resulting in worker injury	S1*	F3
	08.11.03/2 1.04a 02.00	Spill of caustic solution to Room 188 floor due to mechanical contact with line outside of Glovebox 188-1, resulting in injury to worker	S1*	F3
	08.11.04	Spray leak from pump seals or relief valve due to caustic supply line to Glovebox 188-1 shut off, resulting in worker injury	S1*	F3
	03.01/2 09.02	Nitric oxides release when opening drum due to human error or incorrect bottle (drum stored long term) brought into lab, resulting in worker exposure to nitric oxides	S1*	F2
Radiological Release Outside Glovebox				
J	13.01	Release of radiological material to room after bagout of slip lid can due to human error, can dropped, resulting in worker exposure	S1*	F2
	01.02	Bottle drum toppled due to human error, resulting in bottle failure and contamination of worker	S1*	F2
Storage Canister Rupture				
K	08.02.03/1	Release of radiological material to vaults due to improperly set feed pump stroke, resulting in inadequately stabilized plutonium oxide and pressurized can (rupture in vault)	S1*	F3
	08.04.01	Release of radiological material to vaults due to improperly set overflow tube height, resulting in inadequately stabilized plutonium oxide and pressurized can (rupture in vault)	S1*	F3
K (cont'd)	08.04.12/1 08.04.12/2	Release of radiological material to vaults due to improperly set heater controller or failure, resulting in inadequately stabilized plutonium oxide and pressurized can (rupture in vault)	S1*	F3

Table A-4. Plutonium Finishing Plant Laboratory Prototype Calciner S1*, S2 Hazards by Accident Groups

Acc Group	Node /Item ID	General Hazardous Event Considered	Cons Cat	Freq Cat
	11.02/1	Rupture of overpack container in storage vault due to overpressurization of canister (low temperature or short residence time in calciner, incorrect LOI results), resulting in inadequately stabilized plutonium	S1*	F2
Natural Phenomena Initiator: Seismic Event, Ash Fall, and High Wind				
NPH	08.16.00/01/02 08.16.03/04/05	Release of plutonium to room through failed glovebox, windows, seals, and penetrations due to seismic event, resulting in exposure to onsite personnel	S2	F2
	08.16.06/07	Release of caustic from drum to Room 188 due to seismic event toppling of drum, resulting in burns to workers	S1*	F2

This page intentionally left blank.

Table A-5

Plutonium Finishing Plant
Laboratory Prototype Calciner PHA

Item ID	Acc Group	Activity Operation	Hazardous Event	Causes	Consequences	Engineered Safety Features	Administrative Safety Features	Cons Cat[1]	Freq Cat[2]	Remarks
01.00	G	Move bottle drum into Room 188	Worker injury-trips/falls, pallet lowered onto toes, injury to hands, etc.	Human error	Minor worker injury		Use of leather gloves protect hands Safety inspections eliminate tripping hazards	S1	F3	Safety shoes not required
01.01	J	Move bottle drum into Room 188	Floor paint chipped and contamination exposed with sliding drum or if drum toppled	Human error - Sliding of bottle drum on floor	Potential worker contamination	Drum design minimizes likelihood of toppling	Radiation control program PPE & step off pad procedure prevent spread of contamination from area Yellow paint identifies past contamination areas Drum handled by two people	S1	F2	I beams on bottom of drum make low center of gravity
01.02	J	Move bottle drum into Room 188	Drum toppled during handling resulting in contamination of room air	Human error	Spill of solution from bottle into bag; potential contamination of interior of drum if bag ruptures Potential worker exposure when drum righted and lid opened to remove bottle Damage to equipment bag sealer	Drum design minimizes likelihood of toppling	Worker uses respiratory protection when drum opened	S1*	F2	Some bottles have bags that are two to three year old Planned/stored materials have been in drums in Room 236 for years and poses hydrogen accumulation hazard Opening drums with potential hydrogen hazard are not covered in this hazard analysis
01.03	C	Move bottle drum into Room 188	Glovebox gloves pulled off or torn during drum movement	Drum moved too close to glovebox with gloves pulled out contacting drum with mounting ring	Glovebox loss of confinement; potential spread of contamination to room air Worker contamination	Room CAM to detect airborne contamination Glovebox ventilation system (E-4) maintains negative pressure and confinement velocity across breached glove E-3 ventilation system and filters mitigate release to the environment	Air sample taken, analyzed, and approved before respiratory protection removal	S1*	F3	Respiratory protection currently not required by procedure but done out of convenience
01.04a	I	Move bottle drum into Room 188	Drum contacts caustic drum or transfer line resulting in caustic spill or leak	Human error	Caustic drum knocked over Spill of caustic solution	Safety shower in room (no eye wash in room)	Goggles used if not using respiratory protection Spill pig around drum Plugged floor drain prevents draining of caustic into waste system	S1*	F2	Respiratory protection currently not required by procedure but done out of convenience Spill pig is a sock of absorbent Plugged floor drain
01.04b	I	Move bottle drum into Room 188	Drum contacts caustic drum or transfer line resulting in spray leak	Human error	Spray leak into room 188 and worker exposure to caustic aerosol Potential damage to transfer line during transfer	Safety shower in room (no eye wash in room) Plastic sleeve around caustic line knocks down spray leak	Goggles used if respiratory protection not available	S1*	F3	Respiratory protection currently not required by procedure but done out of convenience Spill pig is a sock of absorbent Plugged floor drain
02.00	I	Move replacement drum of caustic into Room 188	Handling accident results in breach of drum	Drum punctured by drum hand truck, dropped or run into	Spill of caustic to floor, worker exposure to caustic aerosol and worker burns (see 1.04a/b)	Safety shower in room (no eye wash in room)	Bung closed when drum moved Chemical hygiene program Worker training and procedure Goggles used if respiratory protection not available Safety shoes and shoe covers protect feet	S1*	F2	

Table A-5

Plutonium Finishing Plant
Laboratory Prototype Calciner PHA

Item ID	Acc Group	Activity Operation	Hazardous Event	Causes	Consequences	Engineered Safety Features	Administrative Safety Features	Cons Cat[1]	Freq Cat[2]	Remarks
02.01	C	Move replacement drum of caustic into Room 188	Pull or tearing of glove off glovebox during down movement	Caustic drum moved too close to glovebox with gloves inverted or contact with drum mounting ring	Glovebox loss of confinement; potential spread of contamination to room air Worker contamination	Room CAM to detect airborne contamination Glovebox ventilation system (E-4) maintains negative pressure and confinement velocity across breached glove E-3 ventilation system and filters mitigate release to the environment	Repiratory protection used during drum handling Air sample taken, analyzed, and approved before respiratory protection removal	S1*	F3	Respiratory protection currently not required by procedure but done out of convenience
02.02	I	Remove/install caustic pump in caustic drum	Worker chemical burn	Spill of residual sodium hydroxide from tubing or pump	Worker injury		Personal protective equipment Chemical hygiene program	S1	F3	
03.00/1	J	Open plutonium nitrate bottle drum	Pinching of finger/gloves when opening drum, radiological aerosol/particulate release when drum opened	Human Error	Breach of protective barrier against radiological contamination Worker injury Worker exposure to radiological material		Leather gloves RCT survey after opening drum Worker uses respiratory protection Air sample taken, analyzed, and approved before respiratory protection removal RCT surveying Visual check for moisture in drum	S1	F3	S1 based on potential minor worker plutonium contamination
03.00/2	J	Open plutonium nitrate bottle drum	Radiological aerosol/particulate release when drum opened	Leak from bag during storage in drum Degradation of bag during long term storage of bottle in drum Bag failure due to gas buildup (radiolytically generated hydrogen, oxygen, & helium)	Breach of protective barrier against rad contamination Worker exposure to radiological material		Leather gloves RCT survey after opening drum Worker uses respiratory protection Air sample taken, analyzed, and approved before respiratory protection removal RCT surveying Visual check for moisture in drum	S1	F3	S1 based on potential minor worker plutonium contamination
03.01/1	D2	Open plutonium nitrate bottle drum	Hydrogen release and potential burn when opening drum	Hydrogen accumulation in plutonium nitrate drum from radiolysis (only applies to bottles stored long term) Hydrogen ignited due to static or mechanical spark	Hydrogen burn and release of radiological material to room air Worker injury	E-3 ventilation system & filters mitigate release to the environment	Grounding strip on drum Nonsparking tools used to open drum Cloth coveralls are static resistant Modesty clothing under whites (to minimize attracting radon and minimize static buildup) Labeling and paperwork to identify drums with potential hydrogen hazard	S1*	F2	Definition of acceptable storage time of drums needed to preclude flammable gas buildup Nitric oxides from radiolysis provides oxidizer in hydrogen burn
03.01/2	I	Open plutonium nitrate bottle drum	Nitric oxide release when opening drum	Radiolysis of nitric acid solution - Incorrect drum containing bottle stored long term brought into lab due to human error	Worker exposure to nitric oxide vapors			S1*	F2	

Table A-5

Plutonium Finishing Plant
Laboratory Prototype Calciner PHA

Item ID	Acc Group	Activity Operation	Hazardous Event	Causes	Consequences	Engineered Safety Features	Administrative Safety Features	Cons Cat[1]	Freq Cat[2]	Remarks
03.02/1	J	Remove bagged bottle of plutonium nitrate from drum and load into glovebox 188 through airlock	Bag breach during handling	Bottle dropped or bag torn during handling	Release of contamination and worker exposure Chemical burn to operator & potential skin contamination	Vent in bottle is 1/16 in which minimizes release of liquid into bag	Worker uses respiratory protection during load in of bottle into glovebox Air sample taken, analyzed, and approved before respiratory protection removal Personal Protective Equipment No exposed skin Bottle is double bagged minimizing the likelihood of release	S1	F3	S1 based on potential minor worker plutonium contamination
03.02/2	F2	Remove bagged bottle of plutonium nitrate from drum and load into glovebox 188 through airlock	Bag breach during handling	Bottle dropped or bag torn during handling	Hydrogen release & burn	Vent in bottle is 1/16 in which minimizes release of liquid into bag	Worker uses respiratory protection during handling of bottle Air sample taken, analyzed, and approved before respiratory protection removal Personal Protective Equipment No exposed skin Bottle is double bagged minimizing likelihood of release Vent in bottle and horsetail vents in bags allow diffusion of hydrogen out of bag and bottle, limiting hydrogen accumulation	S1*	F1	Highly unlikely event due to diffusivity of hydrogen in air No obvious ignition source in this accident Worker contamination
03.03	C	Remove bagged bottle of plutonium nitrate from drum and load into glovebox 188 through airlock	Loss of glovebox confinement due to open airlock	Inner & outer airlock doors open at same time due to human error	Spread of Glovebox contamination to room air with potential worker uptake	Glovebox ventilation system (E-4) sized to maintain negative pressure and confinement velocity across open doors E-3 ventilation systems and filters mitigates release to environment Room CAM to detect airborne contamination	Worker uses respiratory protection during load in of bottles into glovebox Air sample taken, analyzed, and approved before respiratory protection removal Procedure ensures only one door open at a time	S1*	F2	S1* based on potential worker exposure to airborne plutonium
03.04	J	Remove bagged bottle of plutonium nitrate from drum and load into glovebox 188 through airlock	Breach of bags encasing bottle during insertion into airlock resulting in contamination spread	Bags torn on corner of door during load into airlock	Increased contamination of airlock Potential contamination of worker	Glovebox ventilation system maintains confinement velocity across airlock door	Worker uses respiratory protection Air sample taken, analyzed, and approved before respiratory protection removal Training and procedures	S1	F3	S1 based on potential minor worker plutonium contamination
03.05	C	Remove bagged bottle of plutonium nitrate from drum and load into glovebox 188 through airlock	Glove breach during transfer of bottle from airlock into glovebox	Glove torn on inner airlock door	Worker injury and contamination of workers Airborne release through breached glove with workers uptake	E-4 ventilation maintains confinement velocity across breach in glove Airlock door corners are rounded Room CAM E-3 ventilation system	Worker uses respiratory protection Air sample taken, analyzed, and approved before respiratory protection removal Personal protective equipment	S1*	F3	S1* based on potential operator plutonium contamination
04.00/1	A2	Remove bags from bottle and load solution into feed tank	Breach of glove	Glove cut by scissors (see above 3.05)	Increased contamination levels in glovebox Increased exposure to workers during cleanup and operations	6" open top on feed tank Glovebox and E-4 ventilation system confines aerosols generated due to splatter in the spill		S1	F3	S1 based on ALARA concerns in recovering from event

Table A-5

Plutonium Finishing Plant
Laboratory Prototype Calciner PHA

Item ID	Acc Group	Activity Operation	Hazardous Event	Causes	Consequences	Engineered Safety Features	Administrative Safety Features	Cons Cat[1]	Freq Cat[2]	Remarks
04.00/2	B	Remove bags from bottle and load solution into feed tank	Solution spilled inside glovebox	Bottle dropped or feed pump tank missed during fill process Lid left on tank during fill process	Increased contamination levels in glovebox Increased exposure to workers during cleanup and operations	6" open top on feed tank Glovebox and E-4 ventilation system confines aerosols generated due to splatter in the spill		S1	F3	S1 based on ALARA concerns in recovering from event
04.01	D1	Remove bags from bottle and load solution into feed tank	Hydrogen release from bag or bottle when opened	Radiolysis of nitric acid solution in bottle Radiolysis of plastic bottle & bags	Potential ignition of hydrogen from static or mechanical spark Rupture of bag Minor pressurization of glovebox	Glovebox confinement boundary and E-4ventilation system confine release Glovebox ventilation system dilutes hydrogen concentration		S1*	F2	Failure of glovebox not expected due to small quantity of hydrogen expected in bottle or bag Need acceptance criteria for bottles with respect to storage length
04.02	D1	Remove bags from bottle and load solution into feed tank	Incompatible chemical (organic) added to feed tank	Methonol or other organic solution loaded into glovebox and poured into feed tank by mistake - cleaning or drying solution vs plutonium-bearing solution poured into tank	Violent reaction in feed tank and potential fire Flammable gas burn in the calciner Pressurization of glovebox & potential damage to glovebox confinement boundary	E-3 ventilation system and HEPA filters mitigate release to environment Glovebox contamination boundary and E-4 ventilation system confine release Limited flow rate of calciner feed pump limits consequences of burned in calciner Room CAM	Light color of solution indicates wrong material Labeling of containers and lab results to identify compatible solutions Test plan: chemical safety program	S1*	F2	S1* based on potential operator plutonium contamination
04.03	B	Remove bags from bottle and load solution into feed tank	Incompatible chemical (caustic) added to feed tank	Caustic plutonium bearing solutions loaded into glovebox and poured into feed tank	Splatter and boiling of solution in feed tank increasing contamination level of glovebox Formation of mastic in calciner causing plugging of calciner Seizing up of agitator Increased worker dose in cleaning out calciner	E-3 ventilation system and HEPA filters mitigate release to environment Glovebox Confinement boundary and E-4 ventilation system	Labeling of containers and lab results to identify compatible solutions Test plan: chemical safety program	S1	F2	Caustic salts melt before they decompose
05.00	B	Startup calciner system, turn on vacuum before pressurized air then agitator and heaters	Pressurized calciner	Vacuum not turned on before pressurized air or not turned on at all	Release of plutonium dust into glovebox through relief cap Increased worker exposure due to increased contamination level in glovebox	Pressure relief cap prevents failure of calciner Glovebox and E-4 ventilation system confine release	Training and procedures Vacuum system gauges indicate operating vacuum By procedure vacuum gauges are checked before turning on pressurized air	S1	F3	S1 based on ALARA concerns in recovering from event
05.01/1	A2	Startup calciner system turn on vacuum before pressurized air then agitator and heat	Flooding of calciner	Feed inadvertently turned on early (before calciner ready at operating pump)	Plugging of nozzle & calciner, seizing of agitator (process delay) Overflow of solution, plutonium oxide, and plutonium nitrate salts into collection jar	Glovebox confinement boundary & E-4 ventilation system confine release Interlock prevents turning on feed pump before calciner wall is at 700 C	Procedure outlines general sequence for starting up calciner	S1	F3	
05.01/2	A2	Startup calciner system turn on vacuum before pressurized air then agitator and heat	Flooding of calciner	Feed inadvertently turned on early (before calciner ready at operating pump)	Overflow of solution, plutonium oxide, and plutonium nitrate salts into collection jar	Glovebox confinement boundary & E-4 ventilation system confine release Interlock prevents turning on feed pump before calciner wall is at 700 C	Procedure outlines general sequence for starting up calciner	S1	F3	S1 based on ALARA concerns in recovering from event
06.00	E	Bag out empty bottle or waste	Criticality violation	First bottle not bagged out before second bottle loaded in Waste bags not made into noncontainers (cut up and rolled up) due to human error	Potential criticality		Procedures & training Criticality posting Criticality specifications	S1*	F1	No criticality controls for frequency estimates See criticality hazards analysis and CSER for glovebox 188-1

Table A-5

Plutonium Finishing Plant
Laboratory Prototype Calciner PHA

Item ID	Acc Group	Activity Operation	Hazardous Event	Causes	Consequences	Engineered Safety Features	Administrative Safety Features	Cons Cat[1]	Freq Cat[2]	Remarks
06.01	F1	Bag out empty bottles, bags or waste	Fire in glovebox	Accumulation of waste bags, ice cream cartons, and other flammable waste in proximity to hot surfaces of calciner or ignition of accumulated combustibles due to electrical short	Damage to glovebox confinement boundary (burn through of bag out ports melting of plastic panels) Release of radiological material to room 188 air; worker inhalation of rad particles	Heat shields around calciner prevent ignition of combustibles Glovebox high temperature indicator and alarm	Combustible loading limit for glovebox Bayonet equipped, portable, dry chemical fire extinguisher available Waste bags are staged at end of glovebox away from calciner Housekeeping procedures	S1*	F2	Worker contamination
06.02	C	Bag out empty bottle or waste	Loss of glovebox confinement	Bag torn or pulled off glovebox during bag out Bag not properly sealed	Worker uptake of airborne contamination	E-3 ventilation system and filters mitigate release to the environment CAM alerts workers to presence of airborne contamination in room 188	Workers use respiratory protection during bag outs	S1	F3	Contamination spread outside of glovebox
06.03	C	Bag out empty bottle or waste	Contamination release into room	Bagged bottle dropped to floor and ruptured Bag not properly horse tailed Bag torn during handling	Worker uptake of airborne contamination	E-3 ventilation system and filters mitigate release to the environment CAM alerts workers to presence of airborne contamination in room 188	Workers use respiratory protection during bag outs Air sample taken, analyzed, and approved before respiratory protection removal Bottle is double bagged before placing in drum RCT survey of first bag	S1	F3	
07.00	J	Load empty bottle back into drum, move drum out of lab	Contamination of drum exterior	Bag ruptured during handling	Spread of contamination from room 188	E-3 ventilation system filters mitigate release to environment	Double bag on bottle minimizes potential for spread of contamination to drum surfaces RCT survey of first bag RCT survey of drum before moving drum out of room Institutional rad con program Additional RCT survey in hallway	S1	F3	S1 based on potential minor worker plutonium contamination
08.00		Glovebox 188-1 Laboratory Prototype Calciner covered by Hazard and Operability Study						See Hazard and Operability Study in Table A-6 for hazards associated with laboratory calciner operations		
09.00/1	A2	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Pluggage of feed nozzle causes shutdown of process and feed pump damage on subsequent calciner run	Failure to flush feed line due to human error allows solids to build up in nozzle.	Feed pump damage due to deadheading Increased worker direct dose to clear plug and replace/repair pump	Glovebox and glovebox ventilation system confines release from cacliner and filters release before discharge to the environment	Worker training and procedures	S1	F3	S1 based on ALARA concerns in recovering from event
09.00/2	A2	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Pluggage of feed nozzle causes shutdown of process and feed pump damage on subsequent calciner run	Failure to flush feed line due to human error allows solids to build up in nozzle.	Pressurization of calciner during subsequent operation due to liquid surge when pluggage breaks loose, leading to release of plutonium particulate, nitric oxide gases and nitric acid vapor to the glovebox atmosphere	Glovebox and glovebox ventilation system confines release from cacliner and filters release before discharge to the environment	Worker training and procedures	S1	F3	S1 based on ALARA concerns in recovering from event

Table A-5

Plutonium Finishing Plant
Laboratory Prototype Calciner PHA

Item ID	Acc Group	Activity Operation	Hazardous Event	Causes	Consequences	Engineered Safety Features	Administrative Safety Features	Cons Cat[1]	Freq Cat[2]	Remarks
09.01/1	C	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Incompatible chemical reaction in feed tank (e.g., methanol or caustic added by mistake)	Organic solvent (e.g., methanol) or caustic solution added to feed tank by mistake (human error)	Violent reaction in feed tank causing steam and gas releases to glovebox atmosphere resulting in pressurization of glovebox Worker contamination	Glovebox and glovebox ventilation system confine aerosols released from feed tank Glovebox ventilation system removes heat of reaction Three glovebox inlet HEPA filters allow overpressure to vent from glovebox without causing damage to the glovebox confinement boundary	Visual observation of incompatible reaction or polymer formation Labelling of chemical bottles and chemical safety program minimize likelihood of organic or caustic being substituted for plutonium nitrate solution Combustible loading limit and housekeeping practices limit fire to feed tank only	S1*	F2	S1* based on potential worker plutonium contamination
09.01/2	F1	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Incompatible chemical reaction in feed tank (e.g., methanol added by mistake)	Organic solvent (e.g., methanol) solution added to feed tank by mistake (human error)	Potential fire in feed tank when methanol added	Glovebox and glovebox ventilation system confine aerosols released from feed tank Glovebox ventilation system removes heat of reaction Three glovebox inlet HEPA filters allow overpressure to vent from glovebox without causing damage to the glovebox confinement boundary Glovebox limited supply water bottle fire suppression system Building fire suppression system to limit fire spread should glovebox be breached	Visual observation of incompatible reaction or polymer formation Labelling of chemical bottles and chemical safety program minimize likelihood of organic or caustic being substituted for plutonium nitrate solution Bayonet equipped, dry chemical fire extinguisher in hallway outside room 188 for extinguishing small fire Combustible loading limit and housekeeping practices limit fire to feed tank only	S1*	F2	S1* assumes breach of glovebox with worker contamination
09.01/3	B	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Incompatible chemical reaction in feed tank (e.g., caustic added by mistake)	Caustic solution added to feed tank by mistake (human error)	Spattering of radioactive aerosols into the glovebox atmosphere	Glovebox and glovebox ventilation system confine aerosols released from feed tank Glovebox ventilation system removes heat of reaction Three glovebox inlet HEPA filters allow overpressure to vent from glovebox without causing damage to the glovebox confinement boundary	Visual observation of incompatible reaction or polymer formation Labelling of chemical bottles and chemical safety program minimize likelihood of organic or caustic being substituted for plutonium nitrate solution	S1	F2	S1 based on ALARA concerns in recovering from event
09.01/4	E	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Incompatible chemical reaction in feed tank (e.g., caustic added by mistake)	Organic solvent (e.g., methanol) or caustic solution added to feed tank by mistake (human error)	Plutonium polymer formation in feed tank, if caustic added, causing potential criticality specification violation	Feed tank designed as critically safe geometry	Visual observation of incompatible reaction or polymer formation Labelling of chemical bottles and chemical safety program minimize likelihood of organic or caustic being substituted for plutonium nitrate solution	S1	F2	See CSER for prototype calciner operation for controls to prevent criticality from polymer formation) S1 based on ALARA concerns in recovering from event
09.02	I	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Acid bottle dropped outside glovebox during load in	Human error	Worker chemical burns and exposure to nitric oxide gases or nitric acid fumes		Personal protective equipment Worker training and procedures Test plan (chemical safety)	S1*	F3	S1* based on potential worker exposure to toxic chemical
09.03/1	C	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Breach of Glovebox confinement boundary	Bottle pushed all the way through sphincter port without bottle or carton trailing	Contamination spread from glovebox to room air Inhalation uptake by workers	Room CAM Sphincter seal design Glovebox ventilation system maintains negative pressure in glovebox and confinement velocity across open sphincter port or open airlock door	Worker training and procedures Workers use respiratory protection during load in/load out operations	S1*	F2	S1* based on potential worker plutonium contamination

Table A-5

Laboratory Prototype Calciner PHA

Item ID	Acc Group	Activity Operation	Hazardous Event	Causes	Consequences	Engineered Safety Features	Administrative Safety Features	Cons Cat[1]	Freq Cat[2]	Remarks
09.03/2	C	Load flush solution into glovebox and flush calciner feed line (after completion of previous calciner run)	Breach of Glovebox confinement boundary	Both airlock doors opened at the same time during load in of bottle (if airlock used instead of sphincter seal)	Contamination spread from glovebox to room air Inhalation uptake by workers	Room CAM Spinster seal design Glovebox ventilation system maintains negative pressure in glovebox and confinement velocity across open sphincter port or open airlock door	Worker training and procedures Workers use respiratory protection during load in/load out operations through air lock	S1*	F2	S1* based on potential worker plutonium contamination
10.00	B	Transfer collection jar contents to slip lid can	Spill of plutonium oxide to glovebox floor	Jar or can dropped or spilled Can overfilled	Entrainment of plutonium oxide particulate into glovebox air Increased contamination level of glovebox causing increased direct dose to workers	Glovebox and Glovebox ventilation system confine particulate release E-4 ventilation system HEPA filters mitigate release to environment	Worker training and procedures	S1	F3	S1 based on ALARA concerns in recovering from event
11.00	C	LOI sampling (includes taking sample, bagging out sample vial, and performing LOI test)	Breach in glovebox confinement boundary	Port bag torn during bagout Port bag not properly heat sealed or horsetailed	Contamination spread from glovebox to room air Inhalation uptake by workers	Room CAM Glovebox ventilation system maintains negative pressure in glovebox and confinement velocity across open bag port	Worker training and procedures Workers use respiratory protection during load in/load out operations	S1*	F2	S1* based on potential worker plutonium contamination
11.01	J	LOI sampling (includes taking sample, bagging out sample vial, and performing LOI test)	Sample vial dropped after bagout	Human error	Potential breakage of sample bottle and release of radioactive material from bottle into room 188	Room CAM	Worker training and procedures Two bags applied during load out limit potential contamination spread to room air Workers use respiratory protection during load in/load out operations	S1	F3	S1 based on potential minor worker plutonium contamination
11.02	K	LOI sampling (includes taking sample, bagging out sample vial, and performing LOI test)	Rupture of overpack container in storage vault due to overpressure	Inadequate stabilization of plutonium oxide in calciner due to low temperature or short residence time causes buildup of hydrogen in the storage container - Incorrect LOI results give false low reading of water content in plutonium oxide - LOI test not performed - LOI samples mixed up or wrong can sent to vault	Rupture of container in storage vault (lab vault or 2736-ZB vault) with potential worker inhalation of plutonium particles on entry to storage vault	Vault ventilation system filters release to the environment Vault CAM warns of airborne contamination before entry into vault	Worker training and procedures LOI testing to detect inadequately stabilized material Cans not moved to ZB vaults until LOI test results come back acceptable Overpacked slip lid cans temporarily stored in lab vault pending LOI test results and are periodically monitored for bulging	S1*	F2	S1* based on potential worker plutonium contamination
12.00	A1	Weigh can, tape lid on, and reweigh can	No significant hazards identified for this step							Weighing errors pose plutonium accountability problems only
13.00	C	Bagout filled slip lid can	Breach in glovebox confinement boundary	Port bag torn during bagout Port bag not properly heat sealed or horsetailed	Contamination spread from glovebox to room air Inhalation uptake by workers	Room CAM Glovebox ventilation system maintains negative pressure in glovebox and confinement velocity across open bag port	Worker training and procedures Workers use respiratory protection during load in/load out operations	S1*	F2	S1* based on potential worker plutonium contamination

Table A-5

Plutonium Finishing Plant
Laboratory Prototype Calciner PHA

Item ID	Acc Group	Activity Operation	Hazardous Event	Causes	Consequences	Engineered Safety Features	Administrative Safety Features	Cons Cat[1]	Freq Cat[2]	Remarks
13.01	J	Bagout filled slip lid can	Can dropped after bagout	Human error	Potential release of radiological material to room air (if bag breached by drop) Worker contamination	Room CAM	Worker training and procedures Load out bag limits potential contamination spread to room air Workers use respiratory protection during load in/load out operations Slip lid is taped on before bagout Lid is expected to remain on during drop, preventing significant release from can	S1*	F2	S1*/F2 assumes failure of slip lid can and rupture of both bags
14.00/1	J	Canning of bagged slip lid can into overpack (on counter in Room 188)	Contamination spread beyond room 188 due to Inadequate sealed overpack	Overpack inadequately sealed due to human error, canning machine malfunction, or plastic bag caught under lip of seal	Potential spread of contamination to clean area of plant (hallway outside room 188 where secondary overpack applied) Potential skin contamination and minor inhalation uptake of plutonium by workers	Room CAM to detect airborne contamination	Contamination spread from slip lid can unlikely due to double bagging and taped slip lid RCT survey of cans before movement out into hallway RCT survey and self surveys of workers (step off pad procedure)	S1	F3	S1 based on potential minor worker plutonium contamination
14.00/2	A2	Canning of bagged slip lid can into overpack (on counter in Room 188)	Contamination spread beyond room 188 due to Inadequate sealed overpack	Overpack inadequately sealed due to human error, canning machine malfunction, or plastic bag caught under lip of seal	Programmatic Impact - Overpacked can would have to be bagged back into glovebox and reopened increasing likelihood of worker injury and contamination due to puncture hazards during cutting of bag and crushing of overpack cans to make non-containers	Room CAM to detect airborne contamination	Contamination spread from slip lid can unlikely due to double bagging and taped slip lid RCT survey of cans before movement out into hallway RCT survey and self surveys of workers (step off pad procedure)	S1	F3	
15.00	J	Second overpack applied on table in hallway	Contamination of workers transporting package to storage vault	Inadequately sealed inner and outer overpack due to human error or canning machine malfunction (assumes inside of first overpack container is contaminated	Contamination of workers handling transporting package to storage vault		Contamination spread from slip lid can unlikely due to double bagging and taped slip lid RCT survey of cans before movement out into hallway RCT survey and self surveys of workers (step off pad procedure)	S1	F2	S1 based on potential minor worker plutonium contamination
16.00	A1	Transfer overpacked can to vault	Packaged dropped or otherwise impacted during transport to vault	Package dropped during handling prior to placement in transport wagon Transport wagon overturned during transport	No significant consequence expected due to sturdy multiple overpack design and low drop height	Sturdy multiple overpack design will survive credible impacts without failing	Worker training and procedures	S0	F3	
16.01	E	Transfer overpacked can to vault	Criticality specification violation during transport to vault	Too many cans placed in transport wagon Transport wagon not used in violation Wagon pulled too close to other sources of fissile material	Potential criticality with worker exposure to ionizing radiation and fission product gases	Wagon design ensures adequate spacing of containers and minimizes likelihood of containers being spilled together in unsafe geometry	Worker training and procedures Criticality specification requirements	S1*	F1	See appropriate CSER for hazards associated with transportation of plutonium oxide containers.

1. Consequence category is based on "no controls".
2. Frequency category is based on "no controls".

08.16.00/02	NPH	Seismic Event			Seismic Event	Potential continuous operation of calciner with loss of vacuum causing continuous release of plutonium through calciner relief port Release of plutonium to room through failed glovebox, windows, seals, and penetrations Failure of E-4 and E-3 HEPA filters allowing release of glovebox 188-1 contamination to environment	Seismic switch shut down ventilation supply preventing pressurization of Building Sturdy glovebox design (metal walls, glass wire mesh windows, plastic viewing ports)	Large distance to offsite public	S2	F2	
08.16.00/03	E	Seismic Event			Seismic Event	Potential toppling of glovebox (if seismically unqualified) Potential criticality due to consolidation of plutonium and solution in one corner of glovebox	Seismic switch shut down ventilation supply preventing pressurization of building	Large distance to offsite public	S1*	F2	
08.16.00/04	NPH	Seismic Event			Seismic Event	Potential toppling of glovebox (if seismically unqualified) Release of plutonium to room through failed glovebox, windows, seals, and penetrations Failure of E-4 and E-3 HEPA filters allowing release of glovebox 188-1 contamination to environment	Seismic switch shut down ventilation supply preventing pressurization of building	Large distance to offsite public	S2	F2	
08.16.00/05	NPH	Seismic Event			Seismic Event	Failure of Swagelok fitting allowing product collection jar to drop and break releasing plutonium oxide Failure of E-4 and E-3 HEPA filters allowing release of glovebox 188-1 contamination to environment	Seismic switch shut down ventilation supply preventing pressurization of building	Large distance to offsite public	S2	F2	
08.16.00/06	NPH	Seismic Event			Seismic Event	Puncture or toppling of 55 gallon drum of caustic from falling debris	Seismic switch shut down ventilation supply preventing pressurization of building	Large distance to offsite public	S1*	F2	
08.16.00/07	NPH	Seismic Event			Seismic Event	Spray leak of caustic from failed fitting or line	Seismic switch shut down ventilation supply preventing pressurization of building	Large distance to offsite public	S1*	F2	
08.16.01	NPH	Ash Fall			The effects of Ash Fall on the PFP are described in Chapter 3.0 of the PFP FSAR. In general, ashfall represents a roof loading concern, abrasive concern to moving equipment, and an electrical concern due to the conductivity of the ash. The addition of the calciner to Glovebox 188-1 does not significantly alter the effects of ashfall on PFP.				S0	F2	
08.16.02	NPH	Range Fire			A range fire can affect facility power supply may represent a fire threat to Building 234-5Z. The effects of fires have been analyzed in Chapter 9.0 of the PFP FSAR. The addition of Glovebox 188-1 does not significantly change the results of the existing fire analysis. Fires initiated internally to the glovebox are addressed in this Hazard and Operability Study.				S0	F3	
08.16.03	A1	Loss of Facility Electrical Power			The effects on the PFP due to a loss of facility power is not significantly altered by the addition of the calciner to Glovebox 188-1 to the PFP. The effects of loss of power to Glovebox 188-1 as an internal event are addressed in this Hazard and Operability Study.				S0	F3

HYDROGEN CONCENTRATION VERSUS TIME FOR TRANSPORT CONTAINERS

This page intentionally left blank.

HYDROGEN CONCENTRATION VERSUS TIME FOR TRANSPORT CONTAINERS

Hydrogen Generation and Buildup

Three liter polybottles are used to transfer the plutonium nitrate solutions from Glovebox HC-227S to Glovebox 188-1. The bottles, filled in Glovebox HC-227S with a nominal 2.5 L of solution, have a double bag overwrap. The first plastic bag is placed over the bottle during bag-out from the glovebox. The second bag is placed over the bottle outside of the glovebox. The bottles are transported to Glovebox 188-1 in either PR Containers or in Isolated Transport Containers (ITC).

Temporary storage of these containers between departure from Glovebox HC-227S and arrival at Glovebox 188-1 is usually necessary. If the storage is prolonged, free hydrogen, generated by radiolytic decomposition of the solutions, first accumulates in the polybottles, moves by venting and diffusion to the plastic bags and finally into the transport containers. If the concentration of hydrogen in any space reaches the lower flammability limit (LFL), ignition of the gas is possible. A deflagration in a PR container presents a serious hazard from the ejected container lid to facility workers close to the container.

Hydrogen concentration is predicted by making a hydrogen mass balance on the gas phase in any given space, accounting for hydrogen generation by radiolysis and depletion by leakage and diffusion:

$$\text{accumulation rate} = \text{input rate} - \text{output rate} \tag{1}$$

where:

accumulation rate = hydrogen buildup rate in a volume, moles/s
input rate = hydrogen generation by radiolysis, moles/s
output rate = depletion by leakage and diffusion, moles/s

Formulating these components in terms of parameters of the system gives:

$$\text{accumulation rate} = V\frac{dC}{dt} \tag{1a}$$

$$\text{input rate} = G \tag{1b}$$

$$\text{output rate} = QC + DC \tag{1c}$$

where:

V = volume of gas space, cm^3
C = hydrogen concentration, moles/cm^3
G = hydrogen generation rate, moles/s
Q = headspace ventilation rate, cm^3/s
D = diffusional admittance, cm^3/s
t = time, seconds

Substituting equations 1a, 1b, and 1c into Equation (1), the differential equation that describes the buildup of concentration with time is:

$$V\frac{dC}{dt} = G - QC - DC \qquad (2)$$

The solution to Eqn.(2), under conditions where G, Q, D, and V are constants, is:

$$C = \frac{G[1 - \exp - (Q+D)t/V)]}{Q+D} \qquad (3)$$

The maximum in C occurs when t is large, causing the exponential term to go to zero. The maximum, or equilibrium concentration, is:

$$C = \frac{G}{Q+D} \qquad (4)$$

The terms in Equations (3) and (4) are numerically evaluated in the following section, to estimate the value of C.

G - Hydrogen Generation Rate

The plutonium nitrate solution radioisotopic inventory contains various Pu isotopes and Am-241. The hydrogen production rate due to radiolysis is given by the following equation:

$$m'(H_2) = \sum_{i=1}^{i=n} I_i \, E_i \, F \, G(H_2) \, A_i \, d \qquad (4a)$$

where:

$m'(H_2)$ = the hydrogen production rate, molecules/s
I_i = total inventory of the ith isotope, Ci/m^3
E_i = the average energy for the ith isotope, eV/disintegration
F = fraction of ionizing radiation absorbed by the target molecules
$G(H_2)$ = radiolysis constant, molecules H_2 produced/eV of ionizing radiation absorbed
A_i = average activity, Ci/m^3 of waste
d = conversion from Ci to Bq, 3.7×10^{10} Bq/Ci = 3.7×10^{10} disintegrations/s/Ci

Data and Assumptions

For the determination of hydrogen generation in the solution in the polybottles, information and assumptions used to describe the situation are as follows:

- The total quantity of plutonium nitrate solution is assumed to be 2.5 L in a 3 L polybottle. Calculations will also be performed for 1.0 L to see if generation rate, or available volume dominates in determining hydrogen concentration.

- The concentration of Pu in the polybottles can range from 50 g/L to 450 g/L. The bottles are normally filled to no more than 2.5 L. To give bounding hydrogen generation rates, the maximum concentration of 450 g-Pu/L is assumed, giving a total Pu quantity of 1,125 g Pu. Also, for the case mentioned in the first bullet, where the amount of nitrate solution is 1.0 L, at 450 g-Pu/L, the total Pu quantity will be 450 g.

- Isotopic composition of TRU in the nitrate solution is taken from Table 9-44 of the PFP FSAR (FDH 1999), for ^{240}Pu contents > 10%. The isotopes present and the percentage of each are given in column 1, Tables B-1 and B-2. The isotope ^{241}Pu is not included because of its low alpha activity.

- For this analysis, the radiolysis constants $G(H_2)$ for two acid concentrations of the plutonium nitrate solutions are used:

  - The hydrogen radiolysis constant, $G(H_2)$, for 8 M HNO_3 exposed to alphas with an energy of 5.3 MeV is 2.4×10^{-4} molecules H_2/eV (BNWL 1968).

  - $G(H_2)$ for 4 M HNO_3 exposed to alphas with an energy of 5.3 MeV is 5.9×10^{-4} molecules H_2/eV (BNWL 1968).

- F, the fraction of ionizing radiation absorbed by the target molecules, is conservatively assumed to be 1.0.

Tables B-1 (for 8 M nitric acid) and B-2 (for 4 M nitric acid) are used to solve Equation 4a, to determine the potential hydrogen production rate in the polybottle. The values for the variables E_i, $G(H_2)$, A_i, and d are provided, respectively, in the columns. The hydrogen

production rate from each isotope is calculated in the last column as the product of the respective values in each column of a row. The fourth column in the table gives the average energies for each isotope disintegration, values for the variable E_i, in Equation 4a. The average discharge energies for each isotope were determined using the RadDecay computer program (Grove 1990). Column 5 gives the radiolysis constants $G(H_2)$ used. Column 3 provides the specific activities for each isotope. The conversion constant (3.7×10^{10} Bq/Ci) for converting the activities from units of Ci to units of Bq, or disintegrations per second is not shown in the table, but is multiplied by the product of each of the values in a row. The fraction F, which is unity (1) for these solutions where no solids are present, is applied to the sum of the production rate.

Table B-1. Hydrogen Production Rate in 8 M Nitric Acid.

Isotope (%)	Isotope Inventory (g)	Isotope Activity (Ci/g)	Energy per Disintegration (eV/disintegration)	Radiolysis Constant (molecules H_2/eV)	Hydrogen Production Rate per m^3 (molecules/s-m^3)
Pu-238 (0.21%)	2.363	1.71×10^{1}	5.49×10^{6}	2.40×10^{-4}	1.97×10^{15}
Pu-239 (81.39%)	915.750	6.20×10^{-2}	5.10×10^{6}	2.40×10^{-4}	2.57×10^{15}
Pu-240 (16.34%)	183.375	2.27×10^{-1}	5.15×10^{6}	2.40×10^{-4}	1.90×10^{15}
Pu-242 (0.67%)	7.538	3.88×10^{-3}	4.91×10^{6}	2.40×10^{-4}	1.28×10^{12}
Am-241 (2.47%)	27.788	3.43×10^{0}	5.48×10^{6}	2.40×10^{-4}	4.64×10^{15}
Total	1136.814				1.11×10^{16}

Table B-2. Hydrogen Production Rate in 4 M Nitric Acid.

Isotope (%)	Isotope Inventory (g)	Isotope Activity (Ci/g)	Energy per Disintegration (eV/disintegration)	Radiolysis Constant (molecules H_2/eV)	Hydrogen Production Rate per m^3 (molecules/s-m^3)
Pu-238 (0.21%)	2.363	1.71×10^{1}	5.49×10^{6}	5.90×10^{-4}	4.84×10^{15}
Pu-239 (81.39%)	915.750	6.20×10^{-2}	5.10×10^{6}	5.90×10^{-4}	6.32×10^{15}
Pu-240 (16.34%)	183.375	2.27×10^{-1}	5.15×10^{6}	5.90×10^{-4}	4.68×10^{15}
Pu-242 (0.67%)	7.538	3.88×10^{-3}	4.91×10^{6}	5.90×10^{-4}	3.14×10^{12}
Am-241 (2.47%)	27.788	3.43×10^{0}	5.48×10^{6}	5.90×10^{-4}	1.14×10^{16}
Total	1136.814				2.72×10^{16}

The sum of the values in the last column of Table B-1 gives a total estimated hydrogen production rate, of 1.11×10^{16} molecules/s for an 8 M nitric acid solution. Dividing by Avogadro's number gives a molar flow rate of:

$$G = \frac{1.11 \times 10^{16} \text{ molecules/s}}{6.0235 \times 10^{23} \text{ molecules/mole}}$$

$$= 1.84 \times 10^{-8} \text{ moles } H_2\text{/s}$$

$$= (1.84 \times 10^{-8} \text{ moles/s})\left(\frac{22.4 \text{ L}}{\text{mole}}\right)\left(\frac{300 \text{ K}}{273 \text{ K}}\right) = 4.54 \times 10^{-7} \text{ L/s}$$

Similarly, for a 4 M nitric acid solution,

$$G = \frac{2.72 \times 10^{16} \text{ molecules/s}}{6.0235 \times 10^{23} \text{ molecules/mole}}$$

$$= 4.52 \times 10^{-8} \text{ moles } H_2\text{/s}$$

$$= (4.52 \times 10^{-8} \text{ moles/s})\left(\frac{22.4 \text{ L}}{\text{mole}}\right)\left(\frac{300 \text{ K}}{273 \text{ K}}\right) = 1.11 \times 10^{-6} \text{ L/s}$$

When the hydrogen production rate is calculated as above for 1.0 L of 4 M nitric acid solution, the sum of the values in the last column gives a total estimated hydrogen production rate, of 1.09×10^{16} molecules/s.

$$G = \frac{1.09 \times 10^{16} \text{ molecules/s}}{6.0235 \times 10^{23} \text{ molecules/mole}}$$

$$= 1.81 \times 10^{-8} \text{ moles } H_2\text{/s}$$

$$= (1.81 \times 10^{-8} \text{ moles/s})\left(\frac{22.4 \text{ L}}{\text{mole}}\right)\left(\frac{300 \text{ K}}{273 \text{ K}}\right) = 4.46 \times 10^{-7} \text{ L/s}$$

Since the hydrogen production rate for 1.0 L of 4 M nitric acid solution is much less than that for 2.5 L of 4 M solution, the value of 4.52×10^{-8} moles H_2/s (1.11×10^{-6} L/s) is used for all further calculations.

Calculation of Time to Reach Flammability

Since the greatest hazard associated with hydrogen buildup involves a potential deflagration that would eject the PR container lid, the hydrogen generation rate is used to determine the time it takes, assuming that the PR container is perfectly sealed, for the hydrogen

concentration in the PR container to become flammable. A fuel is flammable when the fuel to oxidant ratio is within a range where a flame front will propagate when ignited. A fuel/oxidant ratio where flame propagation is initially possible is termed the lower flammable limit (LFL). The top of the range is the point beyond which the ratio is too rich in fuel to burn and is termed the upper flammable limit (UFL). For hydrogen, the LFL is 4% and the UFL is 75%. In order to assure an adequate margin for safety, 25% of the LFL for hydrogen, or 1% hydrogen, is considered in this analysis as the lower criteria for the hazard of a hydrogen deflagration.

Information and assumptions used to determine the amount of material released are as follows:

- It is assumed that there is no leakage or diffusion from the PR container.
- Hydrogen is assumed to vent unimpeded through the vent path in the polybottle cap and the bags surrounding the polybottle into the PR container atmosphere. This gives the worst-case concentration of hydrogen in the PR container.
- The volume occupied by the polybottle is 3 L.

The internal volume (V_D) of the PR container, which has a 22.5 in. ID and a height of 33.25 in., is:

$$V_D = \pi[(11.25 \text{ in.})(2.54 \text{ cm/in.})]^2(33.25 \text{ in.})(2.54 \text{cm/in.})$$

$$= 216{,}644.52 \text{ cm}^3$$

$$= 216.64 \text{ L}$$

The internal volume (V_{ITC}) of the ITC, which has a 16 in. ID at the top tapering to 12 in. ID at the bottom and a height of 20 in., is:

$$V_{ITC} = \pi\left[\frac{(8 + 6\text{in.})}{2}(2.54 \text{ cm/in.})\right]^2(20 \text{ in.})(2.54 \text{cm/in.})$$

$$= 50{,}451.85 \text{ cm}^3$$

$$= 50.45 \text{ L}$$

Time (t) to reach 1 vol% (25% of LFL) in the PR container space when acid is 8 M is:

$$t = \frac{(216.6 \text{ L} - 3.0 \text{ L})(0.01)}{4.54 \times 10^{-7} \text{ L/s}} = 4.71 \times 10^6 \text{ s} = 54.5 \text{ days}$$

Time (t) to reach 1 vol% (25% of LFL) in the PR container space when acid is 4 M is:

$$t = \frac{(216.6\ L - 3.0\ L)(0.01)}{1.11 \times 10^{-6}\ L/s} = 1.92 \times 10^{6}\ s = 22.3\ days$$

Time (t) to reach 1 vol% (25% of LFL) in the ITC space when acid is 8 M is:

$$t = \frac{(50.5\ L - 3.0\ L)(0.01)}{4.54 \times 10^{-7}\ L/s} = 1.05 \times 10^{6}\ s = 12.1\ days$$

Time (t) to reach 1 vol% (25% of LFL) in the ITC space when acid is 4 M is:

$$t = \frac{(50.5\ L - 3.0\ L)(0.01)}{1.11 \times 10^{-6}\ L/s} = 4.28 \times 10^{5}\ s = 5.0\ days$$

Calculation of Hydrogen Concentration in Bag

The analysis, up to this point, has not considered the terms Q and D in equation 2, because it was assumed that no leakage or diffusion occurred to maximize the concentration for determination of minimum time to 25% of LFL. In order to analyze the accident identified in the hazards analysis (Section 3.2.2), involving the deflagration of hydrogen in the glovebox due to ignition of hydrogen in the bags surrounding the polybottle, the concentration of the hydrogen in the bags must be determined.

To determine the concentration, the complete form of equation 2 and its solution, equation 4, are used.

Q - Ventilation Rate

Ventilation could occur by atmospheric pressure fluctuations and by the outflow of gases. The flow admittance of leak paths is uncertain. It is possible that the drum, bags, and polybottle, inhales and exhales in response to atmospheric pressure fluctuations, but for the case of a double bagged polybottle, it is assumed that there is no ventilation from the bags.

D - Diffusional Admittance

Hydrogen has a high molecular diffusivity and can diffuse through porous boundaries at an appreciable rate. For the current exercise, a best estimate of diffusion rate is made for the exposed sides of the plastic bags. First, a simple version of Fick's law is assumed to apply for the diffusional transport of hydrogen within plastic:

$$N_A = D_H \frac{\Delta C}{\Delta X} \quad (5)$$

where:

N_A = diffusion flux of H_2, moles/cm^{2}s
D_H = molecular diffusivity of H_2 in plastic, cm^2/s
ΔC = concentration difference across the plastic walls, moles H_2/cm^{3}s
ΔX = thickness of plastic, cm

The total transport rate of hydrogen through the plastic bag is the flux multiplied by the cross-sectional area for transport:

$$D_P = AN_A = AD_H \frac{\Delta C}{\Delta X} \quad (6)$$

Equation (6) is expanded with the specific variables:

$$D_P = AN_A = AD_H \frac{C_P - C_A}{t} \quad (7)$$

where:

A = surface area of plastic bag, cm^2
N_A = diffusion flux of H_2, moles/cm^{2}s
D_H = diffusion coefficient of H_2 in plastic, cm^2/s
C_P = concentration of hydrogen on inner surface of plastic bag, moles H_2/cm^{3}s
C_A = concentration of hydrogen in air outside of the bag, assumed to be 0
t = thickness of plastic, cm

The concentration of hydrogen on the inner surface of the plastic is calculated using a Henry's solubility constant:

$$C_P = (S_H)(P_H)$$

where:

S_H = solubility constant of hydrogen in plastic, moles/cm^3-atm
P_H = partial pressure of hydrogen on inside of plastic, atm

The partial pressure of hydrogen can be calculated in terms of the concentration of hydrogen in the plastic, C, using the ideal gas law so that the term for the concentration becomes:

$$C_P = (S_H)(R)(T)(C)$$

where:

S_H = solubility constant of hydrogen in plastic, mol/cm^3-atm
R = ideal gas constant, atm-cm^3/mol-K
T = temperature of the gas, K
C = concentration of hydrogen in the plastic bag, mol/cm^3

If it is assumed that the concentration of hydrogen in the air outside the bag is 0, then $C_A = 0$. Substituting the term for C_P from above into Equation 7 with $C_A = 0$, gives:

$$D = AD_H S_H RT \frac{C}{t} \qquad (8)$$

Data and Assumptions

For the determination of the equilibrium hydrogen concentration in the plastic bag surrounding the polybottle, information and assumptions used to describe the situation are as follows:

- Hydrogen is assumed to vent unimpeded through the vent in the polybottle cap into the plastic bags surrounding the polybottle.
- It is assumed that there is no leakage from the bags, but that hydrogen can diffuse through the plastic. This gives the worst-case concentration of hydrogen in the bag.
- As noted above, the concentration of hydrogen in the space outside the bag, i.e. the space in the PR container, is assumed to be 0.
- Since the polybottle is contained within two bags, each with a wall thickness of 0.012 in., it is assumed that the effective wall thickness of the plastic around the polybottle is 0.024 in.
- For determination of the surface area of the bag, it is assumed that the bag is a cylinder 20 in. in length and 6 in. in diameter.
- Temperature of gases in the PR container is assumed to be 300 K.

- Ideal gas constant, R = 82.05 atm-cm^3/mol-K.
- Diffusion coefficient for hydrogen through plastic, $D_H = 1.45 \times 10^{-6}$ cm^2/s.
- The solubility of hydrogen in plastic is assumed to be similar to the solubility of hydrogen in neoprene, $S_H = 5.42 \times 10^{-6}$ mol/cm^3-atm.

The total area of the cylindrical bag which has a 6 in. (15.24 cm) OD and a height of 20 in. (50.80 cm) is:

$$A = 2\pi(15.24/2 \text{ cm})^2 + \pi(15.24 \text{ cm})(50.80 \text{ cm})$$

$$= 2.80 \times 10^3 \text{ cm}^2$$

Substituting into Equation 8 to determine the diffusion coefficient in terms of C,

$$D = \frac{(2.8 \times 10^3 \text{ cm}^2)(1.45 \times 10^{-6} \text{ cm}^2/\text{s})(5.42 \times 10^{-6} \text{ mol/cm}^3\text{-atm})(82.051 \text{ atm-cm}^3/\text{mol-k})(300 \text{ K}) C}{(0.024 \text{ in.})(2.54 \text{ cm/in.})}$$

$$= (8.89 \times 10^{-3} \text{ cm}^3/\text{s})\, C$$

With the assumption that there is only diffusion of hydrogen from the bag, no leakage, and using the above value for D, Equation 4 becomes:

$$C = \frac{G}{D} = \frac{G}{(8.89 \times 10^{-3} \text{ cm}^3/\text{s})}$$

Since the hydrogen generation rate (G) for 4 M solution was determined to be 4.52×10^{-8} mol/s, the concentration C in the plastic bag becomes:

$$C = \frac{4.52 \times 10^{-8} \text{ mol/s}}{8.89 \times 10^{-3} \text{ cm}^3/\text{s}}$$

$$= 5.08 \times 10^{-6} \text{ mol/cm}^3$$

Since it was assumed that hydrogen vents from the polybottle unimpeded into the plastic bag, the concentration inside the bottle and the bag are the same. The internal volume of the bag and the

polybottle headspace minus the 2.5 L of nitrate solution (volume of polybottle walls, lid, etc., are conservatively neglected) is:

$$V_{bag} = \pi(15.24/2 \text{ cm})^2(50.80 \text{ cm}) - 2500 \text{ cm}^3$$

$$= 6.77 \times 10^3 \text{ cm}^3$$

$$= 6.77 \text{ L of hydrogen}$$

The quantity of hydrogen in the bag and polybottle is then:

$$5.08 \times 10^{-6} \text{ mol/cm}^3 \times 6.77 \times 10^3 \text{ cm}^3$$

$$= 3.44 \times 10^{-2} \text{ moles hydrogen}$$

Introduction

The Plutonium Reclamation Facility (PRF) has stored plutonium nitrate-nitric acid liquid solutions in Product Receiver (PR) Drums in Room 236 for several years. Storing these liquids represents a hazard to the plant since they are corrosive, contain plutonium, and are continuously generating hydrogen-oxygen gas mixtures through radiolysis that may potentially reach flammable limits.

It is desirable to open these drums and remove the liquids for stabilization. Safety concerns must be addressed in opening these drums since a hydrogen-oxygen reaction in the drum vapor space could potentially threaten worker safety.

To adequately assess the potential for a hydrogen-oxygen reaction within the drum vapor space, the hydrogen and oxygen concentrations must be known. Since we have no analytical data, Steady state hydrogen concentrations were calculated from the radiolytic hydrogen production rates and the drum breathing rates. A finite difference model was created to follow the hydrogen concentration as a function of time to verify the creation of a steady state. The results of the steady state calculations and of the finite difference model are presented in a later section. A detailed description of the finite difference model is provided in Attachment 1.

Gas Generation Rates - The radiolytic gas generation rates (G values) depend upon the types of radiation particles, their integrated energies, the chemical composition of the solutions, and the chemical composition of the containers. Other studies (Reference 1) have shown that alpha radiation from plutonium dominates the production of radiolytic gases from hydrogenous substrates. The integrated alpha energies can be calculated by summing the alpha energies obtained from each isotope. This isotope energy is calculated from the plutonium mass, its isotopic distribution, the decay constants for each isotope, and the isotope decay energy.

G values represent the number of gas molecules produced per 100 eV of radiolytic energy absorbed by the substrate. Literature sources for G values in actinide-nitric acid solutions for hydrogen, oxygen, nitrogen, and nitric oxide are given by Savel'ev et. al. (Reference 9), Sheppard (Reference 8), Bibler (Reference 7), and Kuno et al. (Reference 3). The G values in all of these reports are consistent except for oxygen. Sheppard shows oxygen G values decreasing with increasing nitric acid concentration, while the other three show a reverse trend. Despite this discrepancy, Sheppard's G values are used in this report. The reason Sheppard's oxygen G values are accepted is that our solutions are stored in plastic bottles within the PR containers. Sheppard shows that oxygen G values are strongly and negatively affected by the presence of plastic.

G values are not truly constants. They are simply "snapshots" of the gas production efficiency for a given set of conditions. Fortunately alpha driven G values tend to be much less sensitive than beta-gamma G values to radiolysis parameters.

The nitric acid concentration has a powerful negative influence on hydrogen G values. As an example, the hydrogen G value in pure water is 0.45, while the hydrogen G value in 8 M nitric acid is 0.024. The concentration of nitric acid is not known for all of the PR cans in PFP. It is

known that many contain Purex plutonium solutions that were shipped with nitric acid in the 7-8 M range.

Gas Leak Rates - The plastic bottle containing the plutonium solution has a hole in the top designed to vent the bottle. The plastic bag surrounding the bottle uses a "horse-tailed" seal that will not hold gas pressure. Therefore, the first real barrier that controls gas pressure is the PR can drum seal.

Two studies were performed and published on drum leak rates. Cooper's tests (Reference 4) show average drum leak rates ranging from 143 to 274 ml/min over one year at five psig for three drums. These tests were performed on drums with bolted ring closures tightened to 40 feet per pound. No tests were performed on PR can drums with snap ring closures.

These tests used three new drums and lids with Neozan gaskets. Neozan is a plastic gasket material fabricated from a mixture of butadiene and styrene. The exact mixture was not known.

The lid for drum A was removed and replaced on a periodic basis to simulate wear on the gasket. The lids on drums B and C were locked into place and not disturbed for the entire year to allow "cold flow" of the gasket material to occur. Drum C contained a one-liter open beaker of 12 M HNO_3-0.3 M HF to simulate a corrosive environment. Cooper's leak rates at five psig are included as Attachment 2. Cooper's lowest average leak rate occurred on drum B and was 143 cc/min.

Ludowise (Reference 5) also measured leak rates for five drums. The first four contained vent clips and the fifth did not and therefore is comparable to Cooper's tests. Ludowise's fifth non-vented drum leaked at 837 cc/min at five psig. Ludowise's four vented drums leaked approximately four to five times faster than the unvented drum.

Atmospheric Pressure Variations - In calculating the gas flow through leak paths in the drum seal, it is necessary to know both the drum internal pressure, and the external atmospheric pressure. The internal pressure is calculated from the gas inventory in the drum. The external pressure distribution was determined from Crippen's (Reference 2) results.

It would be desirable to reconstruct the natural atmospheric pressure excursion amplitudes and frequencies and apply these to this model, however that can only be performed from the raw data records and these are not readily available. Crippen's report does contain a description of the distribution of pressure fluctuations per hour over a four-year interval. Since the pressure fluctuations are random, an average hourly pressure fluctuation (0.0003768 atmospheres) was calculated and applied alternately in a plus and minus direction such that the drum experienced a constant breathing frequency.

The pressure amplitudes are smaller and the breathing frequency is higher for this model as compared to nature. The justification for the model is that the integral of pressure change versus time is the same for both the model and nature over long periods of time.

Equivalent Leak Path Area - Using the slowest experimentally measured leak (143.1 mls/min at 5 psig, Darcy's formula was used to calculate an equivalent hole area (0.000229448 cm2). Edge effects and internal resistance were neglected since the same type calculation is reversed in the model to estimate leak rates from known pressure differentials. Edge effects and internal resistance parameters therefore cancel over the entire calculational cycle.

Leak Rates- Using the equivalent hole size calculated above and assuming an intitial pressure differential, one can calculate the flow rate by Darcy's formula. This is done in the finite difference model so that flow rates and pressure differentials can be updated on whatever time frequency is desired. This model shows that starting with Crippen's average pressure swing, the pressures equalize within approximately 30 minutes and that maximum gas flow is achieved for each hourly pressure change i.e. we are not limited by too small of an equivalent hole. Another argument to show the equivalent hole size is not a choke point is contained in Table 1.

Table 1- Gas Flow Through PR Can Drums

dP atm	Ft^3/sec	mole/yr
0.0003678	6.239E-05	2282
0.00003678	6.239E-06	228
0.000003678	6.239E-07	22.8

Table 1 shows that when the pressure differential drops to 1% of Crippen's average hourly pressure swing, the gas flow through the drums is still larger than that required for the annual flow (14.4 g-moles/yr).

Once it is understood that that maximum flow is achieved for each pressure swing, one may calculate the annual flow by calculating the hourly flow and multiplying by the number of hours per year. This annual flow will be used in a later section to calculate the steady state hydrogen gas concentration

Calculation of Steady State Hydrogen Concentrations

Two PR cans were chosen for this analysis. The first PR can L1050 was filled with weapons grade Pu nitrate several years ago and stored in Room 236. The contents of L1050 were intended to supply Pu nitrate to the prototype vertical calciner, but were caught in the stop work order. This PR can is fairly representative of many other PR cans in the PFP inventory.

The second is PR can PN-48-02-02-003 and is intended to represent a "worst case". The plutonium nitrate in this can was separated from contaminants in 1988 at the Purex plant, and has been stored at PRF since. The contents of this can have the highest alpha activity of any PR can in PRF for which complete isotopic data is available. The Pu-240 isotopic distribution was adjusted slightly higher to account for the fact that other PR can solutions exist for which only partial isotopic data is available and which possess slightly higher Pu-240 concentrations.

A description of the material contained in the PR cans follows in Table 2.

Table 2- Isotopic Distribution within Selected PR Solutions

ID No.	L1050	PN-48-02-02-003	PN-48-02-02-003 adjusted**

* Sheppard JC, "Alpha Radiolysis of Plutonium (IV)-Nitric Acid solutions," BNWL-751, 1968

Using the gas generation rates in Table 3, and an average hourly pressure fluctuation (as calculated from Crippen's data, one may calculate the steady state hydrogen concentration:

Annual Gas Flow Rate

n(Moles gas) = PV/RT

dn = dP(V/R*T)

dn/dt = 0.0003768 (atm/hr)* 55gal*3.875(L/gal)/(0.08205(L-Atm/M-K)*298K)

= 0.003284moles gas/hr

= 14.4 moles gas/yr

Case 1- 8 Molar HNO3, Container L1050, No Organic Solution

The number of moles of gas produced radiolytically must also be added to the gas flow induced by atmospheric pressure swings. Total gas flow for this case is then

14.4 + 0.2 = 14.6 g-moles/yr

At the steady state:

The production rate of hydrogen - the diffusion rate must equal the mass flow loss rate.

The diffusion rate can be calculated as follows:

Diffusion Through Equivalent Hole

g-mole/hr = K*A*dc/dx

= 0.712 * 3600*0.000229448 cm^2 * ((0.00875/24464-0)/(2.54/8)

=6.63E-07

Diffusion Through Drum Gasket

is calculated first by calculating the solubility of hydrogen in the inner gasket surface

g-mole/cc = 9.01E-06 g-mole/cc/atm* 0.00875 atm =7.88E-08 g-mole/cc

g-mole/hr = 0.00000431*3600*(3.1416*23*2.54*1/16*2.54)*
(7.88E-08-0)/(2.54*1/8)

= 1.122E-07

Total H_2 diffusion rate = 6.625E-07 + 1.122E-07

= 7.747E-07 g-mole/hr

=6.79E-03 g-mole/yr

To finish the calculation:

0.128 g-moles/yr -0.00679 g-moles/yr = 0.12 g-moles H_2/yr

g-moles H_2/g-moles gas = 0.121 g-moles/yr/14.6 moles gas/year

= 0.00828 g-moles H_2/g-moles gas

= 0.828 % H_2

Case 2- 8 Molar HNO3, Container PN-48-02-02-003, no Organic Solution

The number of moles of gas produced radiolytically must also be added to the gas flow induced by atmospheric pressure swings. Total gas flow for this case is then

14.4 + 1.5 = 15.9 g-moles/yr

At the steady state:

The production rate of hydrogen - the diffusion rate must equal the mass flow loss rate.

The diffusion rate can be calculated as follows:

Diffusion Through Equivalent Hole

mole/hr = K*A*dc/dx

= 0.712 * 3600*0.000229448 cm^2 * ((0.0592/24464-0)/(2.54/8)

=7.59E-07

Diffusion Through Drum Gasket

is calculated first by calculating the solubility of hydrogen in the inner gasket surface

g-mole/cc = 9.01E-06 g-mole/cc/atm* 0.0592 atm =5.33E-07 g-mole/cc

g-mole/hr = 0.00000431*3600*(3.1416*23*2.54*1/16*2.54)*
(5.33E-07-0)/(2.54*1/8)

= 4.48E-06

Total H_2 diffusion rate = 7.59E-07 + 4.48E-06

= 5.24E-06 g-mole/hr

=4.59E-02 g-mole/yr

To finish the calculation:

0.940 g-moles/yr -0.0459 g-moles/yr = 0.894 g-moles H_2/yr

g-moles H_2/g-moles gas = 0.894 g-moles/yr/15.9 moles gas/year

= 0.0563 g-moles H_2/g-moles gas

= 5.63 %H_2

Factors that can increase the hydrogen generation rate as compared to those calculated above are:

- Decreased nitric acid concentration. The G values for hydrogen production increase by a factor of 20 as the nitric acid decreases from 8 to 0 M.
- Slower leak rates
- Increased radiolytic energy
- The presence of organic compounds

To establish a more conservative case, the following parameters were established:

- the worst case isotopic concentrations i.e., 13.1% Pu-240 were used
- a 4 M nitric acid concentration was assumed
- 1 vol % organic was included in the model
- The organic was assumed to be a 20 vol % TBP-CCl_4 mixture.

A hydrogen G-value of 0.5 as measured by Rigg and Wild (Reference 9) for wet TBP-HNO_3 mixtures was used to estimate the hydrogen generation rate in the organic phase. This calculation showed the initial hydrogen generation rate in the organic phase was approximately 20 % of that occurring in the aqueous phase. The hydrogen generation rates in both organic and aqueous phases were summed to prepare Table 4 below.

Table 4- Gas Generation Rates*

	L1050	PN-48-02-02-003
alpha ev/yr	3.30E26	2.36E27
G H_2/ev*	0.07	0.07
G O_2/ev*	0.04	0.04
G N_2/ev*	0.005	0.005
H_2 g-mol/yr	0.41	2.92
O_2 g-mol/yr	0.22	1.57
N_2 g-mol/yr	0.0274	0.19

* 4 Molar HNO_3, 1% CCL4 containing 20% TBP
** Sheppard JC, "Alpha Radiolysis of Plutonium (IV)-Nitric Acid solutions," BNWL-751, 1968

Using the results in Table 4, one may calculate steady state hydrogen concentrations as follows:

Case 3- 4 Molar HNO3, Container L1050, 1% Organic
The number of moles of gas produced radiolytically must also be added to the gas flow induced by atmospheric pressure swings. Total gas flow for this case is then

14.4 + 0.66 = 15.1 g-moles/yr

At the steady state:

The production rate of hydrogen - the diffusion rate must equal the mass flow loss rate.

The diffusion rate can be calculated as follows:

Diffusion Through Equivalent Hole

mole/hr = K*A*dc/dx

= 0.712 * 3600*0.000229448 cm^2 * ((0.0272/24464-0)/(2.54/8)

=2.06E-06 gm/hr

Diffusion Through Drum Gasket

is calculated first by calculating the solubility of hydrogen in the inner gasket surface

g-mole/cc = 9.01E-06 g-mole/cc/atm* 0.00875 atm =7.88E-08 g-mole/cc

g-mole/hr = 0.00000431*3600*(3.1416*23*2.54*1/16*2.54)*
(2.45E-07-0)/(2.54*1/8)

= 3.49E-07

Total H_2 diffusion rate = 3.49E-07 + 2.06E-06

= 2.41E-06 g-mole/hr

= 2.11E-02 g-mole/yr

To finish the calculation:

0.41 g-moles/yr -0.0211 g-mole/yr = 0.39 g-moles H_2/yr

g-moles H_2/g-moles gas = 0.39 g-moles/yr/15.1 moles gas/year

= 0.0272 g-moles H_2/g-moles gas

= 2.72 % H_2

Case 4- 4 Molar HNO3, Container PN-48-02-02-003, 1% Organic
The number of moles of gas produced radiolytically must also be added to the gas flow induced by atmospheric pressure swings. Total gas flow for this case is then

14.4 + 4.7 = 19.1 g-moles/yr

At the steady state:

The production rate of hydrogen - the diffusion rate must equal the mass flow loss rate.

The diffusion rate can be calculated as follows:

Diffusion Through Equivalent Hole

mole/hr = K*A*dc/dx

= 0.712 * 3600*0.000229448 cm^2 * ((0.153/24464-0)/(2.54/8)

=1.16E-05 gm/hr

Diffusion Through Drum Gasket

is calculated first by calculating the solubility of hydrogen in the inner gasket surface

g-mole/cc = 9.01E-06 g-mole/cc/atm* 0.153 atm = 1.38E-06 g-mole/cc

g-mole/hr = 0.00000431*3600*(3.1416*23*2.54*1/16*2.54)*
(1.38E-06-0)/(2.54*1/8)

= 1.97E-06

Total H_2 diffusion rate = 1.16E-05 + 1.97E-06

= 1.36E-05 g-mole/hr

= 1.19E-01 g-mole/yr

To finish the calculation:

2.92 g-moles/yr -0.119 g-mole/yr = 2.80 g-moles H_2/yr

g-moles H_2/g-moles gas = 2.8 g-moles/yr/19.1 moles gas/year

= 0.147 g-moles H_2/g-moles gas

= 14.7 % H_2

In cases 1-4, steady state hydrogen calculations were used. Since the PR can drums have been stored for 10 or more years in most cases, we strongly suspect that the steady state has been achieved. To verify this assumption, a finite difference model was run for case 4. The results appear in Figure 1.

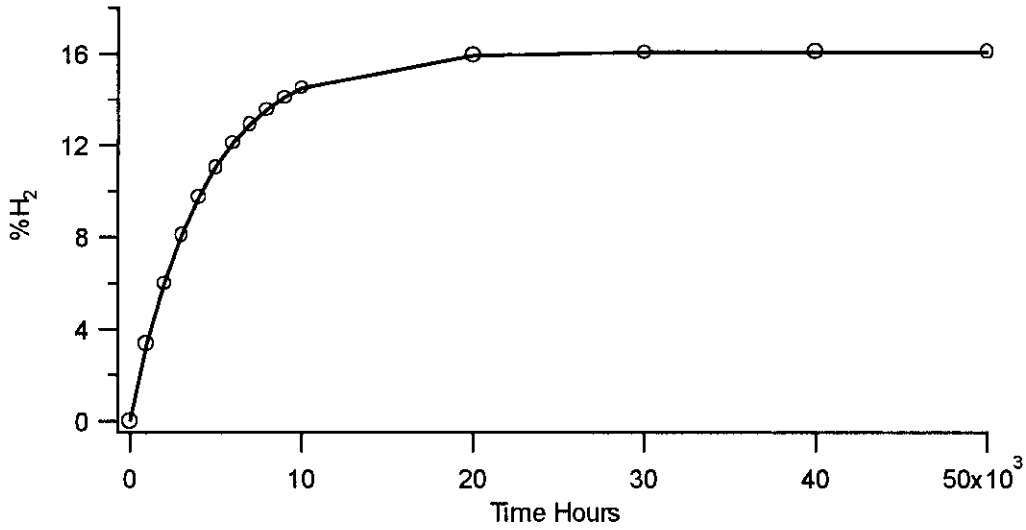

Figure 1- Hydrogen Concentrations in Container PN-48-02-02-003 (Case 4)

Figure 1 shows that the steady state is achieved within 20,000 hours or about 3 years.

It should be understood that the primary factors responsible for the high hydrogen concentrations are high G values resulting from the low nitric acid concentration and high total alpha radiolytic energy.

The results for cases 1 through 4 were obtained using measured leak rates for non-vented drums. Since drums with vent clips have openings at least 10 times larger than those estimated above, it is safe to say that no flammable hydrogen concentrations will be found in vented drums. This statement applies to both snap ring and bolt ring closures due to the design and function of the vent clip.

To be extremely conservative, a bounding hydrogen concentration was calculated for PR cans L1050 and PN-48-02-02-003 assuming no gross leaks and only diffusion through a neoprene gasket. The results are presented in Figure 2.

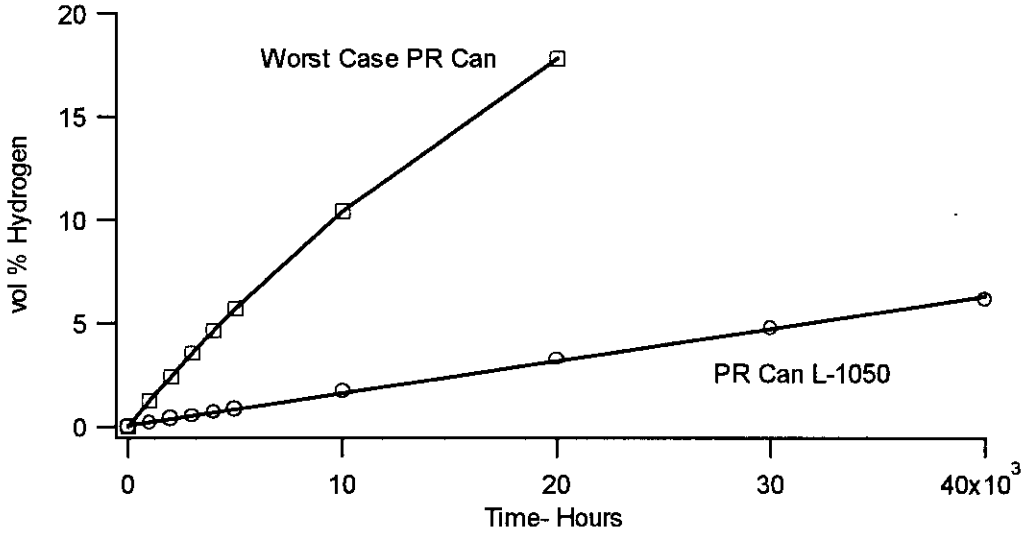

Figure 2- Hydrogen in PR Can Drums Assuming Diffusion Through Gaskets and 8 M HNO_3

For this "diffusion only" case, the worst case fuels grade PR can drum reaches the flammable limit in approximately 3,000 hours and reaches the detonable limit in 20,000 hours. The total pressure within the worst case PR can drum is 1.4 atmospheres at 20,000 hours.

The weapons grade PR can drum reaches the flammable limit in 20,000 hours and reaches the detonable limit in 109,000 hours. The total pressure within PR can drum L1050 is 1.05 atmospheres at 20,000 hours.

Marchetti's (Reference 6) report contains a description of an apparent burn of flammable gases upon opening an L-10 container in 1976. A loud report was heard, the operator saw flames emanating from the drum as it was being opened, and his eyebrows were singed. The operator was grossly contaminated in the incident. This proves that these storage drums can indeed reach a flammable gas concentration, however one cannot ascertain from Marchetti's report the radiolytic and chemical composition of the liquid, whether organic solutions were present, and the leak rate of the drum in question was never measured.

Summary

This study has shown that bolted ring PR can drums with vent clips will not reach a flammable hydrogen concentration under "worst case" conditions. This is primarily because the vent clips increase the vent hole area by roughly a factor of 10 over the natural hole area. Although snap

ring closures were not tested, it is believed the vent clips will function as well on snap ring closures as bolted ring closures.

Non-vented but leaking PR can drums (as defined by 4 test drums with bolted ring closures) only reach flammable hydrogen concentrations for PR cans with the highest isotopic energies. Since most of our drums contain 6-8 molar nitric acid and are not at the worst case condition, this implies that the vast majority of non-vented PR can drums do not contain flammable hydrogen concentrations, although one cannot exclude the possibility of a flammable drum atmosphere.

Non-vented, non-leaking drums that can lose hydrogen only through diffusion are not known nor believed to exist in our inventory. Nevertheless, if one assumes such a case, one may calculate a gaseous diffusion rate through a neoprene gasket that may reach a flammable hydrogen concentration within 3,000 hours and a detonable concentration within 20,000 hours under "worst case" conditions. The "diffusion only" case is considered extremely unlikely, however insufficient data exist to define the exact probability.

Due to the uncertainties in nitric acid concentrations, drum lid leak rates, and organic concentrations and due to the demonstrated ability of at least one solution storage drum to reach a flammable hydrogen concentration, it seems prudent to accept flammable hydrogen concentrations as a bounding condition for PR can drums without vent clips.

Detailed Model Description

The data used in this model description apply to "case 2".

1) Initialization of the model at time 0

Radiolytic Energy

meV Pu-238 is determined as follows:

Wt% Pu-238 = 0.067

Grams Pu = 3180

g-moles Pu-238 = 0.00067*3180/238 = 0.00895201

atoms Pu-238 present initially = 8.95E-03*6.023E23 = 5.39E21

Atoms Pu-238 surviving in 1999 = 5.39E21*Exp(-0.00802*11) = 4.93E21

(11 yrs represents the time since the actinides were separated in Purex)

Decay Rate dpy = $-\lambda N$ = -0.00802*4.93E21 = 3.96E19

MeV per year = dpy*5.592 = 2.21E20 MeV/yr

Similarly the alpha energy from the other isotopes in solution can be calculated and summed.

Gas Production Rates

If all of the alpha energies for each isotope are so calculated and summed, the total alpha energy absorption rate for the worst case is 2.36E27 eV/yr. Using Sheppard's 0.024 G value for 8 M HNO_3 solutions:

H_2 molecules/yr = 2.36E27*0.00024 H_2/ev = 5.66E23

g-mole H_2/hr = (5.66E23/6.023E23)/(365.25*24) = 1.07E-04

g-mole H2/yr = 0.94

Similarly the gas production rates for oxygen, and nitrogen may be calculated:

g-mole O_2/hr = 4.02E-05

g-mole N_2 = 2.19E-05

The NO production rate was not included because of the small G value indicating that it is not significant.

Gas Composition in the Drum

Next, the gas composition in the drum is initialized.

Starting with the standard dry air composition: N_2 = 78.084 vol %, O_2 = 20.946 vol%, CO_2 = 0.033 vol%, Ar = 0.934 vol%, and including the 10.7 torr vapor pressure of water over an 8 M nitric acid solution:

vol % H_2O = 100*10.7/760 = 1.4079

vol% N_2 = 78.084*(100-1.4079)/100 = 76.9847

vol% O_2 = 20.946*(100-1.4079)/100 = 20.6511

vol% CO_2 = 0.033*(100-1.4079)/100 = 0.03254

vol % Ar = 0.934*(100-1.4079)/100 = 0.92085

g-m H_2 = 0

g-m O_2 = (0.206511*55 gal*3.785 L/gal*1 atm)/(0.08205 L-atm/mole-°K*298 °K) = 1.7582

g-m N_2 = (.769847*55*3.785*1)/(0.08250*298) = 6.5545

g-m CO_2 = (0.0003254*55*3.785*1)/(0.08250*298) = 0.00277

g-m Ar = (0.0002085*55*3.785*1)/(0.08205*298) = 0.078401

g-m H_2O = (0.014079*55*3.785*1)/(0.08250*298) = 0.119868

Gas Concentration in the Drum

H_2 g-m/cc = 0/(55gal*3.785 liters/gal*1000 cc/liter) = 0

O_2 g-m/cc = 1.7582/(55*3.785*1000) = 8.4460E-06

Similarly:

N_2 g-m/cc = 3.1485E-05

CO_2 g-m/cc = 1.3306E-8

Ar g-m/cc = 3.766E-07

H_2O g-m/cc = 5.7581E-07

From the gas concentrations one may calculate the gas pressures:

H_2 atm. = 0*1000*0.08205*298 = 0

O_2 atm = 8.4460E-06*1000*0.08205*298 = 0.207

N_2 atm. = 3.1485E-05*1000*0.08205*298 = 0.770

CO_2 atm. = 1.3306E-08*1000*0.08250*298 = 3.25E-04

Ar atm. = 3.7661E-07*1000*0.082305*298 = 9.21E-03

H_2O atm. = 5.7581E-07*1000*0.08205*298 = 1.41E-02

Internal Pressure = $H_2 + O_2 + N_2 + CO_2$ + Ar + H_2O = 1 atm.

External Pressure is initialized at 1 atm.

Initial Pressure differential should be 0 but is calculated at -2.95776E-05 due to rounding of numbers.

Diffusion of Hydrogen through the Neoprene Gasket

The solubility of hydrogen is 9.01E-06 g-m/cc/atm in neoprene.

The equilibrium concentration at the inner face is:

9.01E-06*H_2 partial pressure = 0

Diffusion rate through neoprene is:

g-m H_2/hr = k*A*dc/dx

= 0.00000431cm^2/sec*3600sec*(3.1412*23 in.*2.54 cm/in*1/16 in. *2.54 cm/in.)*(H_2 inner- H_2 outer)/(1/8*2.54) = 0

The diffusion rates of the other gases through neoprene were ignored since the diffusion coefficents and pressure differentials are smaller than for hydrogen.

Gaseous Diffusion through Equivalent Hole

An equivalent hole through the gasket is calculated from experimental pressure leak-rate correlations.

An initial flow rate of 143.1 cc/min is assumed from the slowest flow rate measured by Cooper through a drum gasket at 5 psig.

$ft^3/sec = 143.1/60*(1/2.54)^3*(1/12)^3 = 8.42255E-05$

Now from Darcy's equation for the flow of a compressible gas through an orifice:

$$\text{flow rate} = YCA(2g * \Delta P)/\rho$$

where:

Y = an expansion factor = 0.85 from Crane's handbook
C = Flow coefficient dependent upon the Reynolds number = 0.6 in this application
A = equivalent hole area
g = acceleration of gravity
ΔP = pressure differential
ρ = gas density

Solving for A:

$A = 8.42255\ ft^3/sec/(0.85*0.6*(2*32.2\ ft/sec^2*144\ in.^2/ft^2*5\ lb/in.^2/0.1037\ lb/ft^3)^{0.5}$

$= 2.46975E-07\ ft^2 = 2.29448E-04\ cm^2$

Now the diffusion of gases through this equivalent hole may be calculated:

H_2 g-m/hr = 0.712 cm^2/sec*3600 sec/hr*2.29448E-04 cm^2*(H_2 inner conc – H_2 outer conc)/0.3175 cm

= 0.712 cm^2/sec*3600 sec/hr*2.29448E-04 cm^2*(0-0)/0.3175 cm = 0

The diffusion rate of the other gases through the equivalent hole are calculated similarly.

Gross Leak Rates

The gross leak rate is calculated through Darcy's formula, the equivalent hole size, and the pressure differential between the drum inner pressure and the external atmosphere.

total g-m/hr = 0.6*0.85*2.29448E-04 cm^2*3600 sec/
24,464 cc/g-m*(2*981.4 cm/sec^2*dp/0.0012845)$^{0.5}$
= -0.00372117

Once the gross leak is established, the partial leaks for each gas species can be proportioned according to their molar concentrations.

The reader may note that internal resistance and edge effects were ignored in this calculation for two reasons:

- The number and dimensions of the actual holes are unknown and therefore such effects are impossible to estimate.
- Since we define the equivalent hole from pressure-leak rate measurements, and then use the equivalent hole and pressure differential measurements to calculate the leak rate, the entire calculation is cyclical and such effects cancel out.

2) Reiteration of the Model for the first Hour

The gas inventory at the beginning of the first hour is taken to be the same as calculated above for the initialization. Gas production rates and gas leakage and diffusion rates are calculated.

3) Reiteration of the Model for the Second and Succeeding Hours

During the second and all succeeding hours, the initial gas inventory is established by summing the previous inventory with the production and dissipation rates calculated during the previous hour.

Gas Leak Rates in cc/min

Time Days	Drum A	Drum B	Drum C
0	236	130	213
1	248	142	201
4	331	130	224
8	224	130	201

APPENDIX D

Evaluation of Compressed Air on the Confinement Capability of Laboratory Gloveboxes

This page intentionally left blank.

Evaluation of Compressed Air on the Confinement Capability of Laboratory Gloveboxes.

Glovebox pressurization could cause a release of plutonium with the potential for inhalation by workers in the same room. A release requires breaching a HEPA filter where air normally flows into the glovebox from the room. Pressurization of a glovebox is normally assumed possible only if pressurized gases are forced into the glovebox. Generation of gases by chemical reaction is assumed to be too slow to present a problem under credible operating conditions.

Scenario. Most laboratory gloveboxes are equipped with compressed gas sources where the compressed gas can be air or an inert gas. Dry air gloveboxes are designed such that a failure in the E-4 exhaust system results in a shutdown of the dry air source. Other sources of compressed gas are not interlocked to the E-4 system. In the event of a failure in the E-4 system the compressed gas will continue to be supplied to the glovebox unless it is manually shut off. This analysis treats the consequences of an event where the E-4 system fails and a compressed gas source continues to supply the glovebox due to failure of compressed air lines within the glovebox or from failure of the compressed air supply regulator.

At risk are the glovebox inlet HEPA filters. Glovebox 188-1 in Room 188 has five inlet HEPA filters with dimensions of 8 in. x 8 in. x 5 7/8 in. Rated flow capacity of each filter is 50 scfm. For these filters, rated flow corresponds to approximately 1.3 in. w.g. pressure drop. Typically, 10 in. w.g. is the maximum ΔP a filter can maintain (BWHC 1999). Compressed air is available to Glovebox 188-1 through one outlet which is a 3/8 in. OD, 0.305 in. ID tubular source at a maximum of 90 psig (104.7 psia).

In the event of a failure of the E-4 exhaust system, the maximum instantaneous flow rate from a compressed air line into the glovebox, venting it through a circular orifice of 0.305 in. ID, can be calculated from Equation 3-22 of Crane (1969) for flow of compressible fluids through nozzles and orifices. The flow is given by:

$$q'm = \frac{412\, Y\, d_o^2\, C}{S_g}\sqrt{\Delta P\, \rho_1}$$

where:

q'm = flow rate, scfm
Y = net expansion factor for compressible flow
d_0 = diameter of orifice, in.
C = flow coefficient for square edged orifice
S_g = specific gravity of gas relative to air, 1.0 in this case.
ΔP = differential pressure, psi
ρ_1 = density of gas, lbs/ft^3

The pressure inside the glovebox was assumed to be - 0.3 psig (14.4 psia) due to the successive pressure drops between (1) the atmosphere and the building non-radiation zone, (2)

the building non-radiation zone and radiation zone, and (3) the building radiation zone and the glovebox interior. Pressure drops of 0.1 psi were assumed for each step. The source pressure is gauge pressure relative to the outside atmosphere due to their source at or near the outside atmosphere. The total pressure difference between the source and glovebox interior is then 104.7 -14.4 = 90.3 psia. For conservatism, no credit is taken for pressure drops in the line between the source and the outlet.

The value of Y is a function of the orifice size $d_0\backslash d_1$ (where d_0 = diameter of orifice and d_1 = diameter of pipe), $\Delta P/P$, and the specific heat ratio for the gases of concern, k. The differential pressure (ΔP) was determined from above to be 90.3 psia. The absolute pressure of the compressed air source (P) is 90.3 + 14.7 = 105.0 psia, so:

$$\Delta P/P = 90.3/105.0 = 0.86.$$

For the gases of concern (i.e. air) in this analysis, k = 1.4. For the orifice size in this analysis $d_0\backslash d_1$ is very small and falls in the range of 0 to 0.2. From the graph on pg. A-20 of Crane (1969):

$$Y = 0.75$$

The value of C is a function of the nozzle orifice size ($d_0\backslash d_1$), and the Reynolds Number (Re) of the flow. For the orifice size of concern in this analysis $d_0\backslash d_1$ is very small and falls in the range of 0 to 0.2. From Appendix E, Section E.7.1.2 of BWHC (1999), Re = 6.2×10^4 for the flow through a 1/16 in. conduit, and from Section E.7.1.3 of BWHC (1999), Re = 1.28×10^5 for the flow through a 1/8 in. conduit. In the graph for determination of C on pg. A-20 of Crane (1969), the value of C (when $d_0\backslash d_1$ = 0 to 0.2) is a constant value for Re numbers in the range from 10^4 to 10^6.

From the graph on pg. A-20 of Crane (1969), then:

$$C = 0.985$$

From WHC (1992), $S_g = 1.0$, and $\rho = 0.0764$ lb/ft^3. Accordingly, the estimated flow rate through the orifice with a 0.305 in. diameter is:

$$q'm = \frac{(412)(0.75)(0.305)^2(0.985)}{1.0}\sqrt{(90.3)(0.0764)}$$

$$= 74.37 \text{ scfm.}$$

As stated above, rated flow for each of the five inlet filters for Glovebox 188-1 is 50 scfm, and rated flow corresponds to approximately 1.3 in w.g. pressure drop. Maximum ΔP a filter can maintain is 10 in. w.g.

Pressure drop across a filter is proportional to the square of flow velocity and the square of flow rate:

$$\Delta P \propto \text{velocity}^2 \propto \text{flowrate}^2$$

Then, knowing ΔP = 1.3 in. w.g. for 50 scfm, the pressure drop at the estimated maximum flow through each of the five filters is:

$$\Delta P = \frac{(1.3 \text{ in})(74.4/2 \text{ scfm})^2}{(50 \text{ scfm})^2} = 0.72 \text{ in. w.g.}$$

Since this is much less than 10 in. w.g., there is no danger of filter failure.

Mitigation. Mitigation is provided by administratively limiting the use of pressurized gas in the glovebox. This control limits the quantity of pressurized air or other gas in Glovebox 188-1.

Probability. The pressurization of Glovebox 188-1 due to compressed air is an unlikely event, defined in the PFP FSAR (FDH 1999), Table 9-49, as having an annual probability of occurrence in the range of 1×10^{-2} to 1×10^{-4}. This probability is based on the occurrence of a seismic event that initiates the failure of the E-4 exhaust system.

Consequence. Since the pressure drop at the estimated maximum flow through each of the two filters, 0.72 in. w.g. is much less than 10 in. w.g., there is no danger of filter failure.

Conclusions. The estimated maximum air flow rate from Glovebox 188-1 was calculated to be 74.4 scfm, based on the number of air lines entering the glovebox and the location and pressure of the air source. Figures 6B through 9B of Appendix B of WHC (1992), show that the calculated glovebox interior pressures barely exceed 1.1 in. w.g. (0.04 psi) when exhausting an air flow of 75.2 scfm. The HEPA filters on the gloveboxes operate routinely with a ΔP of up to 3 in. w.g. (0.11 psi); thus, filter breaching at an air flow rate of 75.2 scfm is extremely unlikely. As further confidence, consider that the filters are tested for filtering efficiency by the manufacturer (Flanders Filters, Inc.; Washington, NC) prior to shipment. The efficiency test are performed at an air flow rate of 35 scfm per filter. The pressure difference in the test varies from filter to filter and ranges from 44 to 92 in. w.g. (1.6 to 3.3 psi) without breaching the filter, well beyond the pressure difference allowed for use on Plutonium Finishing Plant gloveboxes. The PPSL gloveboxes are normally installed with at least 2 inlet HEPA filters. A total flow rate of at least 100 scfm through the filters may be possible at each glovebox without breaching any filters.

Use of all available air supply lines into any of the PPSL gloveboxes does not deliver an air flow rate sufficient to cause a breach of containment. Additional flow restrictions are not necessary to keep the deliverable air flow rates less than safe exhaustible flow rates.

APPENDIX E

CALCULATION OF LABORATORY PROTOTYPE CALCINER BURST PRESSURE

This page intentionally left blank.

Calculation of Laboratory Prototype Calciner Burst Pressure

1.0 PURPOSE

This appendix documents the theoretical burst pressure of the calciner at operating temperature.

2.0 METHODOLOGY

The analysis does not consider thermal stresses or stress risers that might develop in various portions of the calciner shell. Instead, a simple hoop stress analysis is performed. Calculating potential failure pressures for flanges, bolts, and fittings would require complicated and time-consuming analyses. The burst pressure estimated in this calculation is non-conservative because it looks at what is likely the strongest part of the calciner vessel; the shell wall instead of the weakest section. This analysis is useful however because it provides the maximum pressure the vessel is likely to withstand.

The burst pressure calculated can be compared against predicted overpressures in the calciner due to explosions, fires, etc. to determine whether calciner ruptures are likely in such events.

For cylindrical vessels, burst pressure due to hoop stress in the wall of the vessel is given by the following equation (Lindeburg 1994):

$$P = 2\sigma t/D \qquad (1)$$

Where:

P = burst pressure, psig
D = outside diameter of the vessel, in.
t = vessel wall thickness, in.
σ = ultimate tensile strength, psi

This equation assumes that the split is longitudinal and that the shell is seamless.

For circumferential split failures, the applicable equation is:

$$P = 4\sigma t/D$$

which gives pressures twice as high as equation (1).

3.0 ASSUMPTIONS

The calciner vessel is assumed to burst due to hoop stress in the wall of the pipe of which it is constructed. This gives potentially non-conservative results as other areas of the calciner may be weaker than the pipe wall due to thermal stress or stress concentration risers.

The pipe wall is assumed to be at an average temperature of 816 °C when it is overpressurized. The calciner normally operates at 1000 °C. A metal temperature of 816 °C was assumed because it is the highest temperature for which tensile strength data is available. Burst pressures calculated at this temperature are somewhat overestimated.

4.0 INPUT DATA

The calciner is constructed from 6 in. diameter, schedule 10, 310 stainless steel pipe. From Perry's handbook (Perry 1984), the outside diameter of the schedule 10 pipe is 6.625 in. and the wall thickness is 0.134 in. Therefore:

$$D = 6.625 \text{ in.}$$
$$t = 0.134 \text{ in.}$$

Ultimate tensile strength values for 310 stainless steel at elevated temperatures was not readily available. However, the allowable tensile stresses (for design purposes) of 310 stainless steel at elevated temperatures can be found in Perry (1984). Table 6-37 of Perry (1984) provides allowable tensile stresses for temperatures up to of 816 °C.

The allowable tensile stress for 310 stainless steel at 816 °C is taken from Table 6-37 of Perry (1984). Table 6-37 shows that the allowable tensile stress ranges from 200 to 800 psi, depending on grain size. The grain size for the stainless steel used in the calciner is unknown. Therefore, the lower allowable value is assumed.

5.0 CALCULATIONS

Because of the safety factors built in to designs, the allowable design stresses tend to be about a factor of three or four below ultimate values. Multiplying the 310 stainless steel design allowable (200 psi) by a factor of three gives an ultimate tensile strength estimate of 600 psi at 816 °C.

Substituting the appropriate values in equation (1) gives:

$$P = 2(600 \text{ psi})(0.134 \text{ in.})/(6.625 \text{ in.}) = 24 \text{ psig}$$

6.0 CONCLUSIONS

The estimated pressure in the calciner deflagration accident, as documented in Section 4.2.3.4 of this addendum, is 63 psig. The deflagration pressure is well above the calculated calciner burst pressure (24 psig) so it is possible that the calciner shell could rupture in the deflagration event.

It should be noted that the above calculated burst pressure is based on static pressure loading. In addition, the burst pressure (24 psig) estimated above is a maximum value since thermal stresses, stress concentration risers, and the shear strengths of bolt threads, etc. were not considered and could result in a lower burst pressure. However, in a true deflagration accident, the load is applied as a short-term impulse. Because of inertial effects, vessels can withstand impulse loads that are greater than static loads. No attempt was made to estimate the impulse load required to fail the vessel due to the low static pressure value calculated.

APPENDIX F

UNMITIGATED DESIGN BASIS EARTHQUAKE ACCIDENT ANALYSIS

This page intentionally left blank.

UNMITIGATED DESIGN BASIS EARTHQUAKE ACCIDENT ANALYSIS

1.0 INTRODUCTION

This Appendix presents an unmitigated Design Basis Earthquake (DBE) accident analysis for the Laboratory Prototype Calciner in Glovebox 188-1. Glovebox 188-1 is seismically qualified such that it will not topple given a DBE. However, the glovebox panels and equipment within the glovebox and supporting services are not qualified and may or may not fail. Accordingly, numerous scenarios, each with a different combination of system and component failures, can be hypothesized. Section 2.0 discusses the event tree constructed to define credible seismic event sequences. Section 3.0 quantitatively evaluates an unmitigated scenario in which the calciner continues to operate after the seismic event but loses vacuum resulting in pressurization and a release of plutonium.

2.0 DESIGN BASIS EARTHQUAKE EVENT TREE

An event tree was developed to identify DBE scenarios for the laboratory prototype calciner and to estimate their associated consequences and probability of occurrence. Event trees are constructed by postulating an initiating event and systematically evaluating subsequent system or component successes or failures. For the calciner event tree, the initiating event is taken to be the DBE. Systems and components evaluated for subsequent success or failure are listed below. These items were selected for evaluation as their failure could directly and significantly contribute to the release of plutonium.

Calciner - the calciner may or may not remain secured in place and maintain its integrity. Loss of integrity results in a spill of the entire calciner contents to the glovebox.

Calciner feed - feed to the calciner (driven by an electric pump) may or may not continue. Continuation of feed increases the quantity of material potentially released. In addition, continuation of feed can pressurize the calciner, given loss of vacuum.

Air supply - air supply to the feed nozzle (provided by the plant air supply system) may or may not continue. Continuation of the air supply can pressurize the calciner given loss of vacuum and also acts to loft powder.

Vacuum - the calciner vacuum (provided by the plant 26-in-Hg vacuum system) may or may not be maintained. Loss of vacuum can result in pressurization of the calciner, given continuation of feed or air supply.

Product tube - the product tube may or may not remain in place as designed. Loss of the product tube results in a spill of the entire calciner contents to the glovebox.

Agitator - the agitator (driven by an electric motor) may or may not continue to operate. Continued operation of the agitator increases the quantity of material spilled to the glovebox given the product tube remains in place.

The product receiver vessel was not included in the event tree as its contribution to the magnitude of the event consequences was judged to be insignificant compared to that of the feed tank and calciner unit, particularly for scenarios that pressurize the calciner unit.

Figure F-1 presents the calciner event tree. The event tree resulted in the identification of thirty event sequences, each representing a unique path through the tree. Each event sequence was qualitatively evaluated to determine the magnitude of the associated release, and assigned a relative release level of minor, small, medium, or large. Nine event sequences, or approximately 30%, resulted in large releases. Large releases are primarily associated with event sequences resulting in a pressurized calciner with continuous feed.

To quantify the event tree, success/failure probabilities were assigned to each system or component. Engineering analyses of the seismic response of the calciner systems and components have not been performed. Accordingly, the assigned probabilities were developed based on consideration of (1) the complexity of the system or component, i.e., complex systems are more likely to fail than simple systems, and (2) the fragility of the system or component, e.g., glass vessels are more likely to fail than steel vessels. The assigned probabilities are as follows:

- Calciner - 0.5 that the calciner survives
- Calciner feed - 0.3 that the calciner feed continues
- Air supply - 0.5 that air supply continues to the feed nozzle
- Vacuum - 0.2 that the vacuum continues
- Product tube - 0.70 that the product tube stays in place
- Agitator - 0.5 that the agitator continues to run.

The individual frequencies (or annual probabilities) of the nine event sequences having large consequences range from 1.5×10^{-5}/yr to 9×10^{-7}/yr. Summing the nine event sequences yields a frequency of 2.7×10^{-5}/yr. It is therefore concluded that a large release of plutonium from the calciner given a DBE is a credible event as the frequency exceeds 1×10^{-6}/yr.

The above described event frequencies are based on qualitative engineering judgement. Consequently, for risk acceptance purposes, all component and system failures are conservatively assumed to occur with a conditional probability of 1 given the occurrence of a DBE at an annual probability of 1×10^{-4}. Therefore, radiological consequences are evaluated against the risk acceptance guidelines given in Figure 9-34 of the PFP FSAR (FDH 1999) at a probability of 1×10^{-4}. This is conservative since larger doses are acceptable at lower probability values, which would be the case if components were determined to fail at probabilities less than 1.

3.0 UNMITIGATED SEISMIC EVENT SCENARIO

The event tree discussed in Section 2.0 of this appendix identified nine unique event sequences resulting in large releases. To quantify the consequences of an unmitigated scenario, it is assumed that the DBE results in a loss of vacuum, but that the calciner remains intact and that the liquid feed injector, agitator, and heaters continue to operate.

The calciner generates dust during normal operation. Air fed in through the feed nozzle and the liquid feed flashed in the oxide bed fluidizes the bed and lofts particulate into the freeboard of the calciner. Additional material is normally made airborne in the freeboard off the ceramic filters due to the action of the backpulsing air. The agitator also kicks up dust. The normal dust loading in the freeboard of the calciner is unknown, but is high enough that the ceramic filters have to be backpulsed with air on average every 40 s to prevent plugging.

Loss of the vacuum system flow will cause the calciner to pressurize and eject the pressure relief cap at an overpressure of approximately 2.0 psi. Two abnormal events that occurred during prior calciner operation indicate the release rate of material through the pressure relief cap could range from 4 g/min to 200 g/min. Scoping calculations indicate that the superficial velocity of the flashed vapor and airflow through the bed material is higher than the terminal settling velocity of much of the particulate material in the bed. Thus, bulk entrainment and ejection of the material from the calciner cannot be discounted. As bed material is ejected and the bed becomes shallower, the bed material becomes easier to entrain. For this analysis it is conservatively assumed that all bed material is lofted into the glovebox through the calciner pressure relief cap over several tens of minutes following the seismic event.

The pressurization of the calciner following loss of vacuum would result in operation of the pressure relief cap and ejection of powder into the glovebox. If uninterrupted, the 4 kg of plutonium in the chamber and the 2.25 kg in the feed could all be processed and ejected. Because the powder is ejected in the air stream, the ARF = 1. A respirable fraction of 3% is assumed, based on Figure 9-28 in the PFP FSAR.

The release of plutonium oxide (Class Y material) and plutonium nitrate (Class W material) are, respectively:

$$Q_y = \text{ARF} \times \text{RF} \times 4{,}000\ \text{g} = 4{,}000\ \text{g} \times 0.03 = 120\ \text{g}$$

$$Q_w = \text{ARF} \times \text{RF} \times 5.0\ \text{L} \times 450\ \text{g/L} = 67.5\ \text{g}$$

In the "ventilation" case, the E-3 and E-4 exhaust fans are assumed to continue to run and the HEPA filters are assumed to fail. Section 9.2.4.7.2 of the PFP FSAR states that 16% of the released material is held up in the exhaust ducts, resulting in release out the 291-Z-1 Stack of 84%. The released amounts of Class Y and Class W materials are about 101 and 57 grams, respectively. The doses are calculated by using the methodology from Section 9.3.6.

$$D(rem) = Q(g) \times \chi/Q'(sec/m^3) \times R(m^3/s) \times C(rem/g)$$

where:

D = Dose

Q = Quantity of plutonium released = 101g Class Y + 57 g Class W

χ/Q' = Atmospheric dispersion coefficient for elevated release =
1.62×10^{-5} s/m^3 for onsite receptor from FSAR Table 9-39
5.73×10^{-6} s/m^3 for offsite receptor from FSAR Table 9-40

R = Breathing rate = 3.3×10^{-4} m^3/s from FSAR Table 9-48

C = Gram plutonium-to-dose conversion factor for Class Y >10% ^{240}Pu, mass weighted average = 8.8×10^7 rem/g (EDE) and 1.3×10^9 rem/g (Bone Surface) from FSAR Tables 9-46 and 9-47, respectively, and;
Class W >10% ^{240}Pu, mass weighted average = 1.03×10^8 rem/g (EDE) and 1.9×10^9 rem/g (Bone Surface)

An example calculation for onsite EDE dose is as follows:
D = (101g Class Y >10%)(1.62×10^{-5} s/m^3)(3.3×10^{-4} m^3/s)(8.8×10^7 rem/g) +
(57 g Class W > 10%)(1.62×10^{-5} s/m^3)(3.3×10^{-4} m^3/s)(1.03×10^8 rem/g) = 78.9 rem.

The EDE doses are approximately:

- onsite = 79 rem
- offsite = 28 rem

The bone surface doses are approximately:

- onsite = 1,280 rem
- offsite = 453 rem

For an event with an annual probability of 1.0×10^{-4}, the risk acceptance guidelines (Figure 9-34 of the PFP FSAR [FDH 1999]) allow an onsite dose of 25 rem EDE and an offsite dose of 4 rem EDE. Thus, this "ventilation case" consequences exceed the risk guidelines for both onsite and offsite individuals.

In the "no ventilation" case, both the building supply and exhaust fans are assumed to shut down during the earthquake. Radiological material released inside the 234-5Z Building can leave only through open doors on the exterior of the building due to wind effects (Section 9.2.4.7.1 of the PFP FSAR). It is estimated that about 38% (71 g) of the material released into the facility could be released at ground level.

The doses due to the release of approximately 71 g of plutonium are:

$$D(rem) = Q(g) \times \chi/Q'(sec/m^3) \times R(m^3/s) \times C(rem/g)$$

where:

D = Dose

Q = Quantity of plutonium released = 45.6 g Class Y and 25.6 g Class W

χ/Q' = Atmospheric dispersion coefficient for ground level release =
4.74×10^{-4} s/m^3 for onsite receptor from FSAR Table 9-39
1.01×10^{-5} s/m^3 for offsite receptor from FSAR Table 9-40

R = Breathing rate = 3.3×10^{-4} m^3/s from FSAR Table 9-48

C = Gram plutonium unit inhalation doses for Class Y >10% ^{240}Pu, mass weighted average = 8.8×10^7 rem/g (EDE) and 1.3×10^9 rem/g (Bone Surface) from FSAR Tables 9-46 and 9-47, respectively, and;
Class W >10% ^{240}Pu, mass weighted average = 1.03×10^8 rem/g (EDE) and 1.9×10^9 rem/g (Bone Surface).

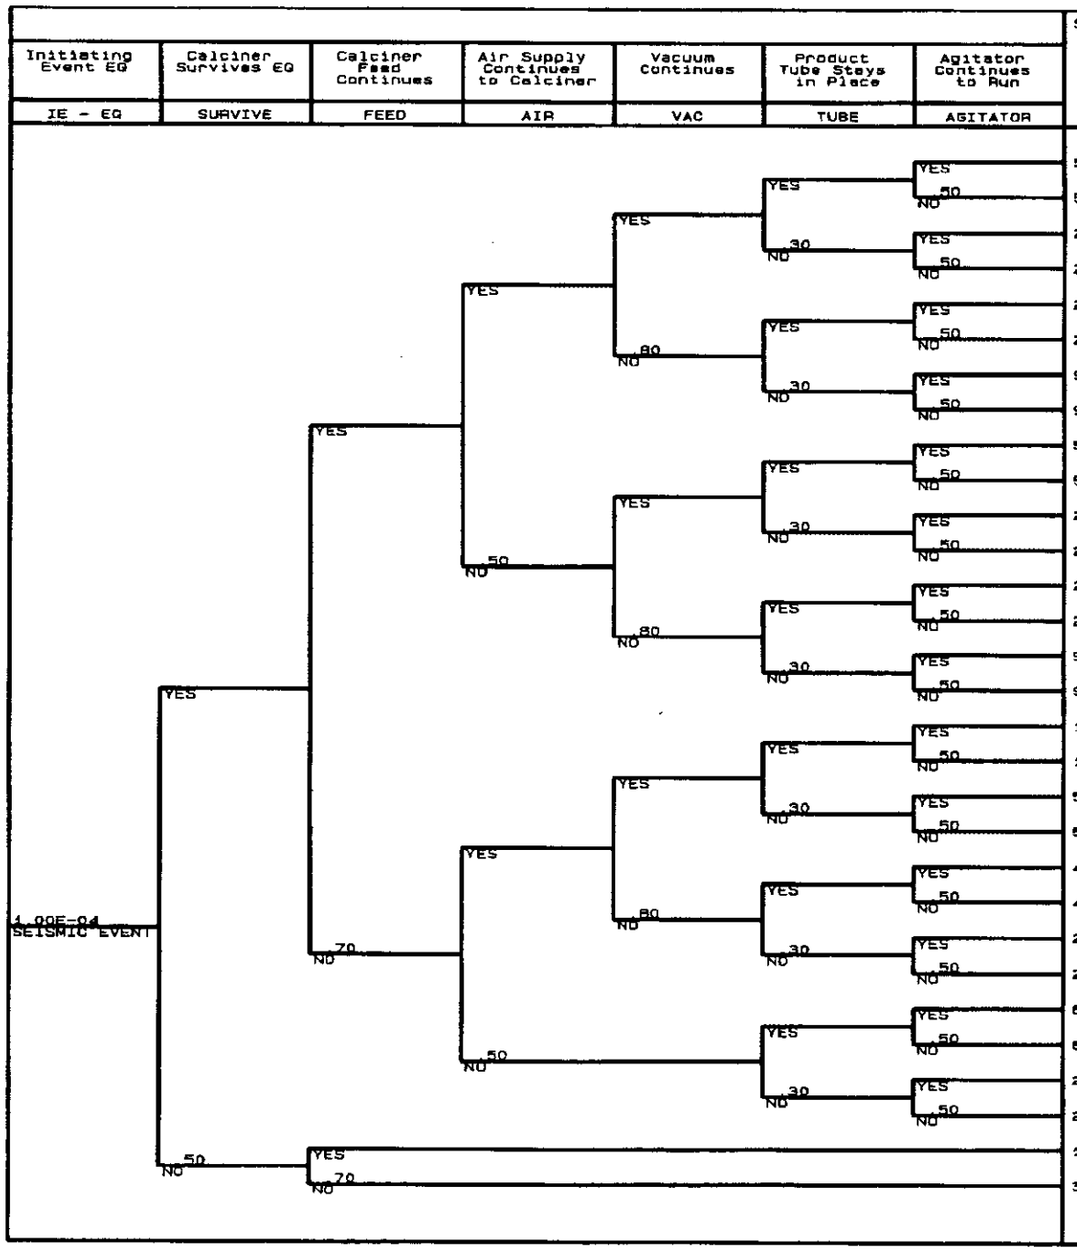
The EDE doses are approximately:

- onsite = 1,040 rem
- offsite = 22 rem

The bone surface doses are approximately:

- onsite = 16,900 rem
- offsite = 360 rem

For an event with an annual probability of 1.0×10^{-4}, the risk acceptance guidelines (PFP FSAR Figure 9-34) allow an onsite dose of 25 rem EDE and an offsite dose of 4 rem EDE. Thus, this "no ventilation case" consequences exceed the risk guidelines for both onsite and offsite individuals by a significant margin.



It is concluded from the analysis of this representative unmitigated scenario and others, that the consequences would exceed the RAGs by large margins. Therefore, it is concluded that a safety class seismic shutdown mechanism is required to prevent unacceptable releases from operation of the calciner during a seismic event.

APPENDIX G

CALCINER METAL MASS AND HEAT TRANSFER POTENTIAL

This page intentionally left blank.

CALCINER METAL MASS AND HEAT TRANSFER POTENTIAL

The purpose of this appendix is to document the estimate of the calciner major metal parts that could transfer heat to the glovebox, glovebox components, equipment, and plutonium materials that could be postulated to spill in the 0.2 g DBE. The major metal components that are of interest because of their high operating temperature and stored heat are the bottom flanges (interface with the support bracket), middle flanges (interface with the upper and lower regions of the body, and the inner chamber. The body and chamber are a pipe-within-a-pipe construction and are made of 310 stainless steel, schedule 10 pipe. The drawing showing these components is SK-2-300303, 10-L/Calciner Assembly, Rev 1, sheet 2. The estimates of metal volumes and masses are provided below.

The volume of each flange is given by:

$$V_f = 3.142 \times (D_o^2 - D_i^2) \times T_f /4$$

where:

D_o = outer diameter of flange = 11.000 in.
D_i = inner diameter of flange = 6.625 in.
T_f = flange thickness = 0.5 in.

The volume of each flange is approximately 30 in^3. Therefore, the volume of four flanges equals 120 in^3.

The volume of the inner pipe section is given by:

$$V_f = 3.142 \times L_p \times D_o \times T_w$$

where:

D_o = outer diameter of pipe = 4.50 in.
L_p = length of pipe section, = 9.0 in.
T_w = pipe wall thickness = 0.12 in.

The volume of the inner pipe section is approximately 15.3 in^3.

The volume of the outer pipe section is given by:

$$V_f = 3.142 \times L_p \times D_o \times T_w$$

where:

D_o = outer diameter of pipe = 6.625 in.
L_p = length of pipe section = 21.0 in.
T_w = pipe wall thickness = 0.134 in.

The volume of the outer pipe section is approximately 58.6 in^3.

Thus, the total volume of the major steel parts is about 195 in^3 (3200 cm^3). The density of stainless steel is about 8 g/cm^3 (ORNL 1975, property code 3304, 316 SS, annealed). The data for 316 stainless steel is used to approximate 310 stainless steel. The total mass is 25,600 g or approximately 26 kg.

The specific heat of 316 stainless steel was also used as a reasonable approximation to 310 stainless steel. The specific heat of this steel ranges from 544 J/kg K (120 cal/g K) at 300 °C to 628 J/kg K (150 cal/g K) at the highest temperature provided in the table, 871 °C (ORNL 1975, property code 3108, 316 SS, annealed). A value for the temperature range of interest was assumed to be 140 cal/kg K.

APPENDIX H

SEISMIC EVENT DOSE CALCULATION FOR LAB CALCINER ONLY

This page intentionally left blank.

SEISMIC EVENT DOSE CALCULATION FOR LAB CALCINER ONLY

1.0 RELEASES FROM GLOVEBOX 188-1 BY LUNG CLEARANCE CLASS AND ^{240}PU CONTENT

Table 5.22.2 of the PFP OSRs (BWHC 1999) establishes a total dispersible Pu limit for the Analytical Laboratory, Plutonium Process Support Laboratory, and Standards Laboratory. The limit is 12,450 g total for all laboratory rooms of which no more than 5,250 g is allowed to have a ^{240}Pu content greater than 10%. This limit is the same as the limits for laboratories stated in Section 9.2.4.6.3.1 of the PFP FSAR (FDH 1999).

As discussed in Section 4.2.5 of this addendum, the typical inventory associated with the calciner is 7 kg which is distributed as follows:

- 4,000 g in the calciner chamber
- 750 g in the product receiver vessel
- 2,250 g in the liquid feed tank.

Plutonium nitrate solutions to be fed to the calciner originate primarily from weapons grade material. For this analysis, it is therefore assumed that all plutonium material associated with the calciner in Glovebox 188-1 has a ^{240}Pu isotopic content of less than 10%. Feed containing >10% ^{240}Pu will be blended to ensure that it has less than 10% ^{240}Pu content.

Plutonium nitrate (Lung Clearance Class W) is more soluble than oxide (Lung Clearance Class Y) and thus has a higher unit dose conversion factor. The above inventory maximizes the quantity of inventory in the glovebox with Class W lung clearance and maximizes the predicted doses because the plutonium nitrate liquid feed tank is assumed to be full at the time of the seismic event with solution having a maximum plutonium content of 450 g/L.

As discussed in Section 4.2.5 of this Addendum, of the 2,250 g of plutonium present as plutonium nitrate, 0.863 g is released into the facility in a seismic event. Of the 4,750 g of plutonium present as an oxide, 11.676 g is released into the facility given accumulator depressurization. If the check valves function as intended, 2.676 g Pu as oxide is released into the facility. In summary, the releases into the facility from the calciner by Lung Clearance class are:

- 0.863 g <10% ^{240}Pu, Class W
- 11.676 g <10% ^{240}Pu, Class Y (accumulator depressurization)
- 2.676 g <10% ^{240}Pu, Class Y (check valves function)

2.0 RELEASES FROM REMAINDER OF LABORATORIES

Given that 7 kg is associated with the prototype calciner Glovebox 188-1, the remaining allowable inventory in the three laboratories (Analytical, PPSL, and Standards laboratories) is 5,450 g. The calculations for releases from the remainder of the facility are found in Section 9.2.4 of the PFP FSAR.

3.0 RELEASES FROM THE LABS BY LUNG CLEARANCE CLASS AND 240PU CONTENT

As discussed in Chapter 9, Section 9.2.4.7 of the PFP FSAR, there are two release scenarios, i.e., "No Ventilation" case and "Ventilation" case. In the "no ventilation" case, the facility ventilation system is assumed to fail or be shut down as a result of the earthquake. Material is released from the facility through open egress paths due to wind effects on the building. In the "ventilation" case, the E-3 and E-4 Exhaust Systems are assumed to continue running, but with failed HEPA filters such that material is released through the 291-Z-1 Stack unfiltered. The FSAR analysis accounts for gravitational settling within the facility. Since material is drawn out of the facility faster in the "ventilation" case, a lower percentage of the material released from the prototype calciner glovebox settles out before release in the "ventilation" case than in the "no ventilation" case. However, the release is elevated in the "ventilation" case, which aids in dispersion.

3.1 "NO VENTILATION" CASE RELEASES

For the "No Ventilation" case, 38% of the material released into the laboratories from the lab calciner is released from the facility, as shown in Chapter 9, Section 9.2.4.7.1 of the PFP FSAR (i.e., of the 12.539 g released into the laboratories, 4.765 is released). The remaining 62% of the respirable plutonium material released into the laboratories settles out due to gravity. Crediting gravitational settling within the facility, the following releases from the facility are calculated:

$$(0.863\ g) \times (0.38) = 0.328\ g < 10\%\ ^{240}Pu, \text{ Class W}$$
$$(11.676) \times (0.38) = 4.437\ g < 10\%\ ^{240}Pu, \text{ Class Y(accumulator depressurization)}$$
$$(2.676\ g) \times (0.38) = 1.017\ g < 10\%\ ^{240}Pu, \text{ Class Y (check valves function)}$$

Thus, the total release is 4.765 grams if the accumulator depressurizes through the calciner bed or 1.345 g if the check valves function.

3.2 "VENTILATION" CASE RELEASES

For the "Ventilation" case, 84% of the material released into the laboratories from the lab calciner is released from the facility, as shown in Chapter 9, Section 9.2.4.7.2 of the PFP FSAR (i.e., of the 12.539 g released into the laboratories, 10.533 is released). The remaining 16% of the respirable plutonium material released into the laboratories settles out due to gravity. Crediting gravitational settling within the facility, the following releases from the facility are calculated:

$$(0.863\ g) \times (0.84) = 0.725\ g < 10\%\ ^{240}Pu, \text{ Class W}$$
$$(11.676) \times (0.84) = 9.808\ g < 10\%\ ^{240}Pu, \text{ Class Y(accumulator depressurization)}$$
$$(2.676\ g) \times (0.84) = 2.248\ g < 10\%\ ^{240}Pu, \text{ Class Y (check valves function)}$$

Thus, the total release is 10.533 grams if the accumulator depressurizes through the calciner bed or 2.973 g if the check valves function.

4.0 DOSE CALCULATIONS

The onsite and offsite EDE and organ doses are calculated consistent with the methodology presented in Chapter 9, Section 9.3.6 of the PFP FSAR:

$$D = (R) \times (\chi/Q') \times (BR) \times (UDF)$$

where:

D = dose to onsite or offsite receptor, rem (EDE or maximum organ)
R = release by lung clearance class and ^{240}Pu content, g
χ/Q' = onsite or offsite atmospheric dispersion coefficient, s/m^3
BR = reference breathing rate, m^3/s
UDF = unit dose factor, EDE or maximum organ, rem/g

The release of material by lung clearance class and ^{240}Pu content is provided above. The "no ventilation" case release occurs at ground level. The "ventilation" case release occurs through the 291-Z-1 Stack and is elevated. From Tables 9-39 and 9-40 of the PFP FSAR, the onsite and offsite ground-level χ/Q's, accounting for building wake and plume meander, are 4.74×10^{-4} s/m^3 and 1.01×10^{-5} s/m^3, respectively. The onsite and offsite elevated χ/Q's are 1.62×10^{-5} s/m^3 and 5.73×10^{-6} s/m^3. The reference breathing rate is 3.3×10^{-4} m^3/s from Table 9-48 of the PFP FSAR. The mass-weighted average EDE and organ unit dose factors are provided in Tables 9-46 and 9-47 of the FSAR. The bone surface gives the maximum organ dose. For <10% ^{240}Pu, Class W, the mass-weighted EDE unit dose factor is 3.7×10^{7} rem/g and the mass-weighted bone surface unit dose factor is 6.7×10^{8} rem/g. For >10% ^{240}Pu, Class W, the mass-weighted EDE unit dose factor is 1.0×10^{8} rem/g and the mass-weighted bone surface

unit dose factor is 1.9×10^9 rem/g. For >10% ^{240}Pu, Class Y, the mass-weighted EDE and bone surface doses are 8.8×10^7 rem/g and 1.3×10^9 rem/g, respectively. For <10% ^{240}Pu, Class Y, the mass-weighted EDE and bone surface doses are 2.8×10^7 rem/g and 3.2×10^8 rem/g, respectively.

4.1 "NO VENTILATION" CASE DOSES, ACCUMULATOR DEPRESSURIZATION

The releases from the facility for this case are (from Section 3.1):

- 0.328 g <10% ^{240}Pu, Class W
- 4.437 g <10% ^{240}Pu, Class Y

The onsite and offsite EDE and organ doses are calculated by ^{240}Pu content and lung clearance class as follows:

<10% ^{240}Pu, Class W

Onsite EDE: $(0.328\ g)(4.74 \times 10^{-4}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.7 \times 10^7\ rem/g) = 1.90$ rem
Onsite Organ: $(0.328\ g)(4.74 \times 10^{-4}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(6.7 \times 10^8\ rem/g) = 34.37$ rem

Offsite EDE: $(0.328\ g)(1.01 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.7 \times 10^7\ rem/g) = 0.04$ rem
Offsite Organ: $(0.328\ g)(1.01 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(6.7 \times 10^8\ rem/g) = 0.73$ rem

<10% ^{240}Pu, Class Y

Onsite EDE: $(4.437\ g)(4.74 \times 10^{-4}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(2.8 \times 10^7\ rem/g) = 19.43$ rem
Onsite Organ: $(4.437\ g)(4.74 \times 10^{-4}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.2 \times 10^8\ rem/g) = 222.09$ rem

Offsite EDE: $(4.437\ g)(1.01 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(2.8 \times 10^7\ rem/g) = 0.41$ rem
Offsite Organ: $(4.437\ g)(1.01 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.2 \times 10^8\ rem/g) = 4.73$ rem

No-ventilation case totals, accumulator depressurization

Onsite EDE: (1.90 rem) + (19.43 rem) = 21.33 rem
Onsite Organ: (34.37 rem) + (222.09 rem) = 256 rem

Offsite EDE: (0.04 rem) + (0.41 rem) = 0.45 rem
Offsite Organ: (0.73 rem) + (4.73 rem) = 5.46 rem

Table H-1 presents the above total doses in a tabular format. The doses are compared in the table against the Risk Acceptance Guidelines (RAG) for an event with a 1×10^{-4} annual probability.

4.2 "VENTILATION" CASE DOSES, ACCUMULATOR DEPRESSURIZATION

The releases from the facility (from Section 3.2 above) are as follows:

- 0.725 g <10% ^{240}Pu, Class W
- 9.808 g <10% ^{240}Pu, Class Y

The onsite and offsite EDE and organ doses are calculated by ^{240}Pu content and lung clearance class as follows:

<10% ^{240}Pu, Class W

Onsite EDE: $(0.725\ g)(1.62 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.7 \times 10^{7}\ rem/g) = 0.14$ rem
Onsite Organ: $(0.725\ g)(1.62 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(6.7 \times 10^{8}\ rem/g) = 2.60$ rem

Offsite EDE: $(0.725\ g)(5.73 \times 10^{-6}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.7 \times 10^{7}\ rem/g) = 0.05$ rem
Offsite Organ: $(0.725\ g)(5.73 \times 10^{-6}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(6.7 \times 10^{8}\ rem/g) = 0.92$ rem

<10% ^{240}Pu, Class Y

Onsite EDE: $(9.808\ g)(1.62 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(2.8 \times 10^{7}\ rem/g) = 1.47$ rem
Onsite Organ: $(9.808\ g)(1.62 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.2 \times 10^{8}\ rem/g) = 16.78$ rem

Offsite EDE: $(9.808\ g)(5.73 \times 10^{-6} s/m^3)(3.3 \times 10^{-4}\ m^3/s)(2.8 \times 10^{7}\ rem/g) = 0.52$ rem
Offsite Organ: $(9.808\ g)(5.73 \times 10^{-6}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.2 \times 10^{8}\ rem/g) = 5.93$ rem

Ventilation case totals, accumulator depressurization

Onsite EDE: (0.14 rem) + (1.47 rem) = 1.61 rem
Onsite Organ: (2.60 rem) + (16.78 rem) = 19.38 rem

Offsite EDE: (0.05 rem) + (0.52 rem) = 0.57 rem
Offsite Organ: (0.92 rem) + (5.93 rem) = 6.85 rem

Table H-2 presents the above total doses in a tabular format. The doses are compared in the table against the RAG for an event with a 1×10^{-4} annual probability.

4.3 "NO VENTILATION" CASE DOSES (check valves function)

The releases from the facility for this case are (from Section 3.1):

- 0.328 g <10% ^{240}Pu, Class W
- 1.017 g <10% ^{240}Pu, Class Y

The onsite and offsite EDE and organ doses for <10% ^{240}Pu , Class W are the same as calculated in Section 4.1. The doses associated with a release of 1.017 g <10% ^{240}Pu, Class Y are as follows:

<10% ^{240}Pu, Class Y

Onsite EDE: (1.017 g)(4.74 x 10^{-4} s/m^3)(3.3 x 10^{-4} m^3/s)(2.8 x 10^7 rem/g) = 4.45 rem
Onsite Organ: (1.017 g)(4.74 x 10^{-4} s/m^3)(3.3 x 10^{-4} m^3/s)(3.2 x 10^8 rem/g) = 50.91 rem

Offsite EDE: (1.017 g)(1.01 x 10^{-5} s/m^3)(3.3 x 10^{-4} m^3/s)(2.8 x 10^7 rem/g) = 0.09 rem
Offsite Organ: (1.017 g)(1.01 x 10^{-5} s/m^3)(3.3 x 10^{-4} m^3/s)(3.2 x 10^8 rem/g) = 1.08 rem

No-ventilation case totals, check valves function

Onsite EDE: (1.90 rem) + (4.45 rem) = 6.35 rem
Onsite Organ: (34.37 rem) + (50.91 rem) = 85.28 rem

Offsite EDE: (0.04 rem) + (0.09 rem) = 0.13 rem
Offsite Organ: (0.73 rem) + (1.08 rem) = 1.81 rem

Table H-3 presents the above total doses in a tabular format. The onsite and offsite EDE doses and organ doses are shown to be below the RAGs.

4.4 "VENTILATION" CASE (check valves function)

The releases from the facility (from Section 3.2 above) are as follows:

- 0.725 g <10% ^{240}Pu, Class W
- 2.248 g <10% ^{240}Pu, Class Y

The onsite and offsite EDE and organ doses for <10% ^{240}Pu , Class W are the same as calculated in Section 4.2. The doses associated with a release of 2.248 g <10% ^{240}Pu, Class Y are as follows:

<10% ^{240}Pu, Class Y

Onsite EDE: (2.248 g)(1.62 x 10^{-5} s/m^3)(3.3 x 10^{-4} m^3/s)(2.8 x 10^7 rem/g) = 0.34 rem
Onsite Organ: (2.248 g)(1.62 x 10^{-5} s/m^3)(3.3 x 10^{-4} m^3/s)(3.2 x 10^8 rem/g) = 3.85 rem

Offsite EDE: (2.248 g)(5.73 x 10^{-6}s/m^3)(3.3 x 10^{-4} m^3/s)(2.8 x 10^7 rem/g) = 0.12 rem
Offsite Organ: (2.248 g)(5.73 x 10^{-6} s/m^3)(3.3 x 10^{-4} m^3/s)(3.2 x 10^8 rem/g) = 1.36 rem

Ventilation case totals

Onsite EDE: (0.14 rem) + (0.34 rem) = 0.48 rem
Onsite Organ: (2.60 rem) + (3.85rem) = 6.45 rem

Offsite EDE: (0.05 rem) + (0.12 rem) = 0.17 rem
Offsite Organ: (0.92 rem) + (1.36 rem) = 2.28 rem

Table H-4 presents the above total doses in a tabular the same format. The onsite and offsite EDE doses and organ doses are shown to be below the RAGs.

5.0 CONSEQUENCES OF SEISMIC EVENT WITH FIRE IN GLOVEBOX 188-1

As discussed in Section 4.2.5.3 of this addendum, Mitigated Seismic Event with Fire, a potential consequence of the 0.2 g DBE is a fire in Glovebox 188-1. This section provides the details of the additional release of plutonium materials and the additional doses due to the fire. In the fire case, all of the additional material released into the facility is plutonium oxide, Class Y, ^{240}Pu <10%. Because of this, the release amounts and dose consequences are simpler than in Sections 3.1 - 4.2 above.

The releases and doses are calculated for the "no ventilation" case and the "ventilation" case.

5.1 "NO-VENTILATION" CASE FOR SEISMIC-INDUCED FIRE

As shown in addendum Section 4.2.5.3, the fire in Glovebox 188-1 due to burning of trash, gloves, and panels adds 1.379 g release into the facility. In this case, 62% settles out and 38% is released from the facility as shown below.

$$(1.379\ g) \times (0.38) = 0.524\ g\ ^{240}Pu < 10\%, \text{ Class Y}$$

The incremental dose due to the above release is calculated as in Section 4.1 above and is as follows:

Onsite EDE: $(0.524\ g)(4.74 \times 10^{-4}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(2.8 \times 10^{7}\ rem/g) = 2.29$ rem
Onsite Organ: $(0.524\ g)(4.74 \times 10^{-4}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.2 \times 10^{8}\ rem/g) = 26.23$ rem

Offsite EDE: $(0.524\ g)(1.01 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(2.8 \times 10^{7}\ rem/g) = 0.05$ rem
Offsite Organ: $(0.524\ g)(1.01 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.2 \times 10^{8}\ rem/g) = 0.56$ rem

Total doses, accumulator depressurization

Adding the fire doses to the dose estimates from Section 4.1 above, gives the following total doses:

Onsite EDE: (21.33 rem) + (2.29 rem) = 23.62 rem
Onsite Organ: (256 rem) + (26.23 rem) = 282 rem

Offsite EDE: (0.45 rem) + (0.05 rem) = 0.50 rem
Offsite Organ: (5.46 rem) + (0.56 rem) = 6.02 rem

Table H-5 presents the above total doses for accumulator depressurization and fire in a tabular format. The doses are compared against the RAG for an event with a 1×10^{-4} annual probability in the table.

Total doses, check valves function

Adding the fire doses to the dose estimates from Section 4.3 above, gives the following doses:

Onsite EDE: (6.35 rem) + (2.29 rem) = 8.64 rem
Onsite Organ: (85.28 rem) + (26.23 rem) = 112 rem

Offsite EDE: (0.13 rem) + (0.05 rem) = 0.18 rem
Offsite Organ: (1.81 rem) + (0.56 rem) = 2.37 rem

Table H-6 presents the above total doses for check valves functioning and fire in a tabular format. The doses are compared against the RAG for an event with a 1×10^{-4} annual probability in the table.

5.2 "VENTILATION" CASE FOR SEISMIC-INDUCED FIRE

As shown in addendum Section 4.2.5.3, the fire in Glovebox 188-1 due to burning of trash, gloves, and panels adds 1.379 grams release into the facility. In this case, 16% settles out and 84% is released from the facility yielding the following result:

$$(1.379\ g) \times (0.84) = 1.158\ g\ ^{240}Pu < 10\%, \text{ Class Y}$$

The incremental dose due to the above release is calculated as in Section 4.2 above and is as follows:

Onsite EDE: $(1.158\ g)(1.62 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(2.8 \times 10^{7}\ rem/g) = 0.17$ rem
Onsite Organ: $(1.158\ g)(1.62 \times 10^{-5}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.2 \times 10^{8}\ rem/g) = 1.98$ rem

Offsite EDE: $(1.158\ g)(5.73 \times 10^{-6}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(2.8 \times 10^{7}\ rem/g) = 0.06\ rem$
Offsite Organ: $(1.158\ g)(5.73 \times 10^{-6}\ s/m^3)(3.3 \times 10^{-4}\ m^3/s)(3.2 \times 10^{8}\ rem/g) = 0.70\ rem$

Total doses, accumulator depressurization

Adding the fire doses to the dose estimates from Section 4.2 above, gives the following total doses:

Onsite EDE: (1.61 rem) + (0.17 rem) = 1.78 rem
Onsite Organ: (19.38 rem) + (1.98 rem) = 21.36 rem

Offsite EDE: (0.57 rem) + (0.06 rem) = 0.63 rem
Offsite Organ: (6.85 rem) + (0.70 rem) = 7.55 rem

Table H-7 presents the above total doses for accumulator depressurization and fire in a tabular format. The doses are compared in the table against the RAG for an event with a 1×10^{-4} annual probability.

Total doses, check valves function

Adding the fire doses to the dose estimates from Section 4.4 above, gives the following doses:

Onsite EDE: (0.48 rem) + (0.17 rem) = 0.65 rem
Onsite Organ: (6.45 rem) + (1.98 rem) = 8.43 rem

Offsite EDE: (0.17 rem) + (0.06 rem) = 0.23 rem
Offsite Organ: (2.28 rem) + (0.70 rem) = 2.98 rem

Table H-8 presents the above total doses in a tabular format. The doses are compared against the RAG for an event with a 1×10^{-4} annual probability in the table.

APPENDIX I

MITIGATED SEISMIC EVENT – ACCUMULATOR AIR FLOW THROUGH THE LABORATORY PROTOTYPE CALCINER

This page intentionally left blank.

MITIGATED SEISMIC EVENT – ACCUMULATOR AIR FLOW THROUGH THE VERTICAL CALCINER

The mitigated seismic event analysis presented in Chapter 4, Section 4.2.5.2 assumes failure of the check valves and solenoid valve in the process air line between the accumulator and the calciner bed. Failure of the valves results in an open path between the accumulator tank and the calciner via the normal process airline. Normal process airflow does not occur due to the action of the seismically qualified solenoid valves upstream of the location where the accumulator airline enters the process airline. As soon as the path opens, the accumulator will depressurize. Air will flow into the oxide bed causing suspension of the oxide and pressurization of the calciner. The pressurization causes the pressure relief cap to lift, allowing some of the suspended oxide to be transported out of the calciner into the glovebox. It is assumed that the solenoid valves between the accumulator and the ceramic filters remain closed.

This analysis will proceed by first describing the oxide bed and the equipment protruding into it. Next, the accumulator depressurization data is used to obtain the airflow velocity. The calciner headspace volume is determined next, to allow for calculation of the headspace concentration. The next two subsections discuss the action of the air jet on the bed. The second of the two discussions is the most important. It is in this section that the plutonium release is determined.

1.0 VERTICAL CALCINER-PUO_2 POWDER BED DIMENSIONS

The shape and dimensions of the oxide bed of the vertical calciner are important to the understanding of the quantity of plutonium potentially suspended during the depressurization of the accumulator. The oxide bed is annular. The inside surface of the bed is a 4 inch Sch. 10 stainless steel pipe having an outside diameter of 4.5 inches. The outside surface is a 6 inch Sch. 10 stainless steel pipe having an inside diameter of 6.357 inches. The bed width is 0.93 inches, giving an area of 15.8 square inches. The bed is 6 to 7 inches deep. The process air and process feed enter the bed through coaxial concentric tubes. Process air flows in the outer tube. The outer tube is stainless steel with an inside diameter of 0.5 inches. The process feed enters through a 0.25 inch stainless steel tube having 0.035 inch thick walls which is located within the process air tube. The flow area for air is 0.12 in^2. The flow area for process feed is 0.05 in^2.

The agitator protrudes into the calciner. The agitator has 4 legs, each 0.3 inches thick and 1 inch wide. The bottom of the legs is near the bottom of the bed. The agitator rotates at 1 revolution per second. The legs are radially located in the middle of the bed, as is the process air and feed inlet. The legs rotate over the air and feed inlet 4 times per second which makes the single air and feed entry point act like many. The legs nearly cover the air inlet tube and do cover the process feed tube each time they rotate over the inlet tube. This results in an intermittent air and feed flow rate into the bed under normal operation. However, as a result of

the seismic event power is cut to the agitator. The size of the legs has the effect of dividing the bed into 4 even quadrants.

2.0 ACCUMULATOR

The accumulator volume is 2.3 L and is normally pressurized to 70 psig (5.76 atm or 84.7 psi, absolute). The flow rate during depressurization was found by testing. The process air line was opened up downstream of the rotameter. This position is near the calciner, which has the advantage of including the majority of the flow losses in the air path. In the test, the accumulator was allowed to depressurize through a valve put into the flow path at this location. The accumulator pressure vs. time was monitored during depressurization. The test showed that the accumulator depressurizes in 15.5 seconds (the average of the two tests). From this data, the ideal gas law and the air line flow area, the volumetric flow rate and air velocity in the bed can be determined. Table I-1 shows the test data.

Table I-1. Accumulator Depressurization Test Data

	Time(in seconds) to reach the pressure indicated	
Pressure (psig)	Test 1	Test 2
70	0	0
40	not recorded	4
30	4	not recorded
20	7	8
10	9	11
0	14.5	16.5

The results of Test 1 will be used as they provide the greatest flow rates through the line.

The air flow is found using the ideal gas law (PV = nRT). At 70 psig (5.76 atm or 84.7 psi, absolute) the accumulator contains 0.54 moles of air, assuming a temperature of 27 °C and a volume of 2.3 L. The density of air at 27 °C and atmospheric pressure is 1.179 g/L. Table I-2 shows the airflow rates. It is assumed that the airflow rates from the test are the same as the air flow rate into the calciner. Credit is not taken for line losses between the rotameter and the inlet to the calciner. The value for "L/s" assumes a pressure of 1 atm (i.e., the expanded volumetric flow rate).

Table I-2. Airflow Rates into the Bed from Accumulator Depressurization

Time	Pressure (psia)	Moles in accumulator	Moles released in the interval	Volumetric flow rate over the interval (L/s)	Velocity in tube, over the interval, m/s
0	84.7	0.54	0	0	0
4	44.7	0.28	0.26	1.6	21
7	34.7	0.22	0.06	0.5	6.5
9	24.7	0.16	0.06	0.7	9
14.5	14.7	0.09	0.07	0.3	4

3.0 CALCINER HEADSPACE VOLUME

The free headspace volume of the calciner above the bed is 315.7 in^3 (5.2L). This is found as follows. The exterior surface of the calciner headspace is made of 2 spools. Each spool is a 6 inch Sch. 10 (6.357 inch inner diameter) stainless steel pipe. The upper spool is 11 inches long. The lower spool is 9 inches long. The oxide bed takes up most of the volume of the lower spool. Using a bulk density of between 2 and 3 g/cm^3 for the oxide, the bed depth is about 6 inches. There is an open annular volume above the bed approximately one inch tall. Therefore the 6 inch diameter open volume above the bed is 13 inches long. Within the upper spool are the 3 ceramic filters. Each are 12 inches long and 2 inches in diameter. The volumes are as follows:

a. Six inch, Sch. 10 pipe, 13 inches long	=	413 in^3
b. Ceramic filters	=	37.7 in^3 each x 3 filters = 113.1 in^3 total
c. Annular space above bed (1 inch tall, 15.8 in^2 area)	=	15.8 in^3
TOTAL		315.7 in^3 (5.2 L)

4.0 BED EXPANSION

Airflow through beds of solids causes the beds to expand, a process known as fluidization. If the airflow is great enough, a spout will form. A spout resembles a water fountain that contains particles instead of water. Beds through which high velocity air flows are called spouted beds. The terminology used above and the correlation's to follow come primarily from *Fluidization* (Davidson et. al. 1985).

Davidson et. al. (1985) shows that typical airflow velocities for fluidization are less than 10 cm/s for beds the size of the calciner bed. Since the air velocity during accumulator depressurization is on the order of 20 m/s, the bed is likely a spouted bed. Page 212 of Davidson et. al. (1985) provides a correlation that provides the minimum velocity for spouting. The equation is as follows:

$$u = (D_1)(D_2)^{0.333}(L_1)^{0.5}$$

where:

- u = minimum velocity for spouting, m/s
- D_1 = d/D_c, where
- d = particle diameter, cm
  - = 0.002 cm (20 micron) based on the mean of the particle sizes by mass (see Attachment 1)
- D_c = bed diameter, cm
  - = 5.7 cm based on the assumption that the equivalent bed is ¼ of the entire bed, and that the annular bed can be represented by a circular bed of the same area.
- D_2 = D_i/D_c
- D_i = orifice diameter, cm

= 1.27 cm based on a 0.5 inch air line tube

L_1 = 2 g H $(\rho_S - \rho_f)/\rho_f$, where

g = acceleration due to gravity, cm/s^2

= 980

H = bed height, cm

= 15.2 cm based on a 6 inch bed

ρ_s = solids density, g/cm^3

= 10 for PuO_2

ρ_f = density of air, g/cm^3

= 5.7×10^{-4} based on 1 atm pressure and 618 K. 618 K is the logarithmic average temperature between 300 K and 1273 K.

Solving for u yields 5 cm/s. If the average temperature (500 °C) were used for ρ_f, u would equal 5.6 cm/s. If the annular width (2.4 cm) were used for D_c, u would equal 16 cm/s. So the bed is well within the range of spouted beds.

5.0 MASS ENTRAINMENT

Mass entrainment information is taken from Chapter 4 of Davidson et. al. (1985) on gas jets in fluidized beds. The first correlation for mass entrainment is found in Figure 4.16 of Davidson et. al. (1985) which presents a plot of mass entrainment rates as a function of height divided by orifice half-width.

The mass entrainment can be found from the evaluation of the plotted parameter W_s/W_{fo}

where:

W_s = mass flow rate of solids

W_{fo} = mass flow rate of air through the orifice

For the calciner, W_{fo} equals 0.93 g/s based on a density of 5.7×10^{-4} g/cm^3, an air velocity of 21 m/s and orifice area of 0.12 in^2.

The data for W_s/W_{fo} data presented comes from experiments with bronze and alumina particles having diameters of 300 micrometers. In the experiment, the air velocity was 90 m/s. Using the graph with the calciner bed depth (15 cm) and orifice half diameter (0.63 cm), the value of W_s/W_{fo} is found to be 25. Using the value for the mass flow rate of air (W_{fo}) in the calciner of 0.93 g/s, W_s is found to be 27 g/s. This entrainment rate however is based on 90 m/s airflow through a bed of 300 micron particles; somewhat different than the 20 m/s air velocity and 20 micron average particle diameter found in the calciner.

The second set of correlation is found in Table 4.3 of Davidson et. al. (1985) which presents other experiments in which mass entrainment was measured. Table I-3 presents this data as well as the corresponding data for the calciner.

Table I-3. Values of W_s/W_{fo} for other Experiments

Experimenter (from Table 4.3 of Davidson et. al. 1985)	Solid Material	Bed Height, cm	Air velocity, m/s	Orifice size, cm	Particle size, mm	W_s/W_{fo}
Toei	glass	--	6	0.5	0.25	4
Behie	plastic	--	61	1.9	0.06	1.3
Merry	lead	45	4	1.9	1	2
Donadono	plastic	4	90	2	2.9	20
Filla (1981)	glass	8	60	0.6	0.8	15
Filla (1985)	plastic	11	60	0.6	2.9	21
Filla (1983)	lead	6.5	60	6	1.8	60
Filla (1983)	plastic	11	60	6	2.9	20
Calciner	PuO_2	16	21	1.3	up to 0.1	--

Using the data for W_s/W_{fo} from Table I-3 and a value of W_{fo} of 1 g/s from the calciner yields an estimated mass flow rate of solids into the calciner headspace of 1.3 – 60 g/s.

A third correlation comes from H. Kono, who presents mass entrainment data for fluidized spouted beds and spouted beds in *Attrition Rates of Relatively Coarse Solid Particles in Various Types of Fluidized Beds* (Kono 1981), page 96. Kono uses 1 mm Si O_2 – Al_2O_3 particles having a density of 2.4 g/cm^3. The fluidized spouted bed in Kono (1981) is the closest analog to the PFP vertical calciner. Data from Figure 14 for 10 cm diameter beds with an airflow of 21 m/s shows a mass entrainment rate of 10 wt %/hr times the quantity "bed diameter (in. cm) raised to the 0.55 power." With a bed diameter of 5.7 cm (based on a ¼ bed) the entrainment rate is 26 wt %/hr. For the 1000 g bed (1/4 bed) in the vertical calciner, the entrainment rate is 0.07 g/s. While the flow rate and bed diameter match those of the calciner, the particles are much larger.

A fourth source of data for entrainment is the process incident that occurred during the testing phase of calciner operation. A plug occurred in the feed tube that plugged both the feed tube and the air tube. When the plug was broken with the clean-out rod, an inadvertent calciner pressurization occurred. Fifty to sixty grams of PuO_2 was discharged into the glovebox through the relief cap. With the airflow at normal flow rate and the vacuum on, the discharged PuO_2 was poured back into the calciner through the relief cap. This is the normal inlet to the calciner for oxide that requires recycle. The operator was unaware that at the time the oxide was poured back in, the ceramic filter was cracked. In the 15 seconds it took to pour the 50 – 60 g of oxide back into the calciner, 2 g appeared in the scrubber. This data suggests that the rest of the oxide fell back to the bed. Using the information above, the calciner headspace concentration is found to be 0.43 g/L (or 430 g/m^3). The value of 0.43 g/L was found as follows:

$$2\ g = (C)(Flow)(t)$$

where:

C = headspace concentration, g/L

Flow = flow through the calciner headspace. The flow is 0.66 ft^3/min
= 0.31 L/s
t = time = 15 s

The flow rate of 0.66 ft^3/min equates to a flow velocity 4 m/s using an orifice area of 0.12 in^2. The total accumulator discharge during the 15 seconds depressurization is found from Table I-2. A total of 11 liters was discharged over the 15 seconds. Using this release and an assumed concentration of 0.43 g/L, the release is found to be 4.7 g, or 0.3 g/s.

The 3 sets of experimental correlations for mass entrainment differ from the conditions within the calciner. The major differences are the air velocity and the particle size. A confounding aspect is that in the analyzed accident the flow will steadily decrease during the depressurization. There is no data to account for this aspect. Steady flow is judged to bound steadily decreasing flow.

The experimental data will next be used to determine scaling ratios for the parameters of interest. The data from Kono (1981), and from Davidson et. al. (1985) shows that the ratio of the entrainment is approximately proportional to the half of the ratio of the particle diameters. This is shown by using Table 4.3 of Davidson et. al. (1985) and comparing the data from Behie (1975) to Filla (1983). Both used 1 g/cm^3 particles with an air velocity of 60 m/s. The value of W_s/W_{fo} for the 0.06 mm particles used by Behie was 1.3. The value for the 3 mm particles used by Filla was 20. So, scaling 1 mm particles of the experimental data to the 20 μm PuO_2 particles (a ratio of 50) would reduce the entrainment by 15. The data for lead particles from Filla (1983) and Merry show a ratio of air velocity of 15, a ratio of particle size of 2 and a ratio of entrainment of 30. The data for plastic particles from Donadono for a velocity of 90 m/s shows the same entrainment as that from Filla (1985) at 60 m/s for the same particle size. Yet data from Kono (1981) shows a factor of 10 decrease in mass entrainment for air velocity of 20 m/s over that at 5 m/s and a factor of 4 decrease for air velocity of 40 m/s over that for 20 m/s. This suggests that for 1 mm particles the change in mass entrainment is greater for changes in velocities below 20 m/s (or so) and less for changes above 20 m/s. Kono's data shows that it is conservative to assume that the ratio of entrainment decreases as the ratio of velocity between 60 m/s (the air velocity for the majority of the experimental data) and 20 m/s (the calciner air flow rate). The following scaling factors will be used.

entrainment scaling = ½ (ratio of particle sizes)(ratio of air velocity)

The mass flow due to entrainment in the experiments, scaled to the calciner particle size and airflow velocity, yields values of mass entrainment of about 0.02 to 1 g/s. This is in the range of the 0.3 g/s found in the process incident.

The mass entrained during the accumulator depressurization is found in Table I-4. The entrainment rate is assumed to be 1 g/s (the high side of the range) during the period of high flow. Use of the high side of the range is conservative, and is used because of the lack of

experimental or theoretical data that closely match the situation in the calciner. It is judged that because of the small headspace, agglomeration (the attraction of smaller particles to produce large particles), interception (the removal of small particles by the settling of the large particles) and the use of the largest entrainment values from the experimental data, the actual entrainment rate will not exceed 1 g/s and could be 1/10 this value. The rate is divided by 2 as the flow during depressurization decreases.

Table I-4. Mass Entrained during Accumulator Depressurization

Time	Velocity	Assumed mass entrainment rate	Total released
0 – 4 s	20 m/s	1 g/s	4 g
4 – 14 s	4 – 9 m/s	0.5 g/s	5 g
			TOTAL: 9 g

It is further assumed that all of the 9 g are respirable. In the section below, it is shown that the calciner headspace could contain as much as 2.2 g at the start of the seismic event. This will also be blown out for a total release of 11.2 g.

This number differs from the release that occurred in the first step of the process incident (the 50-60 g release). The 9 g release comes from entrainment due to air flow. The first part of the process incident involved a slug of liquid process feed and air. Due to the plug the process feed was likely pressurized to 60 psig instead of the normal feed pressure of around 15 psig. It is postulated that the slug of feed and air removed all of the oxide within a cylinder defined by bed height and the radius of the orifice. This assertion matches the data in Kono (1981) and Davidson et. al. (1985). Kono (1981) shows in equations 9 and 10 and Figure 7, that the entraniment rate is a direct function of gas density. While Kono did not consider liquid, his experiments did consider gas densities up to 4.6 g/L (density of air is 1.12 at 27 °C). The density difference between the process feed (at about 1.5 g/cm^3) and air (at 5.7 x 10^{-4} g/cm^3) is 2600. This is not to imply that the difference in carryover should be 2600 times greater but to illustrate that the postulated difference in carryover of 9 g with air flow and 50 - 60 g with air and feed is attributable to the difference in fluids involved. Since the process feed is shut-off in the seismic event, carryover will only occur due to air flow.

It is assumed that the slug of feed and air removed all of the oxide within the cylinder defined by the radius of the orifice and the bed height. The volume of this region is

$$V = (\Pi/4)(\text{orifice dia.})^2(\text{bed height})$$

Solving for V using an orifice diameter of 0.5 in. and bed height of 6 in. yields 1.18 in^3. The oxide in this volume is 40 g based on 2 g/cm^3 bulk density of oxide. Continued airflow and feed flow at a much lower pressure acted to further pressurize the calciner and discharge the initial spike of material. The release of somewhat greater than 40 g matches the "50-60 g"

released. This release would not occur in the seismic event, however, as the feed flow is stopped by the seismically qualified solenoid valves.

If the check valves function, air can enter the calciner through the normal air path from the accumulator, i.e., through the ceramic filters, if the main and individual solenoid valves fail open. Under these conditions, all of the plutonium held up in the headspace will be blown out through the relief cap, as will the plutonium on the ceramic filters. The release from the plutonium in the headspace is 2.2 g based on 0.43 g/L in the 5.2L headspace. The plutonium on the filters is estimated to be 2.7 g. The basis for this quantity is as follows. The air flow through the calciner is 0.66 ft^3/min. Each filter is pulsed every 20 seconds to remove the accumulated oxide. All 3 filters are pulsed each minute. The total accumulation on all 3 of the filters is given by:

$$A = (0.66\ ft^3/min)(28.3\ L/ft^3)(0.43\ g/L)(1\ minute\ cycle\ time) = 8\ g$$

Under normal operation, the one of the solenoid valves pulse every 20 seconds.

During the seismic event, power to solenoid valves is shut off. It is assumed that at the time of the seismic event, one of the solenoid valves pulses and then sticks open. As a result, the 2.7 g on that filter plus the 2.2 g in the headspace will be blown out.

Air entering the filters will be dispersed in all directions as it travels through the line into the filter. There will be some resuspension from the bed which is a few inches below the filters. DOE (1994), Section 4.4.4.2 provides an airborne release rate of 4×10^{-5}/hr for air flow over a bed of powder under wind velocities of less than 2 m/s with gusts to 20 m/s. This value will be increased by a factor of 10 to account for a greater air flow, or unanticipated air circulation patterns. The resuspension release is:

$$R = (4000\ g)(4 \times 10^{-3}/hr)(15\ s/3600\ s/hr) = 0.07\ g$$

The total release is therefore, 5 g. While there are uncertainties in the above calculations it is clear that the release from air blowing through the filter is less than the 9 g released with air flow through the bed.

There could be air flowing through the bed and a single pulse of air through one of the filters if both the check valves and solenoid valves fail. Under this assumption the 2.7 g on one of the filters could instantly be transported to the headspace. The headspace concentration will increase causing additional agglomeration. Some of the oxide on the filters will also be removed by interception. As a result only a fraction of the 2.7 g release off the filters will escape the calciner. It is judged that the conservatism in the 9 g release, due to air flow through the bed, plus the 2.2 g calculated to be in the headspace, covers the release from the filters should air flow to both paths.
